Payara Platform

Version main-7, 2026-06-16

Introduction

This is the documentation for the Payara Platform Enterprise Edition, designed to increase stability and security in production environments and provide customers with access to production-oriented features, tools, and capabilities.

Payara Platform Enterprise consists of Payara Server and Payara Micro. They have a monthly release cadence, are designed for production environments, and new features are added to Payara Platform Enterprise after they have been thoroughly tested for stability.

Download

The Enterprise Edition downloads can be found in the *Payara Enterprise* repository of our Nexus Server. More information can be found in the Payara Enterprise Download guide (only accessible for Enterprise Customers).

History

Payara Server began life in 2014, derived from GlassFish 4.1. Since then, Payara Server has been refined with bug fixes, enhanced with new features, and has grown a strong community following. The documentation here will be updated with all the significant changes made with each new release.

Technical Documentation Structure

Payara Server Documentation

The documentation of the Payara Server distribution. Provides information about configuring and administering Payara Server, as well as how to deploy applications and how to use provided resources in deployed applications.

Payara Micro Documentation

The documentation of the Payara Micro distribution, which is a single file runtime capable of running applications from the command line. Payara Micro is designed to run applications in cloud and containerized environments a well as in embedded and IoT devices. It provides most of the functionality of Payara Server, adding some specific features for flexible deployments and ease of use.

Payara Embedded Documentation

The documentation of the Payara Server Embedded distribution, which can be used to embed a Payara Server runtime in a standard Java application. The embedded distribution is best used on integration testing environments.

Application Development

Documentation on good practices and specific use cases of how to use the Jakarta EE APIs to develop applications that can run effectively on the Payara Platform.

Public API

Documentation on how to use proprietary software components from the Payara Platform Public API

MicroProfile

Documentation on specific details and proprietary features of the implementation of the Eclipse MicroProfile APIs on the Payara Platform.

Ecosystem

Documentation on all Ecosystem tools and plugins available to the Payara Platform to simplify various aspects of application development, deployment and runtime management.

General Info

Overview

This page provides some general information about the Payara Platform Enterprise Edition.

Release Strategy

The Payara Platform Enterprise Edition project is released each month. Each release incorporates fixes and enhancements from Platform engineering and Enterprise-only features.

Versioning Scheme

The general format of a Payara Platform version number is:

```
Major Version Number. Minor Version Number. Patch Version Number
```

Major Version numbers start from **6** (the current major version of Payara Platform) and only increment by 1 when a new major version is released. Fundamental changes will only be released in major Versions. There is currently no set cadence for this version change.

The change of a major version number is a product management and marketing decision.

Customers should expect changes to their applications and configuration scripts to move to a new major version.

Minor Version numbers start from **0** and increment by 1 as required. These version changes will introduce significant features (typically originating from the Product Management process or stabilised and adopted from Community releases).

Features introduced during a minor version change must be backwards compatible with previous minor releases with no intervention required by an operator.
Features introduced during a minor version change can only introduce breaking changes as a last resort and with product management approval and appropriate customer messaging.

The minor version number will reset to **0** on a major version release.

Customers should not expect to change their applications and configuration scripts to move to a minor version unless by choice to take advantage of newly introduced features.

Patch Version numbers will start from **0** and as a minimum increment as required. These version change will introduce bug fixes and patches. The Patch Version number will reset to **0** on a minor version release.

Customer specific versions used for private builds or hotfixes will add a 4th level number where the number reflects a meaningful name to the customer e.g. the number of the hotfix.

For example if a customer specific hotfix is provided for a bugfix identified with *1234* then the release number for that customer will be *6.1.0.1234*

Customers should not expect to change their applications and configuration scripts to move to a patch version.

Examples

The examples shown below are used only to showcase possible future releases and are not be followed up as a release plan when planning updates on your organization.

- `6.0.0` = Major Version `6`, Minor Version `0`, Patch `0`
- `6.1.1` = Major Version `6`, Minor Version `1`, Patch `1`
- `6.1.2` = Major Version `6`, Minor Version `1`, Patch `2`
- `7.0.0` = Major Version `7`, Minor Version `0`, Patch `0`

Supported Platforms

Though it is always possible for new versions to be supported, this page details the JVMs currently supported by the Payara Platform (both Payara Server and Payara Micro).

Supported Java Virtual Machines

The Payara Platform currently runs on the following Java Virtual Machines:

- Azul Zulu JDK (Azul Platform Core): 21 (21.30/21.0.1+)
- Azul Zing JDK (Azul Platform Prime): 21 (21.30/21.0.1+)
- Oracle JDK: 21 (21.0.1+)
- Amazon Corretto: 21 (21.0.1+)
- Adopt Open JDK: 21 (21.0.1+)
- Adopt Open JDK with Eclipse Open J9: 21 (21.0.1+)
- Any other JVM based on OpenJDK 21.0.1+

The Payara Platform runs on the `x64` and `arm64` variants of the above JVMs.

Supported Operating Systems

The Payara Platform currently runs on the following Operating Systems in all the versions listed below and all their newer versions:

- Windows

    - Windows 7+
    - Windows Server 2008+
- Linux
    - Ubuntu 14.04 (Trusty Tahr) LTS+
    - Debian 7 (Wheezy)+
    - CentOS 6+
    - RHEL 5+
    - OpenSUSE 42.2+
    - SUSE 11.4, 12.2+, 15.0+
    - Amazon Linux (all versions)
- Other
    - MacOS(OSX) 10.10.5 (Yosemite)+
    - IBM AIX 7.1+

In general, any Payara Platform distribution runs on any system supported by at least one of the JVMs it runs on.

Third Party Collaborations

Payara Platform Enterprise integrates with various other services that complement your Java deployment experience on the platform.

Azul Platform

Payara's partnership with Azul brings Azul Platform Core and Azul Platform Prime to your application deployment.

Azul Platform Core

Azul Platform Core is designed for enterprise, distribution (ISV), and embedded (OEM) use cases. It provides certified OpenJDK builds, Azul Zulu Builds of OpenJDK (Azul Zulu), with tight security and the cost efficiencies you need to run today's business–critical, Java-based services. These builds are free to use and a drop-in replacement for any other OpenJDK distribution.

Key advantages include:

- **High Trust**: Chosen by leading global brands, Azul Platform Core offers engineering support and 100% open-source builds that are Java SE compliant and TCK verified.
- **High Value**: Azul Platform Core is a one-to-one replacement for Oracle Java SE with the most architectures, package types, and configurations options compared to other OpenJDK providers.
- **High Security**: Azul Platform Core delivers quarterly stabilized security updates for rapid deployment into production, backed by an industry-leading support SLA.

Read more about Azul Platform Core and Azul Zulu JDK here: https://docs.azul.com/core/

Azul Platform Prime

Azul Platform Prime is a high-performance Java platform that delivers up to 37% faster performance compared to other OpenJDK distributions. At its core is Azul Zing, an enhanced build of OpenJDK that serves as the actual JDK running your applications. The platform requires no code changes or recompilation, making integration straightforward for existing Java applications.

Key advantages include:

- **Performance Improvements**: Azul Zing, the enhanced JDK that runs your applications, achieves improved responsiveness and consistency while maintaining performance SLAs, even as loads increase. It provides superior application performance, responsiveness, and efficiency compared to standard OpenJDK distributions.
- **Cost Reduction**: Organizations can reduce cloud compute costs by 20% or more through Azul Zing's more efficient CPU utilization and faster Java code execution, requiring fewer compute resources for the same workload.
- **Advanced Garbage Collection**: Azul Zing includes the C4 Pauseless Garbage Collector, which ensures consistent performance under heavy loads and enables 2-5X more transaction processing without pauses, eliminating the "stop-the-world" pauses that limit scalability in traditional JVMs.
- **Rapid Application Startup**: Azul Zing's ReadyNow technology speeds up application startup and time to peak performance by reusing profiling data, solving traditional Java warm-up issues and allowing applications to start fast and stay fast.
- **Optimizer Hub**: This optional Azul Platform Prime component provides centralized JIT compilation and intelligent curation of optimization profiles, enabling fleet-wide collaboration where multiple Azul Zing JVMs share optimizations and learnings for improved cloud scale, elasticity, and cost efficiencies.

Azul Platform Prime requires opt-in during contract negotiations with sales. Sales will acquire a subscription based on vCPU cores, with annual billing directly from Azul. Customers receive an installation wizard with the JVM enabled. For post-installation enablement, contact sales - the service team will provide two commands to activate it on your existing installation.

Read more about Azul Platform Prime and Azul Zing JDK here: https://docs.azul.com/prime/

Technical Documentation

Payara Server Documentation

Overview

Comprehensive documentation of how to operate and manage a Payara Server installation composed of the following subsections:

General Administration

Details the basics of how to manage the configuration and runtime settings of Payara Server.

Deployment Planning

Contains instructions and recommendations on how to plan an application deployment in Payara Server.

Application Deployment

Details how application deployments work in Payara Server.

High Availability

Details how to configure and use the high-availability features of Payara Server on distributed environments.

Security Guide

A comprehensive guide that offers basic recommendations and advice on how to secure a Payara Server installation.

Command Reference

A complete reference manual of alf available Asadmin CLI commands.

Extensions

Documents the features of all available extensions for Payara Server and how to use them.

Upgrade Guide

A guide with recommendations and strategies for upgrading Payara Server across versions.

Documentation Conventions

The following conventions are applied through the pages in this section to improve readability and familiarity with how Payara Server operates.

Symbol Conventions

The following table explains symbols that might be used in this section.

Symbol	Description	Example	Meaning
`[ ]`	Contains optional arguments and command options.	`ls [-l]`	The `-l` option is not required.
`{ | }`	Contains a set of choices for a required command option.	`-d {y|n}`	The `-d` option requires that you use either the `y` argument or the `n` argument.
`${ }`	Indicates a variable reference or a placeholder reference for a default path.	`${com.sun.javaRoot}`	References the value of the `com.sun.javaRoot` variable.
-	Joins simultaneous multiple keystrokes.	`Control-A`	Press the `Control key while you press the A key.
+	Joins consecutive multiple keystrokes.	`Ctrl+A+N`	Press the Control key, release it, and then press the subsequent keys.
→	Indicates menu item selection in a graphical user interface.	File → New → Templates	From the *File* menu, choose New. From the *New* submenu, choose *Templates*.

Default Paths and File Names

The following table describes the default paths and file names that are used in this book.

Placeholder	Description	Default Value

`as-install`	Represents the base installation directory for Payara Server.
	
	In configuration files, as-install is represented as follows:
	
	`${com.sun.aas.installRoot}`
		Installations on a Linux operating system, and macOS operating system:
		
		`{USER_HOME}/payara7/glassfish`
		
		Installations on a Windows operating system:
		
		`{SystemDrive}:\payara7\glassfish`

`as-install-parent`	Represents the parent of the base installation directory for Payara Server.	Installations on a Linux operating system, and Mac operating system:
		
		`{USER_HOME}/payara7`
		
		Installations on a Windows operating system:
		
		`{SystemDrive}\payara7`

`domain-root-dir`	Represents the directory in which a domain is created by default.	`as-install/domains/`

Placeholder	Description	Default Value
`domain-dir`	Represents the directory in which a domain's configuration is stored. In configuration files, `domain-dir` is represented as follows: `${com.sun.aas.instanceRoot}`	`domain-root-dir/<domain-name>`
`node-dir`	Represents the directory for a configured node.	`as-install/glassfish/nodes/<node-name>`
`instance-dir`	Represents the directory for a server instance.	`node-dir/<instance-name>`

Docker Images

Payara Services Limited provides official Payara Server Docker Images which are updated every release.

These images are hosted on Docker hub in the following locations:

- Payara Server Full Profile Docker Image
- Payara Server Web Profile Docker Image

Payara Enterprise customers have access to a private Docker repository containing Payara Enterprise Edition equivalent images, which are also released and updated every month.

General Administration

Overview

Payara Server provides a runtime for developing and deploying Jakarta EE Platform and Eclipse MicroProfile applications.

As an administrator of Payara Server, your main responsibilities are to establish a secure Payara Server environment and to oversee the services, resources, and users that participate in that environment.

Your key tasks include configuring resources and services, managing Payara Server at runtime, and fixing problems that are associated with the server's operation.

Default Settings and Locations

After installation, you might need to perform some immediate configuration tasks to make your installation function as intended.

If configuration defaults have been accepted, some features are enabled and some not. For an overview of initial configuration tasks for Payara Server services and resources, see Initial

Configuration Tasks.

In addition, you might want to reset default passwords, change names or locations of files, and so on.

The following tables list the default administration values.

The default administrator login is `admin`, with no password, which means that no login is required.

Default Administration Values

Item	Default
Domain Name	`domain1`
Master Password	`changeit`
Administration User	`admin`
Administration Server Port	`4848`
HTTP Port	`8080`
HTTPS Port	`8181`
Pure JMX Clients Port	`8686`
Message Queue Port	`7676`
IIOP Port	`3700`
IIOP/SSL Port	`3820`
IIOP/SSL Port With Mutual Authentication	`3920`

[[Technical Documentation-Payara Server Documentation-General Administration-Overview:::table-default-settings-and-locations-2]] .Default Locations

Item	Default
Command-line Utility (`asadmin`)	`as-install/bin`
Configuration Files	`domain-dir/config`
Log Files	`domain-dir/logs`

Configuration Tasks

Some configuration tasks must be performed directly after installation for your Payara Server environment to work as intended. For example, if you are using a database with Payara Server, you need to set up database connectivity right away.

Some configuration situations are ongoing and will require you to make changes many times during the life of your installation. You can use either the Administration Console or the `asadmin` utility to modify the configuration. Changes are automatically applied to the appropriate

configuration file.

Initial Configuration Tasks

This section maps the common configuration tasks to the command-line procedures in this guide. In some situations, the resource or service is automatically enabled and your configuration tasks involve adjusting or changing the default settings to suit your specific needs.

The following resources and services frequently require configuration immediately after installation:

System Properties

See Administering System Properties.

Domains

The initial `domain1` is created during installation. Additional configuration tasks might include such tasks as configuring additional domains or setting up automatic restart. See Administering Domains.

JVM

The initial tasks for configuring the JVM include creating JVM options.

Logging

By default, logging is enabled, so basic logging works without additional configuration. However, you might want to change log levels, property values, or the location of log files. See Administering the Logging Service.

Monitoring

By default, the monitoring service is enabled. However, monitoring for the individual modules is not enabled, so your first monitoring task is to enable monitoring for the modules that you want to monitor. See Administering the Monitoring Service.

Security

- System Security. Initial configuration tasks might include setting up passwords and certificates. See "Administering System Security" in the Payara Server Security Guide.
- User Security. Initial configuration tasks might include creating authentication realms and file users. See "Administering User Security" in the Payara Server Security Guide.
- Message Security. Initial configuration tasks might include configuring a Java Cryptography Extension (JCE) provider, enabling default and non-default security providers, and configuring message protection policies. See "Administering Message Security" in the Payara Server Security Guide.

Database Connectivity

The initial tasks involved in configuring Payara Server to connect to an external database include creating a Java Database Connectivity (JDBC) connection pool, creating a JDBC resource, and integrating a JDBC driver. See Administering Database Connectivity.

EIS Connectivity

The initial tasks involved in configuring Payara Server to connect to an enterprise information system (EIS) include creating a connector connection pool, creating a connector resource, editing a resource adapter configuration, creating a connector security map, creating a connector work security map, and creating an administered object (if needed). See Administering EIS Connectivity.

Internet Connectivity

The initial tasks involved in making deployed web applications accessible by internet clients include creating HTTP network listeners and virtual servers, and configuring the HTTP listeners for SSL (if needed). See Administering Internet Connectivity.

Object Request Broker (ORB)

An initial configuration task might involve creating an IIOP listener. See Administering the Object Request Broker (ORB).

JavaMail Service

An initial configuration task might involve creating a JavaMail resource. See Administering the JavaMail Service.

Java Message Service (JMS)

Initial configuration tasks might include creating a physical destination, creating connection factories or destination resources, creating a JMS host (if the default JMS host is not adequate), adjusting connection pool settings (if needed), and configuring resource adapters for JMS. See Administering the Java Message Service (JMS).

JNDI Service

An initial configuration task might involve creating a JNDI resource. See Administering the Java Naming and Directory Interface (JNDI) Service.

Information and instructions for accomplishing the tasks by using the Administration Console are contained in the Administration Console online help.

How Dotted Names Work for Configuration

After the initial configuration is working, you will continue to manage ongoing configuration for the life of your Payara Server installation.

You might need to adjust resources to improve productivity, or issues might arise that require settings to be modified or defaults to be reset. In some situations, an `asadmin` subcommand is provided for updating, such as the `update-connector-work-security-map` subcommand. However, most updating is done by using the `list`, `get`, and `set` subcommands with dotted names. For detailed information about dotted names, see the `dotted-names`(5ASC) help page.

Dotted names also apply to monitoring, but the method is slightly different. For information on using dotted names for monitoring, see How the Monitoring Tree Structure Works.

The general process for working with configuration changes on the command line is as follows:

- List the modules for the component of interest.
  The following single mode example uses the `|` (pipe) character and the `grep` command to narrow the search:

  ```
  asadmin list "*" | grep http | grep listener
  ```

  Information similar to the following is returned:

  ```
  configs.config.server-config.network-config.network-listeners.network-
  listener.http-listener-1
  configs.config.server-config.network-config.network-listeners.network-
  listener.http-listener-2
  configs.config.server-config.network-config.protocols.protocol.admin-listener.http
  configs.config.server-config.network-config.protocols.protocol.admin-
  listener.http.file-cache
  configs.config.server-config.network-config.protocols.protocol.http-listener-1
  configs.config.server-config.network-config.protocols.protocol.http-listener-1.http
  configs.config.server-config.network-config.protocols.protocol.http-listener-
  1.http.file-cache
  configs.config.server-config.network-config.protocols.protocol.http-listener-2
  configs.config.server-config.network-config.protocols.protocol.http-listener-2.http
  configs.config.server-config.network-config.protocols.protocol.http-listener-
  2.http.file-cache
  configs.config.server-config.network-config.protocols.protocol.http-listener-2.ssl
  ```

- Get the attributes that apply to the module you are interested in.

  The following multimode example gets the attributes and values for `http-listener-1`:

  ```
  asadmin> get server-config.network-config.network-listeners.network-listener.http-
  listener-1.*
  ```

  Information similar to the following is returned:

  ```
  server.http-service.http-listener.http-listener-1.acceptor-threads = 1
  server.http-service.http-listener.http-listener-1.address = 0.0.0.0
  server.http-service.http-listener.http-listener-1.blocking-enabled = false
  server.http-service.http-listener.http-listener-1.default-virtual-server = server
  server.http-service.http-listener.http-listener-1.enabled = true
  server.http-service.http-listener.http-listener-1.external-port =
  server.http-service.http-listener.http-listener-1.family = inet
  server.http-service.http-listener.http-listener-1.id = http-listener-1
  server.http-service.http-listener.http-listener-1.port = 8080
  server.http-service.http-listener.http-listener-1.redirect-port =
  server.http-service.http-listener.http-listener-1.security-enabled = false
  server.http-service.http-listener.http-listener-1.server-name =
  ```

- Modify an attribute by using the `set` subcommand.

  This example sets the `security-enabled` attribute of `http-listener-1` to true:

  ```
  asadmin> set server.http-service.http-listener.http-listener-1.security-enabled =
  true
  ```

Configuration Files

The bulk of the configuration information about Payara Server resources, applications, and instances is stored in the `domain.xml` configuration file. This file is the central repository for a given administrative domain and contains an XML representation of the Payara Server domain model. The default location for the `domain.xml` file is `domain-dir/config`.

Payara Server maintains a backup of the `domain.xml` file that is named `domain.xml.bak`. The purpose of this file is solely to enable Payara Server to start a domain if the `domain.xml` file cannot be read. Do not modify or delete the `domain.xml.bak` file and do not use this file for any other purpose.

The `logging.properties` file is used to configure logging levels for individual modules. The default `logging.properties` file is located in the same directory as the `domain.xml` file. For further information on the `logging.properties` file, see Logging Properties.

The `asenv.conf` file is located in the `as-install/config` directory. Its purpose is to store the Payara Server environment variables, such as the installation location of the database, Message Queue, and so on.

Changes are automatically applied to the appropriate configuration file. Do not edit the configuration files directly. Manual editing is prone to error and can have unexpected results.

Impact of Configuration Changes

Some configuration changes require that you restart the DAS or Payara Server instances for the changes to take effect. Other changes are applied dynamically without requiring that the DAS or instances be restarted. The procedures in this guide indicate when a restart is required. Payara Server enables you to determine whether the DAS or an instance must be restarted to apply configuration changes.

Some changes to resources or connection pools affect the applications that use the resources or connection pools. These changes do not require restart. However, any applications that use the resources or connection pools must be disabled and re-enabled or redeployed for the change to take effect.

To Determine Whether the DAS or an Instance Requires Restart

1. Ensure that the DAS is running.
   To obtain information about the DAS or an instance, a running server is required.

2. Do one of the following:
    - To determine if the DAS requires restart, list the domains in your Payara Server installation. Use the `list-domains` subcommand for this purpose.

      ```
      asadmin> list-domains [--domaindir domain-root-dir]
      ```

      The domain-root-dir is the directory that contains the directories in which individual domains' configuration is stored. The default is `as-install/domains`, where `as-install` is the base installation directory of the Payara Server software.

      If the DAS requires restart, a statement that restart is required is displayed.

    - To determine if an instance requires restart, list information about the instance.

      Use the `list-instances` subcommand for this purpose:

      ```
      asadmin> list-instances instance-name
      ```

      The instance-name is the name of the instance for which you are listing information.

      If the instance requires restart, one of the following pieces of information is displayed: a statement that restart is required, or a list of configuration changes that are not yet applied to the instance.

Example 1-1 Determine whether the DAS or an instance requires restart

This example determines that the DAS for the domain `domain1` requires restart to apply configuration changes.

```
asadmin> list-domains
domain1 running, restart required to apply configuration changes
Command list-domains executed successfully.
```

Example 1-2 Determine whether the DAS or an instance requires restart

This example determines that the instance `pmd-i1` requires restart to apply configuration changes.

```
asadmin> list-instances pmd-i1
pmd-i1   running;  requires restart
Command list-instances executed successfully.
```

- `list-domains`
- `list-instances`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line.

- `asadmin help list-domains`
- `asadmin help list-instances`

Configuration Changes That Require Restart

The following configuration changes require restart for the changes to take effect:

- Changing JVM options
- Changing port numbers
- Changing log handler elements
- Configuring certificates
- Managing HTTP, JMS, IIOP, JNDI services
- Enabling or disabling secure administration as explained in "Running Secure Admin" in the Payara Server Security Guide

Dynamic Configuration Changes

With dynamic configuration, changes take effect while the DAS or instance is running. The following configuration changes do not require restart:

- Adding or deleting add-on components
- Adding or removing JDBC, JMS, and connector resources and pools (Exception: Some connection pool properties affect applications.)
- Changing a system property that is not referenced by a JVM option or a port
- Adding file realm users
- Changing logging levels
- Enabling and disabling monitoring
- Changing monitoring levels for modules
- Enabling and disabling resources and applications
- Deploying, un-deploying, and redeploying applications

Changes That Affect Applications

Some changes to resources or connection pools affect the applications that use the resources or connection pools. These changes do not require restart. However, any applications that use the resources or connection pools must be disabled and re-enabled or redeployed for the change to take effect.

If you do not know which applications use the changed resources or connection pools, you can apply these changes by restarting the clusters or Payara Server instances to which applications are deployed. However, to minimize the disruption to the services that your applications provide, avoid restarting clusters or instances to apply these changes if possible.

The following changes affect applications:

- Creating or deleting resources (Exception: Changes to some JDBC, JMS, or connector resources do not affect applications.)
- Modifying the following JDBC connection pool properties:
  - `datasource-classname`
  - `associate-with-thread`
  - `lazy-connection-association`
  - `lazy-connection-enlistment`
  - JDBC driver vendor-specific properties
- Modifying the following connector connection pool properties:
  - `resource-adapter-name`
  - `connection-definition-name`
  - `transaction-support`
  - `associate-with-thread`
  - `lazy-connection-association`
  - `lazy-connection-enlistment`
  - Vendor-specific properties

Administration Tools

For the most part, you can perform the same tasks by using either the graphical Administration Console or the `asadmin` command-line utility, however, there are exceptions.

Administration Console

The Administration Console is a browser-based utility that features an easy-to-navigate graphical interface that includes extensive online help for the administrative tasks.

To use the Administration Console, the domain administration server (DAS) must be running. Each domain has its own DAS, which has a unique port number. When Payara Server was installed, you chose a port number for the DAS, or used the default port of 4848. You also specified a username and password if you did not accept the default login (`admin` with no password).

When specifying the URL for the Administration Console, use the port number for the domain to be administered. The format for starting the Administration Console in a web browser is `http://hostname:port`. For example:

```
https://admin.payara.fish:4848
```

If the Administration Console is running on the host where Payara Server was installed, specify `localhost` for the host name. For example:

```
http://localhost:4848
```

If the Administration Console is run on a host different from the host where Payara Server was installed, a secure connection (`https` instead of `http`) is used. Some browsers do not display pages on secure connections by default and must be configured to permit secure protocols (SSL and TLS).

You can display the help material for a page in the Administration Console by clicking the Help button on the page. The initial help page describes the functions and fields of the page itself.

If you try to use the Administration Console from a system through a proxy server on another system back to the original system, while using the system's full host name (instead of `localhost` or `127.0.0.1`) you are denied access because the request is treated as a remote request, which requires that the secure administration feature (secure admin) to be enabled.

To avoid this situation, do one of the following:

- Do not use a proxy server.
- Use `localhost` or `127.0.0.1` as the host name.
- Enable secure admin so that what Payara Server interprets as a remote request is accepted as such.

To enable secure admin, see "Managing Administrative Security" in the Payara Server Security Guide.

`asadmin` Utility

The `asadmin` utility is a command-line tool that runs subcommands for identifying the operation or task that you want to perform. You can run `asadmin` subcommands either from a command prompt or from a script.Running `asadmin` subcommands from a script is helpful for automating repetitive tasks. Basic information about how the `asadmin` utility works can be found in the `asadmin`(1M) help page. For instructions on using the `asadmin` utility, see Using the `asadmin` Utility.

To issue an `asadmin` subcommand in the standard command shell (single mode), go to the `as-install/bin` directory and type the `asadmin` command followed by a subcommand. For example:

```
asadmin list-jdbc-resources
```

You can invoke multiple command mode (multimode) by typing `asadmin` at the command prompt, after which the `asadmin>` prompt is presented. The `asadmin` utility continues to accept subcommands until you exit multimode and return to the standard command shell. For example:

```
asadmin> list-jdbc-resources
```

You can display a help page for any `asadmin` subcommand by typing `help` before the subcommand name. For example:

```
asadmin> help restart-domain
```

or

```
asadmin help restart-domain
```

A collection of the `asadmin` help pages is available in HTML and PDF format in the Payara Server Reference Manual.

REST Interfaces

Payara Server provides representational state transfer (REST) interfaces to enable you to access monitoring and configuration data for Payara Server, including data that is provided by newly installed add-on components. For more information, see Using REST Interfaces to Administer Payara Server.

OSGi Module Management Subsystem

The OSGi module management subsystem that is provided with Payara Server is the Apache Felix OSGi framework .

To administer this framework, use either the Apache Felix Gogo remote shell. This shell is provided with Payara Server. The shell uses the Felix Gogo shell-service to interact with the OSGi module management subsystem.

This tool allows you to perform administrative tasks on OSGi bundles such as:

- Browsing installed OSGi bundles
- Viewing the headers of installed OSGi bundles
- Installing OSGi bundles
- Controlling the life cycle of installed bundles

To Enable the Apache Felix Gogo Remote Shell

By default, the Apache Felix Gogo remote shell in Payara Server is disabled. Before using the shell to administer OSGi bundles in Payara Server, you must enable the shell.

Enabling the Apache Felix Gogo remote shell in Payara Server involves changing the value of the property `glassfish.osgi.start.level.final`. This property controls whether the OSGi start level service enables the shell when the DAS or a Payara Server instance is started.

1. Ensure that the DAS is running.
2. Change the value of the `glassfish.osgi.start.level.final` property from `2` to `3`.

   If the domain includes clustered or standalone instances on remote hosts, perform this step on each remote host. You can change this value either by creating a Java system property or by editing a file.

To change this value by creating a Java system property, create the system property `glassfish.osgi.start.level.final` with a value of `3`:

```
asadmin> create-jvm-options --target target -Dglassfish.osgi.start.level.final=3
```

To change this value by editing a file, edit the plain-text file `as-install/config/osgi.properties` to change the value of the `glassfish.osgi.start.level.final` property from `2` to `3`.

3. Restart the DAS.

For instructions, see To Restart a Domain.

To Run Apache Felix Gogo Remote Shell Commands

The Apache Felix Gogo remote shell is integrated with the Payara Server `asadmin` command line utility. You can use the `asadmin` subcommands `osgi` and `osgi-shell` to access the remote shell and run OSGi shell commands.

To Run Remote Shell Commands Using the `osgi` Subcommand

The `osgi` subcommand delegates the command line to the Apache Felix Gogo remote shell for the execution of OSGi shell commands. Commands are executed by the remote shell and results are returned by the `asadmin` utility. The `osgi` subcommand is supported in remote mode only.

1. Ensure that the server is running. Remote commands require a running server.
2. Access the remote shell by using the `osgi` subcommand. For the full syntax and options for this subcommand, see `osgi`.

To Run Remote Shell Commands Using the `osgi-shell` Subcommand

The `osgi-shell` subcommand provides interactive access to the Apache Felix Gogo remote shell for the execution of OSGi shell commands. OSGi shell commands are executed on the server and results are printed on the client. You can run multiple commands from a file or run commands interactively. The `osgi-shell` subcommand is supported in local mode only. Unlike other local subcommands, however, the DAS and the server instance whose shell is being accessed must be running.

1. Ensure that the server is running.
2. Access the remote shell by using the `osgi-shell` subcommand. For the full syntax and options for this subcommand, see `osgi-shell`.

Example 1-3 To run remote shell commands using the osgi-shell subcommand

This example lists Apache Felix Gogo remote shell commands. Some lines of output are omitted from this example for readability.

```
asadmin> osgi help

felix:bundlelevel
```

```
felix:cd
felix:frameworklevel
gogo:cat
gogo:each
gogo:echo

asadmin> osgi-shell
Use "exit" to exit and "help" for online help.

gogo$ help
felix:bundlelevel
felix:cd
felix:frameworklevel
gogo:cat
gogo:each
gogo:echo
```

Example 1-4 To run remote shell commands using the osgi-shell subcommand 2

This example runs the Felix Remote Shell Command `lb` without any arguments to list all installed OSGi bundles. Some lines of output are omitted from this example for readability.

```
asadmin> osgi lb
START LEVEL 2
ID|State      |Level|Name
 0|Active     |    0|System Bundle
 1|Active     |    1|Metro Web Services API OSGi Bundle
 2|Active     |    1|jakarta.annotation API
Command osgi executed successfully.

asadmin> osgi-shell
Use "exit" to exit and "help" for online help.
gogo$ lb
START LEVEL 2
ID|State      |Level|Name
 0|Active     |    0|System Bundle
 1|Active     |    1|Metro Web Services API OSGi Bundle
 2|Active     |    1|jakarta.annotation API
gogo$
```

Example 1-5 To run remote shell commands using the osgi-shell subcommand 3

This example runs the Felix Remote Shell Command `inspect` with the `service` option and the `capability` option to determine the services that OSGi bundle `251` provides. Some lines of output are omitted from this example for readability.

```
asadmin> osgi inspect service capability 251
Payara EJB Container for OSGi Enabled EJB Applications (251) provides services:
--------------------------------------------------------------------------------
```

```
objectClass = org.glassfish.osgijavaeebase.Extender
service.id = 68
-----
objectClass = org.glassfish.osgijavaeebase.OSGiDeployer
service.id = 69
service.ranking = -2147483648
Command osgi executed successfully.
...
asadmin> osgi -shell
Use "exit" to exit and "help" for online help.
gogo$ inspect service capability 251
Payara EJB Container for OSGi Enabled EJB Applications (251) provides services:
--------------------------------------------------------------------------------
objectClass = org.glassfish.osgijavaeebase.Extender
service.id = 68
...
gogo$
```

Java Monitoring and Management Console (JConsole)

Java SE provides tools to connect to an MBean server and view the MBeans that are registered with the server. JConsole is one such popular JMX Connector Client and is available as part of the standard Java SE distribution.

For instructions on integrating JConsole in the Payara Server environment, see Configuring JConsole to View Payara Server Monitoring Data.

Instructions for Administering Payara Server

Information and instructions on performing most of the administration tasks from the command line are provided in this document and in the `asadmin` utility help pages. For instructions on accessing `asadmin` online help, see To Display Help Information for the `asadmin` Utility or a Subcommand.

Phone Home

All Payara Platform distributions report back a limited amount of information about their specific configuration at launch time. No sensitive data about your machine or specific usage of Payara Server is sent to 0s or any member of the Payara Services team.

Gathered phone home data is sent via a `GET` request to http://www.payara.fish/phonehome

The following is the list of information attributes gathered by the Phone Home service:

Attribute	Example
Payara Server Version	main-7 #badassfish
Java Virtual Machine Version	1.8.0_121
Domain Uptime	36500

Attribute	Example
Number of nodes in the domain	1
Number of instances in the domain	2
Randomly generated UUID	eaa6fe2c-2388-4aa7-fdcc-288c7b318ddfeaa6ef23-2388-4aa7-8dcc-288c7b318ddf

This is the only data which the phone home service gathers from your system.

The UUID is specific to the DAS and is randomly generated on startup, so it is not machine specific.

What is the data used for?

The phone home data is presently used to gather usage statistics about the corresponding distribution, such as how long users typically run instances, and what versions they use.

Previously this could only be done at an extremely simple level from downloads over time, giving us no idea how Payara Server is used beyond specific interactions with contributors and customers which may not accurately represent the state of our user base.

The phone home service was designed as a non-intrusive survey tool which would only gather data specific to Payara and has no contact with any running applications, or indeed anything on your machine other than the mentioned attributes.

Disabling and Enabling Phone Home

The phone home service is enabled by default when starting a Payara Server. The phone home service can be easily disabled in the following ways.

Enable the Phone Home service

```
asadmin> enable-phone-home
```

See `enable-phone-home`

Disable the Phone Home service

Using Asadmin

Run this asadmin command and then restart the server to disable PhoneHome

```
asadmin> disable-phone-home
```

See `disable-phone-home`

Disable by Removing The Service Module

- Navigate to the `${PAYARA_INSTALL_DIR}/glassfish/modules` directory
- Delete the `phonehome-bootstrap.jar` module.

List the current status of the Phone Home service.

```
asadmin> list-phone-home
```

See `list-phone-home`

General Runtime Administration

This chapter provides instructions for performing general administration tasks in the Payara Server environment by using the `asadmin` command-line utility.

Using the `asadmin` Utility

Use the `asadmin` utility to perform administrative tasks for Payara Server from the command line or from a script. You can use this utility instead of the Administration Console interface.

Path to the `asadmin` Utility

The `asadmin` utility is located in the `as-install/bin` directory. To run the `asadmin` utility without specifying the path, ensure that this directory is in your path.

`asadmin` Utility Syntax

The syntax for running the `asadmin` utility is as follows:

```
asadmin [asadmin-util-options] [subcommand [subcommand-options] [operands]]
```

The replaceable items in this syntax are described in the subsections that follow.

Subcommands of the `asadmin` Utility

The subcommand identifies the operation or task that you are performing. Subcommands are case-sensitive. Each subcommand is either a local subcommand or a remote subcommand.

- A local subcommand can be run without a running domain administration server (DAS). However, to run the subcommand and have access to the installation directory and the domain directory, the user must be logged in to the machine that hosts the domain.

- A remote subcommand is always run by connecting to a DAS and running the subcommand there. A running DAS is required.

`asadmin` Utility Options and Subcommand Options

Options control the behavior of the `asadmin` utility and its subcommands. Options are case-sensitive.

The `asadmin` utility has the following types of options:

`asadmin` utility options
: These options control the behavior of the `asadmin` utility, not the subcommand.

  The `asadmin` utility options may precede or follow the subcommand, but `asadmin` utility options after the subcommand are deprecated.

  All `asadmin` utility options must either precede or follow the subcommand. If `asadmin` utility options are specified both before and after the subcommand, an error occurs.

Subcommand Options
: These options control the behavior of the subcommand, not the `asadmin` utility. Subcommand options must follow the subcommand.

A subcommand option may have the same name as an `asadmin` utility option, but the effects of the two options are different.

Options have a long form and a short form.

- The short form of an option has a single dash (`-`) followed by a single character.
- The long form of an option has two dashes (`--`) followed by an option word.

For example, the short form and the long form of the option for specifying terse output are as follows:

- Short form: `-t`
- Long form: `--terse`

Most options require argument values, except `Boolean` options, which toggle to enable or disable a feature.

Operands of `asadmin` Utility Subcommands

Operands specify the items on which the subcommand is to act. Operands must follow the argument values of subcommand options, and are set off by a space, a tab, or double dashes (`--`). The `asadmin` utility treats anything that follows the subcommand options and their values as an operand.

To Run an `asadmin` Utility Subcommand in Single Mode

In single mode, you must type a separate `asadmin` command for each subcommand that you want to use. After the subcommand has run, you are returned to the operating system's command shell.

Any `asadmin` utility options must be specified in each separate `asadmin` command that you run.

If you require the same `asadmin` utility options for multiple subcommands, use the `asadmin` utility in multimode. For more information, see To Start a Multimode Session.

1. In the operating system's command shell, run the `asadmin` utility, specifying the subcommand.
2. If necessary, also specify any required `asadmin` utility options, subcommand options, and operands.

Example 2-1 Running an asadmin Utility Subcommand in Single Mode

```
asadmin list-applications
hello <web>
Command list-applications executed successfully.
```

This example runs the `list-applications` subcommand in single mode. In this example, the default values for all options are used.

The example shows that the application `hello` is deployed on the local host.

Example 2-2 Specifying an asadmin Utility Option With a Subcommand in Single Mode

```
asadmin --host srvr1.example.com list-applications
basic-ezcomp <web>
scrumtoys <web>
ejb31-war <ejb, web>
automatic-timer-ejb <ejb>
Command list-applications executed successfully.
```

This example specifies the `--host asadmin` utility option with the `list-applications` subcommand in single mode. In this example, the DAS is running on the host `srvr1.example.com`.

The example shows that the applications `basic-ezcomp`, `scrumtoys`, `ejb31-war`, and `automatic-timer-ejb` are deployed on the host `srvr1.example.com`.

Example 2-3 Specifying an `asadmin` Utility Option and a Subcommand Option in Single Mode

```
asadmin --host srvr1.example.com list-applications --type web
basic-ezcomp <web>
scrumtoys <web>
ejb31-war <ejb, web>
Command list-applications executed successfully.
```

This example specifies the `--host asadmin` utility option and the `--type` subcommand option with the `list-applications` subcommand in single mode. In this example, the DAS is running on the host `srvr1.example.com` and applications of type `web` are to be listed.

To Display Help Information for the `asadmin` Utility or a Subcommand

Payara Server provides help information about the syntax, purpose, and options of the `asadmin` utility and its subcommands.

This help information is also available in the Payara Server Command Reference Manual.

1. If you are displaying help information for a remote subcommand, ensure that the server is running. Remote subcommands require a running server.
2. Specify the subcommand of interest as the operand of the `help` subcommand. If you run the `help` subcommand without an operand, help information for the `asadmin` utility is displayed.

Example 2-4 Displaying Help Information for the `asadmin` Utility

```
asadmin help
```

This example displays the help information for the `asadmin` utility.

Example 2-5 Displaying Help Information for an `asadmin` Utility Subcommand

```
asadmin help create-jdbc-resource
```

This example displays the help information for the `create-jdbc-resource` subcommand.

To display the available subcommands, use the `list-commands` subcommand. Local subcommands are displayed before remote subcommands. If the server is not running, only local subcommands are displayed.

To Start a Multimode Session

The `asadmin` utility can be used in multiple command mode, or multimode. In multimode, you run the `asadmin` utility once to start a multimode session.During the session, the `asadmin` utility continues to accept subcommands until you end the session and return to the operating system's command shell.

Any `asadmin` utility options that you set for your multimode session are used for all subsequent subcommands in the session.

Starting a multimode session does not require a running DAS.

1. Do one of the following:
   - Run the `asadmin` utility without a subcommand.
   - Use the `multimode` subcommand.
2. If necessary, also specify any `asadmin` utility options that will apply throughout the multimode session.
3. In a multimode session, the `asadmin>` prompt is displayed on the command line. You can now

type `asadmin` subcommands at this prompt to administer Payara Server.

Example 2-6 Starting a Multimode Session With `asadmin` Utility Options

```
asadmin --user admin1 --passwordfile pwd.txt multimode
```

This example starts a multimode session in which the `asadmin` utility options `--user` and `--passwordfile` are set for the session.

Example 2-7 Starting a Multimode Session by Using the `multimode` Subcommand

```
asadmin multimode
```

This example uses the `multimode` subcommand to start a multimode session in which the default `asadmin` utility options are used.

The `asadmin>` prompt is displayed on the command line.

Example 2-8 Running a Subcommand in a Multimode Session

```
asadmin
Use "exit" to exit and "help" for online help.

asadmin> list-domains
Name: domain1 Status: Running
Command list-domains executed successfully.
asadmin>
```

This example starts a multimode session and runs the `list-domains` subcommand in the session.

Starting a Multimode Session From Within an Existing Multimode Session

You can start a multimode session from within an existing session by running the `multimode` subcommand from within the existing session. After you end the second multimode session, you return to your original multimode session.

To End a Multimode Session

At the `asadmin>` prompt, type one of the following commands or key combinations:

- `exit`
- `quit`
- UNIX and Linux systems: `Ctrl-D`
- Windows systems: `Ctrl-Z`

Do not type `Ctrl-C` to end a multimode session. If a domain or Payara Server

instance is started from the multimode session, typing `Ctrl-C` kills the domain or instance process.

You are returned to the operating system's command shell and the `asadmin>` prompt is no longer displayed. If the `asadmin>` prompt is still displayed, you might have opened a multimode session within a multimode session. In this situation, repeat this procedure to end the remaining multimode session.

To enable Multimode Session Event Designators

This feature allows the use of **Bash Event Designators** when using Payara Server's Asadmin CLI in multimode.

An Event Designator is a reference to a command line entry in the history list, which makes it easy for users to refer and re-use previous asadmin subcommands entries.

This feature is disabled by default in Payara Server and has to be enabled first before being used.

If this feature is enabled, all occurrences of the `\` character will be escaped and thus, removed before running the corresponding command. You'll have to escape these characters and turn them into `\\` for any commands to be properly parsed.

Enabling JLine Event Expansion

To enable support for JLine event designators just set the `AS_ADMIN_DISABLE_EVENT_EXPANSION` environment variable to `false`. Follow these steps depending on your operating system:

Linux and *Nix variants

1. Open the Terminal
2. Type the following command

```
export AS_ADMIN_DISABLE_EVENT_EXPANSION=false
```

3. Check that the variable has been correctly set:

```
echo $AS_ADMIN_DISABLE_EVENT_EXPANSION
```

Windows

1. Open Command Prompt as an Administrator
2. Type the following commands

```
setx AS_ADMIN_DISABLE_EVENT_EXPANSION "false" /m
```

```
set AS_ADMIN_DISABLE_EVENT_EXPANSION=false
```

3. Check that the variable has been correctly set:

```
echo %AS_ADMIN_DISABLE_EVENT_EXPANSION%
```

To Run a Set of `asadmin` Subcommands From a File

Running a set of `asadmin` subcommands from a file enables you to automate repetitive tasks.

1. Create a plain text file that contains the sequence of subcommands that you want to run.
2. Run the `multimode` subcommand, specifying the file that you created.

   If necessary, also specify any `asadmin` utility options that are required to enable subcommands in the file to run.

Example 2-9 Running a Set of `asadmin` Subcommands From a File.

```
create-domain --portbase 9000 customdomain
start-domain customdomain
list-commands
stop-domain customdomain
delete-domain customdomain
```

This example contains the following:

- A listing of a file that is named `commands_file.txt`, which contains a sequence of `asadmin` subcommands.
- The command to run the subcommands in the file `commands_file.txt`

The `commands_file.txt` file contains the `asadmin` utility subcommands to perform the following sequence of operations:

1. Creating the domain `customdomain`
2. Starting the domain `customdomain`
3. Listing all available subcommands
4. Stopping the domain `customdomain`
5. Deleting the domain `customdomain`

This example runs the sequence of subcommands in the `commands_file.txt` file. Because the `--portbase` option is specified for the `create-domain` subcommand in the file, the `--port asadmin` utility option must also be set.

```
asadmin --port 9048 multimode --file commands_file.txt
```

For more information about the subcommands in the preceding example, see the following help pages:

- `create-domain`
- `delete-domain`
- `list-commands`
- `multimode`
- `start-domain`
- `stop-domain`

To Run `asadmin` Subcommands in `--detach` Mode

You can use the `--detach` option of the `asadmin` utility to detach `asadmin` subcommands and run them in the background in detach mode. The `asadmin --detach` option is useful for long-running subcommands and enables you to run several independent subcommands from one console or script.

1. Ensure that the server is running. Remote commands require a running server.
2. Detach and run the subcommand by using the `asadmin --detach` option.

Example 2-10 Using the `--detach` Option in Single Mode

```
asadmin --detach create-cluster Cluster1
Job ID: 1
Command create-cluster started successfully.
```

This example uses the `asadmin --detach` option in single mode to run the `create-cluster` subcommand.

Example 2-11 Using the `--detach` Option in Multimode

```
asadmin> create-cluster Cluster1 --detach
Job ID: 1
Command create-cluster started successfully.
```

This example uses the `asadmin --detach` option in multimode to run the `create-cluster` subcommand.

Job IDs are assigned to subcommands that are started using the `asadmin --detach` option or that contain progress information. You can use the `list-jobs` subcommand to list jobs and their job IDs, the `attach` subcommand to reattach to a job and view its status, and the `configure-managed-jobs` subcommand to configure how long information about jobs is kept.

Example 2-12 Listing Jobs

```
asadmin> list-jobs
JOB ID     COMMAND           STATE       EXIT CODE TIME OF COMPLETION
1          create-instance    COMPLETED   SUCCESS   2023-02-15 16:16:16 PST
2          deploy            COMPLETED   FAILURE   2023-02-15 18:26:30 PST
Command list-jobs executed successfully
```

This example runs the `list-jobs` subcommand in multimode to list jobs and job information.

Example 2-13 Attaching to a Subcommand and Checking Its Status

```
asadmin> attach 1
Command create-cluster executed with status SUCCESS.
Command attach executed successfully.
```

This example runs the `attach` subcommand in multimode to attach to the `create-cluster` subcommand with a job ID of `1`. If a subcommand is still in progress, the output displays the current status, such as percentage complete.

Example 2-14 Configuring Managed Jobs

```
asadmin> configure-managed-jobs --job-retention-period=36h
Command configure-managed-jobs executed successfully.
```

This example runs the `configure-managed-jobs` subcommand in multimode to set the job retention period to 36 hours. Time periods can be specified in `Hh|Mm|Ss` format for hours, minutes, or seconds.

For the full syntax and options of the subcommands in the preceding examples, see the following help pages:

- `attach`
- `configure-managed-jobs`
- `list-jobs`

Administering System Properties

Shared server instances will often need to override attributes defined in their referenced configuration. Any configuration attribute can be overridden through a system property of the corresponding name.

To Create System Properties

Use the `create-system-properties` subcommand in remote mode to create or update one or more system properties of the domain or configuration. Any configuration attribute can be overwritten through a system property of the corresponding name.

1. Ensure that the server is running. Remote subcommands require a running server.

2. Create system properties by using the `create-system-properties` subcommand.

Example 2-15 Creating a System Property

```
asadmin> create-system-properties http-listener-port=1088
Command create-system-properties executed successfully.
```

This example creates a system property associated with `http-listener-port=1088` on `localhost`.

To List System Properties

Use the `list-system-properties` subcommand in remote mode to list the system properties that apply to a domain, cluster, or server instance or configuration.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List system properties by using the `list-system-properties` subcommand.

The existing system properties are displayed, including predefined properties such as `HTTP_LISTENER_PORT` and `HTTP_SSL_LISTENER_PORT`.

Example 2-16 Listing System Properties

```
asadmin> list-system-properties
http-listener-port=1088
Command list-system-properties executed successfully.
```

This example lists the system properties on host `localhost`.

To Delete a System Property

Use the `delete-system-property` subcommand in remote mode to delete system properties.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the existing system properties by using the `list-system-properties` subcommand.
3. Delete the system property by using the `delete-system-property` subcommand.
4. If necessary, notify users that the system property has been deleted.

Example 2-17 Deleting a System Property

```
asadmin> delete-system-property http-listener-port
Command delete-system-property executed successfully.
```

This example deletes a system property named `http-listener-port` from `localhost`.

System Properties Inventory

The following properties are used exclusively by Payara Server to configure specific settings across multiple features:

`fish.payara.clientHttpsProtocol`

Sets the TLS version to be used by the asadmin client.

This is separate from the TLS version set for HTTPS communication on a listener.

Valid values are:

- `TLSv1.2`,
- `TLSv1.3`
- `TLSv1.3` (default)

`fish.payara.classloading.delegate`

When set to `false`, libraries from applications, and `domain-dir/lib` will override the library in the `as-install/glassfish/modules` directory

Defaults to `true`.

`fish.payara.admin.command.jline.log.disable`

When set to `true`, JLine logging entries for invalid key bindings and other unwanted errors will be prevented

This is a property used exclusively by the Asadmin CLI

Defaults to `false`

`fish.payara.deployment.transform.namespace`

When set to `true`, namespace transformation (`javax.*` to `jakarta.\*` package refactoring) is always performed.

If the value is `undefined` then auto transformation is performed on the absence of `jakarta.\*` classes in the deployment archive otherwise transformation task is disabled.

Defaults to `null` (undefined)

`fish.payara.permittedFormBasedAuthHttpMethods`

A comma separated list of HTTP methods that are permitted to use for FORM based authentication (`j_security_check`).

If not set all HTTP methods are permitted.

Valid values are:

- `GET`
- `HEAD`

- `POST`
- `PUT`
- `DELETE`
- `CONNECT`
- `OPTIONS`
- `TRACE`
- `PATCH`

Defaults to `null` (undefined)

`fish.payara.shutdowngrace`

After server shutdown is initiated the server waits this period of time (in seconds) to finish ongoing requests before terminating.

New requests are still accepted during this grace period. Accepts values between `0` - `Integer.MAX` and defaults to `0`.

`fish.payara.SO_KEEPALIVE`

Enables keep alive (`SO_KEEPALIVE`) on the sockets created by an IIOP listener. Can be set as a global system property, or as a property on a specific listener (with the latter taking precedence over the global setting if both are set). Defaults to `false`

`org.glassfish.grizzly.DEFAULT_MEMORY_MANAGER`

If option (defined as JVM Option with `-D` or as System Property value) `org.glassfish.grizzly.DEFAULT_MEMORY_MANAGER` is not present in the server/instance configuration, the server will override the Grizzly default and use the `HeapMemoryManager` class.

To override this behaviour (so to use a different memory manager), you must specify this JVM option in the server/instance config with your desired setting.

Valid values are:

- `org.glassfish.grizzly.memory.HeapMemoryManager` (default)
- `org.glassfish.grizzly.memory.PooledMemoryManager`
- `org.glassfish.grizzly.memory.ByteBufferManager`

`deployment.resource.validation`

This option (defined as JVM Option with `-D` or as System Property value) defines if the resources are validated during deployment of the application.

When active, the default value, all JNDI references are verified but those references can be provided by the application itself and thus not yet available at deployment time (for example the `java:module/env/` based ones).

By setting this option to `false`, validation is not performed and deployment will succeed.

However, issues will occur at runtime of the application in case of errors in the references.

Defaults to `true`

`fish.payara.faces.integration.allowFacesCdiInitialisation`

This option specifies whether scanning for Jakarta Faces content during application deployment is enabled. When enabled, if Faces content is detected, it forces an attempt to initialise CDI and Weld, even if bean discovery is set to "none".

A similar property can be set as a property `deploy` command. See deploy for details.

The `deploy` command property has precedence over the value defined by this property.

Default is `false`.

`fish.payara.javax.servlet.jsp.disable-static-field-references`

This option brings back the behaviour of evaluating EL in JSP pages from previous iterations.

When enabled, a static field reference won't be evaluated.

Defaults to `false`

`fish.payara.node.ssh.timeout`

This option sets the SSH timeout in milliseconds for running commands on SSH nodes.

This is a separate timeout to the Asadmin CLI communication or any command specific timeout, this is specifically for the SSH connection used for running certain commands that operate on the remote node itself (e.g. `setup-ssh` and `start-instance`).

If set to an invalid value a warning will be logged and the default will be used.

Accepts values from `1` - `Integer.MAX`. Defaults to `120000ms`

`fish.payara.tenantcontrol.blocking.disable`

This option determines if a server instance should skip its standard checks for if it is available for a Hazelcast `Tenantable` object.

Defaults to `true`.

`fish.payara.upgrade.repo.url`

This option defines the Maven repository URL used by the `upgrade-server` command.

Accepts a URL pointing to the Payara Enterprise Nexus repository to download from (expected to point to the `fish/payara/distributions` directory of the repository).

Defaults to `https://nexus.payara.fish/repository/payara-enterprise-downloadable-artifacts/fish/payara/distributions/`

`hazelcast.cp-subsystem.auto-promote`

When the Payara Server's Data Grid/Hazelcast CP subsystem is enabled (more than `0` members are configured), this option will enable or disable an auto-promote behaviour that will allow other server instances to join the Hazelcast CP subsystem when detected by the DAS.

The CP subsystem is automatically enabled on the Data Grid/Hazelcast when the `hazelcast.cp-subsystem.cp-member-count` system property is set an integer greater than zero.

Defaults to `true`

`hazelcast.auto-partition-group`

Enables/disables Hazelcast group auto-partitioning behaviour in Payara Server's Data Grid.

When auto-partitioning is turned on, instances that join the Data Grid will not follow the default partition group configuration strategy and instead will form individual partition groups. Read more about how partition groups work in the official Hazelcast Platform documentation.

This option is intended to make member partitioning work consistently for highly dynamic environments (like Kubernetes).

Use this option with extreme care

`fish.payara.ready-after-applications`

This option determines when the server is marked as "ready".

When enabled: The server is marked as ready after all post-boot configuration has been applied and all previously deployed applications have been loaded.

When disabled: the server is marked as ready after all `InstanceLifecycleListener` components and services have processed the `server_startup` event, but before post-boot configuration is applied and previously deployed applications are loaded.

Defaults to `true`.

Using Configuration Modularity

With configuration modularity in Payara Server, new modules can be added to Payara Server distributions without modifying the global `domain.xml` configuration file. Default configuration data for modules is stored in the modules themselves, rather than in `domain.xml`, and loaded when needed.

Module configuration elements are stored in `domain.xml` only when the default configuration included in the module is changed or when module configuration elements are added to `domain.xml` using the `create-module-config` subcommand. The `delete-module-config` subcommand removes module configuration elements from `domain.xml`, and the `get-active-module-config` subcommand displays the current active configuration of a module.

To Add the Default Configuration of a Module to `domain.xml`

Use the `create-module-config` subcommand to add the default configuration of a module to `domain.xml`.

1. Ensure that the server is running. Remote subcommands require a running server.

2. Add the default configuration of a module to `domain.xml` by using `create-module-config` subcommand.

Example 2-18 Adding Module Configuration to `domain.xml`

```
asadmin> create-module-config web-container
Command create-module-config executed successfully.
```

This example adds the default configuration of the web container module to `domain1` in `server-config` (the default configuration). Use the `--dryrun` option to preview the configuration before it is added.

To Remove the Configuration of a Module From `domain.xml`

Use the `delete-module-config` subcommand to remove the configuration of a module from `domain.xml` and cause the module to use the default configuration included in the module.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Remove the configuration of a module from `domain.xml` by using the `delete-module-config` subcommand.

Example 2-19 Removing Module Configuration From `domain.xml`

```
asadmin> delete-module-config web-container
Command delete-module-config executed successfully.
```

This example deletes the configuration of the web container module from `domain1` in `server-config` (the default configuration).

To Display the Current Active Configuration of a Module

Use the `get-active-module-config` subcommand to display the current active configuration of a module.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Display the current active configuration of a module by using the `get-active-module-config` subcommand.

Example 2-20 Displaying the Current Active Configuration of a Module

```
asadmin> get-active-module-config jms-service
At location: domain/configs/config[server-config]
<jms-service default-jms-host="default_JMS_host" type="EMBEDDED"
  <jms-host port="7676" host="localhost" name="default_JMS_host"/>
</jms-service>
Command get-active-module-config executed successfully.
```

This example displays the current active configuration of the JMS service in `server-config` (the default configuration).

Administering Resources

This section contains instructions for integrating resources into the Payara Server environment.Information about administering specific resources, such as JDBC, is contained in other chapters.

To Add Resources From an XML File

Use the `add-resources` subcommand in remote mode to create the resources named in the specified XML file. The following resources are supported: JDBC connection pool and resource, JMS, JNDI, and JavaMail resources, custom resource, connector resource and work security map, admin object, and resource adapter configuration.

The XML file must reside in the `domain-dir/config` directory. If you specify a relative path or simply provide the name of the XML file, this subcommand will prepend `domain-dir/config` to this operand.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Add resources from an XML file by using the `add-resources` subcommand. Information about properties for the subcommand is included in this help page.
3. Restart Payara Server. See To Restart a Domain.

Example 2-21 Adding Resources

```
asadmin> add-resources c:\tmp\resource.xml
Command : JDBC resource jdbc1 created successfully.
Command : JDBC connection pool poolA created successfully.
Command add-resources executed successfully.
```

This example creates resources using the contents of the `resource.xml` file on `localhost`.

Listing Various System Elements

To Display the Payara Server Version

Use the `version` subcommand in remote mode to display information about the Payara Server version for a particular server. If the subcommand cannot communicate with the server by using the specified login (user/password) and target (host/port) information, then the local version is displayed along with a warning message.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Display the version by using the `version` subcommand.

Example 2-22 Displaying Version Information

```
asadmin> version
```

```
Version = Payara Server main-7 #badassfish (build 00)
Command version executed successfully.
```

This example displays the version of Payara Server on the local host.

To List Applications

Use the `list-applications` subcommand in remote mode to list the deployed applications. If the `--type` option is not specified, all applications are listed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List applications by using the `list-applications` subcommand.

Example 2-23 Listing Applications

```
asadmin> list-applications --type web
hellojsp <web>
Command list-applications executed successfully.
```

This example lists the web applications on `localhost`.

To List Containers

Use the `list-containers` subcommand in remote mode to list application containers.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List containers by using the `list-containers` subcommand.

Example 2-24 Listing Containers

```
asadmin> list-containers
List all known application containers

faulttolerance
metrics
appclient
jpa
jpa
osgi
connector
grizzly
health
jwtauth
ejb
openapi
webservices
security
payara-resources_ear
```

```
payara-resources
resources_ear
resources
web
ear
cdi
cdi
config
Command list-containers executed successfully.
```

This example lists the containers on `localhost`.

To List Modules

Use the `list-modules` subcommand in remote mode to list the modules that are accessible to the Payara Server module subsystem. The status of each module is included. Possible statuses include NEW and READY.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List modules by using the `list-modules` subcommand.

Example 2-25 Listing Modules

```
asadmin> list-modules
```

This example lists the accessible modules.

Information similar to the following is displayed (partial output):

```

...
Command list-modules executed successfully.
```

To List Subcommands

Use the `list-commands` subcommand in remote mode to list the deployed `asadmin` subcommands. You can specify that only remote subcommands or only local subcommands are listed. By default, this subcommand displays a list of local subcommands followed by a list of remote subcommands.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List subcommands by using the `list-commands` subcommand.

Example 2-26 Listing Subcommands

```
asadmin> list-commands --localonly
create-domain
delete-domain
list-commands
list-domains
login
monitor
start-database
start-domain
stop-domain
stop-database
version
Command list-commands executed successfully.
```

This example lists only local subcommands.

To List Timers

The timer service is a persistent and transactional notification service that is provided by the enterprise bean container and is used to schedule notifications or events used by enterprise beans. All enterprise beans except stateful session beans can receive notifications from the timer service.

Persistent timers set by the service are not destroyed when the server is shut down or restarted.

Use the `list-timers` subcommand in remote mode to list the persistent timers owned by a specific server instance. You can use this information to decide whether to do a timer migration, or to verify that a migration has been completed successfully.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List timers by using the `list-timers` subcommand.

Example 2-27 Listing Timers

```
asadmin> list-timers server
1
The list-timers command was executed successfully.
```

This example lists the timers in a particular standalone server instance. There is one currently active timer set.

To Show Component Status

Use the `show-component-status` subcommand in remote mode to get the status (either enabled or disabled) of the specified deployed component.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Show component status by using the `show-component-status` subcommand.

Example 2-28 Showing Status of a Component

```
asadmin> show-component-status MEjbApp
Status of MEjbApp is enabled
Command show-component-status executed successfully.
```

This example shows the status of the `MEjbApp` component.

- GNU Wget

The implementation of the Payara Server REST interfaces is based on project Jersey. Project Jersey is the reference implementation of Jakarta RESTful Web Services.

Using REST Interfaces for Server Administration

Payara Server provides representational state transfer (REST) interfaces to enable you to access monitoring and configuration data for Payara Server, including data that is provided by newly installed add-on components.

You can access the Payara Server REST interfaces through client applications such as:

- Web browsers
- REST API Clients
- cURL

It allows execution of administration commands in a similar way as the `asadmin` utility, such as:

- Execute administration commands to modify the domain's configuration.
- Retrieve monitoring statistics
- Look at the domain's log entries.

Using REST URLs to Administer Payara Server

Each object in the configuration and monitoring object trees is represented as a REST resource that is accessible through an HTTP uniform resource locator (URL).

Access to REST resources for Payara Server monitoring and configuration data requires a running DAS.

REST URLs to Resources for Configuration and Monitoring Objects

The formats of the URLs to resources that represent objects in the configuration and monitoring object trees are as follows:

- Configuration: `http://host:port/management/domain/path`
- Monitoring: `http://host:port/monitoring/domain/path`

The replaceable items in these URLs are as follows:

host
: The host where the DAS is running.

port
: The HTTP port or HTTPS port for administration.

path
: The path to the object. The path is the dotted name of the object in which each dot (`.`) is replaced with a slash (`/`).

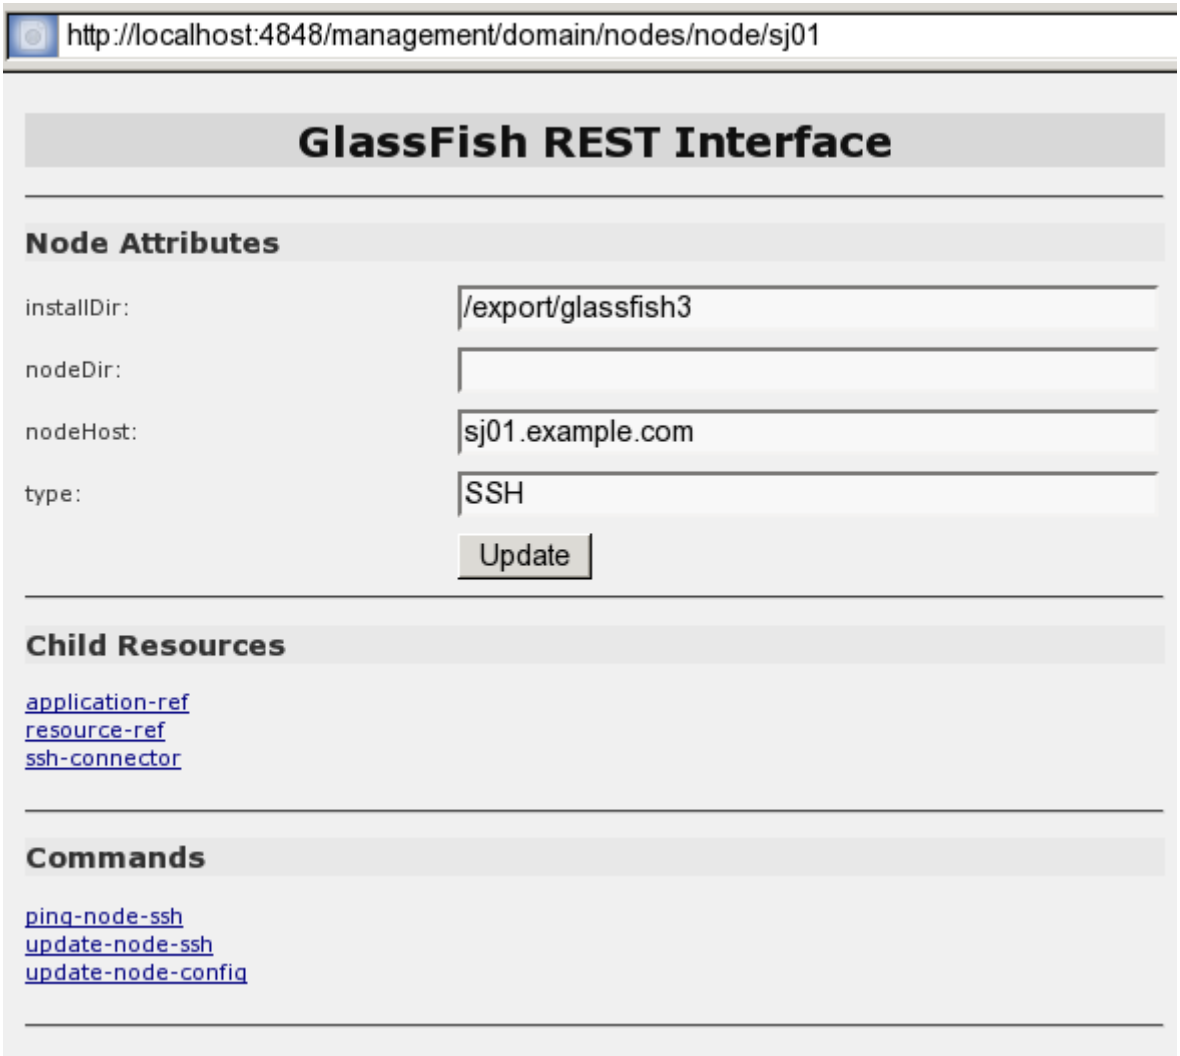
The path to a Payara Server instance is `servers/server/<instance-name>`, where `instance-name` is the name of the instance. For the DAS, `instance-name` is `server` and the path is `servers/server/server`.

If the URL to a REST resource for Payara Server monitoring or configuration data is opened in a web browser, the browser displays a web page that contains the following information about the resource:

- A list of the attributes of the resource and their values. If the resource represents an object in the configuration tree, these attributes are presented in an HTML form that you can use to update the resource. Attributes of a resource for an object in the monitoring tree are read only.
- A list of hypertext links to the children of the resource. This list of links enables you to traverse the tree that contains the resource and to discover the all resources in the tree.
- A list of hypertext links to resources that represent `asadmin` subcommands for non-CRUD operations on the resource.

The following figure shows the web page for the REST resource for managing a domain.

Web Page for the REST Resource for Managing a Domain



REST URLs for Accessing the Log File

The `server.log` file of the DAS is represented as a child that is named `view-log` of the resource for managing the domain. A child of the resource for the `server.log` file represents the log file details

The formats of the URLs to resources that represent the log file are as follows:

- Log file: `http://host:port/management/domain/view-log`
- Log file details: `http://host:port/monitoring/domain/view-log/details`

The replaceable items in these URLs are as follows:

host
: The host where the DAS is running.

port
: The HTTP port or HTTPS port for administration.

You can use the optional `start` parameter in the URL to the resource for the log file to specify the number of characters at the start of the file to skip.

For example, to skip 10,000 characters, specify the URL as `http://localhost:4848/management/domain/view-log?start=10000`. This example assumes that the DAS is running on the local host and uses the default port for administration.

The resource for the log file returns the HTTP header `X-Text-Append-Next`, which contains the entire URL to pass to the `GET` method to return the changes since the last call. You can use this header in client applications to get all log entries that were added in particular interval.

For example, by testing the value of the `X-Text-Append-Next` header in a client thread every 10 seconds, you can monitor the log entries that were added in the last 10 seconds.

Using REST Resource Methods to Administer Payara Server

The Payara Server REST interfaces support methods for accessing objects in the monitoring and configuration object trees.

The following table shows the REST methods for administering monitoring and configuration data and the tasks that you can perform with each method.

Table 1. REST Resource Methods for Administering Monitoring and Configuration Data

Task	REST Method
Determine the methods and method parameters that an object in the tree supports	`GET`
Retrieve data for an object in the tree	`GET`
Add an object to the tree	`POST`
Update an object in the tree	`POST`
Delete an object from the tree	`DELETE`

REST requests that add, update, or delete objects must specify the `X-Requested-By` header with the value `GlassFish REST HTML interface`.

The `GET` method determines the methods and method parameters that an object in the tree supports and provides additional information about the object. For details, see To Retrieve Data for an Object in the Tree.

To Determine the Methods and Method Parameters That an Object in the Tree Supports

The methods and method parameters that an object in the tree supports depend on the REST resource that represents the object:

- REST resources for monitoring support only the `GET` method.
- All REST resources for configuration support the `GET` method.

However, only some REST resources for configuration also support the `POST` method and the `DELETE` method.

Before performing any operations on an object in the tree, determine the methods and method parameters that the object supports.

You can specify the format in which this information is presented. For more information, see Formats for Resource Representation of Configuration Objects.

Each `POST` method and `DELETE` method that a REST resource supports has an equivalent `asadmin` subcommand. The parameters of a `POST` method or a `DELETE` method correspond to the options of the method's equivalent `asadmin` subcommand.

1. Ensure that the server is running. Operations on REST resources for Payara Server data require a running server.
2. Use the `GET` method on the REST resource that represents the object. The `GET` method returns the list of methods that the resource supports. For each method, the list of acceptable message parameters or the list of acceptable query parameters are returned.

This example uses the cURL utility to determine the methods and method parameters that the resource for the node `sj01` supports.

The example uses the following options of the cURL utility:

- `-X` to specify that the `GET` method is used
- `-H` to specify that the resource is represented in JavaScript Object Notation (JSON)

In this example, the DAS is running on the local host and the HTTP port for administration is 4848. The resource supports the `GET` method and the `POST` method.

```
curl -X GET -H "Accept: application/json"
http://localhost:4848/management/domain/nodes/node/sj01
```

```
{
  "command":"Node",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "commands":[
      {"path":"_delete-node","command":"delete-node","method":"DELETE"},
      {"path":"_update-node","command":"_update-node","method":"POST"},
      {"path":"ping-node-ssh","command":"ping-node-ssh","method":"GET"},
      {"path":"update-node-ssh","command":"update-node-ssh","method":"POST"},
      {"path":"update-node-config","command":"update-node-config","method":"POST"}],
    "methods":[
      {"name":"GET"},
      {"name":"POST","messageParameters":{
        "installDir":{"optional":"true","type":"string","key":"false"},
        "nodeDir":{"optional":"true","type":"string","key":"false"},
        "nodeHost":{"optional":"true","type":"string","key":"false"},
        "type":{"optional":"true","type":"string","key":"false"}
        }
      }
    ],
    "entity":{
      "installDir":"\/export\/payara7",
      "name":"sj01",
      "nodeDir":null,
      "nodeHost":
      "sj01.example.com",
      "type":"SSH"
    },
    "childResources":{
      "application-ref":
        "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/application-
ref",
      "resource-ref":
        "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/resource-
ref",
      "ssh-connector":
        "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/ssh-
connector"
    }
  }
}
```

To Retrieve Data for an Object in the Tree

Retrieving data for an object in the tree obtains the following information about the REST resource that represents the object:

- A list of the REST methods that the resource supports
- A list of the attributes of the resource and their values

- A list of URLs to the children of the resource

You can specify the format in which this information is presented. For more information, see Formats for Resource Representation of Configuration Objects.

1. Ensure that the server is running. Operations on REST resources for Payara Server data require a running server.
2. Use the `GET` method on the REST resource that represents the object.

This example uses the cURL utility to retrieve data for the resource for a the node `sj01`. The example uses the following options of the cURL utility:

- `-X` to specify that the `GET` method is used
- `-H` to specify that the resource is represented in JavaScript Object Notation (JSON)

In this example, the DAS is running on the local host and the HTTP port for administration is `4848`.

```
curl -X GET -H "Accept: application/json"
http://localhost:4848/management/domain/nodes/node/sj01
{
  "command":"Node",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "commands":[
      {"path":"_delete-node","command":"delete-node","method":"DELETE"},
      {"path":"_update-node","command":"_update-node","method":"POST"},
      {"path":"ping-node-ssh","command":"ping-node-ssh","method":"GET"},
      {"path":"update-node-ssh","command":"update-node-ssh","method":"POST"},
      {"path":"update-node-config","command":"update-node-config","method":"POST"}],
    "methods":[
      {"name":"GET"},
      {"name":"POST","messageParameters":{
        "installDir":{"optional":"true","type":"string","key":"false"},
        "nodeDir":{"optional":"true","type":"string","key":"false"},
        "nodeHost":{"optional":"true","type":"string","key":"false"},
        "type":{"optional":"true","type":"string","key":"false"}
        }
      }
    ],
    "entity":{
      "installDir":"\/export\/payara7",
      "name":"sj01",
      "nodeDir":null,
      "nodeHost":
      "sj01.example.com",
      "type":"SSH"
    },
    "childResources":{
      "application-ref":
        "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/application-
```

```
ref",
      "resource-ref":
        "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/resource-
ref",
      "ssh-connector":
        "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/ssh-
connector"
    }
  }
}
```

To Add an Object to the Tree

1. Ensure that the server is running. Operations on REST resources for Payara Server data require a running server.
2. Determine the acceptable message parameters for the `POST` method of the resource that represents the parent of the object. For information about how to perform this step, see To Determine the Methods and Method Parameters That an Object in the Tree Supports.
3. Use the `POST` method on the REST resource that represents the parent of the object that you are adding.
4. Confirm that the object has been added. Perform this step on the resource that represents the object that you have just added, not the parent.

   For information about how to perform this step, see To Retrieve Data for an Object in the Tree.

This example uses the cURL utility to add a JDBC resource object to the tree by creating a REST resource to represent the JDBC resource.

In this example, the DAS is running on the local host and the HTTP port for administration is `4848`.

1. This step determines the acceptable message parameters for the `POST` method of the resource `jdbc-resource`.

   ```
   curl -X GET -H "Accept: application/json"

   http://localhost:4848/management/domain/resources/jdbc-resource
   {
     "command":"Jdbc-resource",
     "exit_code":"SUCCESS",
     "extraProperties":{
       "commands":[],
       "methods":[
         {"name":"GET"},
         {"name":"POST","messageParameters":{

   "description":{"acceptableValues":"","optional":"true","type":"string","defaultValu
   e":""},
   ```

```
"enabled":{"acceptableValues":"",optional":"true","type":"boolean",defaultValue":"t
rue"},

"id":{"acceptableValues":"","optional":"false","type":"string","defaultValue":""},

"poolName":{"acceptableValues":"","optional":"false","type":"string","defaultValue"
:""},

"property":{"acceptableValues":"","optional":"true","type":"string","defaultValue":
"},

"target":{"acceptableValues":"","optional":"true","type":"string","defaultValue":""
}
        }
      }
    ],
    "childResources":{
      "jdbc\/__TimerPool":
        "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-
resource\/jdbc%2F__TimerPool",
      "jdbc\/__default":
        "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-
resource\/jdbc%2F__default"
    }
  }
}
```

2. This step adds a resource as a child of the `jdbc-resource` resource. The `-d` option of the cURL utility sets the required message parameters as follows:
   - `id` is set to `jdbc/myjdbcresource`.
   - `connectionpoolid` is set to `DerbyPool`.

   ```
   curl -X POST -H "X-Requested-By: GlassFish REST HTML interface" -d
   id=jdbc/myjdbcresource -d connectionpoolid=DerbyPool
   http://localhost:4848/management/domain/resources/jdbc-resource
   ```

3. This step confirms that the object has been added by retrieving data for the REST resource that represents the object.

   ```
   curl -X GET -H "Accept: application/json"
   http://localhost:4848/management/domain/resources/
   jdbc-resource/jdbc%2Fmyjdbcresource
   {
     "command":"Jdbc-resource",
     "exit_code":"SUCCESS",
     "extraProperties":{
       "commands":[],
       "methods":[
   ```

```
      {"name":"GET"},
      {"name":"POST","messageParameters":{
        "description":{"optional":"true","type":"string","key":"false"},

"enabled":{"optional":"true","type":"boolean","defaultValue":"true","key":"false"},
        "jndiName":{"optional":"true","type":"string","key":"true"},

"objectType":{"optional":"true","type":"string","defaultValue":"user","key":"false"
},
        "poolName":{"optional":"true","type":"string","key":"false"}
        }
      },
      {"name":"DELETE","messageParameters":{

"target":{"acceptableValues":"","optional":"true","type":"string","defaultValue":""
}
        }
      }
    ],
    "childResources":{
      "property":
        "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-
resource\/jdbc%2Fmyjdbcresource\/property"
    }
  }
}
```

To Update an Object in the Tree

1. Ensure that the server is running.

   Operations on REST resources for Payara Server data require a running server.

2. Determine the acceptable message parameters for the `POST` method of the resource that represents the object. For information about how to perform this step, see To Determine the Methods and Method Parameters That an Object in the Tree Supports.
3. Use the `POST` method on the REST resource that represents the object that you are updating.
4. Confirm that the object has been updated. For information about how to perform this step, see To Retrieve Data for an Object in the Tree.

This example uses the cURL utility to update a JDBC resource in the tree by modifying the REST resource that represents the JDBC resource.

In this example, the DAS is running on the local host and the HTTP port for administration is `4848`.

1. This step determines the acceptable message parameters for the `POST` method of the resource `jdbc-myjdbcresource`.

   ```
   curl -X OPTIONS -H "Accept: application/json"
   ```

```
http://localhost:4848/management/domain/resources/jdbc-resource/jdbc-myjdbcresource

{
  "command":"Jdbc-resource",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "commands":[],
    "methods":[
      {"name":"GET"},
      {"name":"POST","messageParameters":{
        "description":{"optional":"true","type":"string","key":"false"},

"enabled":{"optional":"true","type":"boolean","defaultValue":"true","key":"false"},
        "jndiName":{"optional":"true","type":"string","key":"true"},

"objectType":{"optional":"true","type":"string","defaultValue":"user","key":"false"
},
        "poolName":{"optional":"true","type":"string","key":"false"}
        }
      },
      {"name":"DELETE","messageParameters":{

"target":{"acceptableValues":"","optional":"true","type":"string","defaultValue":""
}
        }
      }
    ],
    "childResources":{
      "property":
        "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-
resource\/jdbc%2Fmyjdbcresource\/property"
    }
  }
}
```

2. This step updates the REST resource `jdbc-myjdbcresource` to disable the JDBC resource that `jdbc-myjdbcresource` represents.

The `-d` option of the cURL utility sets the `enabled` message parameter to `disabled`.

+

```
curl -X POST -H "X-Requested-By: GlassFish REST HTML interface" -d "enabled=false"
http://localhost:4848/management/domain/resources/jdbc-resource/jdbc%2Fmyjdbcresource
```

1. This step confirms that the object has been updated by retrieving data for the REST resource that represents the object.

```
curl -X GET -H "Accept: application/json"
```

```
http://localhost:4848/management/domain/resources/
jdbc-resource/jdbc%2Fmyjdbcresource
{
  "command":"Jdbc-resource",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "commands":[],
    "methods":[
      {"name":"GET"},
      {"name":"POST","messageParameters":{
        "description":{"optional":"true","type":"string","key":"false"},

"enabled":{"optional":"true","type":"boolean","defaultValue":"true","key":"false"},
        "jndiName":{"optional":"true","type":"string","key":"true"},
        "objectType":{"optional":"true","type":"string","defaultValue":
        "user","key":"false"},
        "poolName":{"optional":"true","type":"string","key":"false"}
        }
      },
      {"name":"DELETE","messageParameters":{

"target":{"acceptableValues":"","optional":"true","type":"string","defaultValue":""
}
        }
      }
    ],
  "entity":{
    "description":null,
    "enabled":"false",
    "jndiName":"jdbc\/myjdbcresource",
    "objectType":
    "user",
    "poolName":"DerbyPool"
  },
  "childResources":{
    "property":
      "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-resource\/
       jdbc%2Fmyjdbcresource\/property"
    }
  }
}
```

To Delete an Object From the Tree

1. Ensure that the server is running. Operations on REST resources for Payara Server data require a running server.
2. Confirm that the object can be deleted. For information about how to perform this step, see To Determine the Methods and Method Parameters That an Object in the Tree Supports.
3. Confirm that the object has been deleted. Perform this step on the resource that represents the

parent of the object that you have just deleted.

For information about how to perform this step, see To Retrieve Data for an Object in the Tree.

This example uses the cURL utility to delete a JDBC resource from the tree by deleting the REST resource that represents the JDBC resource.

In this example, the DAS is running on the local host and the HTTP port for administration is 4848.

1. This step confirms that the object can be deleted by retrieving the REST methods that the resource `jdbc-myjdbcresource` supports.

   Line breaks and white space are added to enhance readability.

```
curl -X GET -H "Accept: application/json"
http://localhost:4848/management/domain/resources/jdbc-
resource/jdbc%2Fmyjdbcresource

{
  "command":"Jdbc-resource",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "commands":[],
    "methods":[
      {"name":"GET"},
      {"name":"POST","messageParameters":{
        "description":{"optional":"true","type":"string","key":"false"},

"enabled":{"optional":"true","type":"boolean","defaultValue":"true","key":"false"},
        "jndiName":{"optional":"true","type":"string","key":"true"},

"objectType":{"optional":"true","type":"string","defaultValue":"user","key":"false"
},
        "poolName":{"optional":"true","type":"string","key":"false"}
        }
      },
      {"name":"DELETE","messageParameters":{

"target":{"acceptableValues":"","optional":"true","type":"string","defaultValue":""
}
        }
      }
    ],
    "childResources":{
      "property":
        "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-resource\/
        jdbc%2Fmyjdbcresource\/property"
    }
  }
}
```

2. This step deletes the `jdbc/myjdbcresource` resource.

```
curl -X DELETE -H "X-Requested-By: GlassFish REST HTML interface"
http://localhost:4848/management/domain/resources/jdbc-
resource/jdbc%2Fmyjdbcresource
```

3. This step confirms that the object has been deleted by retrieving data for the REST resource that represents the parent of the object.

```
curl -X GET -H "Accept: application/json"
http://localhost:4848/management/domain/resources/jdbc-resource

{
  "command":"Jdbc-resource",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "commands":[],
    "methods":[
      {"name":"GET"},
      {"name":"POST","messageParameters":{

"description":{"acceptableValues":"","optional":"true","type":"string","defaultValu
e":""},

"enabled":{"acceptableValues":"",optional":"true","type":"boolean",defaultValue":"t
rue"},

"id":{"acceptableValues":"","optional":"false","type":"string","defaultValue":""},

"poolName":{"acceptableValues":"","optional":"false","type":"string","defaultValue"
:""},

"property":{"acceptableValues":"","optional":"true","type":"string","defaultValue":
"},

"target":{"acceptableValues":"","optional":"true","type":"string","defaultValue":""
}
        }
      }
    ],
    "childResources":{
      "jdbc\/__TimerPool":
        "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-
resource\/jdbc%2F__TimerPool",
      "jdbc\/__default":
        "https:\/\/localhost:4848\/management\/domain\/resources\/jdbc-
resource\/jdbc%2F__default"
    }
  }
```

```
}
```

Resources for `asadmin` Subcommands That Perform Non-CRUD Operations

The Payara Server REST interfaces also support operations other than create, read, update, and delete (CRUD) operations, for example:

- State Management
- Queries
- Application deployment

These operations are supported through REST resources that represent the `asadmin` subcommands for performing these operations. Each resource is a child of the resource on which the operation is performed. The child resources do not represent objects in the configuration object tree.

For example, the resource that represents a node provides child resources for the following `asadmin` subcommands that perform non-CRUD operations on the node:

- `ping-node-ssh`
- `update-node-config`
- `update-node-ssh`

Securing Payara Server REST Interfaces

The Payara Server REST interfaces support the following authentication schemes for securing the REST interfaces:

- Basic authentication over a secure connection
- Authentication by using session tokens

When security is enabled, you must specify `HTTPS` as the protocol in the URLs to REST resources and provide a username and password.

Setting Up Basic Authentication Over a Secure Connection

Setting up basic authentication over a secure connection to secure Payara Server REST interfaces involves the following sequence of tasks:

1. Adding an `admin-realm` user to the `asadmin` user group
2. Enabling Secure Sockets Layer (SSL)

For information about how to perform these tasks from the command line, see the following documentation:

- To Create an Authentication Realm in the Payara Server Security Guide
- To Create a File User in the Payara Server Security Guide
- To Configure an HTTP Listener for SSL

For information about how to perform these tasks by using the Administration Console, see the following topics in the Administration Console online help:

- To Add a User to the Admin Realm
- To Edit SSL Settings for a Protocol

To Secure REST Interfaces by Using Session Tokens

Basic authentication requires a REST client to cache a user's credentials to enable the client to pass the credentials with each request. If you require a REST client not to cache credentials, your client must use session tokens for authentication.

1. Request a session token by using the `GET` method on the resource at `http://host:port/management/sessions`.

   Payara Server uses basic authentication to authenticate the client, generates a session token, and passes the token to the client.

2. In each subsequent request that requires authentication, use the token to authenticate the client.
3. Create a cookie that is named `gfresttoken` the value of which is the token.
4. Send the cookie with the request.
5. When the token is no longer required, retire the token by using the `DELETE` method on the resource at `http://host:port/management/sessions/{tokenvalue}`.

If a client does not explicitly retire a token, the token is retired after 30 minutes of inactivity.

Formats for Resource Representation of Configuration Objects

The Payara Server REST interfaces represent resources for configuration objects in the following formats:

- JSON
- XML
- HTML

Payara Server enables you to specify the resource representation through the filename extension in the URL or through the HTTP header:

- To specify the resource representation through the filename extension in the URL, specify the appropriate extension as follows:
  - For JSON, specify the `.json` extension.
  - For XML, specify the `.xml` extension.
  - For HTML, omit the extension.
- How to specify the resource representation through the HTTP header depends on the client that

you are using to access the resource. For example, if you are using the cURL utility, specify the resource representation through the `-H` option as follows:

- For JSON, specify `-H "Accept: application/json"`.
- For XML, specify `-H "Accept: application/xml"`.
- For HTML, omit the `-H` option.

JSON Resource Representation for Configuration Objects

The general format for the JSON representation of a resource for a configuration object is as follows:

```
{
  "command":"resource",
  "exit_code":"code",
  "extraProperties": {
    "commands":["command-list"],
    "methods":["method-list"],
    "entity":"attributes",
    "childResources":"children"
  }
}
```

The replaceable items in this format are as follows:

resource

The name of the resource.

code

The result of the attempt to get the resource.

command-list

One or more metadata sets separated by a comma (`,`) that represent the `asadmin` subcommands for performing non—CRUD operations on the resource. For the format of each metadata set, see JSON Representation of a Command in a Command List.

method-list

One or more metadata sets separated by a comma (`,`) that represent the methods that the resource supports. For the format of each metadata set, see JSON Representation of a Method in a Method List.

attributes

Zero or more name-value pairs separated by a comma (`,`). Each name-value pair is specified as `name:value`.

children

Zero or more child resources separated by a comma (`,`). Each child resource is specified as `resource-name:url`.

resource-name

The name of the resource as displayed in client applications that access the parent of the resource.

url

The URL to the child resource.

JSON Representation of a Command in a Command List

The JSON representation of a command in a command list is as follows:

```
{
  "path":"command-path",
  "command":"command-name",
  "method":"rest-method"
}
```

The replaceable items in this format are as follows:

command-path

The relative path to REST resource that represents the command. This path is relative to the URL of the REST resource that is the parent of the resource that represents the command.

command-name

The name of the command as displayed in client applications that access the resource.

rest-method

The REST resource method that the command invokes when the command is run. The method is `GET`, `POST`, or `DELETE`.

JSON Representation of a Method in a Method List

The JSON representation of a method in a method list is as follows:

```
{
    "name":"method-name",
    "messageParameters":{
        "message-parameter-list":[]
    },
    "queryParameters":{
        "query-parameter-list":[]
    }
}
```

The replaceable items in this format are as follows:

method-name

The name of the method, which is `GET`, `POST`, or `DELETE`.

message-parameter-list

Zero or more metadata sets separated by a comma (`,`) that represent the message parameters that are allowed for the method. For the format of each metadata set, see JSON Representation of a Message Parameter or a Query Parameter.

query-parameter-list

Zero or more metadata sets separated by a comma (`,`) that represent the query parameters that are allowed for the method. For the format of each metadata set, see JSON Representation of a Message Parameter or a Query Parameter.

JSON Representation of a Message Parameter or a Query Parameter

The JSON representation of a message parameter or a query parameter is as follows:

```
{
  "parameter-name":{
    "attr-1" : "value",
    "attr-2" : "value",
    "attr-3" : "value"
  }
}
```

The replaceable items in this format are as follows:

parameter-name

The name of the parameter.

attribute-list

A comma-separated list of name-value pairs of attributes for the parameter. Each pair is in the following format:

```
{
  "name":"value"
}
```

Possible attributes are as follows:

`defaultValue`

The default value of the parameter.

`acceptableValues`

The set or range of acceptable values for the parameter.

`type`

The data type of the parameter, which is one of the following types:

- `boolean`

- `int`
- `string`

`optional`

Indicates whether the parameter is optional.

`key`

Indicates whether the parameter is a key parameter.

Example JSON Resource Representation for a Configuration Object

This example shows the JSON representation of the resource for the node `sj01`. In this example, the DAS is running on the local host and the HTTP port for administration is 4848. The URL to the resource in this example is `http://localhost:4848/management/domain/nodes/node/sj01`.

```
{
  "command":"Node",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "commands":[
      {"path":"_delete-node","command":"delete-node","method":"DELETE"},
      {"path":"_update-node","command":"_update-node","method":"POST"},
      {"path":"ping-node-ssh","command":"ping-node-ssh","method":"GET"},
      {"path":"update-node-ssh","command":"update-node-ssh","method":"POST"},
      {"path":"update-node-config","command":"update-node-config","method":"POST"}],
    "methods":[
      {"name":"GET"},
      {"name":"POST","messageParameters":{
        "installDir":{"optional":"true","type":"string","key":"false"},
        "nodeDir":{"optional":"true","type":"string","key":"false"},
        "nodeHost":{"optional":"true","type":"string","key":"false"},
        "type":{"optional":"true","type":"string","key":"false"}
        }
      }
    ],
    "entity":{
      "installDir":"\/export\/payara7",
      "name":"sj01",
      "nodeDir":null,
      "nodeHost":
      "sj01.example.com",
      "type":"SSH"
    },
    "childResources":{
      "application-ref":
       "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/application-
ref",
      "resource-ref":
       "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/resource-
ref",
```

```
      "ssh-connector":
       "https:\/\/localhost:4848\/management\/domain\/nodes\/node\/sj01\/ssh-
connector"
    }
  }
}
```

XML Resource Representation for Configuration Objects

The general format for the XML representation of a resource for a configuration object is as follows:

```
<map>
 <entry key="extraProperties">
  <map>
   <entry key="methods">
    <list>
     methods
    </list>
   </entry>
   <entry key="entity">
    <map>
     attributes
    </map>
   </entry>
   <entry key="commands">
    <list>
     commands
    </list>
   </entry>
   <entry key="childResources">
    <map>
    children
    </map>
   </entry>
  </map>
 </entry>
 <entry key="message"></entry>
 <entry key="exit_code" value="code"></entry>
 <entry key="command" value="resource"></entry>
</map>
```

The replaceable items in this format are as follows:

methods

One or more XML elements that represent the methods that the resource supports. For the format of each element, see XML Representation of a Resource Method.

attributes

Zero or more XML elements that represent the attributes of the resource. Each element specifies a name-value pair as follows:

```
<entry key="name" value="value"></entry>
```

commands

One or more XML elements that represent the `asadmin` subcommands for performing non—CRUD operations on the resource. For the format of each element, see XML Representation of a Command.

children

Zero or more XML elements that represent the children of the resource. Each element is specified as follows:

```
<entry key="resource-name" value="url"></entry>
```

resource-name

The name of the resource as displayed in client applications that access the parent of the resource.

url

The URL to the child resource.

code

The result of the attempt to get the resource.

resource

The name of the resource.

XML Representation of a Resource Method

The XML representation of a method in a method list is as follows:

```
<map>
 <entry key="name" value="method-name"></entry>
 <entry key="messageParameters">
  message-parameter-list
 </entry>
 <entry key="queryParameters">
  message-parameter-list
 </entry>
</map>
```

The replaceable items in this format are as follows:

method-name

The name of the method, which is `GET`, `POST`, or `DELETE`.

message-parameter-list

Zero or more XML elements that represent the message parameters that are allowed for the method. For the format of each element, see XML Representation of a Message Parameter or a Query Parameter.

query-parameter-list

Zero or more XML elements that represent the query parameters that are allowed for the method. For the format of each element, see XML Representation of a Message Parameter or a Query Parameter.

XML Representation of a Command

The XML representation of a command is as follows:

```
<map>
    <entry key="command" value="command-name"></entry>
    <entry key="path" value="command-path"></entry>
    <entry key="method" value="rest-method"></entry>
</map>
```

The replaceable items in this format are as follows:

command-name

The name of the command as displayed in client applications that access the resource.

command-path

The relative path to REST resource that represents the command. This path is relative to the URL of the REST resource that is the parent of the resource that represents the command.

rest-method

The REST resource method that the command invokes when the command is run. The method is `GET`, `POST`, or `DELETE`.

XML Representation of a Message Parameter or a Query Parameter

The XML representation of a message parameter or a query parameter is as follows:

```
<map>
 <entry key="parameter-name">
  <map>
   attributes
  </map>
 </entry>
</map>
```

The replaceable items in this format are as follows:

parameter-name

The name of the parameter.

attributes

One or more XML elements that represent the attributes for the parameter. Each element specifies a name-value pair as follows:

```
<entry key="name" value="value"></entry>
```

Possible attributes are as follows:

`defaultValue`

The default value of the parameter.

`acceptablevalues`

The set or range of acceptable values for the parameter.

`type`

The data type of the parameter, which is one of the following types:

- `boolean`
- `int`
- `string`

`optional`

Indicates whether the parameter is optional. If `true`, the parameter is optional.If `false`, the parameter is required.

`key`

Indicates whether the parameter is key. If `true`, the parameter is key. If `false`, the parameter is not key.

Example XML Resource Representation

This example shows the XML representation of the resource for the node `sj01`. In this example, the DAS is running on the local host and the HTTP port for administration is `4848`. The URL to the resource in this example is `http://localhost:4848/management/domain/nodes/node/sj01`.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<map>
 <entry key="extraProperties">
  <map>
   <entry key="methods">
    <list>
     <map>
      <entry key="name" value="GET"/>
```

```
    </map>
    <map>
     <entry key="name" value="POST"/>
     <entry key="messageParameters">
      <map>
       <entry key="installDir">
        <map>
         <entry key="optional" value="true"/>
         <entry key="type" value="string"/>
         <entry key="key" value="false"/>
        </map>
       </entry>
       <entry key="nodeDir">
        <map>
         <entry key="optional" value="true"/>
         <entry key="type" value="string"/>
         <entry key="key" value="false"/>
        </map>
       </entry>
       <entry key="type">
        <map>
         <entry key="optional" value="true"/>
         <entry key="type" value="string"/>
         <entry key="key" value="false"/>
        </map>
       </entry>
       <entry key="nodeHost">
        <map>
         <entry key="optional" value="true"/>
         <entry key="type" value="string"/>
         <entry key="key" value="false"/>
        </map>
       </entry>
      </map>
     </entry>
    </map>
   </list>
  </entry>
  <entry key="entity">
   <map>
    <entry key="installDir" value="/export/payara7"/>
    <entry key="name" value="sj01"/>
    <entry key="nodeDir" value=""/>
    <entry key="type" value="SSH"/>
    <entry key="nodeHost" value="sj01example.com"/>
   </map>
  </entry>
  <entry key="commands">
   <list>
    <map>
     <entry key="command" value="delete-node"/>
```

```
      <entry key="path" value="_delete-node"/>
      <entry key="method" value="DELETE"/>
     </map>
     <map>
      <entry key="command" value="_update-node"/>
      <entry key="path" value="_update-node"/>
      <entry key="method" value="POST"/>
     </map>
     <map>
      <entry key="command" value="ping-node-ssh"/>
      <entry key="path" value="ping-node-ssh"/>
      <entry key="method" value="GET"/>
     </map>
     <map>
      <entry key="command" value="update-node-ssh"/>
      <entry key="path" value="update-node-ssh"/>
      <entry key="method" value="POST"/>
     </map>
     <map>
      <entry key="command" value="update-node-config"/>
      <entry key="path" value="update-node-config"/>
      <entry key="method" value="POST"/>
     </map>
    </list>
   </entry>
   <entry key="childResources">
    <map>
     <entry key="application-ref"
      value="https://localhost:4848/management/domain/nodes/node/sj01/application-
ref"/>
     <entry key="ssh-connector"
      value="https://localhost:4848/management/domain/nodes/node/sj01/ssh-connector"/>
     <entry key="resource-ref"
      value="https://localhost:4848/management/domain/nodes/node/sj01/resource-ref"/>
    </map>
   </entry>
  </map>
 </entry>
 <entry key="message"/>
 <entry key="exit_code" value="SUCCESS"/>
 <entry key="command" value="Node"/>
</map>
```

HTML Resource Representation for Configuration Objects

The format for the HTML representation of a resource for a configuration object is a web page that provides the following information about the resource:

- A list of the attributes of the resource and their values.
- A list of the methods and method parameters that the resource supports.

Each method and its parameters are presented as a field of the appropriate type in an HTML form.

- A list of hypertext links to the children of the resource.
- A list of hypertext links to resources that represent `asadmin` subcommands for non-CRUD operations on the resource.

Formats for Resource Representation of Monitoring Objects

The Payara Server REST interfaces represent resources for monitoring data in the following formats:

- JSON
- XML
- HTML

JSON Resource Representation for Monitoring Objects

The general format for the JSON representation of a resource for a monitoring object is as follows:

```
{
  "message":"",
  "command":"Monitoring Data",
  "exit_code":"code",
  "extraProperties":{
    "entity":{
    },
    "childResources":{
    }
  }
}
```

The replaceable items in this format are as follows:

code

The result of the attempt to get the resource.

entity

Contains the statistics that the monitoring object provides. For the format of each metadata set, see JSON Representation of a Statistic in a Statistics List.

childResources

Zero or more child resources separated by a comma (`,`). Each child resource is specified as "resource-name":"url".

resource-name

The name of the resource as displayed in client applications that access the parent of the resource.

url

The URL to the child resource.

JSON Representation of a Statistic in a Statistics List

The JSON representation of a counter statistic in a statistics list is as follows:

```
{
  "count": "number",
  "lastsampletime": "dateTime",
  "description": "string",
  "unit": "string",
  "name": "string",
  "starttime": "number"
}
```

The JSON representation of a range statistic in a statistics list is as follows:

```
{
  "highwatermark": "number",
  "lowwatermark": "number",
  "current": "number",
  "lastsampletime": "dateTime",
  "description": "string",
  "unit": "string",
  "name": "string",
  "starttime": "number"
}
```

The replaceable items in these formats are as follows:

statistic

The name of the statistic.

count

Counter statistics only: The current value of the statistic.

highest-value

Range statistics only: The highest value of the statistic since monitoring of the statistic began.

lowest-value

Range statistics only: The lowest value of the statistic since monitoring of the statistic began.

current-value

Range statistics only: The lowest value of the statistic since monitoring of the statistic began.

last-sample-time

The time in UNIX time at which the statistic was last sampled.

description

A textual description of what the statistic represents.

unit

The unit of measurement of the statistic, which is one of the following units of measurement:

`count`

The cumulative value of an attribute that increases with time.

`range`

The lowest value, highest value, and current value of an attribute that can increase or decrease with time.

`boundedrange`

The lowest value, highest value, and current value of an attribute that can increase or decrease with time and has fixed limits.

`string`

A string that represents an attribute value. A string statistic is similar to a count, except that the values are not ordered. Typically, a string statistic represents the state of an object, for example, `CONNECTED`, `CLOSED`, or `DISCONNECTED`.

`time`

Values of an attribute that provide the following timing measurements for an operation:

- The number of times the operation was performed.
- The maximum amount of time to perform the operation once.
- The minimum amount of time to perform the operation once.
- The total amount of time that has been spent performing the operation.
- The average amount of time to perform the operation.

name

The name of the statistic as displayed in client applications that access the resource that contains the statistic.

start-time

The time in UNIX time at which monitoring of the statistic began.

Example JSON Resource Representation for a Monitoring Object

This example shows the JSON representation of the monitoring object that provides class loader statistics for the virtual machine for the Java platform. In this example, the DAS is running on the local host and the HTTP port for administration is `4848`. The URL to the resource in this example is `http://localhost:4848/monitoring/domain/server/jvm/class-loading-system`.

```
{
  "message": "",
  "command":"Monitoring Data",
  "exit_code":"SUCCESS",
  "extraProperties":{
    "entity":{
      "loadedclass-count":{
        "count":8521,
        "lastsampletime":1300726961018,
        "description":"Number of classes currently loaded in the Java virtual
machine",
        "unit":"count",
        "name":"LoadedClassCount",
        "starttime":1300483924126
      },
      "totalloadedclass-count":{
        "count":8682,
        "lastsampletime":1300726961018,
        "description":"Total number of classes that have been loaded since the Java
virtual machine has started execution",
        "unit":"count",
        "name":"TotalLoadedClassCount",
        "starttime":1300483924127
      },
      "unloadedclass-count":{
        "count":161,
        "lastsampletime":1300726961018,
        "description":"Total number of classes unloaded since the Java virtual machine
has started execution",
        "unit":"count",
        "name":"UnLoadedClassCount",
        "starttime":1300483924127
      }
    },"childResources":{}
  }
}
```

XML Resource Representation for Monitoring Objects

The general format for the XML representation of a resource for a monitoring object is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<map>
 <entry key="extraProperties">
  <map>
   <entry key="entity">
    <map>
     statistics
    </map>
```

```
   </entry>
   <entry key="childResources">
    <map>
     children
    </map>
   </entry>
  </map>
 </entry>
 <entry key="message" value=""></entry>
 <entry key="exit_code" value="code"></entry>
 <entry key="command" value="Monitoring Data"></entry>
</map>
```

The replaceable items in this format are as follows:

statistics

Zero or more XML elements that represent the statistics that the monitoring object provides. For the format of each element, see XML Representation of a Statistic.

children

Zero or more XML elements that represent the children of the resource. Each element is specified as follows:

```
<entry key="resource-name" value="url"></entry>
```

resource-name

The name of the resource as displayed in client applications that access the parent of the resource.

url

The URL to the child resource.

code

The result of the attempt to get the resource.

XML Representation of a Statistic

The XML representation of a counter statistic is as follows:

```
<entry key="statistic">
    <map>
        <entry key="unit" value="unit"></entry>
        <entry key="starttime">
            <number>start-time</number>
        </entry>
        <entry key="count">
            <number>count</number>
        </entry>
```

```
        <entry key="description" value="description"></entry>
        <entry key="name" value="name"></entry>
        <entry key="lastsampletime">
            <number>last-sample-time</number>
        </entry>
    </map>
</entry>
```

The XML representation of a range statistic is as follows:

```
<entry key="statistic">
    <map>
        <entry key="unit" value="unit"></entry>
        <entry key="starttime">
            <number>start-time</number>
        </entry>
        <entry key="highwatermark">
            <number>highest-value</number>
        </entry>
        <entry key="lowwatermark">
            <number>lowest-value</number>
        </entry>
        <entry key="current">
            <number>current-value</number>
        </entry>
        <entry key="description" value="description"></entry>
        <entry key="name" value="name"></entry>
        <entry key="lastsampletime">
            <number>last-sample-time</number>
        </entry>
    </map>
</entry>
```

The replaceable items in these formats are as follows:

statistic

The name of the statistic.

unit

The unit of measurement of the statistic, which is one of the following units of measurement:

`count`

The cumulative value of an attribute that increases with time.

`range`

The lowest value, highest value, and current value of an attribute that can increase or decrease with time.

`boundedrange`

The lowest value, highest value, and current value of an attribute that can increase or decrease with time and has fixed limits.

`string`

A string that represents an attribute value. A string statistic is similar to a count, except that the values are not ordered. Typically, a string statistic represents the state of an object, for example, `CONNECTED`, `CLOSED`, or `DISCONNECTED`.

`time`

Values of an attribute that provide the following timing measurements for an operation:

- The number of times the operation was performed.
- The maximum amount of time to perform the operation once.
- The minimum amount of time to perform the operation once.
- The total amount of time that has been spent performing the operation.
- The average amount of time to perform the operation.

start-time

The in time in UNIX time at which monitoring of the statistic began.

count

Counter statistics only: The current value of the statistic.

highest-value

Range statistics only: The highest value of the statistic since monitoring of the statistic began.

lowest-value

Range statistics only: The lowest value of the statistic since monitoring of the statistic began.

current-value

Range statistics only: The lowest value of the statistic since monitoring of the statistic began.

description

A textual description of what the statistic represents.

name

The name of the statistic as displayed in client applications that access the resource that contains the statistic.

last-sample-time

The time in UNIX time at which the statistic was last sampled.

Example XML Resource Representation for a Monitoring Object

This example shows the XML representation of the monitoring object that provides class loader statistics for the virtual machine for the Java platform.

In this example, the DAS is running on the local host and the HTTP port for administration is 4848. The URL to the resource in this example is http://localhost:4848/monitoring/domain/server/jvm/class-loading-system.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<map>
 <entry key="extraProperties">
  <map>
   <entry key="entity">
    <map>
     <entry key="unloadedclass-count">
      <map>
       <entry key="unit" value="count"/>
       <entry key="starttime">
        <number>1300483924127</number>
       </entry><entry key="count">
        <number>161</number>
       </entry>
       <entry key="description" value="Total number of classes unloaded since the Java
virtual machine has started execution"/>
       <entry key="name" value="UnLoadedClassCount"/>
       <entry key="lastsampletime">
        <number>1300726989505</number>
       </entry>
      </map>
     </entry>
     <entry key="totalloadedclass-count">
      <map>
       <entry key="unit" value="count"/>
       <entry key="starttime">
        <number>1300483924127</number>
       </entry>
       <entry key="count">
         <number>8682</number>
       </entry>
       <entry key="description" value="Total number of classes that have been
        loaded since the Java virtual machine has started execution"/>
       <entry key="name" value="TotalLoadedClassCount"/>
       <entry key="lastsampletime">
        <number>1300726989505</number>
       </entry>
      </map>
    </entry>
     <entry key="loadedclass-count">
      <map>
       <entry key="unit" value="count"/>
       <entry key="starttime">

        <number>8521</number>
```

```
       </entry>
       <entry key="description" value="Number of classes currently loaded in
        the Java virtual machine"/>
       <entry key="name" value="LoadedClassCount"/>
       <entry key="lastsampletime">
        <number>1300726989505</number>
       </entry>
      </map>
     </entry>
    </map>
   </entry>
   <entry key="childResources">
    <map/>
   </entry>
  </map>
 </entry>
 <entry key="message" value=""/>
 <entry key="exit_code" value="SUCCESS"/>
 <entry key="command" value="Monitoring Data"/>
</map>
```

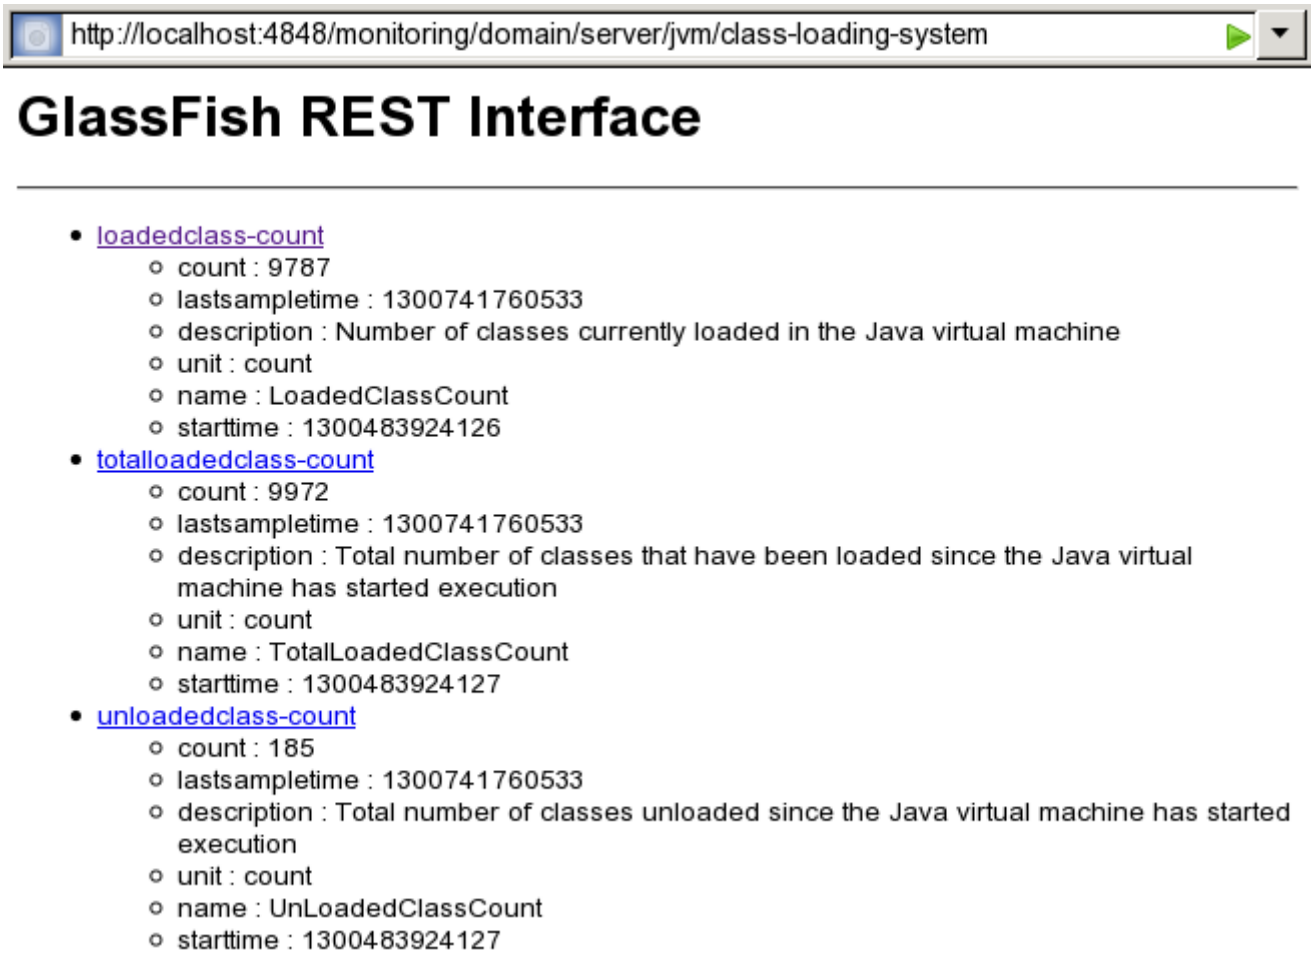
HTML Resource Representation for Monitoring Objects

The format for the HTML representation of a resource for a monitoring object is a web page that provides the following information about the resource:

- A list of the statistics that the resource provides.
- A list of hypertext links to the children of the resource.

The following figure shows the web page for the REST resource that provides class loader statistics for the virtual machine for the Java platform.

Web Page for the REST Resource That Provides Class Loader Statistics



Formats for Resource Representation of Log File Details

The Payara Server REST interfaces represent resources for log file details in the following formats:

- JSON
- XML

JSON Resource Representation for Log File Details

The general format for the JSON representation of a resource for log file details is as follows:

```
{
  "records": [
  ]
}
```

The replaceable item in this format is a record list array, which is one or more metadata sets separated by a comma (,) that represent the log records in the log file. For the format of each metadata set, see JSON Representation of a Log Record in a Record List.

JSON Representation of a Log Record in a Record List

The JSON representation of a log record in a record list is as follows:

```
{
  "recordNumber":"record-number",
  "loggedDateTimeInMS":"logged-date",
  "loggedLevel":"log-level",
  "productName":"product-name",
  "loggerName":"logger-class-name",
  "nameValuePairs":"_ThreadID=thread-id;_ThreadName=thread-name;",
  "messageID":"message-id",
  "Message":"message-text"
}
```

The replaceable items in this format are as follows:

record-number

A serial number in the form of a decimal integer that uniquely identifies the log record.

logged-date

The date and time in UNIX time that the record was created.

log-level

The severity level of the message in the log record. For more information, see Setting Log Levels.

product-name

The current name and version of the server runtime.

logger-class-name

The fully qualified name of the Java class of the logger class that created the log message. Each component of Payara Server provides its own logger class.

For detailed information about the names of logger classes in the Payara Server, see Logger Namespaces.

thread-id

The numerical identifier of the thread that created the message.

thread-name

The name of the thread that created the message.

message-id

A unique identifier for the message. For messages from Payara Server, this identifier consists of a module code and a numerical value, for example, `CORE5004`. All `SEVERE` and `WARNING` messages and some `INFO` messages from Payara Server contain a message identifier.

message-text

The text of the log message.

[[Technical Documentation-Payara Server Documentation-General Administration-Using REST Interfaces for Server Administration:::example-json-resource-representation-for-log-file-details]]

.Example JSON Resource Representation for Log File Details

This example shows the JSON representation of the resource for log file details. In this example, the DAS is running on the local host and the HTTP port for administration is 4848. The URL to the resource in this example is `http://localhost:4848/management/domain/view-log/details`.

```
{
  "records": [
    {
      "recordNumber":475,
      "loggedDateTimeInMS":1300743782815,
      "loggedLevel":"INFO",
      "productName":"Payara Server main-7",
      "loggerName":"org.glassfish.admingui",
      "nameValuePairs": "_ThreadID=25;_ThreadName=Thread-1;",
      "messageID":"",
      "Message":"Admin Console: Initializing Session Attributes..."
    },
    {
      "recordNumber":474,
      "loggedDateTimeInMS":1300728893368,
      "loggedLevel":"INFO",
      "productName":"Payara main-7",

}
```

XML Resource Representation for Log File Details

The general format for the XML representation of a resource for log file details is as follows:

```
<records>
 records
</records>
```

The replaceable item in this format is the records, which is one or more XML elements that represent the log records in the log file. For the format of each element, see XML Representation of a Log Record.

XML Representation of a Log Record

The XML representation of a log record is as follows:

```
<record loggedDateTimeInMS="logged-date" loggedLevel="log-level" loggerName="logger-
class-name" messageID="message-id" nameValuePairs="_ThreadID=thread-id;_thread-name;"
productName="product-name" recordNumber="record-number"/>
```

The replaceable items in this format are as follows:

logged-date
: The date and time in UNIX time that the record was created.

log-level
: The severity level of the message in the log record. For more information, see Setting Log Levels.

logger-class-name
: The fully qualified name of the Java class of the logger class that created the log message. Each component of Payara Server provides its own logger class.

  For detailed information about the names of logger classes in Payara Server, see Logger Namespaces.

message-id
: A unique identifier for the message. For messages from Payara Server, this identifier consists of a module code and a numerical value, for example, `CORE5004`. All `SEVERE` and `WARNING` messages and some `INFO` messages from Payara Server contain a message identifier.

thread-id
: The numerical identifier of the thread that created the message.

thread-name
: The name of the thread that created the message.

product-name
: The current name and version of the server runtime.

record-number
: A serial number in the form of a decimal integer that uniquely identifies the log record.

Example XML Resource Representation for Log File Details

This example shows the XML representation of the resource for log file details. In this example, the DAS is running on the local host and the HTTP port for administration is 4848. The URL to the

resource in this example is http://localhost:4848/management/domain/view-log/details.

```
<records>
 <record loggedDateTimeInMS="1300743782815" loggedLevel="INFO"
loggerName="org.glassfish.admingui" messageID=""
nameValuePairs="_ThreadID=25;_ThreadName=Thread-1;" productName="Payara main-7"
recordNumber="475"/>
 <record loggedDateTimeInMS="1300728893368" loggedLevel="INFO"
loggerName="jakarta.enterprise.system.core.com.sun.enterprise.v3.admin.adapter"
messageID="" nameValuePairs="_ThreadID=238;_ThreadName=Thread-1;" productName="Payara
main-7" recordNumber="474"/>
 <record loggedDateTimeInMS="1300728893367" loggedLevel="INFO"
loggerName="jakarta.enterprise.system.core.com.sun.enterprise.v3.server"
messageid="core10010" nameValuePairs="_ThreadID=238;_ThreadName=Thread-1;"
productName="Payara main-7" recordNumber="473"/>
</records>
```

Supported Content Types in Requests to REST Resources

The Payara Server REST interfaces support the following types in the content-type header of a client request:

- JSON
- XML
- Form URL encoded

How to specify the type in the content-type header depends on how you are sending the request. For example, if you are using the cURL utility, specify the type through the `-H` option as follows:

- For JSON, specify `-H "Content-type: application/json"`.
- For XML, specify `-H "Content-type: application/xml"`.
- For form URL encoded, specify `-H "Content-type: application/x-www-form-urlencoded"`.

Administering Domains

This chapter provides procedures for administering domains in the Payara Server environment by using the `asadmin`command-line utility.

Instructions for accomplishing the tasks in this chapter by using the Administration Console are contained in the Administration Console online help.

About Administering Domains

A domain contains a group of Payara Server instances that are administered together. Each domain has a domain administration server (DAS) that hosts administrative applications.

Payara Server Instances

A Payara Server instance is a single Virtual Machine for the Java platform (Java Virtual Machine or JVM machine) on a single node in which Payara Server is running. A node defines the host where the Payara Server instance resides. The JVM machine must be compatible with the Jakarta EE.

Payara Server instances form the basis of an application deployment.

Whenever a domain is created, Payara Server creates a default instance that is named `server`. If a single instance meets your requirements, you can use this instance for deploying applications without the need to administer Payara Server instances explicitly. You administer the default instance when you administer its domain.

If you require multiple instances, you must administer the instances explicitly. For more information, see "Administering Payara Server Instances" in the Payara Server High Availability section.

For an instance, you can also create virtual servers. Virtual servers do not span instances. For many purposes, you can use virtual servers instead of multiple instances in operational deployments. Virtual servers enable you to offer, within a single instance, separate domain names, IP addresses, and some administration capabilities to organizations or individuals. To these users, a virtual server behaves like a dedicated web server, but without the hardware and basic web server maintenance.

For more information about virtual servers, see Administering Virtual Servers.

Domains for Administering Payara Server

A domain is an administrative boundary that contains a group of Payara Server instances that are administered together. Each instance can belong to only one domain. A domain provides a preconfigured runtime for user applications. Each domain has its own configuration data, log files, and application deployment areas that are independent of other domains. If the configuration is changed for one domain, the configurations of other domains are not affected.

Domains enable different organizations and administrators to share securely a single Payara Server installation. Each organization or administrator can administer the instances in a single domain without affecting the instances in other domains.

At installation time, Payara Server creates a default domain that is named `domain1`. After installation, you can create additional domains as necessary.

When a domain is created, you are prompted for the administration username and password. If you accept the default, the user `admin` is created without password. To reset the administration password, see To Change an Administration Password in Payara Server Security Guide.

Domain Administration Server (DAS)

The domain administration server (DAS) is a specially designated Payara Server instance that hosts administrative applications. The DAS is similar to any other Payara Server instance, except that the DAS has additional administration capabilities. The DAS authenticates the administrator, accepts requests from administration tools, and communicates with other instances in the domain to carry

out the requests from administration tools.

Each domain has its own DAS with a unique administration port number. The default administration port is 4848, but a different port can be specified when a domain is created.

The DAS has the master copy of the configuration data for all instances in a domain. If an instance is destroyed, for example, because a host failed, the instance can be re-created from the data in the DAS.

The DAS is the default Payara Server instance in a domain and is named `server`. If a single instance meets your requirements, you can use the DAS for deploying applications and for administering the domain.

The graphical Administration Console communicates with a specific DAS to administer the domain that is associated with the DAS. Each Administration Console session enables you to configure and manage only one domain. If you create multiple domains, you must start a separate Administration Console session to manage each domain.

Creating, Logging In To, and Deleting a Domain

To Create a Domain

After installing Payara Server and creating the default domain (`domain1`), you can create additional domains by using the local `create-domain` subcommand. This subcommand creates the configuration of a domain. Any user who has access to the `asadmin` utility on a given system can create a domain and store the domain configuration in a folder of choice. By default, the domain configuration is created in the default directory for domains. You can override this location to store the configuration elsewhere.

You are required to specify an administrative user when you create a domain, or you can accept the default login identity which is username `admin` with no password.

1. Select a name for the domain that you are creating.
   You can verify that a name is not already in use by using the `list-domains` subcommand
2. Create a domain by using the `create-domain` subcommand.
   Information about the options for this subcommand is included in this help page.
3. Type an admin user name and password for the domain.
   To avoid setting up an admin login, you can accept the default `admin`, with no password. Pressing Return also selects the default.

Example 3-1 Creating a Domain

This example creates a domain named `domain1` . When you type the command, you might be prompted for login information.

```
asadmin> create-domain --adminport 4848 domain1
Enter admin user name[Enter to accept default]>
Using port 4848 for Admin.
Default port 8080 for HTTP Instance is in use. Using 1161
```

```
Using default port 7676 for JMS.
Using default port 3700 for IIOP.
Using default port 8081 for HTTP_SSL.
Using default port 3820 for IIOP_SSL.
Using default port 3920 for IIOP_MUTUALAUTH.
Default port 8686 for JMX_ADMIN is in use. Using 1162
Distinguished Name of the self-signed X.509 Server Certificate is:
[CN=moonbeam.gateway.2wire.net,OU=Payara,O=Payar Foundation,L=Great
Malvern,ST=Worcestershire,C=UK]]
Domain domain1 created.
Command create-domain executed successfully.
```

To start the Administration Console in a browser, enter the URL in the following format:

```
http://hostname:4848
```

For this example, the domain's log files, configuration files, anddeployed applications now reside in the following directory:

```
domain-root-dir`/mydomain`
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-domain` at the command line.

To Create a Domain From a Custom Template

A custom template enables you to customize the configuration of any domain that you create from the template.

1. Create a domain to use as the basis for the template.
   For more information, see To Create a Domain.
2. Use the `asadmin` utility or the Administration Console to configure the domain.
   Your configuration changes will be included in the template that you create from the domain.
3. Copy the domain's `domain.xml` file under a new name to the as-install`/lib/templates` directory.
   A domain's `domain.xml` file is located in the domain-dir`/config` directory.
4. In a plain text editor, edit the file that you copied to replace with tokens values that are to be substituted when a domain is created.
   Each token is identified as `token-name` where token-name is one of the following names:

   `ADMIN_PORT`

   Represents the port number of the HTTP port or the HTTPS port for administration. This token is replaced with one of the following values in the command to create a domain from the template:

   - The value of the `--adminport` option
   - The value of the `domain.adminPort` property

`CONFIG_MODEL_NAME`

Represents the name of the configuration that is created for the domain that is being created. This token is replaced with the string `server-config`.

`DOMAIN_NAME`

Represents the name of the domain that is being created. This token is replaced with the operand of `create-domain` subcommand.

`HOST_NAME`

Represents the name of the host on which the domain is being created. This token is replaced with the fully qualified host name of the host where the domain is being created.

`HTTP_PORT`

Represents the port number of the port that is used to listen for HTTP requests. This token is replaced with one of the following values in the command to create a domain from the template:

- The value of the `--instanceport` option
- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `domain.instancePort` property

`HTTP_SSL_PORT`

Represents the port number of the port that is used to listen for secure HTTP requests. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `http.ssl.port` property

`JAVA_DEBUGGER_PORT`

Represents the port number of the port that is used for connections to the Java Platform Debugger Architecture (JPDA) debugger. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `java.debugger.port` property

`JMS_PROVIDER_PORT`

Represents the port number for the Java Message Service provider. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `jms.port` property

`JMX_SYSTEM_CONNECTOR_PORT`

Represents the port number on which the JMX connector listens. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `domain.jmxPort` property

`ORB_LISTENER_PORT`

Represents the port number of the port that is used for IIOP connections. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `orb.listener.port` property

`ORB_MUTUALAUTH_PORT`

Represents the port number of the port that is used for secure IIOP connections with client authentication. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `orb.mutualauth.port` property

`ORB_SSL_PORT`

Represents the port number of the port that is used for secure IIOP connections. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `orb.ssl.port` property

`OSGI_SHELL_TELNET_PORT`

Represents the port number of the port that is used for connections to the Apache Felix Remote Shell . This shell uses the Felix shell service to interact with the OSGi module management subsystem. This token is replaced with one of the following values in the command to create a domain from the template:

- A value that the `create-domain` subcommand calculates from the value of the `--portbase` option
- The value of the `osgi.shell.telnet.port` property

`SERVER_ID`

Represents the name of the DAS for the domain that is being created. This token is replaced with the string `server`.

5. Create the domain that you want to be based on a custom template.
   In the command to create the domain, pass the name of file that you edited in the previous step as the `--template` option of the `create-domain` subcommand.
6. Before starting the domain, verify that the domain's `domain.xml` file is valid.
   Use the `verify-domain-xml` subcommand for this purpose.
   Information about the options for this subcommand is included in the subcommand's help page.

For information about how these tokens are used in the default template, examine the `as-install/lib/templates/domain.xml` file.

See Also

- `To Create a Domain`
- `create-domain`
- `verify-domain-xml`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line.

- `asadmin help create-domain`
- `asadmin help verify-domain-xml`

To List Domains

Use the `list-domains` subcommand to display a list of domains and their statuses. If the domain directory is not specified, the contents of the domain-root-dir, the default for which is as-install`/domains`, is listed. If there is more than one domain, the domain name must be specified.

To list domains that were created in other directories, specify the `--domaindir` option.

List domains by using the `list-domains` subcommand.

Example 3-2 Listing Domains

This example lists the domains in the default domain root directory:

```
asadmin> list-domains
Name: domain1 Status: Running
Name: domain4 Status: Not Running
Name: domain6 Status: Not Running
Command list-domains executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-domain` at the command line.

To Log In to a Domain

All remote subcommands require that credentials be specified in terms of an administration user name and its password. By default, the domain is created with an identity that allows an `asadmin` user to perform administrative operations when no identity is explicitly or implicitly specified.

The default identity is in the form of a user whose name is `admin` and has no password. If you specify no user name on the command line or on prompt, and specify no password in the `--passwordfile` option or on prompt, and you have never logged in to a domain using either the `login` subcommand or the `create-domain` subcommand with the `--savelogin` option, then the `asadmin` utility will attempt to perform a given administrative operation without specifying any identity.

A server (domain) allows administrative operations to be run using this default identity if the following conditions are true:

- The server (domain) uses file realm for authentication of administrative users.
  If this condition is not true, you will need to specify the user name and password.
- The file realm has one and only one user (what the user name is does not matter).
  If this condition is not true, you will also need to specify the user name.
- That one user has no password.
  If this condition is not true, you will need to specify the password.

By default, all of these conditions are true, unless you have created the domain with a specific user name and password. Thus, by default, the only administrative user is `admin` with no password.

Use the `login` subcommand in local mode to authenticate yourself (log in to) a specific domain. After such login, you do not need to specify the administration user or password for subsequent operations on the domain. The `login` subcommand can only be used to specify the administration password. For other passwords that remote subcommands require, use the `--passwordfile` option, or specify the password at the command prompt. You are always prompted for the administration user name and password.

There is no logout subcommand. If you want to log in to another domain, invoke `asadmin login` with new values for `--host` and `--port`.

1. Determine the name of the domain that you are logging in to.
   To list the existing domains:

   ```
   asadmin list-domains
   ```

2. Log in to the domain by using the `login` command.

Example 3-3 Logging In To a Domain on a Remote Machine

This example logs into a domain located on another machine. Options are specified before the `login` subcommand.

```
asadmin> --host foo --port 8282 login
```

```
Please enter the admin user name>admin Please enter the admin password>
Trying to authenticate for administration of server at host [foo] and port [8282] ...
Login information relevant to admin user name [admin]
for host [foo] and admin port [8282] stored at [/.asadminpass] successfully.
Make sure that this file remains protected. Information stored in this
file will be used by asadmin commands to manage associated domain.
```

Example 3-4 Logging In to a Domain on the Default Port of Localhost

This example logs into a domain on `myhost` on the default port. Options are specified before the login subcommand.

```
asadmin> --host myhost login
Please enter the admin user name>admin
Please enter the admin password>
Trying to authenticate for administration of server at host [myhost] and port [4848]
...
An entry for login exists for host [myhost] and port [4848], probably from
an earlier login operation.
Do you want to overwrite this entry (y/n)?y
Login information relevant to admin user name [admin] for host [myhost]
and admin port [4848] stored at [/home/joe/.asadminpass] successfully.
Make sure that this file remains protected. Information stored in this file will be
used by
asadmin commands to manage associated domain.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help login` at the command line. For additional information about passwords, see Administering Passwords in Payara Server Security Guide.

To Delete a Domain

Use the `delete-domain` subcommand to delete an existing domain from a server. Only the root user or the operating system user who is authorized to administer the domain can run this subcommand.

Before You Begin

A domain must be stopped before it can be deleted.

1. List domains by using the `list-domains` subcommand.
2. If necessary, notify domain users that the domain is being deleted.
3. Ensure that the domain you want to delete is stopped.
   If needed, see To Stop a Domain.
4. Delete the domain by using the `delete-domain` subcommand.

Example 3-5 Deleting a Domain

This example deletes a domain named `domain1` from the location specified.

```
asadmin> delete-domain --domaindir ..\domains domain1
Domain domain1 deleted.
Command delete-domain executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-domain` at the command line.

Starting and Stopping a Domain

To Start a Domain

When you start a domain or server, the domain administration server (DAS) is started. After startup, the DAS runs constantly, listening for and accepting requests.

If the domain directory is not specified, the domain in the default domain root directory is started. If there are two or more domains, the `domain_name` operand must be specified. Each domain must be started separately.

This subcommand is supported in local mode only.

Start a domain by using the `start-domain` subcommand.

Example 3-6 Starting a Domain

This example starts `domain2` in the default domain directory.

```
asadmin> start-domain domain2
```

If there is only one domain, you can omit the domain name. If you do not include the password, you might be prompted to supply it.

```
Name of the domain started: [domain1] and its location:
[C:\prelude\v3_prelude_release\distributions\web\target\glassfish
domains\domain1].
Admin port for the domain: [4848].
```

You can also view the full syntax and options of the subcommand by typing `asadmin help start-domain` at the command line.

To Stop a Domain

Stopping a domain or server shuts down its domain administration server (DAS). When stopping a domain, the DAS stops accepting new connections and then waits for all outstanding connections to complete. This shutdown process takes a few seconds. While the domain is stopped, the

Administration Console and most of the `asadmin` subcommands cannot be used. This subcommand is particularly useful in stopping a runaway server. For more controlled situations, you can use the `restart-domain` subcommand.

1. If necessary, notify users that you are going to stop the domain.
2. Stop the domain by using the `stop-domain` subcommand.

Example 3-7 Stopping a Domain (or Server)

This example stops `domain1` in the default directory, where `domain1` is the only domain present in the directory.

```
asadmin> stop-domain
Waiting for the domain to stop ...........
Command stop-domain executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help stop-domain` at the command line.

To Restart a Domain

Use the `restart-domain` subcommand in remote mode to restart the Domain Administration Server (DAS) of the specified host. When restarting a domain, the DAS stops accepting new connections and then waits for all outstanding connections to complete. This shutdown process takes a few seconds. Until the domain has restarted, the Administration Console and most of the `asadmin` subcommands cannot be used.

This subcommand is particularly useful for environments where the server machine is secured and difficult to get to. With the right credentials, you can restart the server from a remote location as well as from the same machine.

If the server will not restart, use the `stop-domain` subcommand followed by the `start-domain` subcommand.

1. Ensure that the server is running.
   Remote subcommands require a running server.
2. Restart the domain by using the `restart-domain` subcommand.

Example 3-8 Restarting a Domain (or Server)

This example restarts `mydoimain4` in the default directory.

```
asadmin> restart-domain mydomain4
Waiting for the domain to restart ...........
Command restart-domain executed successfully.
```

Example 3-9 Restarting a Domain in a Browser

This example invokes the `restart-domain` subcommand in a browser.

```
http://yourhost:4848/__asadmin/restart-domain
```

You can also view the full syntax and options of the subcommand by typing `asadmin help restart-domain` at the command line.

Configuring a DAS or a Payara Server Instance for Automatic Restart

Use the `create-service` subcommand in local mode to configure your system to automatically restart a domain administration server (DAS) or a Payara Server instance. Payara Server enables you to configure a DAS or an instance for automatic restart on the following operating systems:

- Windows
- Linux
- Oracle Solaris

To ensure that automatic restart functions correctly on Windows, you must prevent service shutdown when a user logs out.

To Configure a DAS or an Instance for Automatic Restart on Windows

On Windows systems, the `create-service` subcommand creates a Windows service to represent the DAS or instance. The service is created in the disabled state. After this subcommand creates the service, you must use the Windows Services Manager or the Windows Services Wrapper to start, stop, uninstall, or install the service. To administer the service from the Windows command line, use the `sc.exe` tool.

This subcommand must be run as the OS-level administrator user.

1. Create the service by using the `create-service` subcommand.
2. After the service is created, start the service by using the Windows Services Manager or the Windows Services Wrapper.
   For example, to start the service for the default domain by using the `sc.exe` tool, type:

   ```
   C:\> sc start domain1
   ```

If you are using the `sc.exe` tool to administer the service, use the tool as follows:

- To obtain information about the service, use the `sc query` command.
- To stop the service, use the `sc stop` command.
- To uninstall the service, use the `sc delete` command.

Example 3-10 Creating a Service to Restart a DAS Automatically on Windows

This example creates a service for the default domain on a system that is running Windows.

```
asadmin> create-service
Found the Windows Service and successfully uninstalled it.
The Windows Service was created successfully.  It is ready to be started.  Here are
the details:
ID of the service: domain1
Display Name of the service:domain1 GlassFish Server
Domain Directory: C:\glassfishv3\glassfish\domains\domain1
Configuration file for Windows Services Wrapper: C:\glassfishv3\glassfish\domains\
domain1\bin\domain1Service.xml
The service can be controlled using the Windows Services Manager or you can use the
Windows Services Wrapper instead:
Start Command:  C:\glassfishv3\glassfish\domains\domain1\bin\domain1Service.exe  start
Stop Command:   C:\glassfishv3\glassfish\domains\domain1\bin\domain1Service.exe  stop
Uninstall Command:  C:\glassfishv3\glassfish\domains\domain1\bin\domain1Service.exe
uninstall
Install Command:  C:\glassfishv3\glassfish\domains\domain1\bin\domain1Service.exe
install

This message is also available in a file named PlatformServices.log in the domain's
root directory
Command create-service executed successfully.
```

Example 3-11 Querying the Service to Restart a DAS Automatically on Windows

This obtains information about the service for the default domain on a system that is running Windows.

```
C:\> sc query domain1

SERVICE_NAME: domain1
        TYPE               : 10  WIN32_OWN_PROCESS
        STATE              : 1  STOPPED
        WIN32_EXIT_CODE    : 1077  (0x435)
        SERVICE_EXIT_CODE  : 0  (0x0)
        CHECKPOINT         : 0x0
        WAIT_HINT          : 0x0
```

To Configure a DAS or an Instance for Automatic Restart on Linux

On Linux systems, the `create-service` subcommand creates a System-V-style initialization script `/etc/init.d/GlassFish_`domain-or-instance-name and installs a link to this script in any `/etc/rc`N.d` directory that is present, where N is `0`, `1`, `2`, `3`, `4`, `5`, `6`, and `S`. After this subcommand creates the script, you must use this script to start, stop, or restart the domain or instance.

The script automatically restarts the domain or instance only during a reboot. If the domain or

instance is stopped, but the host remains running, the domain or instance is not restarted automatically. To restart the domain or instance, you must run the script manually.

You might no longer require the domain or instance to be automatically restarted during a reboot. In this situation, use the operating system to delete the initialization script and the link to the script that the `create-service` subcommand creates.

The `create-service` subcommand must be run as the OS-level root user.

Create the service by using the `create-service` subcommand.

Example 3-12 Creating a Service to Restart a DAS Automatically on Linux

This example creates a service for the default domain on a system that is running Linux.

```
asadmin> create-service
Found the Linux Service and successfully uninstalled it.
The Service was created successfully. Here are the details:
Name of the service:domain1
Type of the service:Domain
Configuration location of the service:/etc/init.d/GlassFish_domain1
User account that will run the service: root
You have created the service but you need to start it yourself.
Here are the most typical Linux commands of interest:

* /etc/init.d/GlassFish_domain1 start
* /etc/init.d/GlassFish_domain1 stop
* /etc/init.d/GlassFish_domain1 restart

For your convenience this message has also been saved to this file:
/export/payara7/glassfish/domains/domain1/PlatformServices.log
Command create-service executed successfully.
```

To Configure a DAS or an Instance for Automatic Restart on Oracle Solaris

On Oracle Solaris systems, the `create-service` subcommand creates an Oracle Solaris Service Management Facility (SMF) service that restarts a DAS or an instance. The service grants to the process the privileges of the user that runs the process. When you create an SMF service, the default user is the superuser. If you require a different user to run the process, specify the user in `method_credential`.

If your process is to bind to a privileged port of Oracle Solaris, the process requires the `net_privaddr` privilege. The privileged ports of the Oracle Solaris operating system have port numbers less than 1024.

To determine if a user has the `net_privaddr` privilege, log in as that user and type the command `ppriv -l | grep net_privaddr`.

After you create and enable the SMF service, if the domain or instance is stopped, SMF restarts it.

Before You Begin

To run the `create-service` subcommand, you must have `solaris.smf.*` authorization. For information about how to set the authorizations, see the `useradd` man page and the `usermod` man page. You must also have write permission in the directory tree: `/var/svc/manifest/application/SUNWappserver`. Usually, the superuser has both of these permissions. Additionally, Oracle Solaris administration commands such as `svccfg`, `svcs`, and `auths` must be available in the PATH.

If a particular Payara Server domain or instance should not have default user privileges, modify the manifest of the service and reimport the service.

1. Create the service by using the `create-service` subcommand.
2. After the service is created, enable the service by using the `svcadm enable` command.
   For example, to enable the SMF service for the default domain, type:

   ```
   svacdm enable /appserver/domains/domain1
   ```

Example 3-13 Creating a Service to Restart a Domain Automatically on Oracle Solaris

This example creates a service for the default domain on a system that is running Oracle Solaris.

```
asadmin> create-service
The Service was created successfully. Here are the details:
Name of the service:application/GlassFish/domain1
Type of the service:Domain
Configuration location of the service:/home/gfuser/glassfish-installations
/glassfishv3/glassfish/domains
Manifest file location on the system:/var/svc/manifest/application
/GlassFish/domain1_home_gfuser_glassfish-installations_glassfishv3
_payara_domains/Domain-service-smf.xml.
You have created the service but you need to start it yourself.
Here are the most typical Solaris commands of interest:
* /usr/bin/svcs -a | grep domain1 // status
* /usr/sbin/svcadm enable domain1 // start
* /usr/sbin/svcadm disable domain1 // stop
* /usr/sbin/svccfg delete domain1 // uninstall
Command create-service executed successfully
```

For information about administering the service, see the following Oracle Solaris documentation:

- Managing Services (Overview) in System Administration Guide: Basic Administration
- Managing Services (Tasks) in System Administration Guide: Basic Administration
- `auths`
- `svcs`
- `svcadm`

- `svccfg`
- `useradd`
- `usermod`
- `rbac`
- `smf_security`

To Prevent Service Shutdown When a User Logs Out on Windows

By default, the Java Virtual Machine (VM) receives signals from Windows that indicate that Windows is shutting down, or that a user is logging out of Windows, which causes the system to shut itself down cleanly. This behavior causes the Payara Server service to shut down. To prevent the service from shutting down when a user logs out, you must set the `-Xrs` Java VM option.

1. Ensure that the DAS is running.
2. Set the `-Xrs` Java VM option for the DAS.
   Use the `create-jvm-options` subcommand for this purpose.

   ```
   asadmin> create-jvm-options -Xrs
   ```

3. Set the `-Xrs` Java VM option for the Java VM within which the `asadmin` utility runs.
   To set this option, edit the `asadmin.bat` file to add the `-Xrs` option to the line that runs the `admin-cli.jar` file.
4. In the as-install`\bin\asadmin.bat` file, edit the line to read as follows:

   ```
   %JAVA% -Xrs -jar "%~dp0..\modules\admin-cli.jar" %*
   ```

5. In the as-install-parent`\bin\asadmin.bat` file, edit the line to read as follows:

   ```
   %JAVA% -Xrs -jar "%~dp0..\glassfish\modules\admin-cli.jar" %*
   ```

6. If the Payara Server service is running, restart the service for your changes to take effect.

Backing Up and Restoring a Domain

To Back Up a Domain

Use the `backup-domain` subcommand in local mode to make a backup of a specified domain.

When you use the `backup-domain` subcommand, Payara Server creates a ZIP file backup of all the files and subdirectories in the domain's directory, domain-root-dir`/domain-dir, except for the `backups` subdirectory.

The `backup-domain` subcommand provides several options to meet particular needs, including:

- `--backupdir` to specify a directory in which to store the backup instead of the default domain-

root-dir`/domain-dir/backups`.

- `--description` to provide a description of the backup to be stored in the backup itself.

1. Ensure that the domain is stopped .
   The `backup-domain` subcommand operates only when the domain is stopped.
2. Back up the domain by using the `backup-domain` subcommand.
3. Restore the domain to its previous state, if necessary.
   Start or resume the domain.

Example 3-14 Backing Up the Default Domain

This example makes a backup of the default domain, `domain1`, storing the backup file in `/net/backups.example.com/glassfish`:

```
asadmin> backup-domain --backupdir /net/backups.example.com/domains domain1
Backed up domain1 at Mon Jan 17 08:16:22 PST 2011.
Command backup-domain executed successfully
```

You can also view the full syntax and options of the subcommand by typing `asadmin help backup-domain` at the command line.

To Restore a Domain

Use the `restore-domain` subcommand in local mode to use a backup file to restore the files and subdirectories in a specified domain's directory.

The `restore-domain` subcommand can use backup files created by the `backup-domain` subcommand and by automatic backup configurations, both full backups and configuration-only backups. Automatic backup configurations are available only in Payara Server.

1. If necessary, notify domain users that the domain is being restored from backup.
2. Ensure that the domain is stopped.
   The `restore-domain` subcommand operates only when the domain is stopped.
   To determine whether the domain is running, use the `list-domains` subcommand, as described in To List Domains.
   To stop the domain, use the `stop-domain` subcommand as described in To Stop a Domain.
3. Restore backup files for a domain by using the `restore-domain` subcommand.
4. Verify that the restore has succeeded.
5. If necessary, notify users that the domain has been restored and is available.

Example 3-15 Restoring the Default Domain

This example restores files for the default domain, `domain1`, from the most recent backup stored in a specified backup directory:

```
asadmin> restore-domain --backupdir /net/backups.example.com/domains domain1
```

```
Restored the domain (domain1) to /home/user1/payara/glassfish/domains/domain1
Command restore-domain executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin restore-domain --help` at the command line.

To List Domain Backups

Use the `list-backups` subcommand in local mode to display information about backups of a specified domain stored in a specified backup directory.

The `list-backups` subcommand provides several options to meet particular needs, including `--backupdir` to specify a directory where backups are stored instead of the default domain-dir`/backups`.

List backups by using the `list-backups` subcommand.

Example 3-16 Listing Backups of the Default Domain

This example lists the backups of the default domain, `domain1`, that are stored in the `/net/backups.example.com/glassfish` directory:

```
asadmin> list-backups --backupdir /net/backups.example.com/domains domain1
CONFIG        USER   BACKUP DATE                    FILENAME
              user1  Mon Jan 17 08:16:22 PST 2011  domain1_2011_01_17_v00001.zip
monthly-full  user1  Wed Dec 01 00:00:00 PST 2010  domain1_2010_12_01_v00001.zip
monthly-full  user1  Sat Jan 01 00:00:03 PST 2011  domain1_2011_01_01_v00001.zip
monthly-full  user1  Tue Feb 01 00:00:01 PST 2011  domain1_2011_02_01_v00001.zip
Command list-backups executed successfully.
```

Note that this listing includes backups created automatically by a backup configuration. This feature is available only in Payara Server.

You can also view the full syntax and options of the subcommand by typing `asadmin help list-backups` at the command line.

Re-Creating the Domain Administration Server (DAS)

For mirroring purposes, and to provide a working copy of the DAS, you must have:

- One host (`olddashost`) that contains the original DAS.
- A second host (`apphost`) that contains a cluster with server instances running applications and catering to clients. The cluster is configured using the DAS on the first host.
- A third host (`newdashost`) where the DAS needs to be re-created in a situation where the first host crashes or is being taken out of service.

You must maintain a backup of the DAS from the first host using the `backup-domain` subcommand as described in To Back Up a Domain. You can automatically

maintain a backup of the DAS using the automatic backups feature of Payara Server.

Payara Server includes `asadmin` subcommands that simplify this procedure. If you are using Payara Server, see To Migrate the DAS.

To Migrate the DAS

The following steps are required to migrate the DAS from the first host (`olddashost`) to the third host (`newdashost`).

1. Install Payara Server on `newdashost` just as it was installed on `olddashost`.
   This is required so that the DAS can be properly restored on `newdashost` without causing path conflicts.
2. Use the `restore-domain` subcommand to restore the latest backup file onto `newdashost`.
   For example:

   ```
   asadmin> restore-domain --backupdir /net/backups.example.com/glassfish
   ```

   This example assumes that backups are stored in a network-accessible location. If this is not the case, manually copy the latest backup file from offline storage to a directory on `newdashost`.
   You can backup any domain. However, while re-creating the domain, the domain name should be same as the original.
3. Stop the domain on `olddashost`, if it is running.
4. Start the domain on `newdashost` by using the `start-domain` subcommand.
   For example:

   ```
   asadmin> start-domain domain1
   ```

5. If the domain on `olddashost` was centrally administered, set up centralized administration on `newdashost`.
   See Enabling Centralized Administration of Payara Server Instances in the Payara Server High Availability section for instructions.
6. Verify that instances on other hosts are visible to the new DAS on `newdashost`:

   ```
   asadmin> list-instances --long
   ```

7. Change the DAS host values for properties under the node on `apphost`.
   In the file `as-install/nodes/node-name/agent/config/das.properties` file, change the `agent.das.host` property value to refer to `newdashost` instead of `olddashost`.
8. Use the new DAS to restart clusters and standalone instances on `apphost`:

   Restarting the clustered and standalone instances on `apphost` triggers their recognition of the

new DAS on `newdashost`.

a. Use the `list-clusters` subcommand to list the clusters in the domain.

b. Use the `stop-cluster` subcommand to stop each cluster.

c. Use the `list-instances` subcommand to list the instances in the domain.

d. Use the `restart-instance` subcommand to restart each standalone instance.

e. Use the `start-cluster` subcommand to start each cluster.
If the domain does not use centralized administration, use the `start-local-instance` subcommand to start the cluster instances on apphost.

9. Verify that instances on apphost are running:

```
asadmin> list-instances --long
```

10. Decommission and discontinue use of the DAS on olddashost.

Additional Domain Tasks

To Display Domain Uptime

Use the `uptime` subcommand in remote mode to display the length of time that the domain administration server (DAS) has been running since it was last started.

1. Ensure that the server is running.
Remote subcommands require a running server.
2. Display uptime by using the `uptime` subcommand.

Example 3-17 Displaying the DAS Uptime

This example displays the length of time that the DAS has been running.

```
asadmin> uptime
Uptime: 1 Weeks, 4 days, 0 hours, 17 minutes, 14 seconds, Total milliseconds:
951434595
Command uptime executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help uptime` at the command line.

To Switch a Domain to Another Supported Java Version

Payara Server requires Java SE 11 as the underlying virtual machine for the Java platform (Java Virtual Machine or JVM machine).

Do not downgrade to an earlier Java version after a domain has been created with a newer JVM machine. If you must downgrade your JVM machine, downgrade it only for individual domains.

1. If you have not already done so, download the desired Java SDK (not the JRE) and install it on your system.
2. Start the domain for which you are changing the JDK.
   Use the following format:

   ```
   as-install/bin/asadmin start-domain domain-name
   ```

   For a valid JVM installation, locations are checked in the following order:

   a. `domain.xml` (`java-home` inside `java-config`)
   b. `asenv.conf` (setting `AS_JAVA="path to java home"`)
      If a legal JDK is not found, a fatal error occurs and the problem is reported back to you.
   c. If necessary, change the JVM machine attributes for the domain.
      In particular, you might need to change the `JAVA_HOME` environment variable. For example, to change the `JAVA_HOME` variable, type:

      ```
      as-install/bin/asadmin set "server.java-config.java-home=path-to-java-home"
      ```

To Change the Administration Port of a Domain

Use the `set` subcommand in remote mode to change the administration port of a domain.

The HTTP port or the HTTPS port for administration of a domain is defined by the `--adminport` option of the `create-domain` subcommand when the domain is created. If this port must be reallocated for another purpose, change the port on which the DAS listens for administration requests.

1. Ensure that the server is running.
   Remote subcommands require a running server.
2. Set the port number to its new value.
   Use the `set` subcommand for this purpose.

   ```
   $ asadmin set
   server-config.network-config.network-listeners.network-listener.admin-
   listener.port=new-port-number
   ```

   The new-port-number is the new value that you are setting for the port number.

   After you set the port number to its new value, running the `list-domains` subcommand incorrectly reports that the DAS is not running. The `list-domains` subcommand reports the correct state again only after you stop and restart the domain as explained in the steps that follow.

3. Stop the domain, specifying the host on which the DAS is running and the old administration port number of the domain.

You must specify the old port number because the DAS is still listening for administration requests on this port. If you omit the port number, the command fails because the `stop-domain` subcommand attempts to contact the DAS through the new port number.

Only the options that are required to complete this task are provided in this step. For information about all the options for controlling the behavior of the domain, see the `stop-domain` help page.

```
$ asadmin --host host-name --port old-port-number stop-domain
```

host-name

The name of the host on which the DAS is running. If you run the `stop-domain` subcommand on the host where the DAS is running, you must specify the actual host name and not `localhost`. If you specify `localhost`, the `stop-domain` subcommand fails.

old-port-number

The value of administration port number of the domain before you changed it in the preceding step.

1. Start the domain.

Only the options that are required to complete this task are provided in this step. For information about all the options for controlling the behavior of the domain, see the `start-domain` help page.

```
$ start-domain [domain-name]
```

The domain-name is the name of the domain to start. If only one domain subdirectory is contained in the `domains` directory, you may omit this option.

Example 3-18 Changing the Administration Port of a Domain

This example changes the administration port of the domain `domain1` from 4848 to 4849. The DAS is running on the host `xk01.example.com`.

```
$ asadmin set
server-config.network-config.network-listeners.network-listener.admin-
listener.port=4849
server-config.network-config.network-listeners.network-listener.admin-
listener.port=4849
Command set executed successfully.
$ asadmin --host xk01.example.com --port 4848 stop-domain
Waiting for the domain to stop ....
Command stop-domain executed successfully.
$ asadmin start-domain
Waiting for domain1 to start .......................
```

```
Successfully started the domain : domain1
domain  Location: /export/payara7/glassfish/domains/domain1
Log File: /export/payara7/glassfish/domains/domain1/logs/server.log
Admin Port: 4849
Command start-domain executed successfully.
```

See Also

- `create-domain`
- `set`
- `start-domain`
- `stop-domain`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help create-domain`
- `asadmin help set`
- `asadmin help start-domain`
- `asadmin help stop-domain`

Administering the Java Virtual Machine

The Java Virtual Machine is an interpretive computing engine responsible for running the byte codes in a compiled Java program. The virtual machine translates the Java byte codes into the native instructions of the host machine. Payara Server, being a Java process, requires a virtual machine to run and support the Java applications running on it. JVM settings are part of an Payara Server configuration.

Administering JVM Options

The commands can be used to configure the JVM settings for Payara Server.

To Create JVM Options

Use the `create-jvm-options` subcommand in remote mode to create JVM options in the Java configuration element of the `domain.xml` file.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create JVM options by using the `create-jvm-options` subcommand. To create more than one JVM option, use a colon (:) to separate the options. If the JVM option itself contains a colon (:), use the backslash (\) to offset the colon delimiter.Information about properties for the subcommand is included in this help page.
3. To apply your changes, restart Payara Server.

Example 4-1 Creating JVM Options Example

This example sets multiple Java system properties.

```
asadmin> create-jvm-options -Dunixlocation=/root/example:
-Dvariable=\$HOME:
-Doption1=-value1
created 4 option(s)
Command create-jvm-options executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-jvm-options` at the command line.

To List JVM Options

Use the `list-jvm-options` subcommand in remote mode to list the existing JVM options.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List JVM options by using the `list-jvm-options` subcommand.

Example 4-2 Listing JVM Options

This example lists all JVM options.

```
asadmin> list-jvm-options
-Djava.security.auth.login.config=${com.sun.aas.instanceRoot}/config/login.conf
-XX: LogVMOutput
-XX: UnlockDiagnosticVMOptions
-Dcom.sun.enterprise.config.config_environment_factory_class=com.sun.enterprise.
config.serverbeans.AppserverConfigEnvironmentFactory
-Djavax.net.ssl.keyStore=${com.sun.aas.instanceRoot}/config/keystore.jks
-XX:NewRatio=2
-Djava.security.policy=${com.sun.aas.instanceRoot}/config/server.policy
-Djdbc.drivers=org.apache.derby.jdbc.ClientDriver
-Djavax.net.ssl.trustStore=${com.sun.aas.instanceRoot}/config/cacerts.jks
-client
-Djava.ext.dirs=${com.sun.aas.javaRoot}/lib/ext${path.separator}${com.sun.aas.ja
vaRoot}/jre/lib/ext${path.separator}${com.sun.aas.instanceRoot}/lib/ext${path.se
parator}${com.sun.aas.derbyRoot}/lib
-Xmx512m
-XX:LogFile=${com.sun.aas.instanceRoot}/logs/jvm.log
Command list-jvm-options executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-jvm-options` at the command line.

To Delete JVM Options

Use the `delete-jvm-options` subcommand in remote mode to delete JVM options from the Java

configuration element of the `domain.xml` file.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List JVM options by using the `list-jvm-options` subcommand.
3. If necessary, notify users that the JVM option is being deleted.
4. Delete JVM options by using the `delete-jvm-options` subcommand. To remove more than one JVM option, use a colon (:) to separate the options. If the JVM option itself contains a colon, use the backslash (\) to offset the colon delimiter.
5. To apply your changes, restart Payara Server.

Example 4-3 Deleting a JVM Option

This example removes a single JVM option.

```
asadmin> delete-jvm-options -Doption1=-value1

deleted 1 option(s)
Command delete-jvm-options executed successfully.
```

Example 4-4 Deleting Multiple JVM Options

This example removes multiple JVM options.

```
asadmin> delete-jvm-options -Doption1=-value1:-Dvariable=\$HOME
deleted 2 option(s)
Command delete-jvm-options executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-jvm-options` at the command line.

Payara Platform Proprietary JVM Options

The following is a list of the proprietary JVM Options available for configuration:

Config File Encoding

Property

`fish.payara.configFileEncoding`

Aim

Sets the domain.xml parser character encoding. The domain will fail to start if you are using characters not covered by UTF-8 in your configuration without this property configured.

Acceptable Values

Any JDK supported file encoding charset

Configuring JDK Versions for JVM Options

It is possible to allow specific JVM options configured for a Payara Server instance to be applied only on specific JDK versions. The configuration is flexible since it allows the user to define minimum and maximum versions of all JDKs upon which each JVM option should be applied.

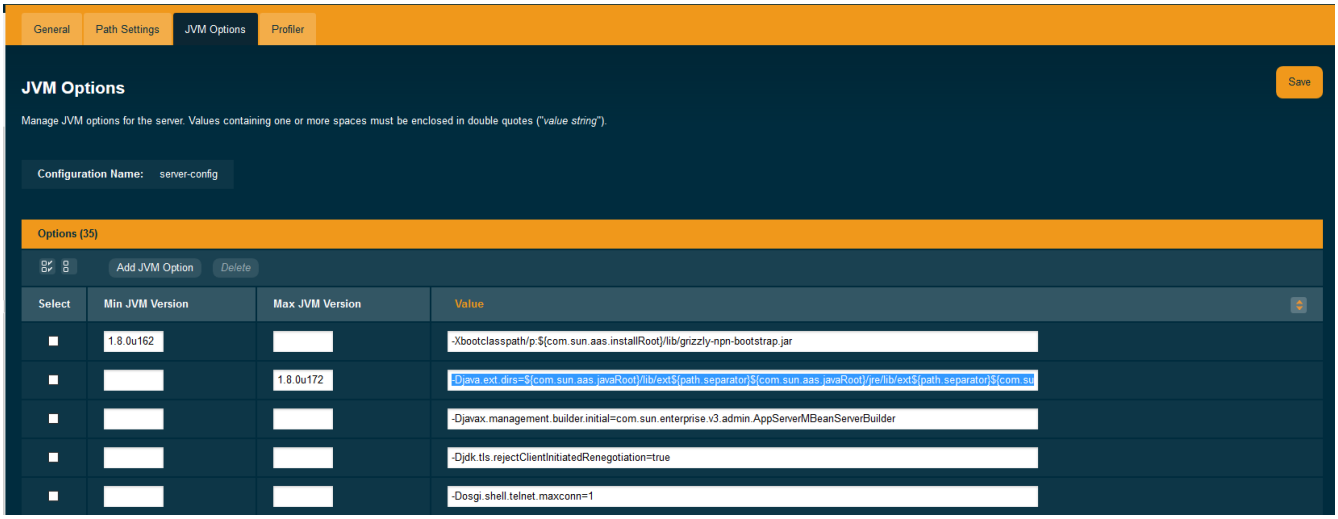
JDK versions must follow standard the standard JDK versioning scheme. The syntax that can be used allows for different levels of granularity in the specified JDK versions. Any of the following would be acceptable:

- `1.8.0.162`
- `1.8.0u162`
- `1.8.0`
- `1.8`

If no minimum and/or maximum JDK versions are set for a particular JVM option, it shall be applied no matter which JDK is being used to run the server's instance.

Using the Admin Console

To configure the JDK versions for JVM options in the admin console, head to the **Configurations** → **<instance configuration>** → **JVM Settings** and on the **JVM Options** tab specify the versions in the table:



You can omit either the minimum or maximum versions by leaving the fields blank.

Using Asadmin commands

The `create-jvm-options` asadmin command allows the minimum and maximum JDK versions to be set in the following ways:

1. Use the `--min-jvm` and `--max-jvm` arguments to set the versions when running the command:

```
asadmin create-jvm-options --target=server-config --min-jvm=1.8.0u162 "-
```

```
Djava.awt.headless\=true"

asadmin create-jvm-options --target=server-config --max-jvm=1.8.0u172 "-
XX\:+UnlockDiagnosticVMOptions"
```

When using these arguments to set multiple JVM options, the specified versions will be applied for each option.

2. Specify the versions using the `[MIN_VERSION | MAX_VERSION]` text syntax for the inclusive version range before each JVM option:

```
asadmin create-jvm-options --target=server-config "[1.8.0u162|]-
Djava.awt.headless\=true"

asadmin create-jvm-options --target=server-config "[|1.8.0u172]-
XX\:+UnlockDiagnosticVMOptions"

asadmin create-jvm-options --target=server-config "[1.8.0u168|1.8.0u172]-
XX\:NewRatio\=2"
```

The `delete-jvm-options` asadmin command does not require you to specify the JDK version when deleting a JVM option, though you can if you wish.

For example, given the option `[1.8.0.160|1.8.0.200]XX\:NewRatio=3`, either of the following commands are acceptable:

```
asadmin delete-jvm-options "XX\:NewRatio=3"

asadmin delete-jvm-options "[1.8.0.160|1.8.0.200]XX\:NewRatio=3"
```

To Generate a JVM Report

Use the `generate-jvm-report` subcommand in remote mode to generate a JVM report showing the threads (dump of a stack trace), classes, memory, and loggers for a specified instance, including the domain administration server (DAS). You can generate the following types of reports: summary (default), class, thread, log.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Generate the report by using the `generate-jvm-report` subcommand.

Example 4-5 Generating a JVM Report

This example displays summary information about the threads, classes, and memory.

```
asadmin> generate-jvm-report --type summary
Operating System Information:
Name of the Operating System: Windows XP
```

```
Binary Architecture name of the Operating System: x86, Version: 5.1
Number of processors available on the Operating System: 2
System load on the available processors for the last minute: NOT_AVAILABLE.
(Sum of running and queued runnable entities per minute).
.
,
.
user.home = C:\Documents and Settings\Jennifer
user.language = en
user.name = Jennifer
user.timezone = America/New_York
user.variant =
variable = \$HOME
web.home = C:\Preview\v3_Preview_release\distributions\web\target\
Payara\modules\web
Command generate-jvm-report executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help generate-jvm-report` at the command line.

Administration Console Features

This page documents features specific to the administration console, focusing on Payara Server enhancements.

Asadmin Recorder

This feature allows you to record the actions you take in the admin console as asadmin commands, aiding with automating or reproducing your setup across multiple Payara Server installations.

Starting and Stopping the Asadmin Recorder

You can enable or disable the asadmin recorder on its configuration page (detailed in the following section), or by using the following asadmin commands:

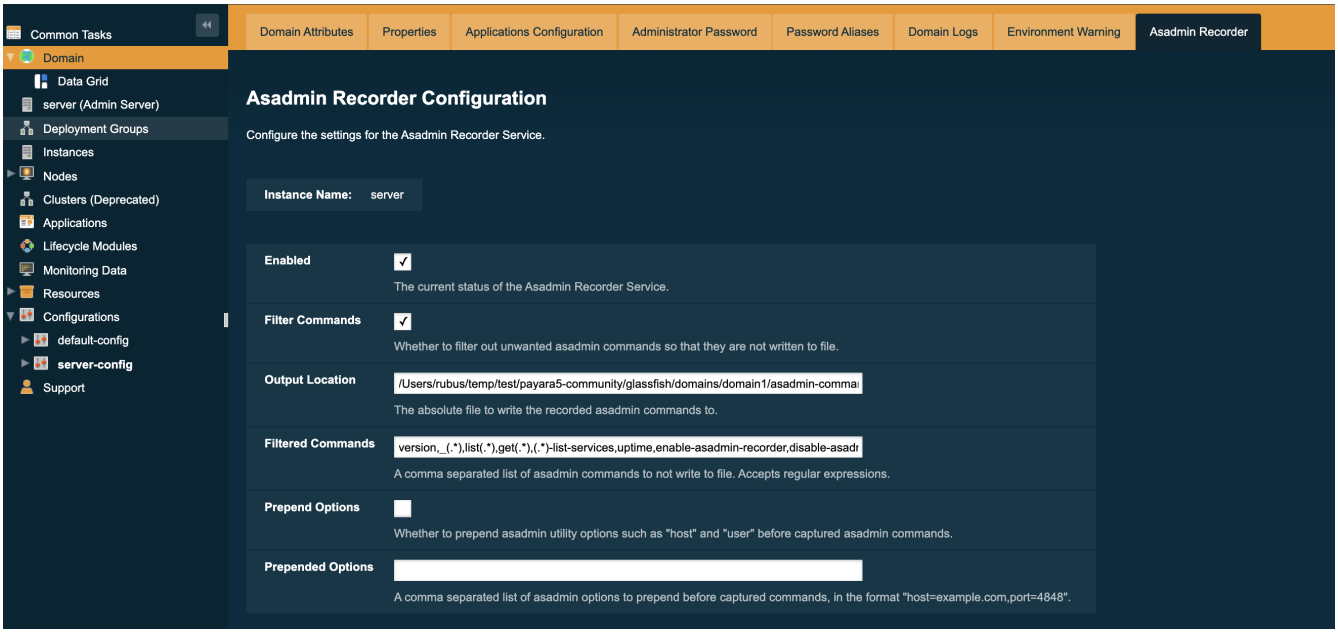
- `enable-asadmin-recorder`
- `disable-asadmin-recorder`
- `set-asadmin-recorder-configuration`

Once enabled or disabled, the asadmin recorder will remain enabled/disabled until specifically enabled or disabled again through the web console or using the appropriate Asadmin CLI command.

This means that the asadmin recorder will remain enabled or disabled across server restarts.

Configuring the Asadmin Recorder

To configure the asadmin recorder, navigate to the following page in the admin console: *server* → *Asadmin Recorder*:



You will be presented with the following configuration options:

Enabled

Sets whether the asadmin recorder service should be enabled or disabled.

Filter Commands

Sets whether to exclude the `asadmin` commands and regular expressions listed in the *Filtered Commands* setting from being recorded.

Output Location

The absolute file path for the `asadmin` commands to be written to. This defaults to a file called *asadmin-commands.txt* in the domain directory.

Filtered Commands

A comma separated list of asadmin commands and regular expressions to be excluded from being recorded if the *Filter Commands* option is enabled.

The default regular expressions and asadmin commands set in the *Filtered Commands* option are a selection of commands and regular expressions that are typically not needed for any automation purposes, yet are still sometimes called by commands and through navigation of the admin console.

If you remove any of these commands from the filtered commands list, or choose not to filter any commands at all, the asadmin commands script is liable to get filled up with these commands. Due to this behavior, it is advised that you only add to this list, only removing the defaults if you really need to.

Be sure to click on the *Save* button to have any changes you make take effect.

In addition to using the admin console, you can configure the asadmin recorder service using the `set-asadmin-recorder-configuration` command. See `set-asadmin-recorder-configuration`

Running the Generated Scripts

Documentation on running asadmin scripts can be found in this section.

Asadmin Commands

The following is the list of available asadmin commands to configure the asadmin recorder:

- `get-asadmin-recorder-configuration`
- `set-asadmin-recorder-configuration`
- `enable-asadmin-recorder`
- `disable-asadmin-recorder`
- `asadmin-recorder-enabled`

Admin Console Auditing Service

This feature allows users to log all actions and operations executed via the admin console for auditing purposes.

Configuring the Auditing Service

All operations executed by users with access to the admin console will be translated to events that correspond to the specific admin user that executed the operation and the `asadmin` command (and its parameters) that is equivalent to the operation being executed in the admin console. For example if the default `admin` user modifies the monitoring level of the *Web Services Container*, the following event will be generated:

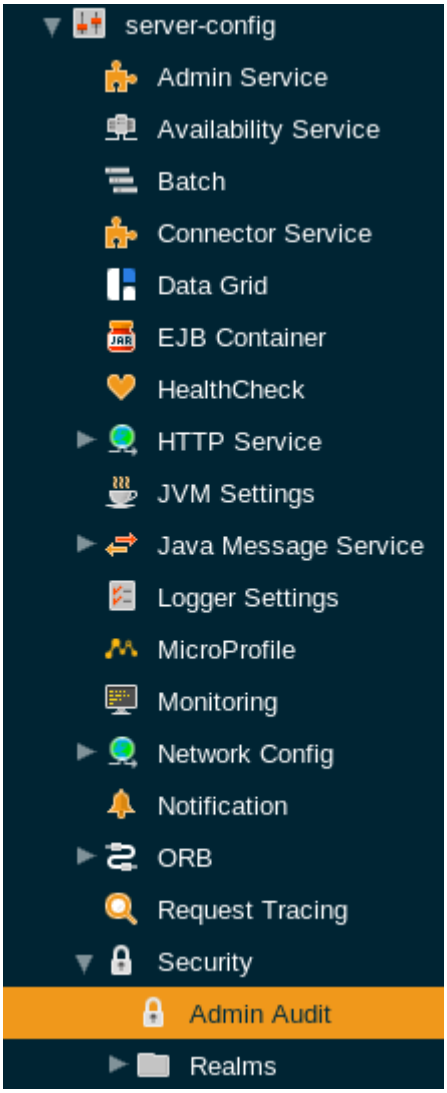
```
AUDIT - admin issued command set with parameters
{
    DEFAULT: [configs.config.server-config.monitoring-service.module-monitoring-
levels.web-services-container=HIGH]
}
```

The auditing service will relay these events to the Notification Service. In this manner, administrators can be alerted of suspicious activity as soon as possible.

This service can be configured from the admin console and from the command line.

From the Admin Console

The auditing service configuration can be found in the web console under `Configurations` → `<configuration-name>` → `Security` → `Admin Audit`:



Once enabled, actions in the admin console that have a corresponding `asadmin` command will be sent to the Notification service.

Check the **Enabled** option (and the **Dynamic** option too if you don't want to restart the domain) to switch the auditing service on.

The **Audit Level** options sets the level of operations that will be logged:

MODIFIERS

(Default setting) All operations that modify the configuration of the server in some capacity.

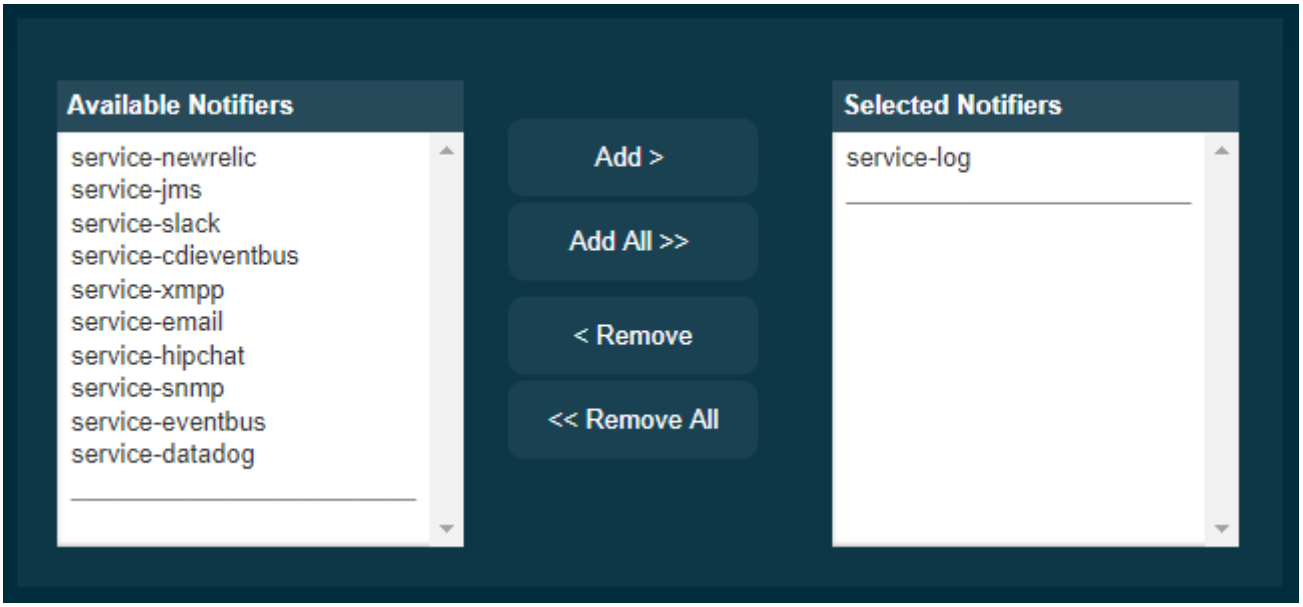
ACCESSORS

All operations query the configuration of the server in some capacity.

INTERNAL

All existing operations, including internal operations of the server.

Aside from this configuration setting, you can also define which notifiers will be used to relay the admin console audit events by moving them to the **Selected Notifiers** box.



Keep in mind that for audit events to be relayed to the selected notifiers, both the Notification Service and each selected notifier must be enabled and configured beforehand.

You don't need to manually add each notifier on this screen. When enabling a notifier on its configuration screen, the server will **automatically** add it to the list of selected notifiers for the Admin audit service. This same result occurs when enabling the notifier using the appropriate *asadmin* command.

From the Command Line

The following is the list of available asadmin commands to configure the auditing service:

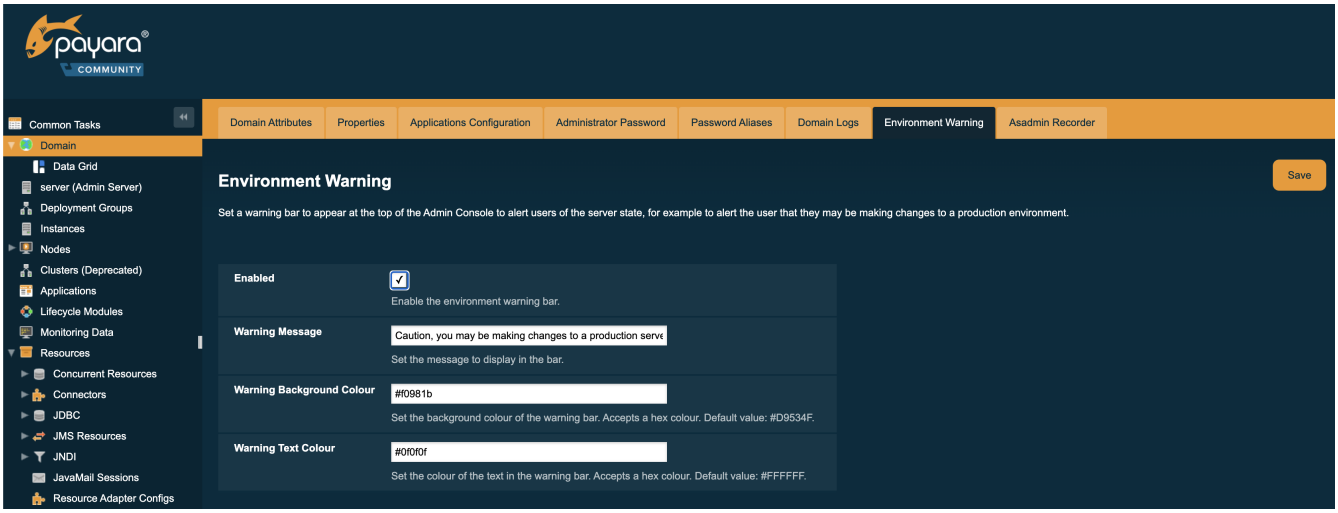
- `set-admin-audit-configuration`
- `get-admin-audit-configuration`

Admin Console Environment Warning

When working with multiple shared environments, it is common for restrictions to be in place on what modifications can be allowed for a given domain. For example, the test environment cannot deviate significantly from the target production environment without potentially invalidating the test.

One way to ensure no accidental changes are made would be to revoke access to the admin console, but this has the downside of preventing engineers from seeing the current settings in the event that a bug is found.

As an alternative, Payara Server ships with a configurable warning bar to ensure any user will see a warning message in while viewing the console:



The warning can be configured in the admin console as seen in the screenshot above. There is a new "*Environment Warning*" tab in the "*Domain*" section which allows you to configure the text and colours of the warning message.

Configuring the Environment Warning via Asadmin

The following is the list of available asadmin commands to get and set the configuration the Environment Warning.

- `set-environment-warning-configuration`
- `get-environment-warning-configuration`

Administering Thread Pools

This chapter provides procedures for administering thread pools in the Payara Server environment by using the `asadmin` command-line utility.

Instructions for accomplishing these tasks by using the Administration Console are contained in the Administration Console online help.

About Thread Pools

The Virtual Machine for the Java platform ((Java Virtual Machine) or JVM machine) can support many threads of execution simultaneously. To help performance, Payara Server maintains one or more thread pools. It is possible to assign specific thread pools to connector modules, to network listeners, or to the Object Request Broker (ORB).

One thread pool can serve multiple connector modules and enterprise beans. Request threads handle user requests for application components. When Payara Server receives a request, it assigns the request to a free thread from the thread pool. The thread executes the client's requests and returns results. For example, if the request needs to use a system resource that is currently busy, the thread waits until that resource is free before allowing the request to use that resource.

Configuring Thread Pools

You can specify the minimum and maximum number of threads that are reserved for requests from applications. The thread pool is dynamically adjusted between these two values.

Default Thread Pool Size

The thread pool `thread-pool-1` starts with a minimum size of **2** instead of **1** (like in previous versions)

This includes the benefit of allowing users to execute tasks concurrently using the `ManagedExecutorService` and `ManagedScheduledExecutorService` components included with Java EE Concurrency Utilities (JSR-236). Without this change, new tasks submitted to these service components would just have been queued in a linear fashion.

This minor optimization is configured on the default domain template (so all newly created domains inherit it).

To Create a Thread Pool

Use the `create-threadpool` subcommand in remote mode to create a thread pool.

The minimum thread pool size that is specified signals the server to allocate at least that many threads in reserve for application requests. That number is increased up to the maximum thread pool size that is specified. Increasing the number of threads available to a process allows the process to respond to more application requests simultaneously.

If one resource adapter or application occupies all the Payara Server threads, thread starvation might occur. You can avoid this by dividing the Payara Server threads into different thread pools.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a new thread pool by using the `create-threadpool` subcommand.
   Information about options for the subcommand is included in this help page.
3. To apply your changes, restart Payara Server. See To Restart a Domain.

Restart is not necessary for thread pools used by the web container.

Example 5-1 Creating a Thread Pool

```
asadmin> create-threadpool --maxthreadpoolsize 100
--minthreadpoolsize 20 --idletimeout 2 threadpool-1
Command create-threadpool executed successfully
```

This example creates `threadpool-l`.

To List Thread Pools

Use the `list-threadpools` subcommand in remote mode to list the existing thread pools.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the existing thread pools by using the `list-threadpools` subcommand.

Example 5-2 Listing Thread Pools

```
asadmin> list-threadpools
threadpool-1
Command list-threadpools executed successfully
```

This example lists the existing thread pools.

To Update a Thread Pool

Use the `set` subcommand to update the values for a specified thread pool.

1. List the existing thread pools by using the `list-threadpools` subcommand.
2. Modify the values for a thread pool by using the `set` subcommand.
   The thread pool is identified by its dotted name.
3. To apply your changes, restart Payara Server. See To Restart a Domain.

Restart is not necessary for thread pools used by the web container.

Example 5-3 Updating a Thread Pool

```
asadmin> set server.thread-pools.thread-pool.http-thread-pool.max-thread-pool-size=8
Command set executed successfully
```

This example sets the `max-thread-pool-size` from its previous value to 8.

To Delete a Thread Pool

Use the `delete-threadpool` subcommand in remote mode to delete an existing thread pool. Deleting a thread pool will fail if that pool is referenced by a network listener.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the existing thread pools by using the `list-threadpools` subcommand.
3. Delete the specified thread pool by using the `delete-threadpool` subcommand.
4. To apply your changes, restart Payara Server. See To Restart a Domain.

Restart is not necessary for thread pools used by the web container.

Example 5-4 Deleting a Thread Pool

```
asadmin> delete-threadpool threadpool-1
Command delete-threadpool executed successfully
```

This example deletes `threadpool-1`.

EJB Thread Pool

The EJB Thread Pool is for prepared EJB beans which are ready for usage, this means there is no instantiation and initialization overhead when the bean is used. It can also be used to limit the number of concurrent beans in use.

An individual bean can specify a configuration that overrides the configuration of the EJB container in the `<bean-pool>` element of the `glassfish-ejb-jar.xml` file.

EJB Thread Pool Configuration Properties

The EJB Thread Pool has the following properties configured by default.

Setting Name	Default Value	Description
Core Pool Size	16	The minimum number of threads in the EJB container thread pool
Max Pool Size	32	The maximum number of threads in the EJB container thread pool
Keep Alive Seconds	60	The time, in seconds, which threads in excess of thread-core-pool-size are deleted
Queue Capacity	Integer.MAX_VALUE (2,147,483,647)	The size, in bytes, of the thread pool queue which stores new requests while new threads are created if more than thread-core-pool-size number of threads are running.
Allow Core Thread Timeout	false	All threads, including core threads, are subject to termination after thread-keep-alive-seconds
Prestart All Core Threads	false	Threads in the EJB container thread pool are started even if no requests have arrived, and the pool has a non-empty queue

Configuring the EJB Thread Pool

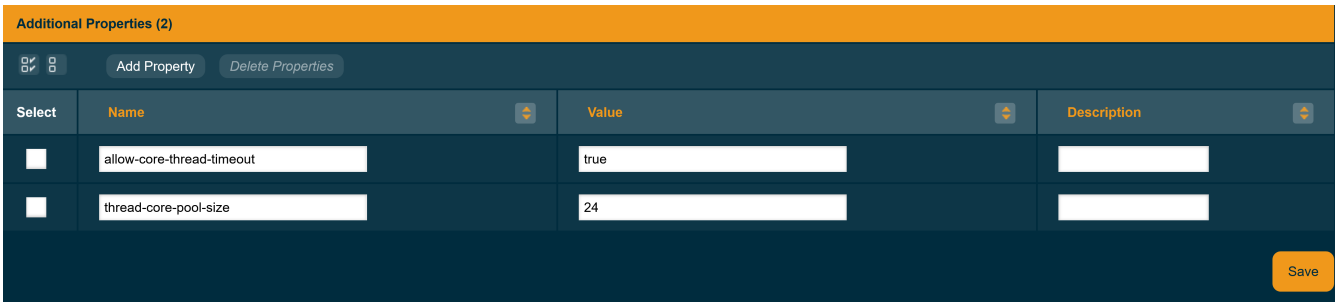
The EJB thread pool can be configured with either the admin console or the asadmin CLI, by making use of the following configuration properties.

Property Name	Value Constraints
thread-core-pool-size	Cannot be less than 0, larger than max int, and must be larger than `thread-max-pool-size`
thread-max-pool-size	Cannot be less than 1 or greater than max int
thread-keep-alive-seconds	Cannot be less than 0 or greater than max int
thread-queue-capacity	Cannot be less than 1 or greater than max int
allow-core-thread-timeout	Must be true or false
prestart-all-core-threads	Must be true or false

Using the Admin Console

To configure the EJB thread pool using the admin console, go to Configuration → [instance-configuration] → EJB Container and scroll down to see `Additional Properties`.

Add a new additional property, set the Name to the property name from the table above of the property you want to set, and set the Value to a valid value for that property.



Using the Asadmin CLI

To configure the EJB thread pool with the asadmin CLI, execute the following set command, replacing the configName with the name of your configuration, the property name with a property name from the table above and a valid value for that property.

```
asadmin set configs.config.${configName}.ejb-
container.property.${propertyName}=${propertyValue}
```

Administering the Logging Service

This chapter provides instructions on how to configure logging and how to view log information in the Payara Server environment.

Instructions for accomplishing these tasks and editing logging service properties in the Administration Console are available from the Administration Console online help.

About Logging

Logging is the process by which Payara Server captures information about events that occur, such as configuration errors, security failures, or server malfunction. This data is recorded in log files and is usually the first source of information when problems occur. Analyzing the log files can help you to follow events that occur in the server runtime and determine the overall health of the server.

Although application components can use the Apache Commons Logging Library to record messages, the platform standard JSR 47 Logging API is recommended for better log configuration.

For more information about Logging in Java, see:

- JSR 47 Specification
- Logging Overview

Log Files

Payara Server log records are captured in the server log file, which captures information about the operation of a server instance running in the domain. Each instance, managed server instance (that is, each cluster member), and the domain administration server (DAS) has an individual server log file.

Log File Names and Locations

In a Payara Server domain, log files have the following name and location by default:

Instance	Default Log File Name and Location
DAS	`domain-dir/logs/server.log`
Server instance	`instance-dir/logs/server.log`
Cluster instance	`instance-dir/logs/server.log`

For example, in a domain hosted on a given machine that includes a cluster with two managed servers (`ClusterServer1` and `ClusterServer1`) and a standalone instance (`StandaloneServer`), the log files might be arranged in the following directory structure. In this directory structure, the `server.log` file for the DAS is located in `domain-dir/logs`.

```
as-install-parent directory
     glassfish/
         domains/
             domain-dir/
                         logs/
                            server.log
         nodes/
             hostname/
                         ClusterServer1/
                                     logs/
                                        server.log
                         ClusterServer2/
                                     logs/
                                        server.log
                         StandaloneServer/
                                     logs/
                                        server.log
```

You can change the default name or location of a log file by modifying the logging properties file for the corresponding instance, described in To Change the Name and Location of the Log File.

Log Records

Payara Server writes log records in either the Oracle Diagnostics Logging (ODL) format or the Uniform Log Formatter (ULF) format. The default format is ODL. For information about changing the format, see Setting the Log File Format.

A custom formatter can also be used by specifying the fully qualified name of a class that extends the `java.util.logging.Formatter` class. The custom formatter class can be packaged in a JAR file and placed in the `domain-dir/lib/ext` directory, or implemented as a Hundred-Kilobyte Kernel (HK2) service and the JAR containing the formatter implementation placed in the `as-install/modules` directory.

Log records formatted in the ODL format are displayed as follows:

```
[yyyy-mm-ddThh:mm:ss.SSS-Z][ProductName-Version][Log Level][Message
ID][LoggerName][Key Value Pairs][[Message]]
```

- `[` and `]` mark the beginning and end of fields in the record. Some fields may be empty.
- `yyyy-mm-dd`T`hh:mm:ss.SSSS-Z` represents the date and time that the record was created. For example: `2013-04-12T08:08:30.154-0700`
- ProductName-Version represents the current version of Payara Server. For example: `payara`
- Log Level represents the log level.

  You can set any of the following values: `EMERGENCY`, `ALERT`, `SEVERE`, `WARNING`, `INFO`, `CONFIG`, `FINE`, `FINER`, and `FINEST`.

  The default is `INFO`.

- Message ID consists of a module code that indicates the origin of the message and the message number. For example: `AS-WEB-GLUE-00172`
- LoggerName represents a hierarchical logger namespace that identifies the source of the log module. For example: `jakarta.enterprise.web`
- Key Value Pairs represents pairs of key names and values. For example: `timeMillis: 1365779310154`
- Message represents the text of the log message.

  For multiline messages, `\[[` marks the end of the first line, and `]]` marks the end of the message. Multiline messages start on a new line after the message header and are indented.

The following is an example of a log record formatted in the ODL format:

```
[2013-04-12T08:08:30.154-0700] [Payara Server main-7] [INFO] [AS-WEB-GLUE-00172]
[jakarta.enterprise.web] [tid: _ThreadID=217 _ThreadName=admin-listener(21)]
[timeMillis: 1365779310154] [levelValue: 800] [[
  Loading application [payroll] at [/payroll]]]
```

Log records formatted in the ULF format are displayed as follows:

```
[#|yyyy-mm-ddThh:mm:ss.SSS-Z|Log Level|ProductName-Version|LoggerName|Key Value
Pairs|Message|#]
```

- `[` and `]` mark the beginning and end of the record.
- The vertical bar (`|`) separates the fields of the record.
- yyyy-mm-dd`T`hh:mm:ss.SSSS-Z represents the date and time that the record was created. For example: `2013-04-18T09:27:44.315-0700`
- Log Level represents the log level. You can set any of the following values: `EMERGENCY`, `ALERT`, `SEVERE`, `WARNING`, `INFO`, `CONFIG`, `FINE`, `FINER`, and `FINEST`. The default is `INFO`.
- ProductName-Version represents the current version of Payara Server. For example: `Payara Server main-7`
- LoggerName represents a hierarchical logger namespace that identifies the source of the log module. For example: `jakarta.enterprise.web.core`
- Key Value Pairs represents pairs of key names and values and can include a message ID. For example: `_MessageID=AS-WEB-CORE-00306`.

  Message IDs are included for all Payara Server `EMERGENCY`, `ALERT`, `SEVERE`, and `WARNING` messages, and for many `INFO` messages.

- Message represents the text of the log message. Multiline messages start on a new line after the message header and are indented.

The following is an example of a log record formatted in the ULF format:

```
[#|2013-04-18T09:27:44.315-0700|INFO|Payara Server main-7|jakarta.enterprise.web.core|
_ThreadID=15;_ThreadName=RunLevelControllerThread-
1366302462682;_TimeMillis=1366302464315;_LevelValue=800;_MessageID=AS-WEB-CORE-00306;|
Setting JAAS app name glassfish-web|#]
```

The Administration Console presents log records in a more readable display. For information about viewing log records using the Administration Console, see Viewing Log Records.

Log Rotation

By default, when a log file grows to 2 MB, Payara Server renames (rotates) the file to incorporate a timestamp and creates a new log file. The log file is renamed as `server.log` date, where date is the date and time that the file was rotated.

You can configure the logging service to change the default settings for log file rotation, as explained in Setting Log File Rotation.

Logger Namespaces

Payara Server provides a logger for each of its modules. The following list is an example of the logger namespaces in a server instance as they appear when using the `list-log-levels` subcommand.

```
ShoalLogger     <CONFIG>
com.hazelcast   <WARNING>
```

```
com.sun.enterprise.server.logging.GFFileHandler <ALL>
com.sun.enterprise.server.logging.SyslogHandler <ALL>
jakarta.mail    <INFO>
java.util.logging.ConsoleHandler        <FINEST>

For information about how to display logger namespaces and log levels, see To List Log Levels. For information about how to display a list of loggers and logger details, see To List Loggers.

Logging Targets

Each instance in a Payara Server domain has a dedicated log file, and each instance and cluster has its own logging properties file. To configure logging for an instance or a cluster, Payara Server allows you target specific log files or logging properties files when you do the following:

- Set global or module-specific log levels
- Rotate log files or compress them into a ZIP archive
- Change logging property attributes
- List log levels or log attributes

The following subcommands optionally accept a target specification. A target can be a configuration name, server name, cluster name, or instance name, and is specified as either an operand or as a value passed using the `--target` option. If no target is specified when using any of these subcommands, the default target is the DAS.

Subcommand	Description	Target Specification
`collect-log-files`	Collects all available log files into a ZIP archive.	`--target`=`target-name
`list-log-attributes`	Lists logging attributes in the logging properties file.	target-name operand
`list-log-levels`	Lists the loggers in the logging properties file and their log levels	target-name operand
`rotate-log`	Rotates the log file by renaming it and creating a new log file to store new messages.	`--target`=`target-name
`set-log-attributes`	Sets the specified logging attributes in the logging properties file.	`--target`=`target-name
`set-log-file-format`	Sets the log file formatter.	`--target`=`target-name
`set-log-levels`	Sets the log level for one or more loggers listed in the logging properties file.	`--target`=`target-name

Logging Properties

The DAS as well as each configuration, instance, and cluster has its own set of logging properties that are maintained in individual configuration files. A logging properties file is named `logging.properies` and includes the following information:

- Log file name and location
- Logger names and levels

- Properties for custom handlers
- Log rotation and logger format properties

By default, in a Payara Server domain, logging properties files are created in the following locations:

Target	Default Location of Logging Properties File
DAS	`domain-dir/config/logging.properties`
A configuration	`domain-dir/config/<config-name>/logging.properties`, where `<config-name>` represents the name of a configuration that is shared by one or more instances or clusters.
An instance	`domain-dir/config/<instance-name>-config/logging.properties`, where `<instance-name>` represents the name of the instance.
A cluster	`domain-dir/config/<cluster-name>-config/logging.properties`, where `<cluster-name>` represents the name of the cluster.

Configuring the Logging Service

Changing the Name and Location of Logging Service Files

This section explains how to change the name and location of the following logging service files:

- Log file
- Logging properties file

To Change the Name and Location of the Log File

To change the name and location of the log file, first use the `list-log-attributes` subcommand to obtain the current log attribute setting for the log file name and location.

Then use the `set-log-attributes` subcommand to specify the new name or location. The default target for these two subcommands is the DAS. However, you can optionally specify one of the following targets:

- Configuration name — to target all instances or clusters that share a specific configuration name.
- Server name — to target only a specific server.
- Instance name — to target only a specific instance.
- Cluster name — to target only a specific cluster.

1. Ensure that the target server or cluster is running. Remote subcommands require a running server.
2. Use the `list-log-attributes` subcommand in remote mode to obtain the current log attribute settings.

   The name and location of the log file is set with the `com.sun.enterprise.server.logging.GFFileHandler.file` attribute of the logging properties

file. Optionally you can target a configuration, server, instance, or cluster.

If you do not specify a target, the log attribute settings for the DAS are displayed.

3. Use the `set-log-attributes` subcommand in remote mode to define a custom name or location of the log file.

   If you do not specify a target, the log file for the DAS is targeted by default. If you target a cluster, the name of the cluster log file for each member instance can be changed (the server log file name cannot).

Example - To Change the Name and Location of the Log File

This example changes the name of the cluster log file for `Cluster1` to `cluster1.log`. `Cluster1` has two server instances: `ClusterServer1` and `ClusterServer2`.

```
asadmin list-log-attributes Cluster1

com.sun.enterprise.server.logging.GFFileHandler.alarms <false>
com.sun.enterprise.server.logging.GFFileHandler.file
<${com.sun.aas.instanceRoot}/logs/server.log>
com.sun.enterprise.server.logging.GFFileHandler.flushFrequency  ①
.
.
.
log4j.logger.org.hibernate.validator.util.Version <warn>
Command list-log-attributes executed successfully.
asadmin> set-log-attributes --target Cluster1
com.sun.enterprise.server.logging.GFFileHandler.file=
${com.sun.aas.instanceRoot}/logs/cluster1.log
com.sun.enterprise.server.logging.GFFileHandler.file
logging attribute set with value ${com.sun.aas.instanceRoot}/logs/cluster1.log
These logging attributes are set for Cluster1.
ClusterServer1 :
com.sun.enterprise.server.logging.GFFileHandler.file
logging attribute set with value ${com.sun.aas.instanceRoot}/logs/cluster1.log
These logging attributes are set for Cluster1.

ClusterServer2 :
com.sun.enterprise.server.logging.GFFileHandler.file
logging attribute set with value ${com.sun.aas.instanceRoot}/logs/cluster1.log
These logging attributes are set for Cluster1.

Command set-log-attributes executed successfully.
```

You can view the full syntax and options of these subcommands by typing `asadmin help list-log-levels` and `asadmin help set-log-attributes` at the command line.

To Change the Name and Location of the Logging Properties File

You can set the name and location of the logging properties file by setting the `java.util.logging.config.file` system property. By setting this system property, you can have a single logging properties file that is used by all instances running on the same host.

Setting the `java.util.logging.config.file` system property causes all other Payara Server logging properties files on the host to be overridden.

1. Set the `java.util.logging.config.file` system property.

   For example, you can use the following command:

   ```
   java -Djava.util.logging.config.file=properties_file
   ```

   Alternatively, you can use the Administration Console to set this system property.

2. To apply your change, restart Payara Server.

Example - To Change the Name and Location of the Logging Property File

The following example changes the location of the logging properties file to `/space/mylogging/logging.properties`:

```
java -Djava.util.logging.config.file=/space/mylogging/logging.properties
```

Setting Log Levels

The log level determines the granularity of the message that is logged, from error only (`EMERGENCY`) to detailed debug (`FINEST`). The following values apply: `EMERGENCY`, `ALERT`, `SEVERE`, `WARNING`, `INFO`, `CONFIG`, `FINE`, `FINER`, and `FINEST`.

These log levels are hierarchically inclusive, which means that if you set a particular log level, such as INFO, the messages that have log levels above that level (`EMERGENCY`, `ALERT`, `SEVERE`, and `WARNING`,) are also included. If you set the log level to the lowest level, `FINEST`, your output includes all the messages in the file. The default setting is `INFO`.

You can list current log levels of all loggers specified in the `logging properties` file. In some cases, loggers that have not been created by the respective containers will also appear in the list.

You can set log levels that are global or logger-specific. When you set a global log level, the log level goes into effect for all loggers. If you set the log level for a specific logger that is different from the global log level, the logger-specific setting takes precedence. In addition, when setting log levels, you can target a configuration, server, instance, or cluster.

Because setting log levels is a dynamic operation, you do not need to restart Payara Server for changes to take effect.

Setting either global or logger-specific log levels is done by using the `set-log-levels` subcommand.

Listing log levels is done by using the `list-log-levels` subcommand.

To List Log Levels

Payara Server provides the means to list all loggers and their log levels. Listing the loggers provides a convenient means to view current loggers and log levels either prior to or after making log level changes.

Use the `list-log-levels` subcommand in remote mode to list the modules and their current log levels. The default target for this subcommand is the DAS. However, you can optionally specify one of the following targets:

- Configuration name — to target all instances or clusters that share a specific configuration name.
- Server name — to target a specific server.
- Instance name — to target a specific instance.
- Cluster name — to target a specific cluster.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. List the existing module loggers and log levels by using the `list-log-levels` subcommand.

Example - To List Log Levels Part 1

This example shows a partial list of the existing loggers and their log levels in the DAS.

```
asadmin list-log-levels

jakarta.enterprise.system.tools.admin <INFO>
java.util.logging.ConsoleHandler <FINEST>
jakarta.enterprise.system.container.web <INFO>
jakarta.enterprise.system.util <INFO>
jakarta.enterprise.resource.webcontainer.jsf.timing <INFO>
javax <INFO>
jakarta.enterprise.resource.corba <INFO>
...
Command list-log-levels executed successfully.
```

Example - To List Log Levels Part 2

This example shows a partial list of the loggers and log levels for the instance `MyServer2`.

```
asadmin list-log-levels MyServer2

java.util.logging.ConsoleHandler <FINEST>
jakarta.enterprise.resource.corba  <INFO>
jakarta.enterprise.resource.javamail   <INFO>
jakarta.enterprise.resource.jdo <INFO>
jakarta.enterprise.resource.jms <INFO>
```

```
jakarta.enterprise.resource.jta <INFO>
jakarta.enterprise.resource.resourceadapter <INFO>
jakarta.enterprise.resource.sqltrace <FINE>
...
Command list-log-levels executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help list-log-levels` at the command line.

To Set the Global Log Level

The global log level specifies the events that are logged across all loggers. The default level for messages output to the console is `INFO` (which also includes `EMERGENCY`, `ALERT`, `SEVERE`, and `WARNING` messages).

Use the `set-log-levels` subcommand in remote mode to set the global log level. The default target for this subcommand is the DAS. However, you can optionally specify one of the following targets using the `--target` option:

- Configuration name — to target all instances or clusters that share a specific configuration name.
- Server name — to target a specific server.
- Instance name — to target a specific instance.
- Cluster name — to target a specific cluster.

1. Ensure that the target server or cluster is running.
2. Set the global log level by using the `set-log-levels` subcommand, specifying the log level of the `java.util.logging.ConsoleHandler` logger.

   The `ConsoleHandler` has a separate log level setting that limits the messages that are displayed. For example:

   ```
   java.util.logging.ConsoleHandler <FINEST>
   ```

Example - To Set the Global Log Level

By setting the log level of the `ConsoleHandler`, you set the global log level for all loggers. This example sets the global log level in the DAS to `INFO`:

```
asadmin set-log-levels java.util.logging.ConsoleHandler=INFO

java.util.logging.ConsoleHandler package set with log level INFO.
These logging levels are set for server.

Command set-log-levels executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help set-log-levels`

at the command line.

To Set Module Log Levels

A module log level specifies the events that are logged for a particular logger. The default level for messages output to the console is `INFO` (which also includes `EMERGENCY`, `ALERT`, `SEVERE`, and `WARNING` messages). The global log level is overridden by a module-specific log level.

By default, the module log level is set to `FINE`. The lines for the loggers in the logging properties file might look like this:

```
jakarta.enterprise.system.tools.level=FINE
jakarta.enterprise.system.container.ejb.level=FINE
jakarta.enterprise.system.core.security.level=FINE
jakarta.enterprise.system.tools.admin.level=FINE
jakarta.enterprise.level=FINE
jakarta.enterprise.system.container.web.level=FINE
```

Because setting log levels is a dynamic operation, you do not need to restart Payara Server for changes to take effect.

1. Ensure that the target server or cluster is running.

   Remote subcommands require a running server.

2. List the existing module loggers and their log levels by using the `list-log-levels` subcommand.
3. Set the log level for a module by using the `set-log-levels` subcommand.

   Your choices are `EMERGENCY`, `ALERT`, `SEVERE`, `WARNING`, `INFO`, `CONFIG`, `FINE`, `FINER`, and `FINEST`.

Example - To Set the Module Log Levels Part 1

This example sets the log level for the web container logger to WARNING on the target instance `ManagedServer1`:

```
asadmin set-log-levels --target ManagedServer1

jakarta.enterprise.system.container.web=WARNING
jakarta.enterprise.system.container.web package set with log level WARNING.
These logging levels are set for ManagedServer1.
ManagedServer1 :
jakarta.enterprise.system.container.web package set with log level WARNING.
These logging levels are set for ManagedServer1.

Command set-log-levels executed successfully.
```

Example - To Set the Module Log Levels Part 2

The following example sets the log level for security and web container loggers in the DAS.

```
asadmin set-log-levels jakarta.enterprise.system.core.security=FINE:

jakarta.enterprise.system.container.web=WARNING
jakarta.enterprise.system.container.web package set with log level WARNING.
jakarta.enterprise.system.core.security package set with log level FINE.
These logging levels are set for server.

Command set-log-levels executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help set-log-levels` at the command line.

Setting the Log File Format

You can set the format for log records in log files.

To Set the Log File Format

Use the `set-log-file-format` subcommand in remote mode to set the formatter used by Payara Server to format log records in log files. You can also use the `set-log-attributes` subcommand.

Log formats for all server instances in a cluster will be the same. For information about log formats, see Log Records.

Changing the log format forces log rotation to avoid mixed format in the same file.

1. Ensure that the target server or cluster is running. Remote commands require a running server.
2. Set the formatter by using the `set-log-file-format` subcommand.
3. To apply your change, restart Payara Server.

Example - To Set the Log File Format Part 1

This example sets the log file format to `ULF` for standalone instance `ManagedServer1` using the `set-log-file-format` subcommand.

```
asadmin set-log-file-format --target ManagedServer1 ulf

The log file formatter is set to com.sun.enterprise.server.logging.UniformLogFormatter
for instance ManagedServer1.
Command set-log-file-format executed successfully.
```

Example - To Set the Log File Format Part 2

This example sets the log file format to `ULF` for standalone instance `ManagedServer1` using the `set-log-attributes` subcommand.

```
asadmin set-log-attributes --target ManagedServer1
```

```
com.sun.enterprise.server.logging.GFFileHandler.formatter=ulf

com.sun.enterprise.server.logging.GFFileHandler.formatter logging attribute value set
to ulf.
The logging attributes are saved successfully for ManagedServer1-config.
Command set-log-attributes executed successfully.
```

You can view the full syntax and options of the `set-log-file-format` subcommand by typing `asadmin help set-log-file-format` at the command line. You can view the full syntax and options of the `set-log-attributes` subcommand by typing `asadmin help set-log-attributes` at the command line.

ANSI Coloured Logging

Payara Server supports the use of ANSI coloured log entries when running in verbose mode under the uniform log format (ULF).

To enable ANSI colours run the following command using the Asadmin CLI:

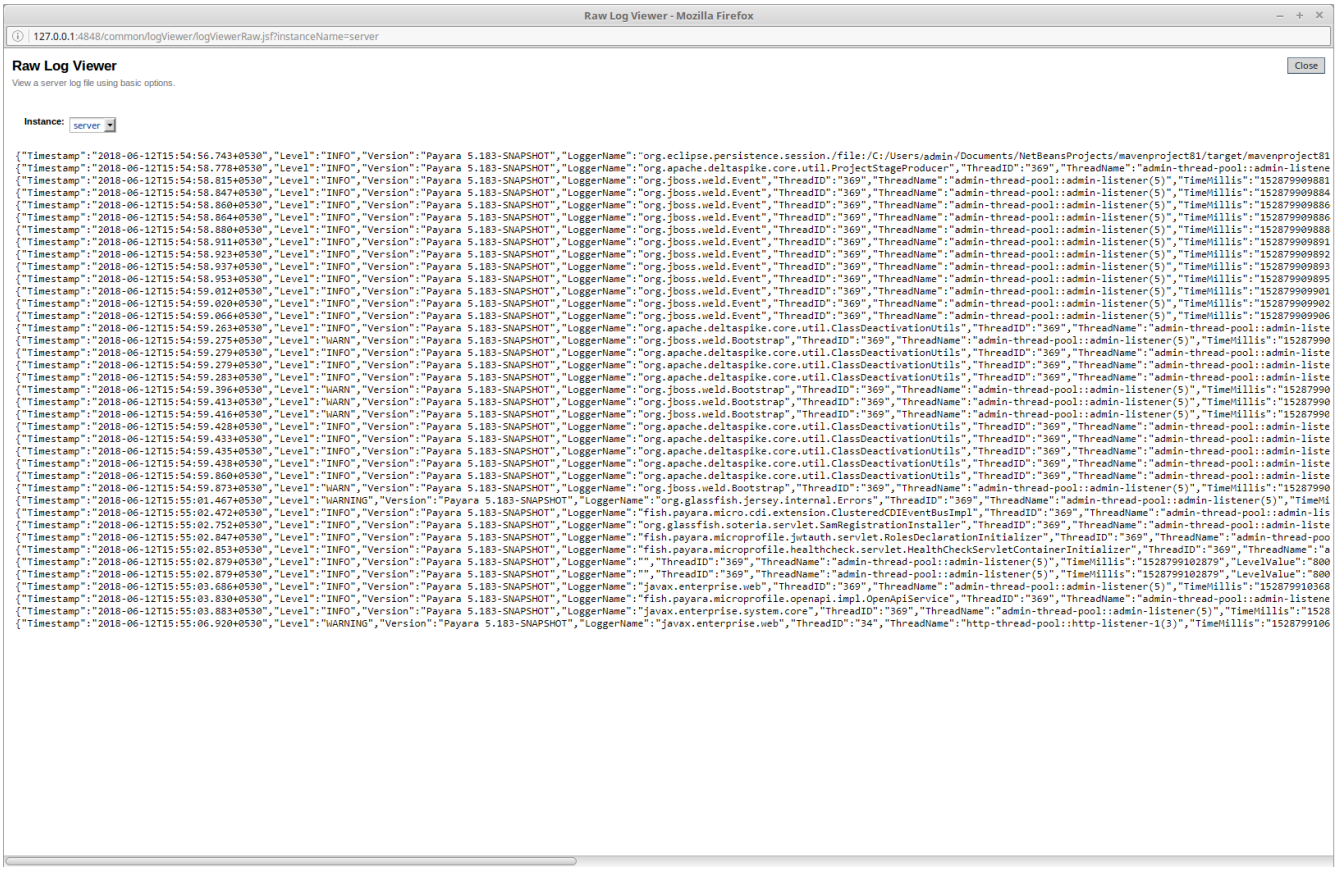
```
asadmin> set-log-attributes
com.sun.enterprise.server.logging.UniformLogFormatter.ansiColor=true
```

This setting is enabled by default when a domain is started in Linux and macOS environments.

JSON Log Format

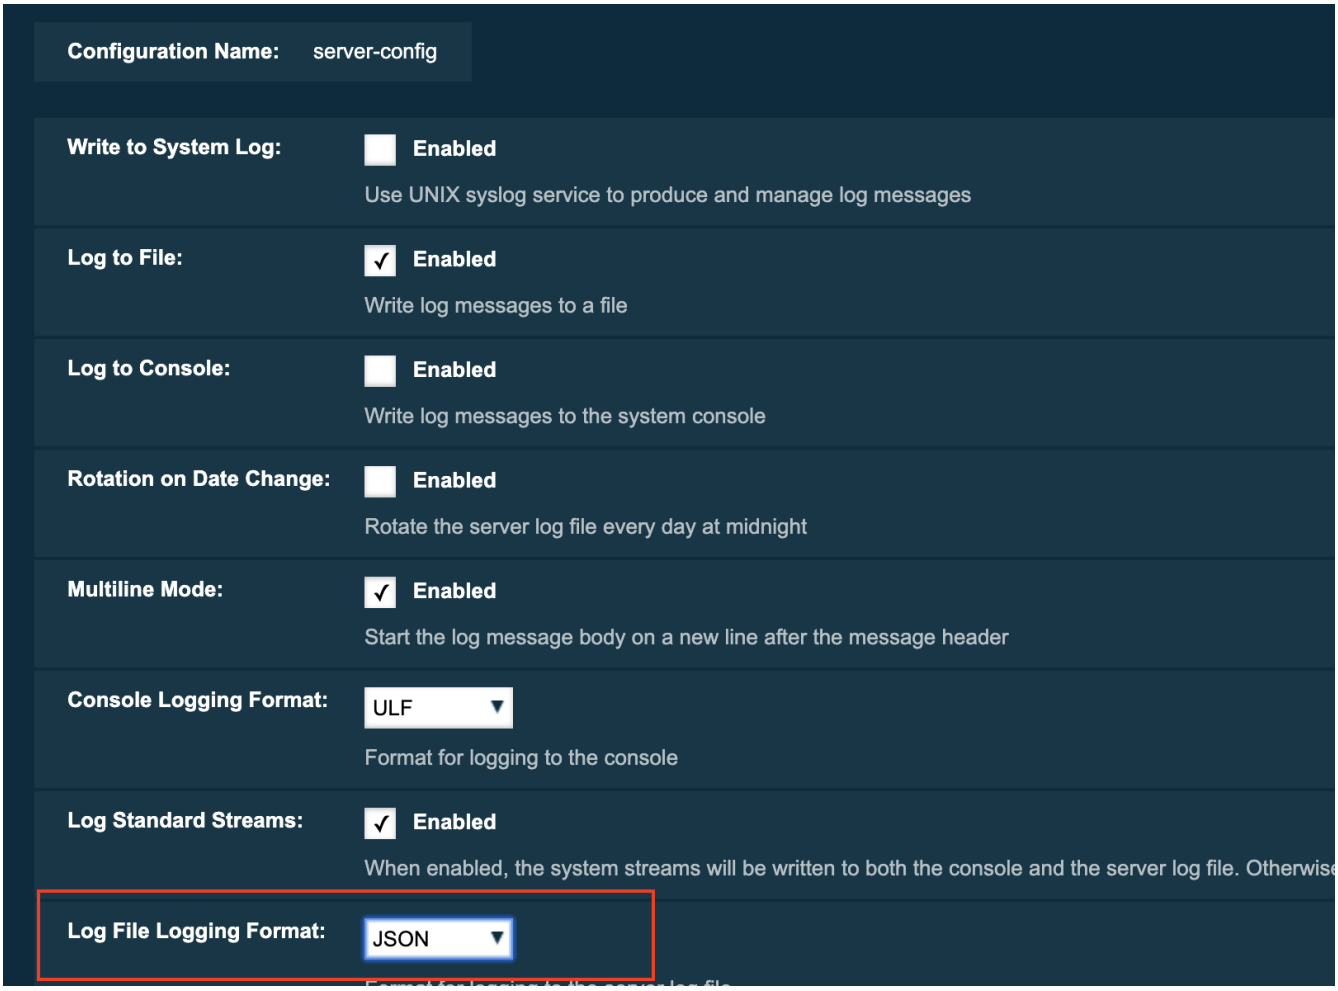
Besides the standard Uniform Log Format (ULF) and Oracle Diagnostics Logging (ODL) formats Payara Server provides a JSON format. With this format, every entry is formatted as a JSON object string. These entries can be easily processed by any JSON parser for further data processing.

Once the JSON formatter is enabled, the server's log file may look similar to this sample:



Enable the JSON formatter using the Web Admin Console

To enable the JSON formatter using the Admin Console, just select `JSON` from the list of Logging Formats, either for `Console` or `Log File`:



Enable the JSON formatter using the Asadmin CLI

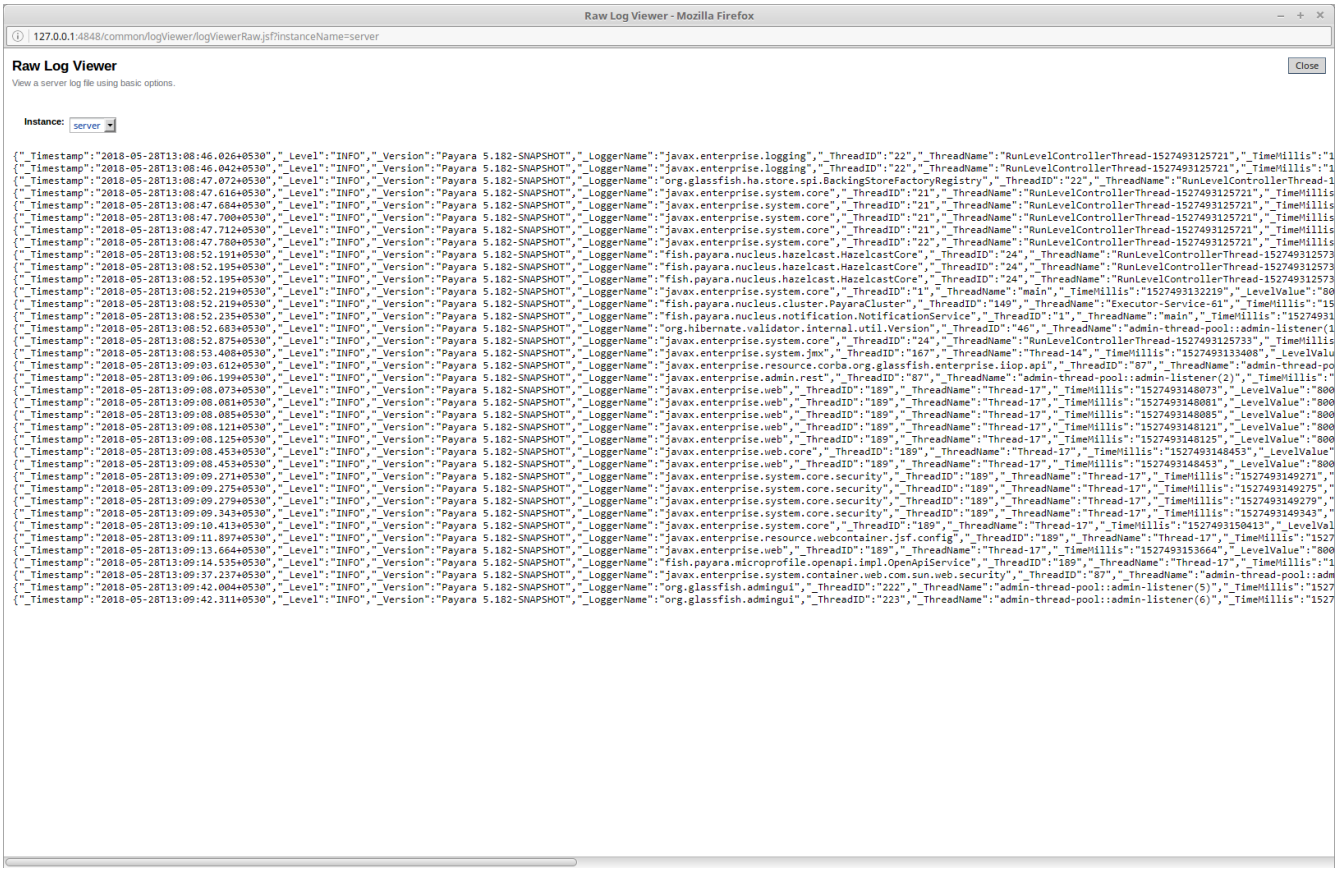
The following command will enable the JSON formatter:

```
asadmin> set-log-attributes
com.sun.enterprise.server.logging.GFFileHandler.formatter='fish.payara.enterprise.serv
er.logging.JSONLogFormatter'
```

Configure Prefixed field names

In some situations, the JSON representation of a log entry may use field names that clash with existing standard field names that logging gathering tools may use them for specific purposes.

To solve this problem, Payara Server can be configured to automatically prefix all field names in the JSON object representation with an underscore (_) character. See the following sample to get an idea of how such a JSON payload would look like:



The following Asadmin command will enable this configuration setting:

```
asadmin set-log-attributes
fish.payara.deprecated.jsonlogformatter.underscoreprefix=true
```

Support for Additional Fields

The JSON Log Formatter also supports the customization of additional fields through the `setParameters` method of the `LogRecord` class. This action is done when logging a new entry at runtime, so it is limited to an application business logic context.

Here's a quick example of how to pass additional fields to the resulting JSON object by using a map with a single entry:

```
public class ApplicationComponent{

    public void businessMethod(){
        var lr = new LogRecord(Level.INFO, "Sample message");
        lr.setParameters(new Object[]{Collections.singletonMap("key", "value")});
        logger.log(lr);
    }
}
```

To Exclude Fields in Log Records

Use the `set-log-attributes` subcommand in remote mode to exclude specific name-value fields

from log records. If the `excludeFields` attribute is not specified, all name-value fields are included.

The following fields can be excluded:

- `tid`
- `userId`
- `ecid`
- `timeMillis`
- `levelVal`
- `version`

Follow these instructions:

1. Ensure that the target server or cluster is running.

   Remote commands require a running server.

2. Exclude fields by using the `set-log-attributes` subcommand, specifying the following attribute and the fields to exclude: `com.sun.enterprise.server.logging.GFFileHandler.excludeFields=fields` where `fields` is a comma-separated list of the name-value fields to exclude from the log file.
3. To apply your change, restart Payara Server.

Example - To Exclude Fields in Log Records

This example excludes the `userId` and `levelVal` name-value fields in log records for standalone instance `ManagedServer1`:

```
asadmin set-log-attributes --target ManagedServer1
com.sun.enterprise.server.logging.GFFileHandler.excludeFields=userId,levelVal

com.sun.enterprise.server.logging.GFFileHandler.excludeFields logging attribute value
set to userId,levelVal.
The logging attributes are saved successfully for ManagedServer1-config.

Command set-log-attributes executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help set-log-attributes` at the command line.

To Set Multiline Mode

Use the `set-log-attributes` command in remote mode to set multiline mode. When multiline mode is enabled (the default), the body of a log message starts on a new line after the message header and is indented.

1. Ensure that the target server or cluster is running.

Remote commands require a running server.

2. Set multiline mode by using the `set-log-attributes` subcommand, specifying the following attribute and its value (`true` or `false`): `com.sun.enterprise.server.logging.GFFileHandler.multiLineMode=value`
3. To apply your change, restart Payara Server.

Example - To Set Multiline Mode

Multiline mode is enabled by default. The following example disables multiline mode in log files for standalone instance `ManagedServer1`:

```
asadmin set-log-attributes --target ManagedServer1

com.sun.enterprise.server.logging.GFFileHandler.multiLineMode=false
com.sun.enterprise.server.logging.GFFileHandler.multiLineMode logging attribute value
set to false.
The logging attributes are saved successfully for ManagedServer1-config.

Command set-log-attributes executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help set-log-attributes` at the command line.

Setting Log File Rotation

As explained in Log Files, Payara Server by default rotates log files when they reach `2 MB` in size.

However, you can change the default rotation settings. For example, you can change the file size at which the server rotates the log file, or you can configure a server to rotate log files based on a time interval.

In addition to changing when rotation occurs, you can also:

- Specify the maximum number of rotated files that can accumulate.

  By default, Payara Server does not limit the number of rotated log files that are retained. However, you can set a limit.

  After the number of log files reaches this limit, subsequent file rotations delete the oldest rotated log file.

- Rotate the log file manually.

  A manual rotation forces the immediate rotation of the target log file.

Changing the default log rotation settings is done using the `set-log-attributes` subcommand, and rotating log files manually is done using the `rotate-log` subcommand.

To Change the Rotation File Size

Use the `set-log-attributes` subcommand in remote mode to change the log rotation file size. The default target of this subcommand is the DAS.

Optionally, you can target a configuration, server, instance, or cluster. The minimum size that can be set is `500 KB`.

1. Ensure that the target server or cluster is running.
2. Change the rotation file size limit by using the `set-log-attributes` subcommand, specifying the following attribute and the desired limit in bytes: `com.sun.enterprise.server.logging.GFFileHandler.rotationLimitInBytes=bytes`
3. To apply your change, restart Payara Server.

Example - To Change the Rotation File Size

The following example sets the log file rotation size to 1 MB for the standalone instance `ManagedServer1`:

```
asadmin set-log-attributes --target ManagedServer1
com.sun.enterprise.server.logging.GFFileHandler.rotationLimitInBytes=1000000

com.sun.enterprise.server.logging.GFFileHandler.rotationLimitInBytes
logging attribute set with value 1000000.
These logging attributes are set for ManagedServer1.
ManagedServer1 :
com.sun.enterprise.server.logging.GFFileHandler.rotationLimitInBytes
logging attribute set with value 1000000.
These logging attributes are set for ManagedServer1.

Command set-log-attributes executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help set-log-attributes` at the command line.

To Change the File Rotation Interval

Use the `set-log-attributes` subcommand in remote mode to change the log file rotation time limit interval. The default target of this subcommand is the DAS. Optionally, you can target a configuration, server, instance, or cluster. The default value is `0`.

1. Ensure that the target server or cluster is running.
2. Change the rotation time limit by using the `set-log-attributes` subcommand, specifying the following attribute and the desired limit in minutes: `com.sun.enterprise.server.logging.GFFileHandler.rotationTimelimitInMinutes=minutes`
3. To apply your change, restart Payara Server.

Example - To Change the File Rotation Interval

The following example sets the log file rotation time limit for the cluster `Cluster1`, which has the instances `ClusterServer1` and `ClusterServer2`.

```
asadmin set-log-attributes --target Cluster1
com.sun.enterprise.server.logging.GFFileHandler.rotationTimelimitInMinutes=10

com.sun.enterprise.server.logging.GFFileHandler.rotationTimelimitInMinutes
logging attribute set with value 10.
These logging attributes are set for Cluster1.
ClusterServer1 :
com.sun.enterprise.server.logging.GFFileHandler.rotationTimelimitInMinutes
logging attribute set with value 10.
These logging attributes are set for Cluster1.

ClusterServer2 :
com.sun.enterprise.server.logging.GFFileHandler.rotationTimelimitInMinutes
logging attribute set with value 10.
These logging attributes are set for Cluster1.

Command set-log-attributes executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help set-log-attributes` at the command line.

To Change the Limit Number of Retained Files

Use the `set-log-attributes` subcommand in remote mode to change the limit on the number of log files that the server creates to store old log messages. The default target of this subcommand is the DAS.Optionally, you can target a configuration, server, instance, or cluster. The default limit value is `0`, which results in no limit placed on the number of rotated log files that are retained.

1. Ensure that the target server or cluster is running.
2. Change the limit number of retained log files by using the `set-log-attributes` subcommand, specifying the following attribute and the desired file limit number: `com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles=minutes`

The behavior of the `com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles` attribute is as follows:

- If the property is not set, Payara Server keeps a maximum of 10 rotated log files.
- If the property is set to an invalid number or null, Payara Server keeps a maximum of 10 rotated log files.
- If the property is set to 0, Payara Server retains all rotated log files (that is, sets no maximum).

    1. To apply your change, restart Payara Server.

Example - To Change the Limit Number of Retained Files

The following example sets the log limit number of retained log files for the DAS to `10`.

```
asadmin set-log-attributes

com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles=10
com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles
logging attribute set with value 10.
These logging attributes are set for server.
Command set-log-attributes executed successfully.
```

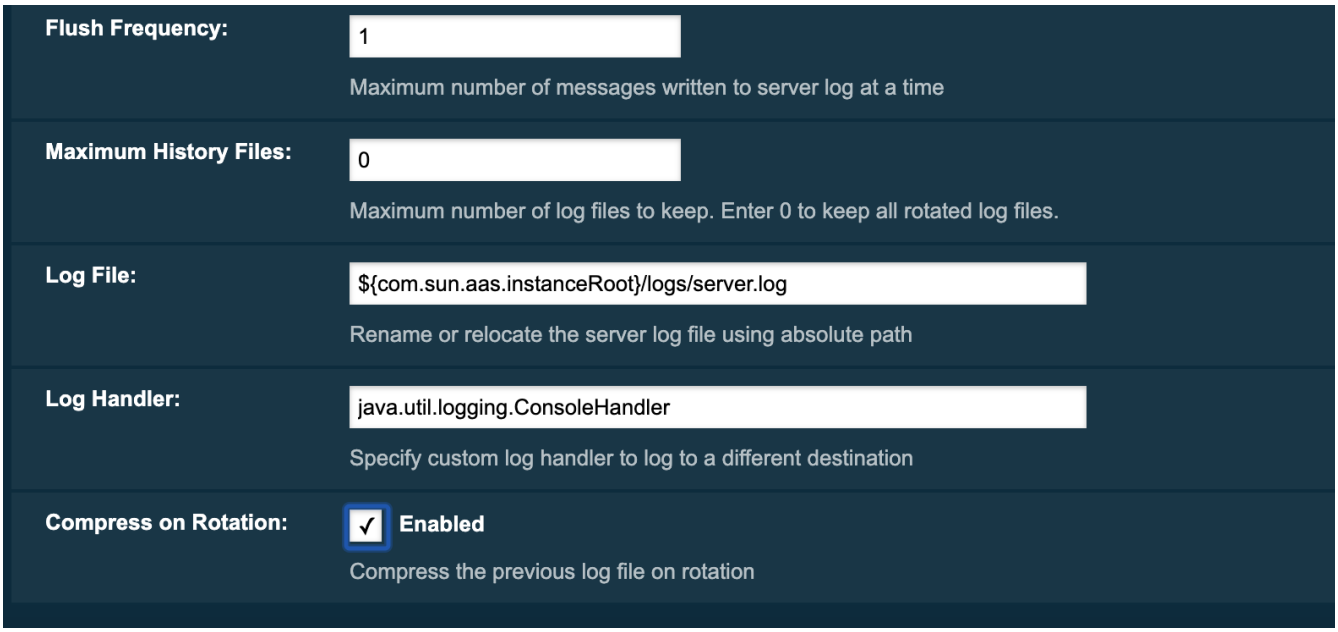
You can view the full syntax and options of the subcommand by typing `asadmin help set-log-attributes` at the command line.

Log File Compression on Rotation

Payara Server can be configured to automatically compress rotated log files in an automatic manner to save disk space.

Using the Web Admin Console

When log rotation is enabled, you can turn on automatic compression in the `Logger Settings` section of the Admin Console, by ticking the `Compress on Rotation` checkbox:



Using the Asadmin CLI

Use the following command to enable or disabled the automatic compression of log files on rotation:

```
asadmin> set-log-attributes
com.sun.enterprise.server.logging.GFFileHandler.compressOnRotation='true'
```

To Rotate Log Files Manually

You can rotate log files manually by using the `rotate-log` subcommand in remote mode. The default target of this subcommand is the DAS. Optionally, you can target a configuration, server, instance, or cluster. When you use this subcommand, the target log file is immediately moved to a new time-stamped file and a new log file is created.

Because log rotation is a dynamic operation, you do not need to restart Payara Server for changes to take effect.

1. Ensure that the target server or cluster is running.
2. Rotate log files by using the `rotate-log` subcommand.

Example - To Rotate Log Files Manually

The following example rotates the `server.log` file for `ManagedServer2` to `server.log_`yyyy-mm-dd`T`hh-mm-ss`, where `yyyy-mm-dd`T`hh-mm-ss` represents the time when the file is rotated, and creates a new `server.log` file in the default location.

```
asadmin> rotate-log --target ManagedServer2
Command rotate-log executed successfully.
```

You can view the full syntax and options of the subcommand by typing `asadmin help rotate-log` at the command line.

Adding a Custom Logging Handler

By default, Payara Server log records are captured in a server log file using the format described in Log Records.

However, you may find that you want to log messages to a different location, such as a database or a remote server, or log messages from specific loggers to your own file. This can be done by implementing a custom log handler.

This section explains how to add a custom log handler to the Payara Server logging service.

To Add a Custom Log Handler

A comma-separated list of log handlers is installed during startup of the Java Virtual Machine (JVM) host. The default log handler that is provided in the `logging.properties` file, `ConsoleHandler`, is configured as follows:

```
handlers=java.util.logging.ConsoleHandler
```

In Payara Server, the best approach to developing a custom handler is to define a Hundred-Kilobyte Kernel (HK2) component that implements the handler contract. Payara Server registers this handler automatically because it is an HK2 component. There is no task required of the administrator.

The custom handler class should be packaged in an OSGi module and the JAR file placed in the `as-install/modules` directory.

To configure a custom handler that is not developed as an HK2 component, add the new handler to the `logging.properties` file after the developer has put the custom handler JAR file into the `domain-dir/lib/ext` directory.

Before You Begin

If you set a handler by setting the handlers attribute in the logging properties file, the class that extends `java.util.logging.Handler` must be in the server classpath.

1. Ensure that the target server or cluster is running. Remote subcommands require a running server.
2. Use the `set-log-attributes` subcommand to add the handler to the `handlers` attribute.

   The default target of this subcommand is the DAS. Optionally you can target a configuration, server, instance, or cluster.
3. To apply your changes, restart Payara Server.

Example - To Add a Custom Log Handler

This example adds the custom logger `com.example.logging.MyHandler` to the logging properties file of the DAS.

```
asadmin set-log-attributes
handlers=java.util.logging.ConsoleHandler,com.example.logging.MyHandler

handlers logging attribute set with value
java.util.logging.ConsoleHandler,com.example.logging.MyHandler.
These logging attributes are set for server.

Command set-log-attributes executed successfully.
```

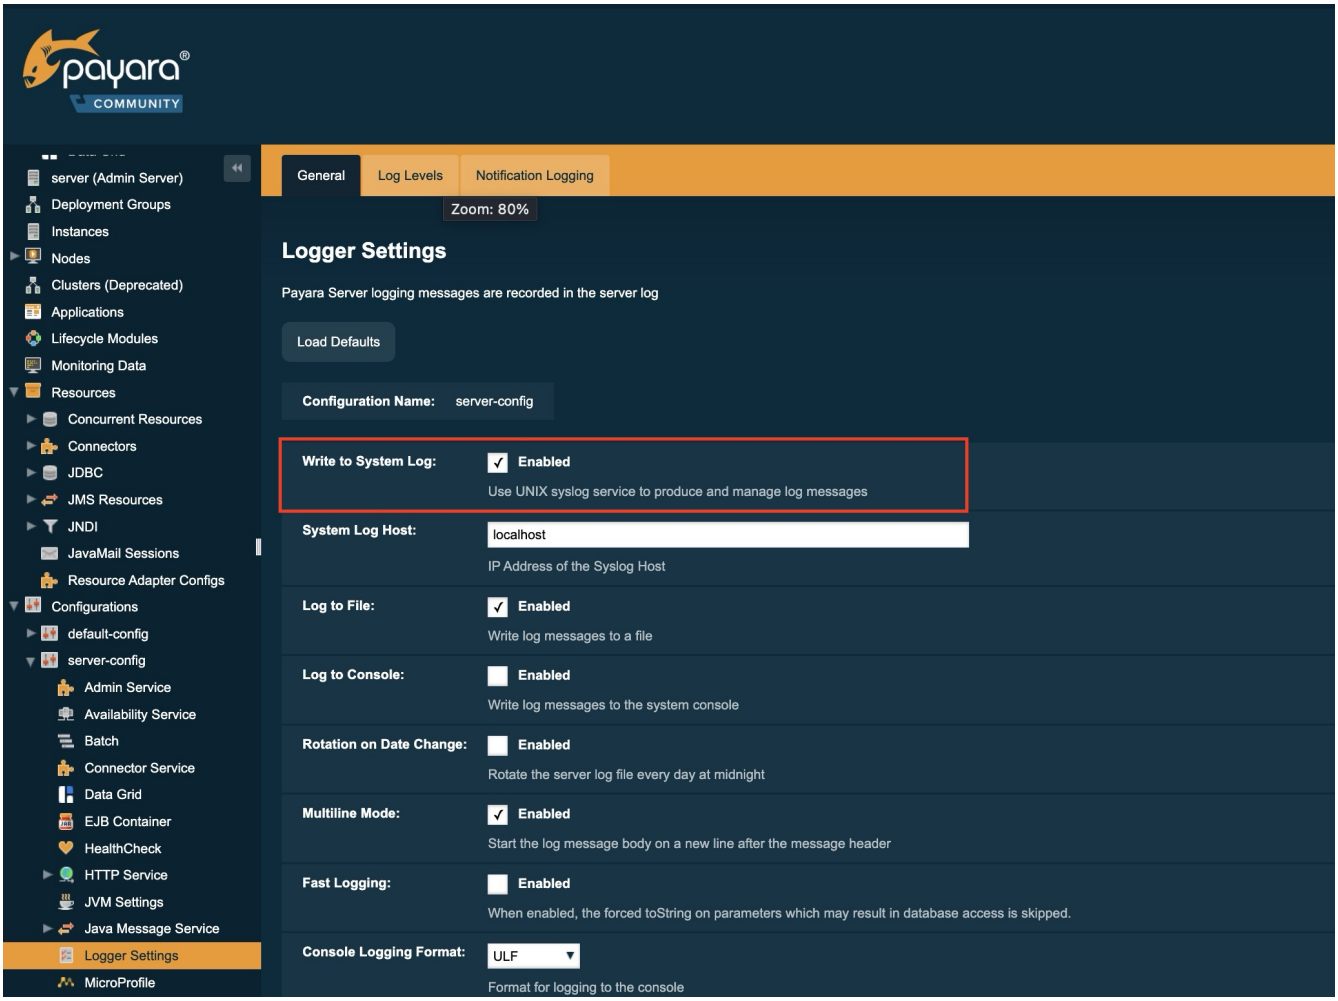
You can view the full syntax and options of the subcommand by typing `asadmin help set-log-attributes` at the command line.

Write to System Log

The **Write to System Log** option allows you to enable and disable the action of logging to the system log. Disabling this option should help to minimize disk usage.

Enable Write to System Log using the Admin Console

To configure the `Write to System Log` option using the Admin Console:



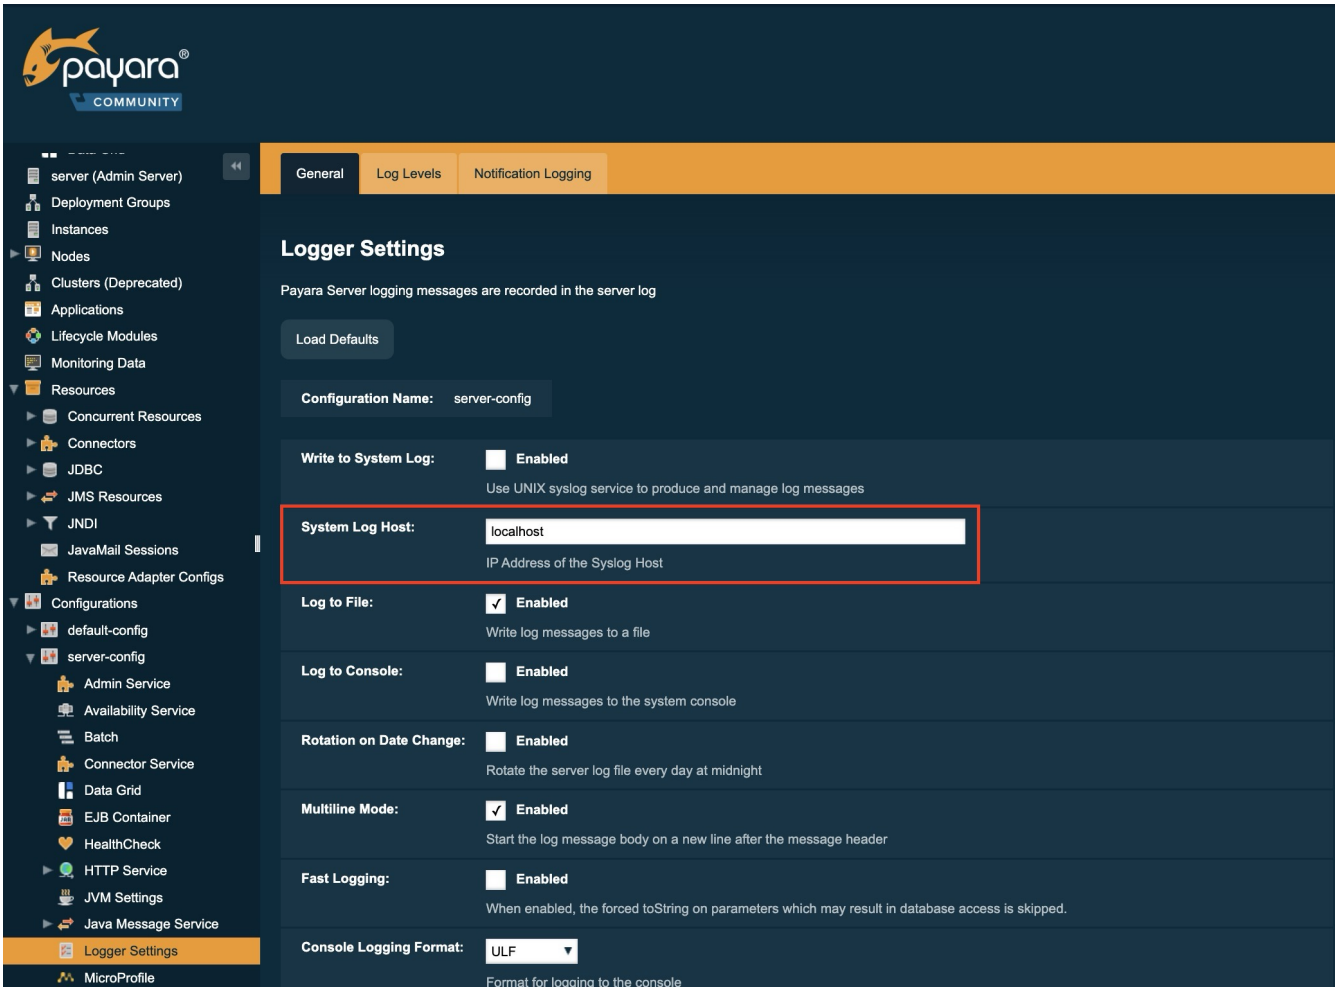
Enable Write to System Log using the Asadmin CLI

Use the following command to enable or disable the Write to System Log feature:

```
asadmin set-log-attributes
com.sun.enterprise.server.logging.SyslogHandler.useSystemLogging=true
```

Set the System Log Host using the Admin Console

To configure the `System Log Host` option using the Admin Console:



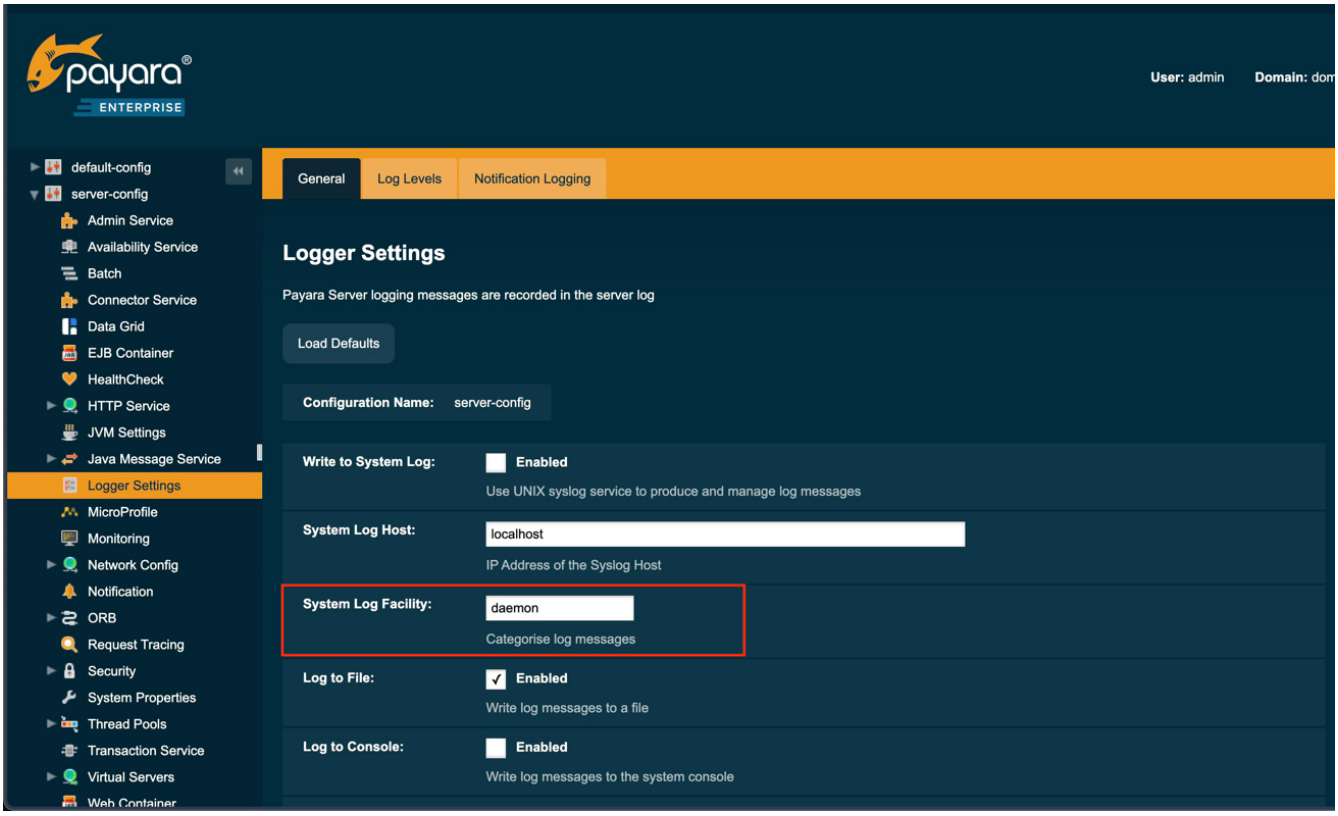
Set the System Log Host using the Asadmin CLI

Use the following command to set the system log host:

```
asadmin set-log-attributes
com.sun.enterprise.server.logging.SyslogHandler.host=localhost
```

Set the System Log Facility using the Admin Console

To configure the `System Log Facility` option using the Admin Console:



Set the System Log Facility using the Asadmin CLI

Use the following command to set the system log facility:

```
asadmin set-log-attributes
com.sun.enterprise.server.logging.SyslogHandler.facility=daemon
```

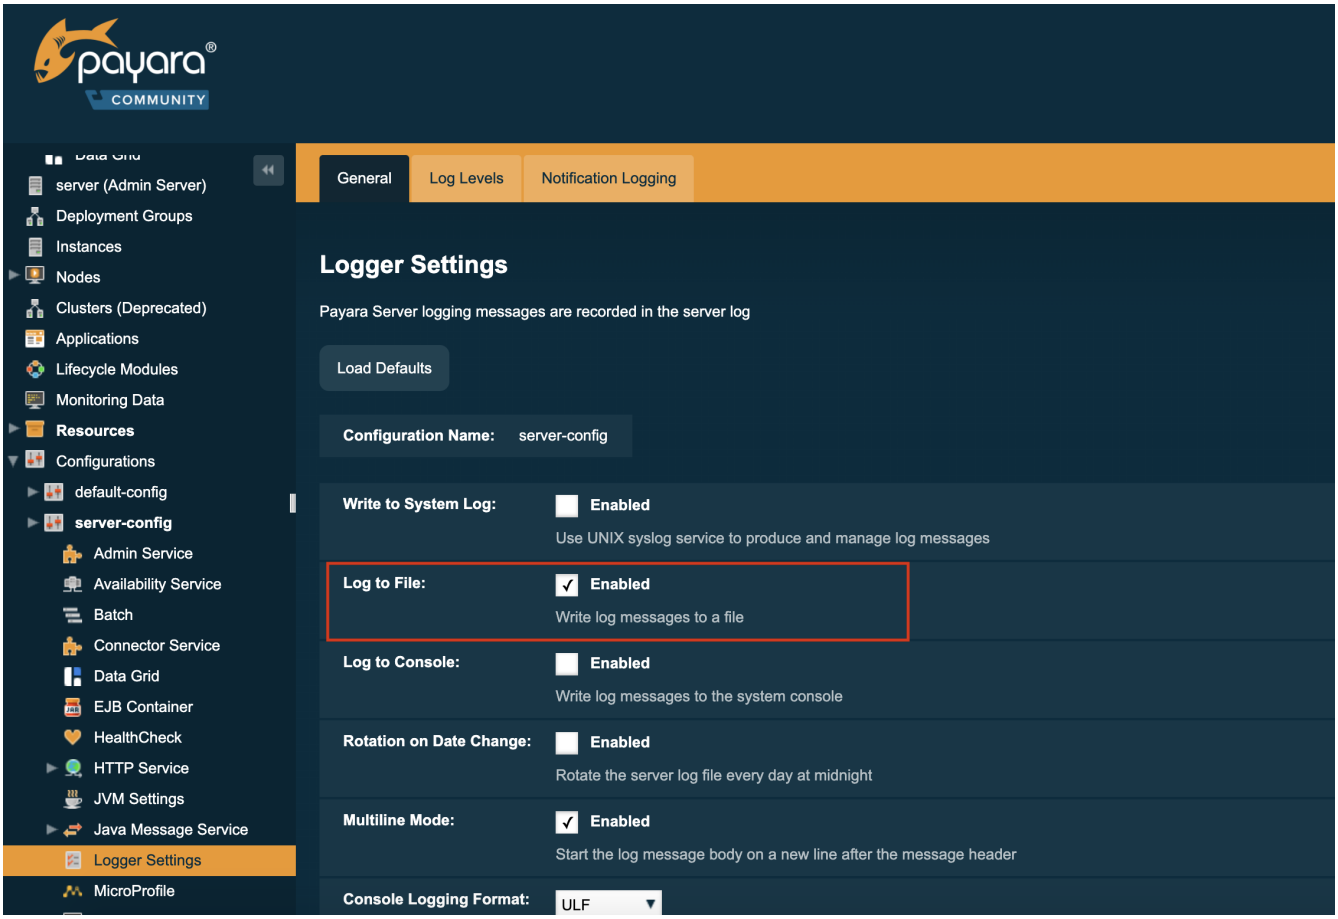
Log to File

The **Log to File** option allow you to enable and disable the action of logging to a file. When disabled this should help to minimize disk usage.

This option will be more accommodating if Payara Server is running in cloud environment where disk space is scarce.

Enable Log to File using the Admin Console

To configure the `Log to File` option using theAdmin Console:



Enable Log to File using the Asadmin CLI

Use the following command to enable or disable the logging to a file feature:

```
asadmin set-log-attributes
com.sun.enterprise.server.logging.GFFileHandler.logtoFile=false
```

Log To Console

The `Log to Console` option controls if the server writes the logging entries directly to the console. The property only has an effect when the server or instance is started in verbose mode.

To enable the log to console option you simply have to start the domain or instance using the `verbose` option:

```
asadmin start-domain --verbose
```

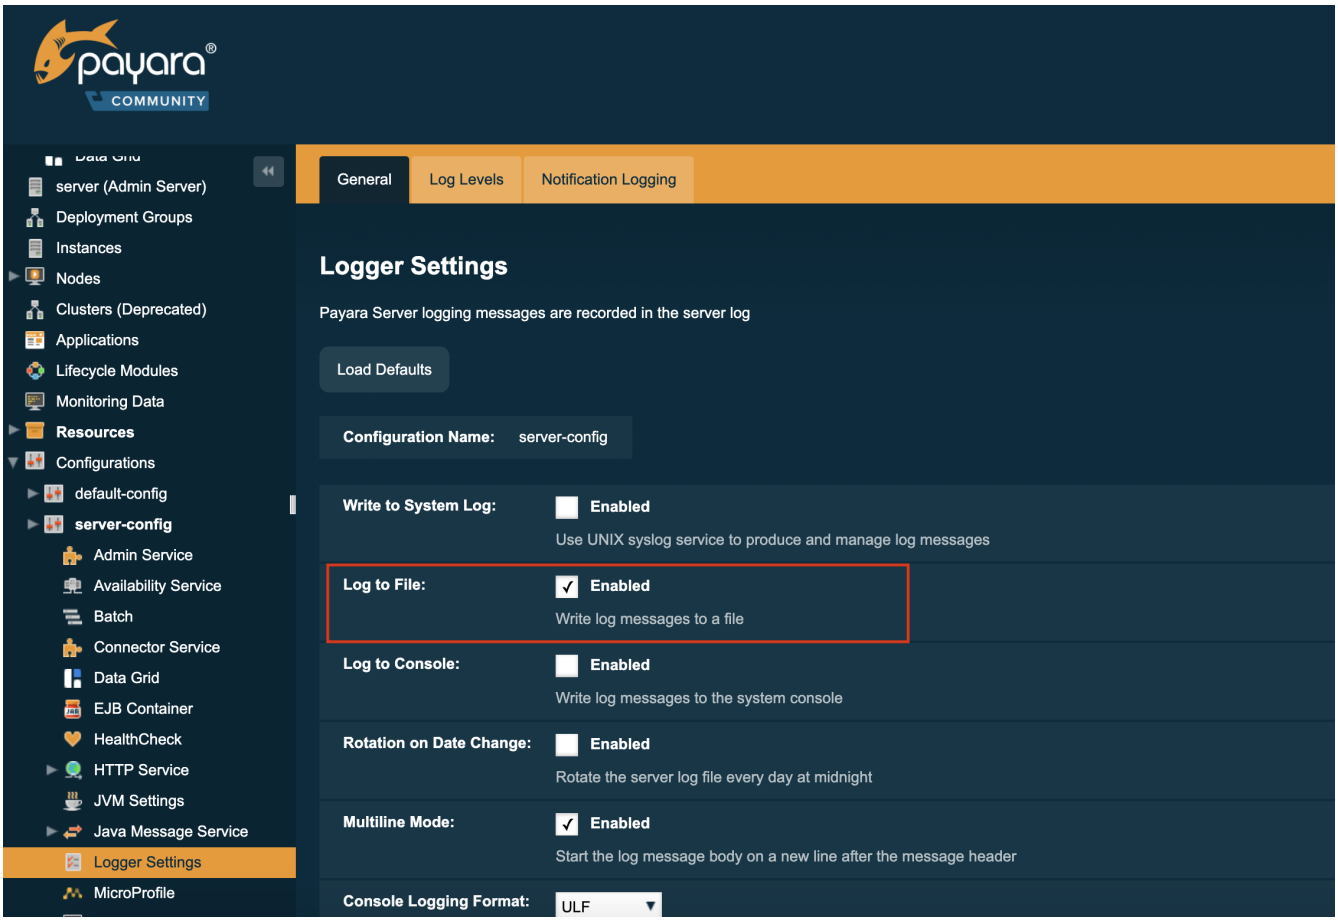
When the server or domain is not started in verbose mode, the `java.util.ConsoleHandler` will not be active for logging, although it is defined as handler in the `logging.properties` file because there is no console attached with the corresponding server process.

When in verbose mode, the **Log to Console** option will also be active, regardless of the initial value set in the `logging.properties` file as otherwise, no log output would be visible on the console.

Once the server is run in verbose mode, you can use either the Admin Console or the Asadmin CLI to modify this setting.

Configure Logging To Console using the Admin Console

To configure the `Log to Console` option using the Admin Console:



Configure Logging To Console using the Asadmin CLI

Use the following command to enable or disable the log to console feature:

```
asadmin> set-log-attributes
com.sun.enterprise.server.logging.GFFileHandler.logtoConsole=false
```

Fast Logging

Whenever logging occurs on an application, if the `LogRecord` in question contains set parameters, they will undergo a forced transformation by having a `toString()` method call.

In most cases this is the desirable outcome, but will not provide the best performance. You can enable the **Fast Logging** setting to skip this forced parameter transformation at runtime.

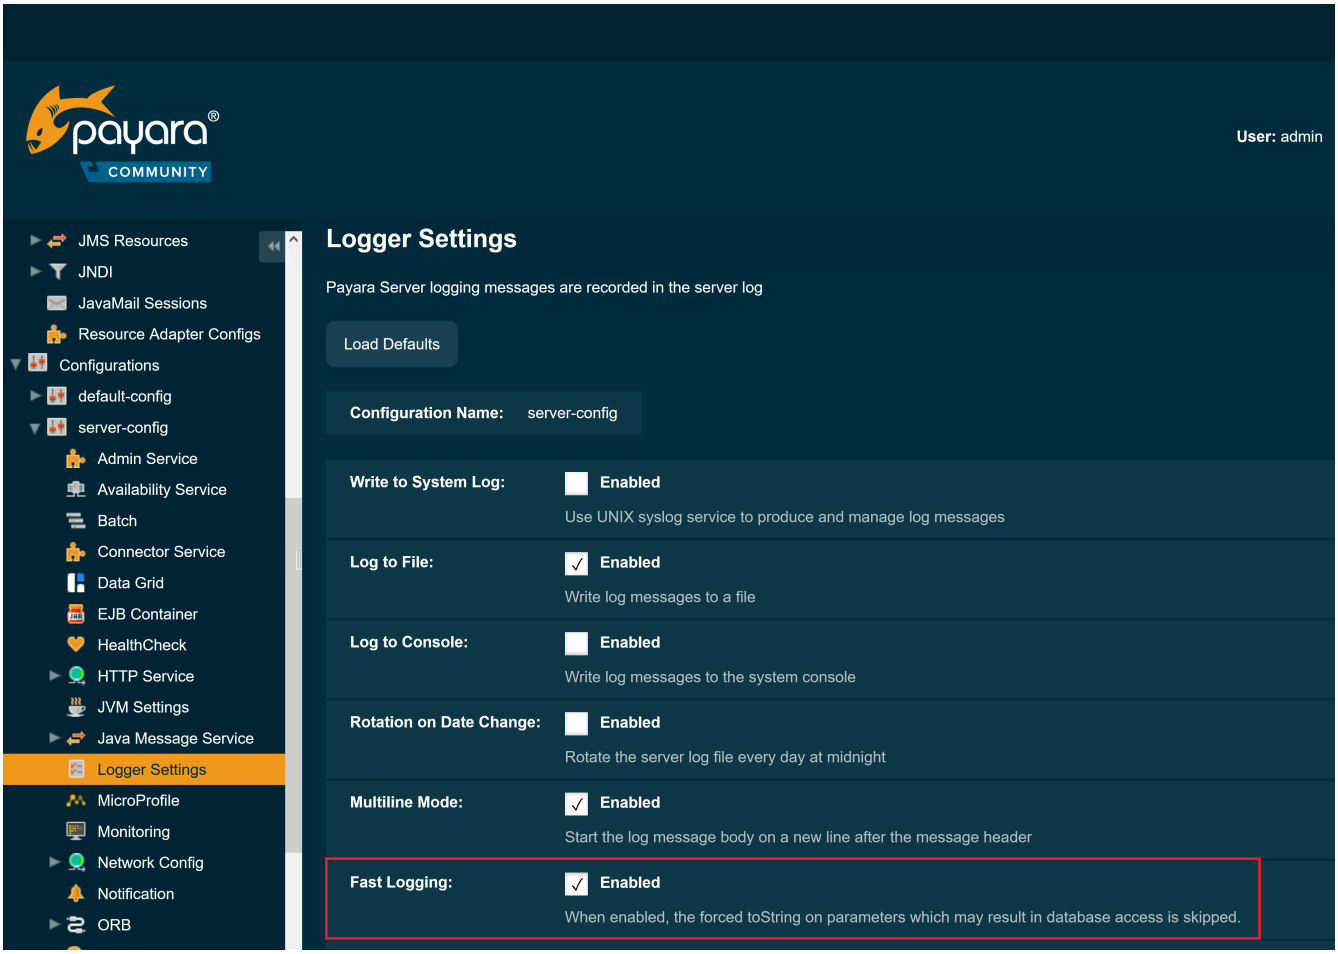
A common use case of this feature would be to prevent database access done by JPA entities, as it is a common occurrence for entity data to be logged out for auditing purposes.

Enabling this setting can cause log entries that contain mutable parameters to be

> out of sync when they are resolved.
> Exert caution when using fast logging, as it may cause stale information to be printed out to the log.

Using the Admin Console

To configure the `Fast Logging` option, set it in the Logger settings.



Using Asadmin CLI

Use the following command to enable or disable fast logging:

```
asadmin set-log-attributes
com.sun.enterprise.server.logging.GFFileHandler.fastLogging=true
```

Environment Variable Support

The `logging.properties` configuration file supports environment variable substitution like in this example:

```
.level=${ENV=logLevel}
```

Whenever the server starts up or the logging properties are updated, the value for the `.level` property will be taken from the environment variable `logLevel`.

Viewing Log Records

The recommended means for general viewing of logging information is to use the Log Viewer in the Administration Console. The Log Viewer simplifies reading, searching, and filtering log file contents. For instructions, see the Administration Console online help.

Payara Server also allows you to collect log files into a ZIP archive, which provides the means to obtain and view log files for an instance or cluster even when it is not currently running.

The following section explains how to collect all available log files for an instance or cluster and compile them into a single ZIP archive, which is done by using the `collect-log-files` subcommand.

To Collect Log Files into a ZIP Archive

Use the `collect-log-files` subcommand in remote mode to collect log files into a ZIP archive. The default target of this subcommand is the DAS. Optionally you can target a configuration, server, instance, or cluster.

1. Ensure that the target server or cluster is running.

   Remote subcommands require a running server.

2. Use the `collect-log-files` subcommand to create the ZIP archive.

   The default location in which the ZIP archive is created is the `domain-dir/collected-logs` directory. The `collect-log-files` subcommand allows you to specify a non-default directory in which the ZIP archive is to be created by using the `--retrieve` option set to `true`, followed by the directory name.

   The name of the ZIP file contains the timestamp, as follows: `log_`yyyy-mm-dd_hh-min-sec`.zip`

Example - To Collect Log Files into a .zip Archive

This example shows collecting the log files for the cluster `MyCluster` and compiling them into a ZIP archive in the `/space/output` directory.

```
asadmin collect-log-files --target MyCluster --retrieve true /space/output

Log files are downloaded for ClusterServer1.
Log files are downloaded for ClusterServer2.
Created Zip file under /space/output/log_2011-02-10_13-35-25.zip.

Command collect-log-files executed successfully.
```

When the ZIP file created by the preceding command is uncompressed, the following directory structure is created:

```
as-install-parent/
       glassfish/
            domains/
```

```
                domain-dir/
                       collected_logs/
                                    logs/
                                       ClusterServer1/
                                                    server.log
                                       ClusterServer2/
                                                    server.log
```

You can view the full syntax and options of the subcommand by typing `asadmin help collect-log-files` at the command line.

Listing Loggers

You can list and view information about all public loggers in your distribution of Payara Server.

To List Loggers

Use the `list-loggers` subcommand in remote mode to list the logger name, subsystem, and description of loggers in your distribution of Payara Server. Internal loggers are not listed.

1. Ensure that the target server or cluster is running.

   Remote commands require a running server.

2. List loggers by using the `list-loggers` subcommand.

Example - To List Loggers

This example lists the logger name, subsystem, and description for each logger. Some lines of output are omitted from this example for readability.

```
asadmin list-loggers

Logger Name                              Subsystem         Logger Description
...
jakarta.enterprise.monitoring              Monitoring        Monitoring Logger
jakarta.enterprise.system.core.ee          AS-CORE           Jakarta EE Core Kernel
jakarta.enterprise.system.jmx              JMX               JMX System Logger
jakarta.enterprise.system.tools.admin      ADMIN             Administration Services
...
Command list-loggers executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-loggers` at the command line.

Access Logging Max File Size

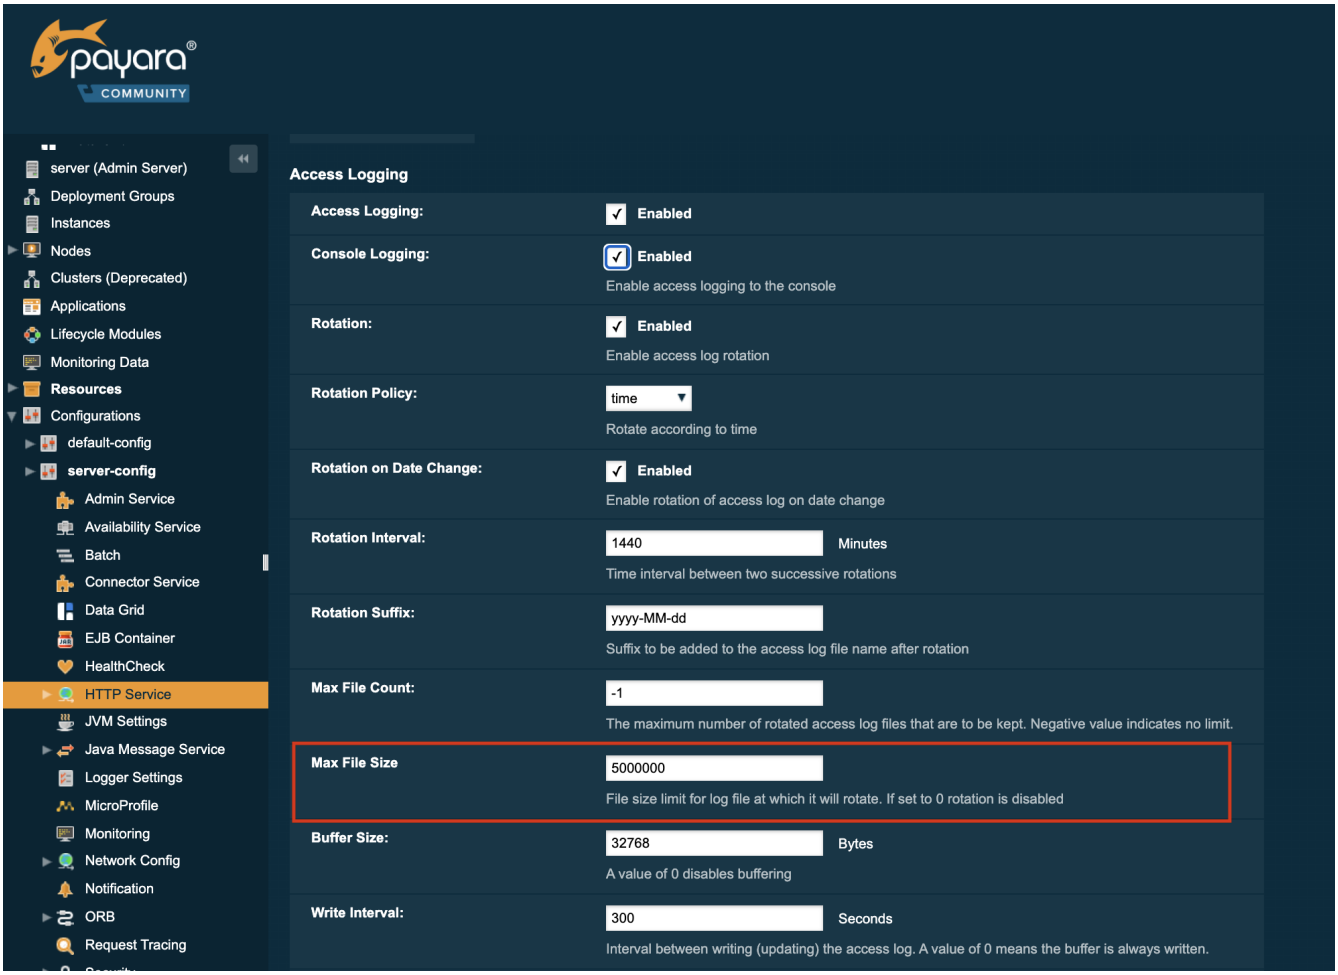
Payara Server provides different ways to rotate HTTP access log files. This section will detail the use of the max size of the log file to trigger a rotation.

The **Max File Size** option provides a way to change the file size at which the server rotates the access log file. This option accepts an integer value specifying the maximum size of the log file, after which a file rotation will occur.

If the value for this option is set to `0`, HTTP access log rotation will be disabled.

Using the Admin Console

To configure the **Max File Size** option using the Admin Console:



Using the Asadmin CLI

Use the following command to set maximum file size option:

```
asadmin> set configs.config.server-config.http-service.access-log.maximum-file-
size=5000000
```

For more information on how to configure HTTP Access logging, see Administering HTTP Configurations.

Notification Service Logging

The Notification Service captures information about events which come from other services, such as the JMX Monitoring Service, the HealthCheck service or the Request Tracing service and captures

this information so that all configured notifiers can redirect these events. The Log Notifier, turned on by default, will print these notifications events in the server's log.

It is possible to configure the Log Notifier to store its output in a separate log file.

If this setting is enabled, the default log file will be found at `domain-dir/logs/notification.log`

The Notification Logging Service uses its own collection of logging properties which are separate from the standard logging facilities of Payara Server. However, they are stored in the same configuration file.

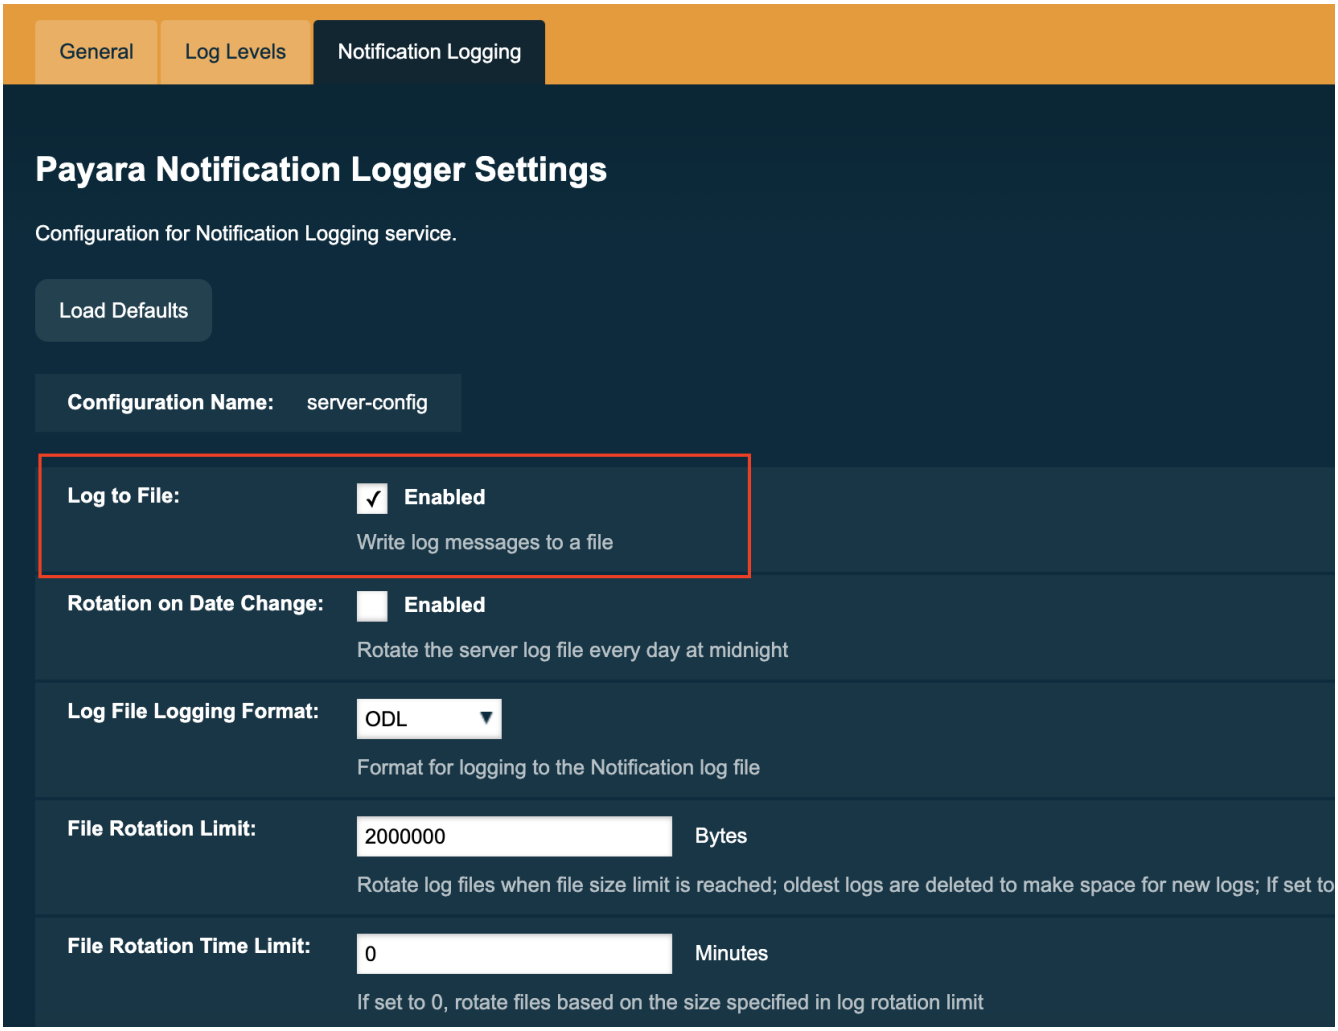
Configuring the Notification Logging Service

Enabling or Disabling Logging to a File

The **Log to File** option will provide a way to enable and disable logging to a file of Payara Server Notifications. When disabled this should help to minimize disk usage. This option will be more accommodating if Payara Server is running in cloud environment where disk space is scarce.

Using the Admin Console

To configure the **Log to File** option using Admin Console:



Using the Asadmin CLI

You use the following Asadmin command to enable/disable the logging to a file setting:

```
asadmin set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.logtoFile=false
```

Configuring Log File Rotation

By default, The notification log rotation is set to rotate when the log file reaches 2 Megabytes(MB). Nonetheless, there are number of ways log rotation can be configured.

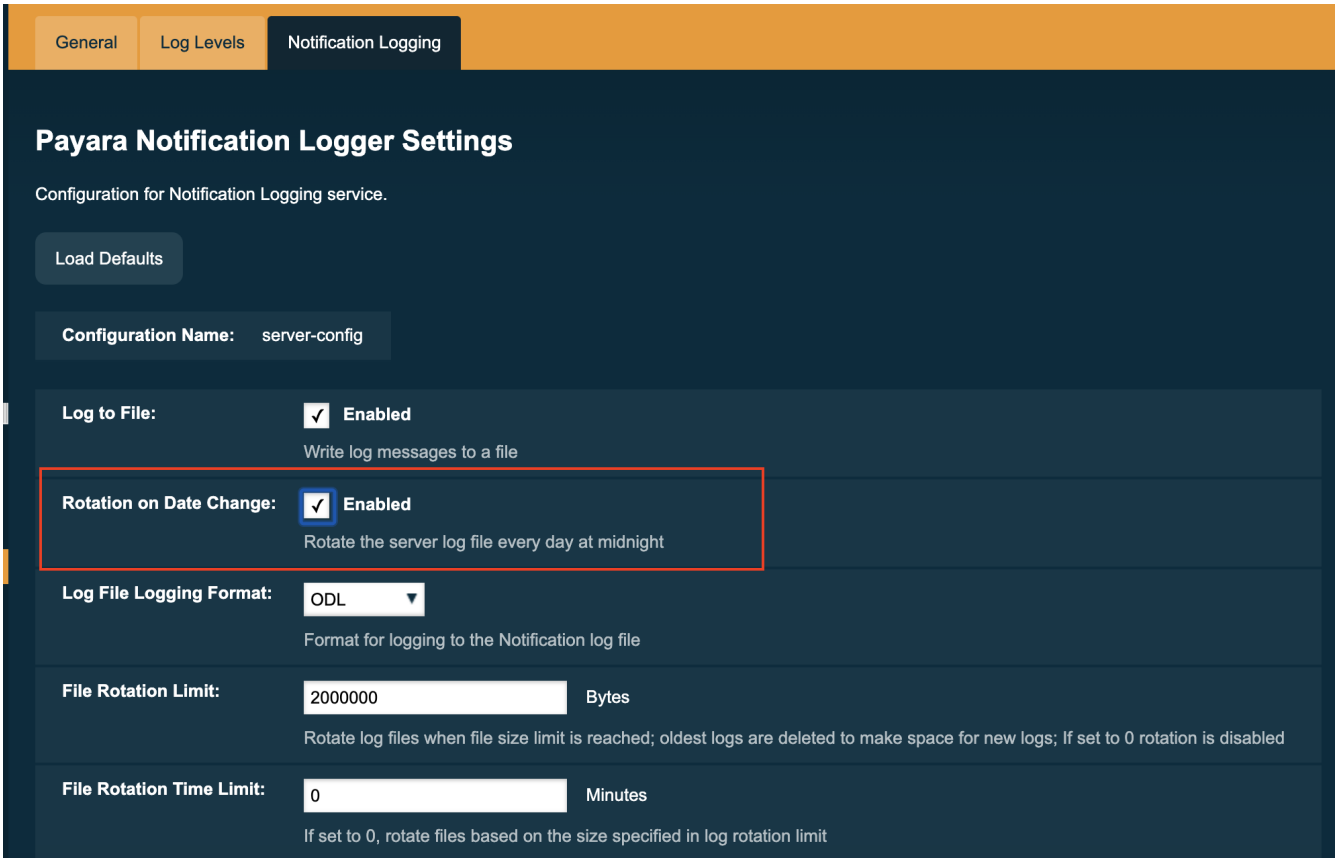
Size of file at which the log rotates can be changed, it can be set to rotate at date change, rotate when time limit is reached and, finally based on maximum number of history files.

Rotation on Date Change

The **Rotation On Date Change** option provides a way to set the log rotation when the system date changes (at midnight, by default).

Using the Admin Console

To configure the **Rotation on Date Change** option using the Admin Console:



Using the Asadmin CLI

Use the following Asadmin command to enable or disabled the log rotation on date change setting:

```
asadmin set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.rotationOnDateChan
ge=false
```

Rotation on File Size

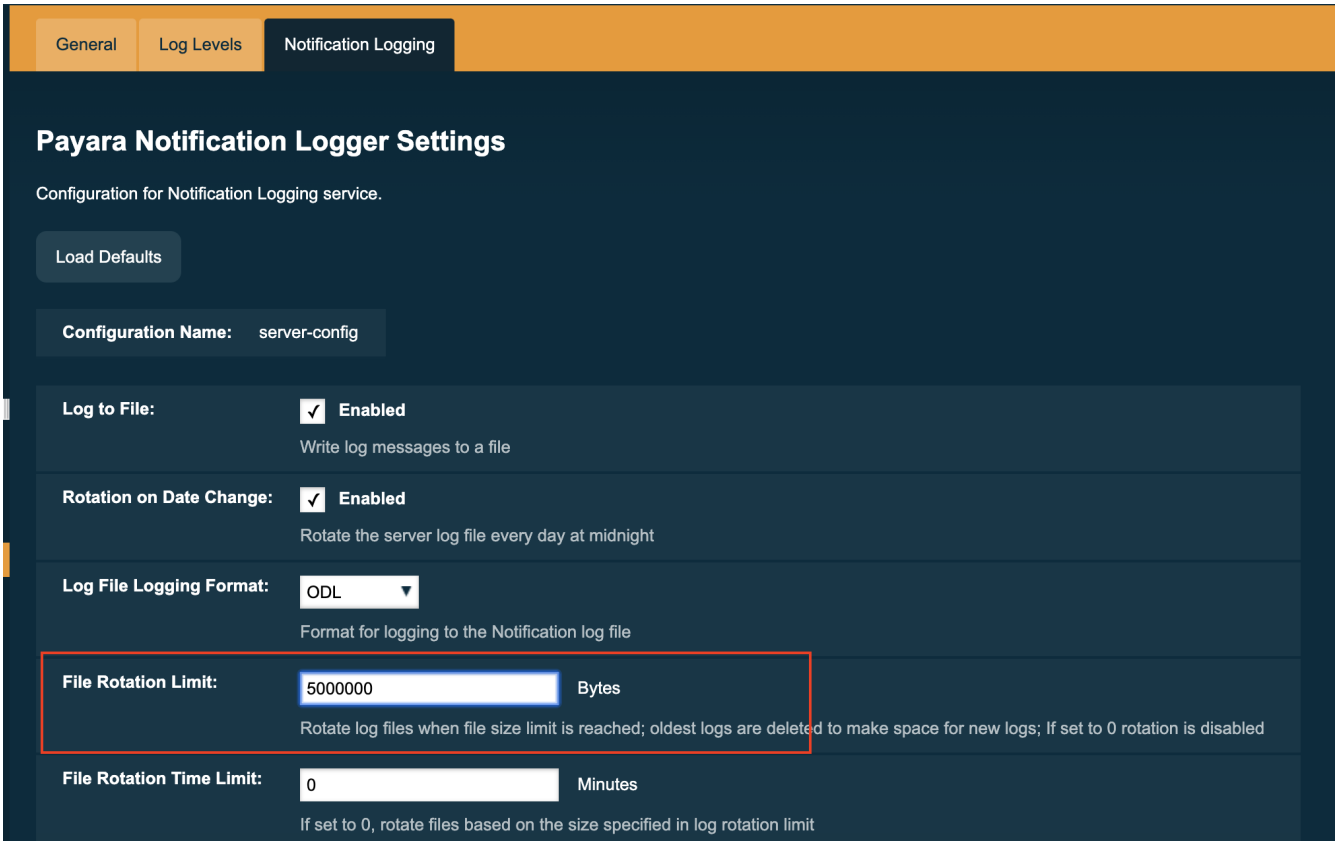
The **File Rotation Limit** option provides a way to change the file size at which the server triggers the log file rotation. This option accepts an integer value specifying the maximum size of the log file, after which a file rotation will occur.

The minimum size it can be set to is `500KB` (`500.000` bytes).

If the value for this option is set to `0`, log rotation will be disabled.

Using the Admin Console

To configure the **File Rotation Limit** option using the Admin Console:



Using the Asadmin CLI

Use the following Asadmin command to set the file rotation limit:

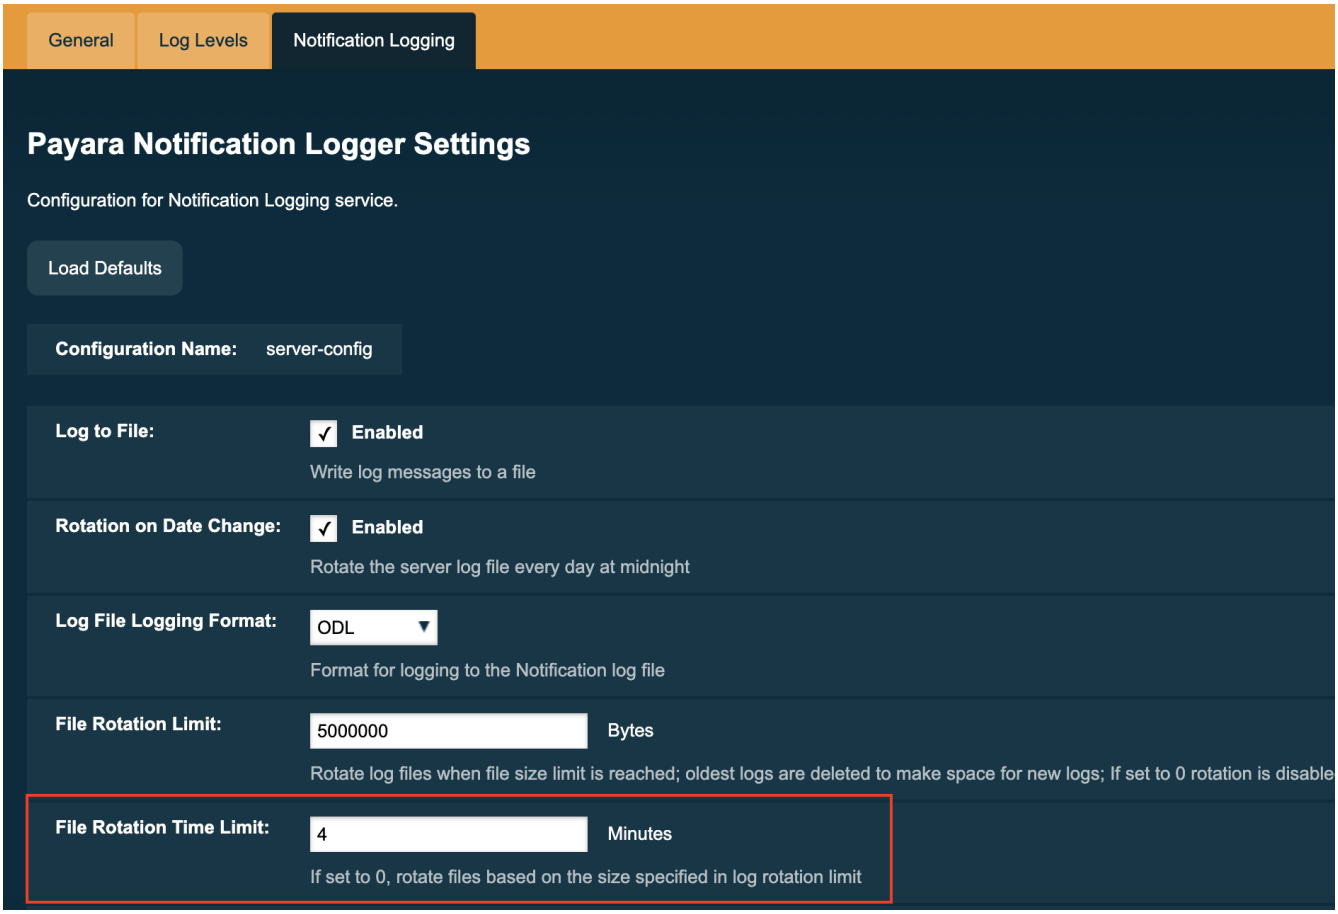
```
asadmin set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.rotationLimitInByt
es=500000
```

Rotation on Time Limit

The **File Rotation Time Limit** option provides a way to trigger the notification log file rotation based on a fixed time limit. The value of this setting is an integer that defines the time limit in minutes until the log rotation gets triggered.

Using the Admin Console*

To configure the **File Rotation Time Limit** option using the Admin Console:



Using the Asadmin CLI

Use the following command to set the fixed time limit used to trigger the log rotation:

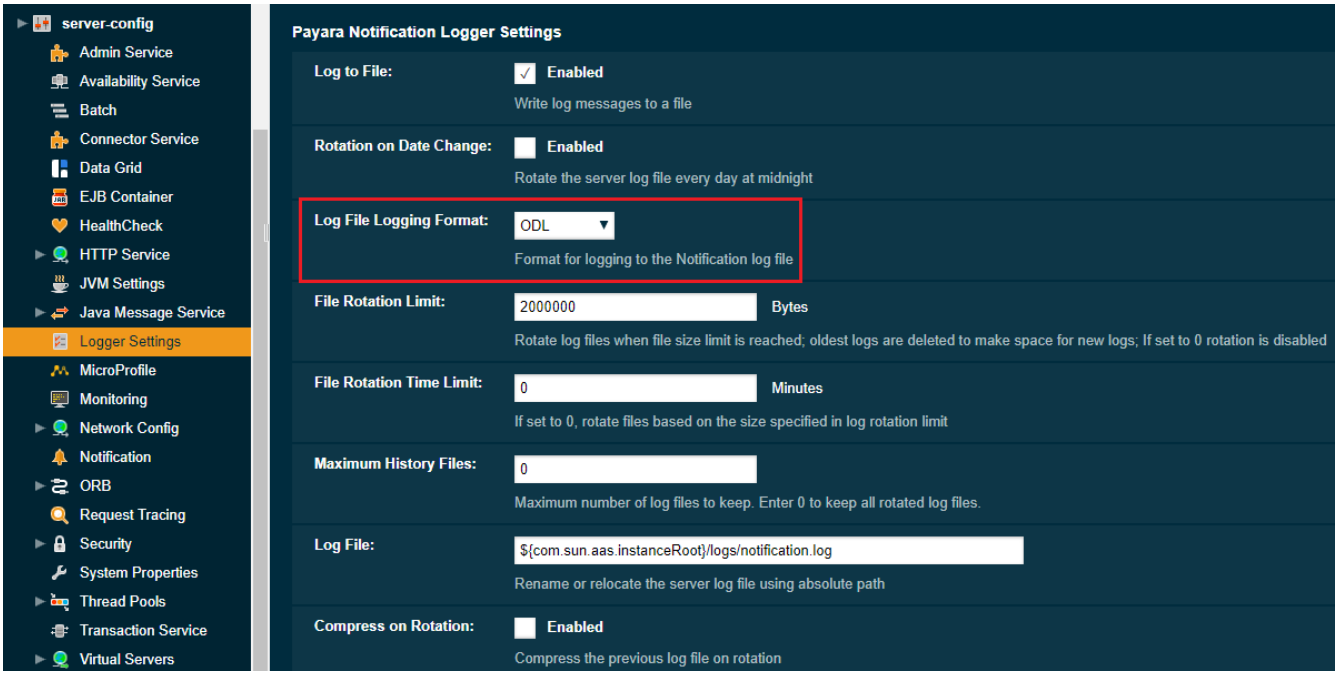
```
asadmin set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.rotationTimelimitI
nMinutes=4
```

Change the Logging Format

The **Log File Logging Format** option can be used to change the notification log entries' format. There are 3 logging formats available: `ULF`, `ODL` and `JSON`, each one represented by a specific formatter class present in the Payara Platform API.

Using the Admin Console

To configure the **Log File Logging Format** option using the Admin Console:



Using the Asadmin CLI

Use the following command to change the logging format:

```
asadmin set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.formatter=fish.pay
ara.enterprise.server.logging.JSONLogFormatter
```

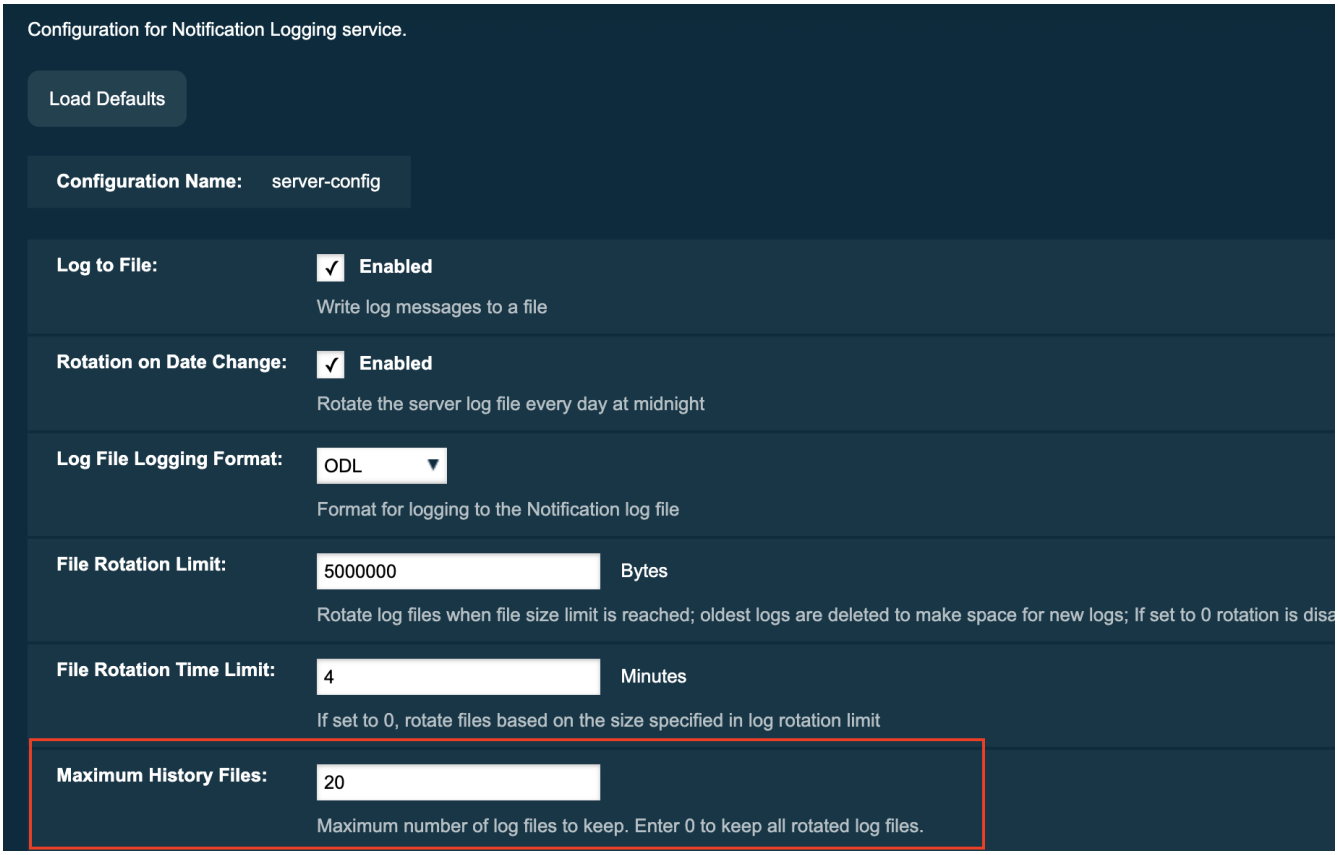
Set the Maximum Number of Historic Files

The `Maximum History Files` option provides a way to set the limit on the number of notification log files that can be created by Payara Server.

Once the number of files reaches the set limit, the oldest rotated log file is deleted. If the value for this option is set `0`, all the rotated log files are preserved.

Using the Admin Console

To configure the `Maximum History File` option using the Admin Console:



Using the Asadmin CLI

Use the following command to set the limit on the number of log files that can be created by Payara Server:

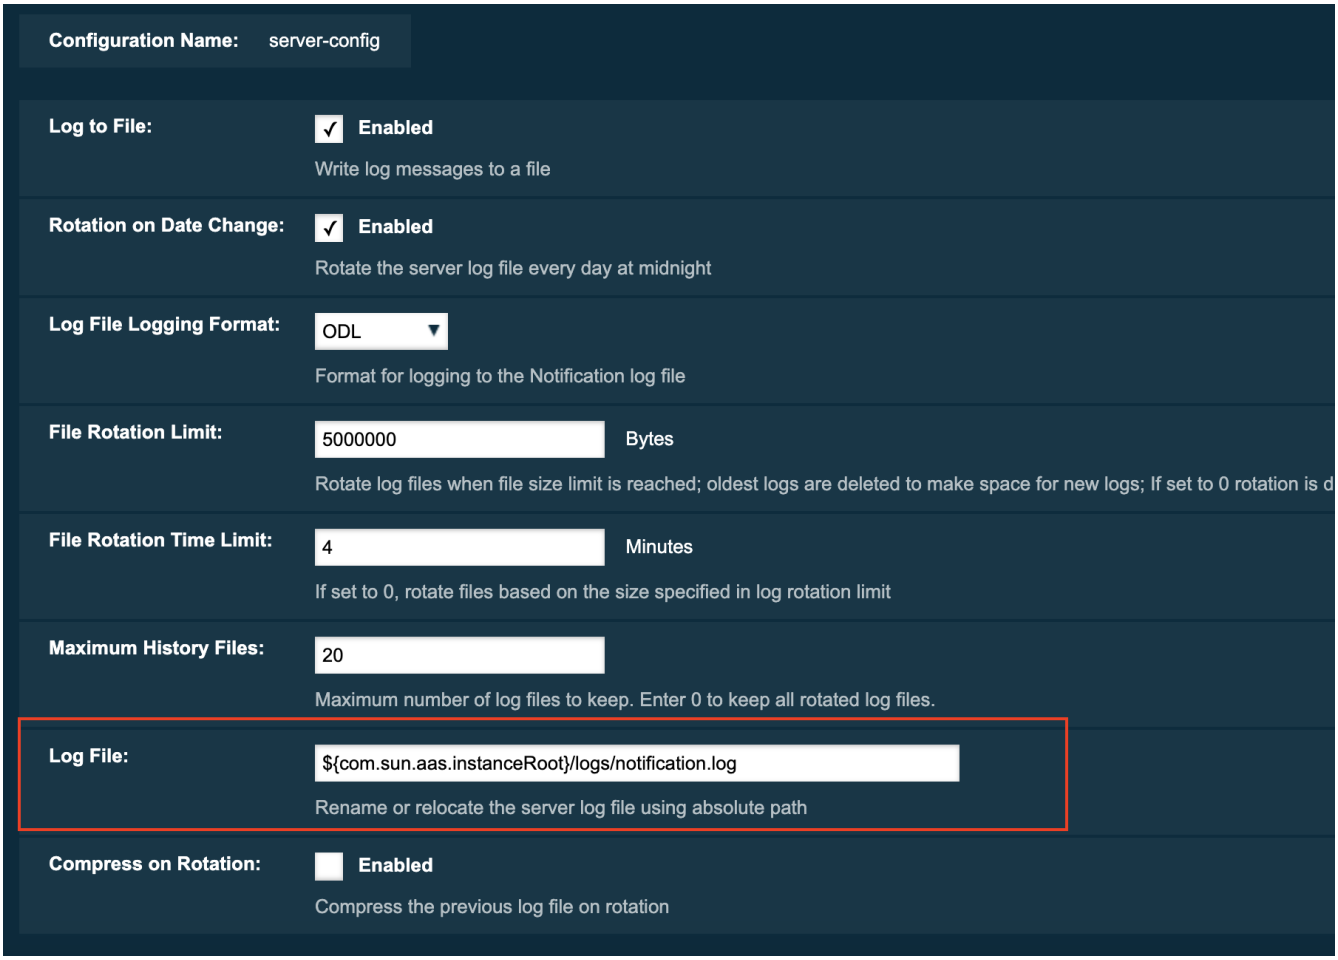
```
asadmin set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.maxHistoryFiles=20
```

Change the Name and Location of the Log File

The `Log File` option provides a way to change the default name and location of the notification log files.

Using the Admin Console

To configure `Log File` option using Admin Console:



Using the Asadmin CLI

Use the following command to change the default name and location of the server log files:

```
asadmin set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.file=${com.sun.aas
.instanceRoot}/notification/testNotification.log
```

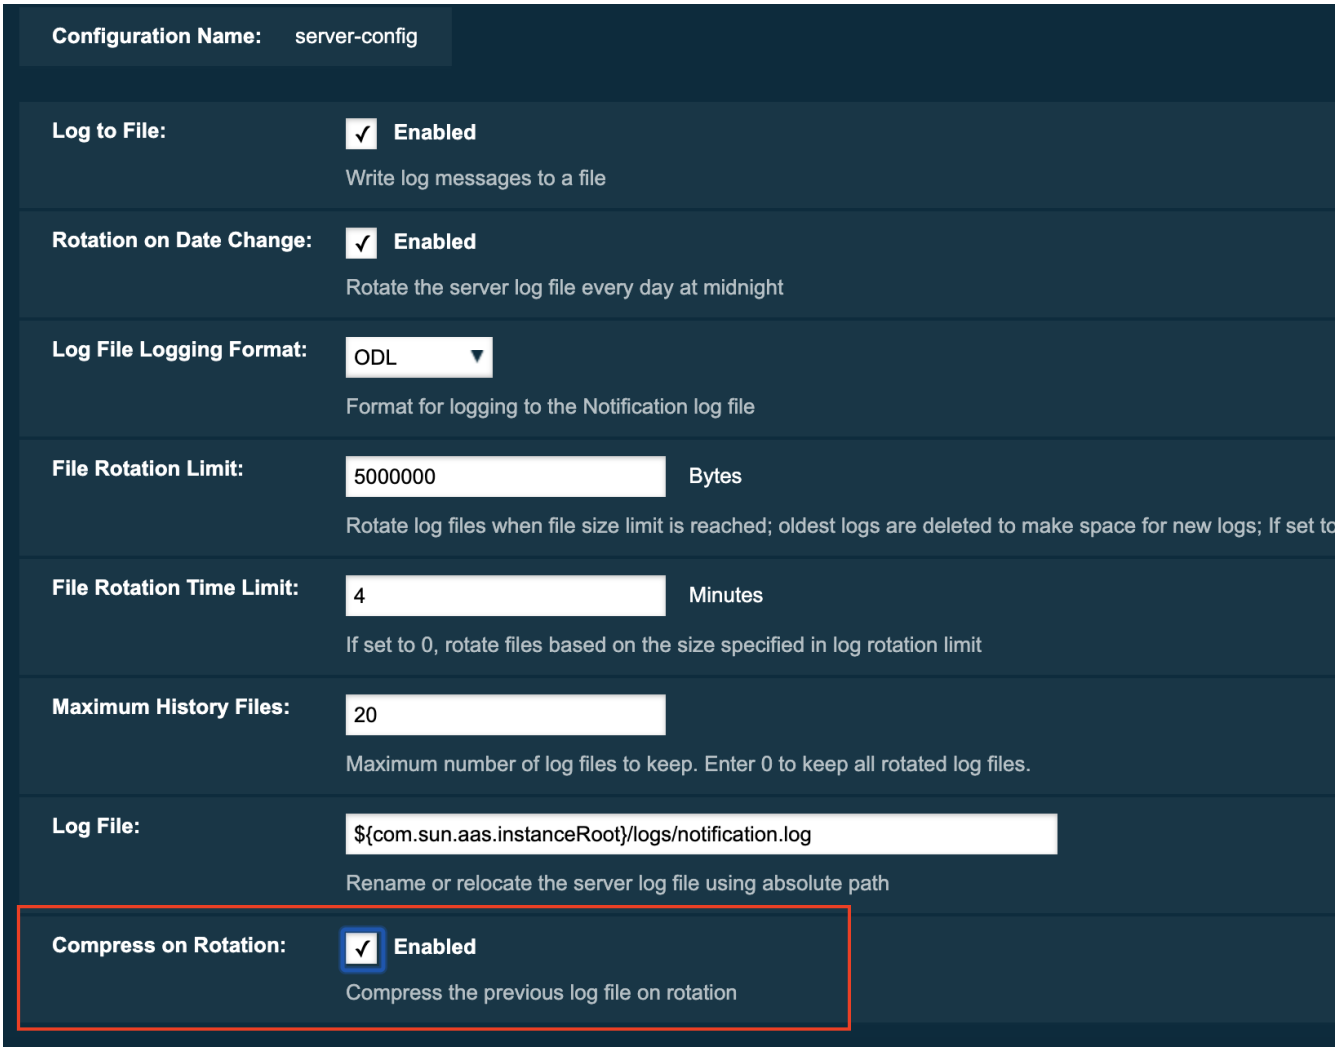
As seen in the sample command, you can use the `${com.sun.aas.instanceRoot}` system property to reference the current domain directory location.

Enable File Compression on Rotation

The `Compress on Rotation` option provides a way to enable the automatic compression of notification log files on rotation.

Using the Admin Console

To configure the `Compress on Rotation` option using the Admin Console:



Using the Asadmin CLI

Use the following command to enable or disable compression of log files on rotation:

```
asadmin> set-log-attributes
fish.payara.enterprise.server.logging.PayaraNotificationFileHandler.compressOnRotation
=true
```

Administering the Monitoring Service

This chapter explains how to monitor the Payara Server components and services by using the `asadmin` command-line utility. Instructions for configuring JConsole to monitor Payara Server resources are also provided.

Instructions for monitoring by using the Administration Console are contained in the Administration Console online help.

About Monitoring

Monitoring is the process of reviewing the statistics of a system to improve performance or solve problems. The monitoring service can track and display operational statistics, such as the number of requests per second, the average response time, and the throughput. By monitoring the state of

various components and services deployed in Payara Server, you can identify performance bottlenecks, predict failures, perform root cause analysis, and ensure that everything is functioning as expected.Data gathered by monitoring can also be useful in performance tuning and capacity planning.

For this release of Payara Server, monitoring is exposed in a modular way so that many client modules can access and display the monitoring statistics. These clients include the Administration Console, the `asadmin` utility, AMX, and REST interfaces.

How the Monitoring Tree Structure Works

A monitorable object is a component, subcomponent, or service that can be monitored. Payara Server uses a tree structure to track monitorable objects. Because the tree is dynamic, the tree changes as Payara Server components are added or removed.

In the tree, a monitorable object can have child objects (nodes) that represent exactly what can be monitored for that object. All child objects are addressed using the dot (.) character as a separator. These constructed names are referred to as dotted names. Detailed information on dotted names is available in the `dotted-names`(5ASC) help page.

The following command lists the monitorable child objects of the instance `server`:

```
asadmin> list --monitor "server.*"

server.applications
server.connector-service
server.http-service
server.jms-service
server.jvm
server.network
server.orb
server.resources
server.security
server.thread-pool
server.transaction-service
server.web
```

Each object is represented by a dotted name. Dotted names can also address specific attributes in monitorable objects. For example, the `jvm` object has a `memory` attribute with a statistic called `maxheapsize`. The following dotted name addresses the attribute:

```
server.jvm.memory.maxheapsize
```

Although an object is monitorable, it is not necessarily being actively monitored. For instructions on activating monitoring, see Configuring Monitoring.

Tree Structure of Monitorable Objects

Each monitorable object has a hierarchical tree structure. In the tree, a replaceable such as *statistics represents the name of the attribute that you can show statistics for.

Applications Tree Hierarchy

The `applications` tree contains the following nodes:

```
server.applications
   |--- application1
   |    |--- ejb-module-1
   |    |        |--- ejb1 *
   |    |                 |--- bean-cache (for entity/sfsb) *
   |    |                 |--- bean-pool (for slsb/mdb/entity) *
   |    |                 |--- bean-methods
   |    |                      |---method1 *
   |    |                      |---method2 *
   |    |                 |--- timers (for s1sb/entity/mdb) *
   |    |--- web-module-1
   |    |        |--- virtual-server-1 *
   |    |                      |---servlet1  *
   |    |                      |---servlet2  *
   |--- standalone-web-module-1
   |    |        |----- virtual-server-2 *
   |    |                      |---servlet3 *
   |    |                      |---servlet4 *
   |    |        |----- virtual-server-3 *
   |    |                      |---servlet3 *(same servlet on different vs)
   |    |                      |---servlet5 *
   |--- standalone-ejb-module-1
   |    |        |--- ejb2 *
   |    |                 |--- bean-cache (for entity/sfsb) *
   |    |                 |--- bean-pool (for slsb/mdb/entity) *
   |    |                 |--- bean-methods
   |    |                      |--- method1 *
   |    |                      |--- method2 *
   |    |                 |--- timers (for s1sb/entity/mdb) *
   |--- jersey-application-1
   |    |--- jersey
   |    |        |--- resources
                          resource-0
                              hitcount
                                   *statistic
   |--- application2
```

An example dotted name might be:

```
server.applications.hello.server.request.maxtime
```

An example dotted name under the EJB `method` node might be:

```
server.applications.ejbsfapp1.ejbsfapp1ejbmod1\.jar.SFApp1EJB1
```

An example Jersey dotted name might be:

```
server.applications.helloworld-webapp.jersey.resources.resource-
0.hitcount.resourcehitcount-count
```

For available statistics, see EJB Statistics, Jersey Statistics, and Web Statistics.

Connector Service Tree Hierarchy

The `connector-service` tree holds monitorable attributes for pools such as the connector connection pool. The `connector-service` tree contains the following nodes:

```
server.connector-service
        resource-adapter-1
             connection-pools
                  pool-1
             work-management
```

An example dotted name might be `server.connector-service.resource-adapter-1.connection-pools.pool-1`. For available statistics, see JMS/Connector Service Statistics.

HTTP Service Tree Hierarchy

The `http-service` tree contains the following nodes:

```
server.http-service
       virtual-server
           request
               *statistic
       _asadmin
           request
               *statistic
```

An example dotted name under the virutal-server node might be `server.http-service.virtual-server1.request.requestcount`. For available statistics, see HTTP Service Statistics.

JMS/Container Service Tree Hierarchy

The `jms-service` tree holds monitorable attributes for connection factories (connection pools for resource adapters) and work management (for Message Queue resource adapters). The `jms-service` tree contains the following nodes:

```
server.jms-service
        connection-factories
             connection-factory-1
        work-management
```

An example dotted name under the `connection-factories` node might be `server.jms-service.connection-factories.connection-factory-1` which shows all the statistics for this connection factory. For available statistics, see JMS/Connector Service Statistics.

JVM Tree Hierarchy

The `jvm` tree contains the following nodes:

```
server.jvm
           class-loading-system
           compilation-system
           garbage-collectors
           memory
           operating-system
           runtime
```

An example dotted name under the `memory` node might be `server.jvm.memory.maxheapsize`. For available statistics, see JVM Statistics.

Network Tree Hierarchy

The network statistics apply to the network listener, such as `admin-listener`, `http-listener-1`, `ttp-listener-2`. The `network` tree contains the following nodes:

```
server.network
          type-of-listener
              keep-alive
                    *statistic
              file-cache
                    *statistic
              thread-pool
                    *statistic
              connection-queue
                     *statistic
```

An example dotted name under the `network` node might be `server.network.admin-listener.keep-alive.maxrequests-count`. For available statistics, see Network Statistics.

ORB Tree Hierarchy

The `orb` tree holds monitorable attributes for connection managers. The `orb` tree contains the following nodes:

```
server.orb
    transport
        connectioncache
            inbound
                *statistic
            outbound
                *statistic
```

An example dotted name might be `server.orb.transport.connectioncache.inbound.connectionsidle-count`. For available statistics, see ORB Statistics (Connection Manager).

Resources Tree Hierarchy

The `resources` tree holds monitorable attributes for pools such as the JDBC connection pool and connector connection pool. The `resources` tree contains the following nodes:

```
server.resources
       connection-pool
           request
               *statistic
```

An example dotted name might be `server.resources.jdbc-connection-pool1.numconnfree.count`. For available statistics, see Resource Statistics (Connection Pool).

Security Tree Hierarchy

The security tree contains the following nodes:

```
server.security
       ejb
          *statistic
       web
          *statistic
       realm
          *statistic
```

An example dotted name might be `server.security.realm.realmcount-starttime`. For available statistics, see Security Statistics.

Thread Pool Tree Hierarchy

The `thread-pool` tree holds monitorable attributes for connection managers, and contains the following nodes:

```
server.thread-pool
               orb
                   threadpool
```

```
                        thread-pool-1
                            *statistic
```

An example dotted name might be `server.thread-pool.orb.threadpool.thread-pool-1.averagetimeinqueue-current`. For available statistics, see Thread Pool Statistics.

Transactions Service Tree Hierarchy

The `transaction-service` tree holds monitorable attributes for the transaction subsystem for the purpose of rolling back transactions. The `transaction-service` tree contains the following nodes:

```
server.transaction-service
         statistic
```

An example dotted name might be `server.tranaction-service.activeids`. For available statistics, see Transaction Service Statistics.

Web Tree Hierarchy

The `web` tree contains the following nodes:

```
server.web
           jsp
              *statistic
           servlet
              *statistic
           session
              *statistic
           request
              *statistic
```

An example dotted name for the `servlet` node might be `server.web.servlet.activeservletsloadedcount`. For available statistics, see Web Module Common Statistics.

About Monitoring for Add-on Components

An add-on component typically generates statistics that Payara Server can gather at runtime. Adding monitoring capabilities enables an add-on component to provide statistics to Payara Server in the same way as components that are supplied in the Payara Server distributions. As a result, you can use the same administrative interfaces to monitor statistics from any installed Payara Server component, regardless of the origin of the component.

Tools for Monitoring Payara Server

The following `asadmin` subcommands are provided for monitoring the ervices and components of Payara Server:

- The `enable-monitoring`, `disable-monitoring`, or the `get` and `set`subcommands are used to turn monitoring on or off. For instructions, see Configuring Monitoring.
- The `monitor type` subcommand is used to display basic data for a particular type of monitorable object. For instructions, see Viewing Common Monitoring Data.
- The `list --monitor` subcommand is used to display the objects that can be monitored with the `monitor` subcommand. For guidelines and instructions, see Guidelines for Using the `list` and `get` Subcommands for Monitoring.
- The `get` subcommand is used to display comprehensive data, such as the attributes and values for a dotted name. The `get` subcommand used with a wildcard parameter displays all available attributes for any monitorable object. For additional information, see Guidelines for Using the `list` and `get` Subcommands for Monitoring.

Configuring Monitoring

By default, the monitoring service is enabled for Payara Server, but monitoring for the individual modules is not. To enable monitoring for a module, you change the monitoring level for that module to `LOW` or `HIGH`, You can choose to leave monitoring `OFF` for objects that do not need to be monitored.

- `LOW`. Simple statistics, such as create count, byte count, and so on
- `HIGH`. Simple statistics plus method statistics, such as method count, duration, and so on
- `OFF`. No monitoring, no impact on performance

To Enable Monitoring

Use the `enable-monitoring` subcommand to enable the monitoring service itself, or to enable monitoring for individual modules. Monitoring is immediately activated, without restarting Payara Server.

You can also use the `set` subcommand to enable monitoring for a module. Using the `set` command is not a dynamic procedure, so you need to restart Payara Server for your changes to take effect.

- Determine which services and components are currently enabled for monitoring.

  ```
  asadmin> get server.monitoring-service.module-monitoring-levels.*
  ```

  This example output shows that the HTTP service is not enabled (OFF for monitoring), but other objects are enabled:

  ```
  configs.config.server-config.monitoring-service.module-monitoring-levels.web-
  container=HIGH
         configs.config.server-config.monitoring-service.module-monitoring-
  levels.http-service=OFF
             configs.config.server-config.monitoring-service.module-monitoring-
  levels.jvm=HIGH
  ```

- Enable monitoring by using the `enable-monitoring` subcommand. Server restart is not required.

Example - Enable Monitoring

This example enables the monitoring service without affecting monitoring for individual modules.

```
asadmin> enable-monitoring
Command enable-monitoring executed successfully
```

Example - Configure Monitoring

This example enables the monitoring service and enables the use of MBeans (JMX Monitoring) and the AMX subsystem in one command:

```
asadmin> set-monitoring-service-configuration --enabled=true --mbeansenabled=true
--target=server
Command set-monitoring-service-configuration executed successfully
```

Example - Enable Monitoring Levels

This example enables monitoring for the HTTP service by setting the monitoring level to `HIGH` (you must restart the server for changes to take effect).

```
asadmin> set server.monitoring-service.module-monitoring-levels.http-service=HIGH
Command set executed successfully
```

An alternative to the previous command that doesn't require a server restart is the following:

```
asadmin> set-monitoring-level --module=http-service --level=HIGH --target=server
```

The `set-monitoring-level` command can be used to configure the monitoring levels of multiple modules as well:

```
asadmin> set-monitoring-level --module=jvm,http-service --level=HIGH --target=server
```

To Disable Monitoring

Use the `disable-monitoring` subcommand to disable the monitoring service itself, or to disable monitoring for individual modules. Monitoring is immediately stopped, without restarting Payara Server.

You can also use the `set-monitoring-level` subcommand to disable monitoring for a module. To do this, set its `--level` option to `OFF`.

- Determine which modules are enabled for monitoring using the `get-monitoring-level`

command:

```
asadmin get-monitoring-level --target=server

Module                        Monitoring Level
cloud                         OFF
cloud-elasticity              OFF
cloud-orchestrator            OFF
cloud-tenant-manager          OFF
cloud-virt-assembly-service   OFF
connector-connection-pool     OFF
connector-service             OFF
deployment                    OFF
ejb-container                 OFF
http-service                  LOW
jdbc-connection-pool          OFF
jersey                        OFF
jms-service                   OFF
jpa                           OFF
jvm                           HIGH
orb                           OFF
security                      OFF
thread-pool                   OFF
transaction-service           OFF
web-container                 OFF
web-services-container        OFF

Command get-monitoring-level executed successfully.
```

As the io

- Disable monitoring for a service or module by using the `disable-monitoring` subcommand. Server restart is not required.

Example Disable Monitoring

This example disables the monitoring service without changing the monitoring levels for individual modules.

```
asadmin> disable-monitoring
Command disable-monitoring executed successfully
```

Example Disable Monitoring for specific modules

This example disables monitoring for specific modules. Their monitoring levels are set to `OFF`.

```
asadmin> disable-monitoring --modules web-container,ejb-container
Command disable-monitoring executed successfully
```

Viewing Common Monitoring Data

Use the `monitor` subcommand to display basic data on commonly-monitored objects.

To View Common Monitoring Data

Use the `--type` option of the `monitor` subcommand to specify the object for which you want to display data, such as `httplistener`, `jvm`, `webmodule`. If you use the `monitor` subcommand without specifying a type, an error message is displayed.

Output from the subcommand is displayed continuously in a tabular format. The `--interval` option can be used to display output at a particular interval (the default is 30 seconds).

Before You Begin

A monitorable object must be configured for monitoring before you can display data on the object. See To Enable Monitoring.

1. Determine which type of monitorable object you want to monitor.
   Your choices for 5.0 are `jvm`, `httplistener`, and `webmodule`.
2. Request the monitoring data by using the `monitor` subcommand.

Example 8-6 View Common Monitoring Data

This example requests common data for type `jvm` on instance `server`.

```
asadmin> monitor --type jvm server

UpTime(ms)                          Heap and NonHeap Memory(bytes)
current                  min        max        low        high       count

9437266                  8585216    619642880  0          0          93093888
9467250                  8585216    619642880  0          0          93093888
```

You can also view the full syntax and options of the subcommand by typing `asadmin help monitor` at the command line.

Common Monitoring Statistics

*HTTP Listener Common Statistics

The statistics available for the `httplistener` type are shown in the following table.

Table 8-1 HTTP Listener Common Monitoring Statistics

Statistic	Description
`ec`	Error count. Cumulative value of the error count
`mt`	Maximum time. Longest response time for a request; not a cumulative value, but the largest response time from among the response times

Statistic	Description
pt	Processing time. Cumulative value of the times taken to process each request, with processing time being the average of request processing times over request
rc	Request count. Cumulative number of requests processed so far

JVM Common Statistics

The statistics available for the jvm type are shown in the following table.

Table 8-2 JVM Common Monitoring Statistics

Statistic	Description
count	Amount of memory (in bytes) that is guaranteed to be available for use by the JVM machine
high	Retained for compatibility with other releases
low	Retained for compatibility with other releases
max	The maximum amount of memory that can be used for memory management.
min	Initial amount of memory (in bytes) that the JVM machine requests from the operating system for memory management during startup
UpTime	Number of milliseconds that the JVM machine has been running since it was last started

Web Module Common Statistics

The statistics available for the webmodule type are shown in the following table.

Table 8-3 Web Module Common Monitoring Statistics

Statistic	Description
ajlc	Number of active JavaServer Pages (JSP) technology pages that are loaded
asc	Current active sessions
aslc	Number of active servlets that are loaded
ast	Total active sessions
mjlc	Maximum number of JSP pages that are loaded
mslc	Maximum number of servlets that are loaded
rst	Total rejected sessions
st	Total sessions
tjlc	Total number of JSP pages that are loaded
tslc	Total number of servlets that are loaded

Viewing Comprehensive Monitoring Data

By applying the `list` and `get` subcommands against the tree structure using dotted names, you can display more comprehensive monitoring data, such as a description of each of the statistics and its unit of measurement.

Guidelines for Using the `list` and `get` Subcommands for Monitoring

The underlying assumptions for using the `list` and `get` subcommands with dotted names are:

- A `list` subcommand that specifies a dotted name that is not followed by a wildcard (`*`) lists the current node's immediate children. For example, the following subcommand lists all immediate children belonging to the `server` node:

  ```
  list --monitor server
  ```

- A `list` subcommand that specifies a dotted name followed by a wildcard of the form `.*` lists a hierarchical tree of child nodes from the specified node. For example, the following subcommand lists all children of the `applications` node, their subsequent child nodes, and so on:

  ```
  list --monitor server.applications.*
  ```

- A `list` subcommand that specifies a dotted name preceded or followed by a wildcard of the form *dottedname or dotted * name or dottedname * lists all nodes and their children that match the regular expression created by the specified matching pattern.
- A `get` subcommand followed by a `. or a` gets the set of attributes and their values that belong to the node specified.

For example, the following table explains the output of the `list` and `get` subcommands used with the dotted name for the `resources` node.

Table 8-4 Example Resources Level Dotted Names

Subcommand	Dotted Name	Output
`list --monitor`	`server.resources`	List of pool names.
`list --monitor`	`server.resources.``connection-pool1`	No attributes, but a message saying "Use `get` subcommand with the `--monitor` option to view this node's attributes and values."
`get --monitor`	`server.resources.``connection-pool1.*`	List of attributes and values corresponding to connection pool attributes.

For detailed information on dotted names, see the `dotted-names` help page.

To View Comprehensive Monitoring Data

Although the `monitor` subcommand is useful in many situations, it does not offer the complete list of all monitorable objects. To work with comprehensive data for an object type, use the `list monitor` and the `get` `monitor` subcommands followed by the dotted name of a monitorable object.

Before You Begin

A monitorable object must be configured for monitoring before you can display information about the object. See To Enable Monitoring if needed.

- List the objects that are enabled for monitoring by using the `list` subcommand.
  For example, the following subcommand lists all components and services that have monitoring enabled for instance `server`.

  ```
  asadmin> list --monitor "*"
  server.web
  server.connector-service
  server.orb
  server.jms-serviceserver.jvm
  server.applications
  server.http-service
  server.thread-pools
  ```

- Get data for a monitored component or service by using the `get` subcommand.

Example 8-7 Viewing Attributes for a Specific Type

This example gets information about all the attributes for object type `jvm` on instance `server`.

```
asadmin> get --monitor server.jvm.*
server.jvm.class-loading-system.loadedclasscount = 3715
server.jvm.class-loading-system.totalloadedclasscount = 3731
server.jvm.class-loading-system.unloadedclasscount = 16
server.jvm.compilation-system.name-current = HotSpot Client Compiler
server.jvm.compilation-system.totalcompilationtime = 769
server.jvm.garbage-collectors.Copy.collectioncount = 285
server.jvm.garbage-collectors.Copy.collectiontime = 980
server.jvm.garbage-collectors.MarkSweepCompact.collectioncount = 2
server.jvm.garbage-collectors.MarkSweepCompact.collectiontime = 383
server.jvm.memory.committedheapsize = 23498752
server.jvm.memory.committednonheapsize = 13598720
server.jvm.memory.initheapsize = 0
server.jvm.memory.initnonheapsize = 8585216
server.jvm.memory.maxheapsize = 66650112
server.jvm.memory.maxnonheapsize = 100663296
server.jvm.memory.objectpendingfinalizationcount = 0
server.jvm.memory.usedheapsize = 19741184
server.jvm.memory.usednonheapsize = 13398352
server.jvm.operating-system.arch-current = x86
```

```
server.jvm.operating-system.availableprocessors = 2
server.jvm.operating-system.name-current = Windows XP
server.jvm.operating-system.version-current = 5.1
server.jvm.runtime.classpath-current = glassfish.jar
server.jvm.runtime.inputarguments-current = []
server.jvm.runtime.managementspecversion-current = 1.0
server.jvm.runtime.name-current = 4372@ABBAGANI_WORK
server.jvm.runtime.specname-current = Java Virtual Machine Specification
server.jvm.runtime.specvendor-current = Sun Microsystems Inc.
server.jvm.runtime.specversion-current = 1.0
server.jvm.runtime.uptime = 84813
server.jvm.runtime.vmname-current = Java HotSpot(TM) Client VM
server.jvm.runtime.vmvendor-current = Sun Microsystems Inc.
server.jvm.runtime.vmversion-current = 1.5.0_11-b03
```

Example 8-8 Viewing Monitorable Applications

This example lists all the monitorable applications for instance `server`.

```
asadmin> list --monitor server.applications.*
server.applications.app1
server.applications.app2
server.applications.app1.virtual-server1
server.applications.app2.virtual-server1
```

Example 8-9 Viewing Attributes for an Application

This example gets information about all the attributes for application `hello`.

```
asadmin> get --monitor server.applications.hello.*
server.applications.hello.server.activatedsessionstotal = 0
server.applications.hello.server.activejspsloadedcount = 1
server.applications.hello.server.activeservletsloadedcount = 1
server.applications.hello.server.activesessionscurrent = 1
server.applications.hello.server.activesessionshigh = 1
server.applications.hello.server.errorcount = 0
server.applications.hello.server.expiredsessionstotal = 0
server.applications.hello.server.maxjspsloadedcount = 1
server.applications.hello.server.maxservletsloadedcount = 0
server.applications.hello.server.maxtime = 0
server.applications.hello.server.passivatedsessionstotal = 0
server.applications.hello.server.persistedsessionstotal = 0
server.applications.hello.server.processingtime = 0.0
server.applications.hello.server.rejectedsessionstotal = 0
server.applications.hello.server.requestcount = 0
server.applications.hello.server.sessionstotal =
server.applications.hello.server.totaljspsloadedcount = 0
server.applications.hello.server.totalservletsloadedcount = 0
```

Example 8-10 Viewing a Specific Attribute

This example gets information about the `jvm` attribute `runtime.vmversion-current` on instance `server`.

```
asadmin> get --monitor server.jvm.runtime.vmversion-current
server.jvm.runtime.vmversion-current = 10.0-b23
```

Comprehensive Monitoring Statistics

You can get comprehensive monitoring statistics by forming a dotted name that specifies the statistic you are looking for. For example, the following dotted name will display the cumulative number of requests for the HTTP service on `virtual-server1`:

`server.http-service.virtual-server1.request.requestcount`

EJB Statistics

EJBs fit into the tree of objects as shown in Applications Tree Hierarchy. Use the following dotted name pattern to get EJB statistics for an application:

```
server.applications.appname.ejbmodulename.ejbname.bean-cache.statistic
```

EJB statistics for an application are available after the application is executed. If the application is deployed but has not yet been executed, all counts will show default values. When the application is undeployed, all its monitoring data is lost.

EJB Cache Statistics

Use the following dotted name pattern for EJB cache statistics:

```
server.applications.appname.ejbmodulename.bean-cache.ejbname.statistic
```

The statistics available for EJB caches are listed in the following table.

Table 8-5 EJB Cache Monitoring Statistics

Statistic	Data Type	Description
`cachemisses`	RangeStatistic	The number of times a user request does not find a bean in the cache.
`cachehits`	RangeStatistic	The number of times a user request found an entry in the cache.
`numbeansincache`	RangeStatistic	The number of beans in the cache. This is the current size of the cache.

Statistic	Data Type	Description
numpassivations	CountStatistic	Number of passivated beans. Applies only to stateful session beans.
numpassivationerrors	CountStatistic	Number of errors during passivation. Applies only to stateful session beans.
numexpiredsessionsremoved	CountStatistic	Number of expired sessions removed by the cleanup thread. Applies only to stateful session beans.
numpassivationsuccess	CountStatistic	Number of times passivation completed successfully. Applies only to stateful session beans.

EJB Container Statistics

Use the following dotted name pattern for EJB container statistics:

```
server.applications.appname.ejbmodulename.container.ejbname
```

The statistics available for EJB containers are listed in the following table.

Table 8-6 EJB Container Monitoring Statistics

Statistic	Data Type	Description
createcount	CountStatistic	Number of times an EJB's `create` method is called.
messagecount	CountStatistic	Number of messages received for a message-driven bean.
methodreadycount	RangeStatistic	Number of stateful or stateless session beans that are in the `MethodReady` state.
passivecount	RangeStatistic	Number of stateful session beans that are in `Passive` state.
pooledcount	RangeStatistic	Number of entity beans in pooled state.
readycount	RangeStatistic	Number of entity beans in ready state.
removecount	CountStatistic	Number of times an EJB's `remove` method is called.

EJB Method Statistics

Use the following dotted name pattern for EJB method statistics:

```
server.applications.appname.ejbmodulename.bean-methods.ejbname.statistic
```

The statistics available for EJB method invocations are listed in the following table.

Table 8-7 EJB Method Monitoring Statistics

Statistic	Data Type	Description
executiontime	CountStatistic	Time, in milliseconds, spent executing the method for the last successful/unsuccessful attempt to run the operation. This is collected for stateless and stateful session beans and entity beans if monitoring is enabled on the EJB container.
methodstatistic	TimeStatistic	Number of times an operation is called; the total time that is spent during the invocation, and so on.
totalnumerrors	CountStatistic	Number of times the method execution resulted in an exception. This is collected for stateless and stateful session beans and entity beans if monitoring is enabled for the EJB container.
totalnumsuccess	CountStatistic	Number of times the method successfully executed. This is collected for stateless and stateful session beans and entity beans if monitoring enabled is true for EJB container.

EJB Pool Statistics

Use the following dotted name pattern for EJB pool statistics:

```
server.applications.appname.ejbmodulename.bean-pool.ejbname.statistic
```

The statistics available for EJB pools are listed in the following table.

Table 8-8 EJB Pool Monitoring Statistics

Statistic	Data Type	Description
jmsmaxmessagesload	CountStatistic	The maximum number of messages to load into a JMS session at one time for a message-driven bean to serve. Default is 1. Applies only to pools for message driven beans.
numbeansinpool	RangeStatistic	Number of EJBs in the associated pool, providing information about how the pool is changing.
numthreadswaiting	RangeStatistic	Number of threads waiting for free beans, giving an indication of possible congestion of requests.
totalbeanscreated	CountStatistic	Number of beans created in associated pool since the gathering of data started.
totalbeansdestroyed	CountStatistic	Number of beans destroyed from associated pool since the gathering of data started.

Timer Statistics

Use the following dotted name pattern for timer statistics:

```
server.applications.appname.ejbmodulename.timers.ejbname.statistic
```

The statistics available for timers are listed in the following table.

Table 8-9 Timer Monitoring Statistics

Statistic	Data Type	Description
numtimerscreated	CountStatistic	Number of timers created in the system.
numtimersdelivered	CountStatistic	Number of timers delivered by the system.
numtimersremoved	CountStatistic	Number of timers removed from the system.

HTTP Service Statistics

The HTTP service fits into the tree of objects as shown in HTTP Service Tree Hierarchy.

HTTP Service Virtual Server Statistics

Use the following dotted name pattern for HTTP service virtual server statistics:

```
server.http-service.virtual-server.request.statistic
```

The HTTP service statistics for virtual servers are shown in the following table.

Table 8-10 HTTP Service Virtual Server Monitoring Statistics

Statistic	Data Type	Description
count200	CountStatistic	Number of responses with a status code equal to 200
count2xx	CountStatistic	Number of responses with a status code in the 2xx range
count302	CountStatistic	Number of responses with a status code equal to 302
count304	CountStatistic	Number of responses with a status code equal to 304
count3xx	CountStatistic	Number of responses with a status code equal in the 3xx range
count400	CountStatistic	Number of responses with a status code equal to 400
count401	CountStatistic	Number of responses with a status code equal to 401
count403	CountStatistic	Number of responses with a status code equal to 403
count404	CountStatistic	Number of responses with a status code equal to 404
count4xx	CountStatistic	Number of responses with a status code equal in the 4xx range
count503	CountStatistic	Number of responses with a status code equal to 503
count5xx	CountStatistic	Number of responses with a status code equal in the 5xx range

Statistic	Data Type	Description
countother	CountStatistic	Number of responses with a status code outside the 2xx, 3xx, 4xx, and 5xx range
errorcount	CountStatistic	Cumulative value of the error count, with error count representing the number of cases where the response code was greater than or equal to 400
hosts	StringStatistic	The host (alias) names of the virtual server
maxtime	CountStatistic	Longest response time for a request; not a cumulative value, but the largest response time from among the response times
processingtime	CountStatistic	Cumulative value of the times taken to process each request, with processing time being the average of request processing times over the request count
requestcount	CountStatistic	Cumulative number of requests processed so far
state	StringStatistic	The state of the virtual server

Jersey Statistics

Jersey fits into the tree of objects as shown in Applications Tree Hierarchy.

Use the following dotted name pattern for Jersey statistics:

```
server.applications.jersey-application.jersey.resources.resource-0.hitcount.statistic
```

The statistics available for Jersey are shown in the following table.

Table 8-11 Jersey Statistics

Statistic	Data Type	Description
resourcehitcount	CountStatistic	Number of hits on this resource class
rootresourcehitcount	CountStatistic	Number of hits on this root resource class

JMS/Connector Service Statistics

The JMS/Connector Service fits into the tree of objects as shown in JMS/Container Service Tree Hierarchy.

Connector Connection Pool Statistics (JMS)

Use the following dotted name pattern for JMS/Connector Service connection pool statistics:

```
server.connector-service.resource-adapter-1.connection-pool.statistic
```

JMS/Connector Service statistics available for the connector connection pools are shown in the following table.

In order to improve system performance, connection pools are initialized lazily; that is, a pool is not initialized until an application first uses the pool or the pool is explicitly pinged. Monitoring statistics for a connection pool are not available until the pool is initialized.

Table 8-12 Connector Connection Pool Monitoring Statistics (JMS)

Statistic	Data Type	Description
averageconnwaittime	CountStatistic	Average wait time of connections before they are serviced by the connection pool.
connectionrequestwaittime	RangeStatistic	The longest and shortest wait times of connection requests. The current value indicates the wait time of the last request that was serviced by the pool.
numconnfailedvalidation	CountStatistic	Total number of connections in the connection pool that failed validation from the start time until the last sample time.
numconnused	RangeStatistic	Total number of connections that are currently being used, as well as information about the maximum number of connections that were used (the high watermark).
numconnfree	RangeStatistic	Total number of free connections in the pool as of the last sampling.
numconntimedout	CountStatistic	Total number of connections in the pool that timed out between the start time and the last sample time.
numconncreated	CountStatistic	Number of physical connections, in milliseconds, that were created since the last reset.
numconndestroyed	CountStatistic	Number of physical connections that were destroyed since the last reset.
numconnacquired	CountStatistic	Number of logical connections acquired from the pool.
numconnreleased	CountStatistic	Number of logical connections released to the pool.
waitqueuelenght	CountStatistic	Number of connection requests in the queue waiting to be serviced.

Connector Work Management Statistics (JMS)

Use the following dotted name pattern for JMS/Connector Service work management statistics:

```
server.connector-service.resource-adapter-1.work-management.statistic
```

JMS/Connector Service statistics available for connector work management are listed in the following table.

Table 8-13 Connector Work Management Monitoring Statistics (JMS)

Statistic	Data Type	Description
activeworkcount	RangeStatistic	Number of work objects executed by the connector.
completedworkcount	CountStatistic	Number of work objects that were completed.
rejectedworkcount	CountStatistic	Number of work objects rejected by the Payara Server.
submittedworkcount	CountStatistic	Number of work objects submitted by a connector module.
waitqueuelength	RangeStatistic	Number of work objects waiting in the queue before executing.
workrequestwaittime	RangeStatistic	Longest and shortest wait of a work object before it gets executed.

JVM Statistics

The JVM fits into the tree of objects as show in JVM Tree Hierarchy.

JVM Class Loading System Statistics

Use the following dotted name pattern for JVM class loading system statistics:

```
server.jvm.class-loading-system.statistic
```

With Java SE, additional monitoring information can be obtained from the JVM. Set the monitoring level to LOW to enable the display of this additional information. Set the monitoring level to HIGH to also view information pertaining to each live thread in the system. More information about the additional monitoring features for Java SE is available in Monitoring and Management for the Java Platform .

The Java SE monitoring tools are discussed at https://docs.oracle.com/en/java/javase/17/docs/specs/man/index.html.

The statistics that are available for class loading in the JVM for Java SE are shown in the following table.

Table 8-14 JVM Monitoring Statistics for Java SE Class Loading

Statistic	Data Type	Description
loadedclasscount	CountStatistic	Number of classes that are currently loaded in the JVM

Statistic	Data Type	Description
totalloadedclasscount	CountStatistic	Total number of classes that have been loaded since the JVM began execution
unloadedclasscount	CountStatistic	Number of classes that have been unloaded from the JVM since the JVM began execution

The statistics available for threads in the JVM in Java SE are shown in the following table.

Table 8-15 JVM Monitoring Statistics for Java SE - Threads

Statistic	Data Type	Description
allthreadids	StringStatistic	List of all live thread ids.
currentthreadcputime	CountStatistic	CPU time for the current thread (in nanoseconds) if CPU time measurement is enabled. If CPU time measurement is disabled, returns -1.
daemonthreadcount	CountStatistic	Current number of live daemon threads.
monitordeadlockedthreads	StringStatistic	List of thread ids that are monitor deadlocked.
peakthreadcount	CountStatistic	Peak live thread count since the JVM started or the peak was reset.
threadcount	CountStatistic	Current number of live daemon and non-daemon threads.
totalstartedthreadcount	CountStatistic	Total number of threads created and/or started since the JVM started.

JVM Compilation System Statistics

Use the following dotted name pattern for JVM compilation system statistics:

```
server.jvm.compilation-system.statistic
```

The statistics that are available for compilation in the JVM for Java SE are shown in the following table.

Table 8-16 JVM Monitoring Statistics for Java SE Compilation

Statistic	Data Type	Description
name-current	StringStatistic	Name of the current compiler
totalcompilationtime	CountStatistic	Accumulated time (in milliseconds) spent in compilation

JVM Garbage Collectors Statistics

Use the following dotted name pattern for JVM garbage collectors statistics:

```
server.jvm.garbage-collectors.statistic
```

The statistics that are available for garbage collection in the JVM for Java SE are shown in the following table.

Table 8-17 JVM Monitoring Statistics for Java SE Garbage Collectors

Statistic	Data Type	Description
collectioncount	CountStatistic	Total number of collections that have occurred
collectiontime	CountStatistic	Accumulated time (in milliseconds) spent in collection

JVM Memory Statistics

Use the following dotted name pattern for JVM memory statistics:

```
server.jvm.memory.statistic
```

The statistics that are available for memory in the JVM for Java SE are shown in the following table.

Table 8-18 JVM Monitoring Statistics for Java SE Memory

Statistic	Data Type	Description
committedheapsize	CountStatistic	Amount of heap memory (in bytes) that is committed for the JVM to use
committednonheapsize	CountStatistic	Amount of non-heap memory (in bytes) that is committed for the JVM to use
initheapsize	CountStatistic	Size of the heap initially requested by the JVM
initnonheapsize	CountStatistic	Size of the non-heap area initially requested by the JVM
maxheapsize	CountStatistic	Maximum amount of heap memory (in bytes) that can be used for memory management
maxnonheapsize	CountStatistic	Maximum amount of non-heap memory (in bytes) that can be used for memory management
objectpendingfinalizationcount	CountStatistic	Approximate number of objects that are pending finalization

Statistic	Data Type	Description
usedheapsize	CountStatistic	Size of the heap currently in use
usednonheapsize	CountStatistic	Size of the non-heap area currently in use

JVM Operating System Statistics

Use the following dotted name pattern for JVM operating system statistics:

```
server.jvm.operating-system.statistic
```

The statistics that are available for the operating system for the JVM machine in Java SE are shown in the following table.

Table 8-19 JVM Statistics for the Java SE Operating System

Statistic	Data Type	Description
arch-current	StringStatistic	Operating system architecture
availableprocessors	CountStatistic	Number of processors available to the JVM
name-current	StringStatistic	Operating system name
version-current	StringStatistic	Operating system version

JVM Runtime Statistics

Use the following dotted name pattern for JVM runtime statistics:

```
server.jvm.runtime.statistic
```

The statistics that are available for the runtime in the JVM runtime for Java SE are shown in the following table.

Table 8-20 JVM Monitoring Statistics for Java SE Runtime

Statistic	Data Type	Description
classpath-current	StringStatistic	Classpath that is used by the system class loader to search for class files
inputarguments-current	StringStatistic	Input arguments passed to the JVM; not including arguments to the `main` method
managementspecversion-current	StringStatistic	Management specification version implemented by the JVM
name-current	StringStatistic	Name representing the running JVM
specname-current	StringStatistic	JVM specification name

Statistic	Data Type	Description
specvendor-current	StringStatistic	JVM specification vendor
specversion-current	StringStatistic	JVM specification version
uptime	CountStatistic	Uptime of the JVM (in milliseconds)
vmname-current	StringStatistic	JVM implementation name
vmvendor-current	StringStatistic	JVM implementation vendor
vmversion-current	StringStatistic	JVM implementation version

Network Statistics

Network fits into the tree of objects as shown in Network Tree Hierarchy.

Network Keep Alive Statistics

Use the following dotted name pattern for network keep alive statistics:

```
server.network.type-of-listener.keep-alive.statistic
```

Statistics available for network keep alive are shown in the following table.

Table 8-21 Network Keep Alive Statistics

Statistic	Data Type	Description
countconnections	CountStatistic	Number of connections in keep-alive mode.
counttimeouts	CountStatistic	Number of keep-alive connections that timed out.
secondstimeouts	CountStatistic	Keep-alive timeout value in seconds.
maxrequests	CountStatistic	Maximum number of requests allowed on a single keep-alive connection.
countflushes	CountStatistic	Number of keep-alive connections that were closed.
counthits	CountStatistic	Number of requests received by connections in keep-alive mode.
countrefusals	CountStatistic	Number of keep-alive connections that were rejected.

Network Connection Queue Statistics

Use the following dotted name pattern for network connection queue statistics:

```
server.network.type-of-listener.connection-queue.statistic
```

Statistics available for network connection queue are shown in the following table.

Table 8-22 Network Connection Queue Statistics

Statistic	Data Type	Description
countopenconnections	CountStatistic	The number of open/active connections
countoverflows	CountStatistic	Number of times the queue has been too full to accommodate a connection
countqueued	CountStatistic	Number of connections currently in the queue
countqueued15minutesaverage	CountStatistic	Average number of connections queued in the last 15 minutes
countqueued1minuteaverage	CountStatistic	Average number of connections queued in the last 1 minute
countqueued5minutesaverage	CountStatistic	Average number of connections queued in the last 5 minutes
counttotalconnections	CountStatistic	Total number of connectionsthat have been accepted
counttotalqueued	CountStatistic	Total number of connections that have been queued
maxqueued	CountStatistic	Maximum size of the connection queue
peakqueued	CountStatistic	Largest number of connections that were in the queue simultaneously
tickstotalqueued	CountStatistic	(Unsupported) Total number of ticks that connections have spent in the queue

Network File Cache Statistics

Use the following dotted name pattern for network file cache statistics:

```
server.network.type-of-listener.file-cache.statistic
```

Statistics available for network file cache are shown in the following table.

Table 8-23 Network File Cache Statistics

Statistic	Data Type	Description
contenthits	CountStatistic	Number of hits on cached file content
contentmisses	CountStatistic	Number of misses on cached file content
heapsize	CountStatistic	Current cache size in bytes
hits	CountStatistic	Number of cache lookup hits
infohits	CountStatistic	Number of hits on cached file info
infomisses	CountStatistic	Number of misses on cached file info

Statistic	Data Type	Description
mappedmemorysize	CountStatistic	Size of mapped memory used for caching in bytes
maxheapsize	CountStatistic	Maximum heap space used for cache in bytes
maxmappedmemorysize	CountStatistic	Maximum memory map size used for caching in bytes
misses	CountStatistic	Number of cache lookup misses data type
opencacheentries	CountStatistic	Number of current open cache entries

Network Thread Pool Statistics

Use the following dotted name pattern for network thread pool statistics:

```
server.network.type-of-listener.thread-pool.statistic
```

Statistics available for network thread pool are shown in the following table.

Table 8-24 Network Thread Pool Statistics

Statistic	Data Type	Description
corethreads	CountStatistic	Core number of threads in the thread pool
currentthreadcount	CountStatistic	Provides the number of request processing threads currently in the listener thread pool
currentthreadsbusy	CountStatistic	Provides the number of request processing threads currently in use in the listener thread pool serving requests
maxthreads	CountStatistic	Maximum number of threads allowed in the thread pool
totalexecutedtasks	CountStatistic	Provides the total number of tasks, which were executed by the thread pool

ORB Statistics (Connection Manager)

The ORB fits into the tree of objects as shown in ORB Tree Hierarchy.

Use the following dotted name patterns for ORB statistics:

```
server.orb.transport.connectioncache.inbound.statistic
server.orb.transport.connectioncache.outbound.statistic
```

The statistics available for the connection manager in an ORB are listed in the following table.

Table 8-25 ORB Monitoring Statistics (Connection Manager)

Statistic	Data Type	Description
connectionsidle	CountStatistic	Total number of connections that are idle to the ORB
connectionsinuse	CountStatistic	Total number of connections in use to the ORB
totalconnections	BoundedRangeStatistic	Total number of connections to the ORB

Resource Statistics (Connection Pool)

By monitoring connection pool resources you can measure performance and capture resource usage at runtime. Connections are expensive and frequently cause performance bottlenecks in applications. It is important to monitor how a connection pool is releasing and creating new connections and how many threads are waiting to retrieve a connection from a particular pool.

The connection pool resources fit into the tree of objects as shown in Resources Tree Hierarchy.

Use the following dotted name pattern for general connection pool statistics:

```
server.resources.pool-name.statistic
```

Use the following dotted name pattern for application-scoped connection pool statistics:

```
server.applications.application-name.resources.pool-name.statistic
```

Use the following dotted name pattern for module-scoped connection pool statistics:

```
server.applications.application-name.module-name.resources.pool-name.statistic
```

The connection pool statistics are shown in the following tables.

In order to improve system performance, connection pools are initialized lazily; that is, a pool is not initialized until an application first uses the pool or the pool is explicitly pinged. Monitoring statistics for a connection pool are not available until the pool is initialized.

Table 8-26 General Resource Monitoring Statistics (Connection Pool)

Statistic	Data Type	Description
averageconnwaittime	CountStatistic	Average wait-time-duration per successful connection request

Statistic	Data Type	Description
connrequestwaittime	RangeStatistic	Longest and shortest wait times, in milliseconds, of connection requests since the last sampling. current value indicates the wait time of the last request that was serviced by the pool
numconnacquired	CountStatistic	Number of logical connections acquired from the pool since the last sampling
numconncreated	CountStatistic	Number of physical connections that were created by the pool since the last reset
numconndestroyed	CountStatistic	Number of physical connections that were destroyed since the last reset
numconnfailedvalidation	CountStatistic	Number of connections in the connection pool that failed validation from the start time until the last sampling time
numconnfree	RangeStatistic	Number of free connections in the pool as of the last sampling
numconnnotsuccessfullymatched	CountStatistic	Number of connections rejected during matching
numconnreleased	CountStatistic	Number of connections released back to the pool since the last sampling
numconnsuccessfullymatched	CountStatistic	Number of connections successfully matched
numconntimedout	CountStatistic	Number of connections in the pool that timed out between the start time and the last sampling time
numconnused	RangeStatistic	Number of connections that are currently being used, as well as information about the maximum number of connections that were used (high watermark)
frequsedsqlqueries	StringStatistic	List of the most frequently used SQL queries (Available only when SQL Tracing is enabled)
numpotentialconnleak	CountStatistic	Number of potential connection leaks
numpotentialstatementleak	CountStatistic	Number of potential statement leaks (Available only when Statement Leak Detection is enabled)

Statistic	Data Type	Description
numstatementcachehit	CountStatistic	Number of statements that were found in the statement cache (Available only when the Statement Cache is enabled)
numstatementcachemiss	CountStatistic	Number of statements that were not found in the statement cache (Available only when the Statement Cache is enabled)
waitqueuelength	CountStatistic	Number of connection requests in the queue waiting to be serviced

Table 8-27 Application Specific Resource Monitoring Statistics (Connection Pool)

Statistic	Data Type	Description
numconnacquired	CountStatistic	Number of logical connections acquired from the pool since the last sampling
numconnreleased	CountStatistic	Number of connections released back to the pool since the last sampling
numconnused	RangeStatistic	Number of connections that are currently being used, as well as information about the maximum number of connections that were used (high watermark)

Security Statistics

Security fits into the tree of objects as shown in Security Tree Hierarchy.

EJB Security Statistics

Use the following dotted name pattern for EJB security statistics:

```
server.security.ejb.statistic
```

The statistics available for EJB security are listed in the following table.

Table 8-28 EJB Security Monitoring Statistics

Statistic	Data Type	Description
policyconfigurationcount	CountStatistic	Number of policy configuration
securitymanagercount	CountStatistic	Number of EJB security managers

Web Security Statistics

Use the following dotted name pattern for web security statistics:

```
server.security.web.statistic
```

The statistics available for web security are listed in the following table.

Table 8-29 Web Security Monitoring Statistics

Statistic	Data Type	Description
`websecuritymanagercount`	CountStatistic	Number of security managers
`webpolicyconfigurationcount`	CountStatistic	Number of policy configuration objects

Realm Security Statistics

Use the following dotted name pattern for realm security statistics:

```
server.security.realm.statistic
```

The statistics available for realm security are listed in the following table.

[[Technical Documentation-Payara Server Documentation-General Administration-Administering the Monitoring Service:::table-realm-security-statistics]] .Table 8-30 Realm Security Monitoring Statistics

Statistic	Data Type	Description
`realmcount`	CountStatistic	Number of realms

Thread Pool Statistics

The thread pool fits into the tree of objects as shown in Thread Pool Tree Hierarchy.

Thread Pool Monitoring Statistics

Use the following dotted name pattern for thread pool statistics:

```
server.thread-pool.thread-pool.statistic
```

The statistics available for the thread pool are shown in the following table.

Table 8-31 Thread Pool Monitoring Statistics

Statistic	Data Type	Description
`averagetimeinqueue`	BoundedRangeStatistic	Average amount of time (in milliseconds) a request waited in the queue before being processed

Statistic	Data Type	Description
averageworkcompletiontime	BoundedRangeStatistic	Average amount of 0time (in milliseconds) taken to complete an assignment
currentbusythreads	CountStatistic	Number of busy threads
currentnumberofthreads	BoundedRangeStatistic	Current number of request processing threads
numberofavailablethreads	CountStatistic	Number of available threads
numberofworkitemsinqueue	BoundedRangeStatistic	Current number of work items waiting in queue
totalworkitemsadded	CountStatistic	Total number of work items added to the work queue as of last sampling

JVM Statistics for Java SE-Thread Information

The statistics available for `ThreadInfo` in the JVM in Java SE are shown in the following table.

Table 8-32 JVM Monitoring Statistics for Java SE - Thread Info

Statistic	Data Type	Description
blockedcount	CountStatistic	Total number of times that the thread entered the `BLOCKED` state.
blockedtime	CountStatistic	Time elapsed (in milliseconds) since the thread entered the `BLOCKED` state. Returns -1 if thread contention monitoring is disabled.
lockname	StringStatistic	String representation of the monitor lock that the thread is blocked to enter or waiting to be notified through the `Object.wait` method.
lockownerid	CountStatistic	ID of the thread that holds the monitor lock of an object on which this thread is blocking.
lockownername	StringStatistic	Name of the thread that holds the monitor lock of the object this thread is blocking on.
stacktrace	StringStatistic	Stack trace associated with this thread.
threadid	CountStatistic	ID of the thread.
threadname	StringStatistic	Name of the thread.
threadstate	StringStatistic	State of the thread.
waitedtime	CountStatistic	Elapsed time (in milliseconds) that the thread has been in a `WAITING` state. Returns -1 if thread contention monitoring is disabled.

Statistic	Data Type	Description
waitedcount	CountStatistic	Total number of times the thread was in WAITING or TIMED_WAITING states.

Transaction Service Statistics

The transaction service allows the client to freeze the transaction subsystem in order to roll back transactions and determine which transactions are in process at the time of the freeze. The transaction service fits into the tree of objects as shown in Transactions Service Tree Hierarchy.

Use the following dotted name pattern for transaction service statistics:

```
server.transaction-service.statistic
```

The statistics available for the transaction service are shown in the following table.

Table 8-33 Transaction Service Monitoring Statistics

Statistic	Data Type	Description
activecount	CountStatistic	Number of transactions currently active.
activeids	StringStatistic	The ID's of the transactions that are currently active. Every such transaction can be rolled back after freezing the transaction service.
committedcount	CountStatistic	Number of transactions that have been committed.
rolledbackcount	CountStatistic	Number of transactions that have been rolled back.
state	StringStatistic	Indicates whether the transaction has been frozen.

Web Statistics

The web module fits into the tree of objects as shown in Web Tree Hierarchy.

Web Module Servlet Statistics

Use the following dotted name pattern for web module servlet statistics:

```
server.applications.web-module.virtual-server.servlet.statistic
server.applications.application.web-module.virtual-server.servlet.statistic
```

The available web module servlet statistics are shown in the following table.

Table 8-34 Web Module Servlet Statistics

Statistic	Data Type	Description
errorcount	CountStatistic	Cumulative number of cases where the response code is greater than or equal to 400.

Statistic	Data Type	Description
maxtime	CountStatistic	Maximum amount of time the web container waits for requests.
processingtime	CountStatistic	Cumulative value of the amount of time required to process each request. The processing time is the average of request processing times divided by the request count.
requestcount	CountStatistic	The total number of requests processed so far.
servicetime	CountStatistic	Aggregate response time in milliseconds.

Web JSP Statistics

Use the following dotted name pattern for web JSP statistics:

```
server.applications.web-module.virtual-server.statistic
server.applications.application.web-module.virtual-server.statistic
```

The available web JSP statistics are shown in the following table.

Table 8-35 Web JSP Monitoring Statistics

Statistic	Data Type	Description
jspcount-current	RangeStatistic	Number of active JSP pages
jsperrorcount	CountStatistic	Total number of errors triggered by JSP page invocations
jspreloadedcount	CountStatistic	Total number of JSP pages that were reloaded
totaljspcount	CountStatistic	Total number of JSP pages ever loaded

Web Request Statistics

Use the following dotted name pattern for web request statistics:

```
server.applications.web-module.virtual-server.statistic
server.applications.application.web-module.virtual-server.statistic
```

The available web request statistics are shown in the following table.

Table 8-36 Web Request Monitoring Statistics

Statistic	Data Type	Description
errorcount	CountStatistic	Cumulative value of the error count, with error count representing the number of cases where the response code was greater than or equal to 400
maxtime	CountStatistic	Longest response time for a request; not a cumulative value, but the largest response time from among the response times

Statistic	Data Type	Description
processingtime	CountStatistic	Average request processing time, in milliseconds
requestcount	CountStatistic	Cumulative number of the requests processed so far

Web Servlet Statistics

Use the following dotted name pattern for web servlet statistics:

```
server.applications.web-module.virtual-server.statistic
server.applications.application.web-module.virtual-server.statistic
```

The available web servlet statistics are shown in the following table.

Table 8-37 Web Servlet Monitoring Statistics

Statistic	Data Type	Description
activeservletsloadedcount	RangeStatistic	Number of currently loaded servlets
servletprocessingtimes	CountStatistic	Cumulative servlet processing times , in milliseconds
totalservletsloadedcount	CountStatistic	Cumulative number of servlets that have been loaded into the web module

Web Session Statistics

Use the following dotted name pattern for web session statistics:

```
server.applications.web-module.virtual-server.statistic
server.applications.application.web-module.virtual-server.statistic
```

The available web session statistics are shown in the following table.

Table 8-38 Web Session Monitoring Statistics

Statistic	Data Type	Description
activatedsessionstotal	CountStatistic	Total number of activated sessions
activesessionscurrent	RangeStatistic	Number of currently active sessions
activesessionshigh	CountStatistic	Maximum number of concurrently active sessions
expiredsessionstotal	CountStatistic	Total number of expired sessions
passivatedsessionstotal	CountStatistic	Total number of passivated sessions
persistedsessionstotal	CountStatistic	Total number of persisted sessions
rejectedsessionstotal	CountStatistic	Total number of rejected sessions

Statistic	Data Type	Description
sessionstotal	CountStatistic	Total number of sessions created

Configuring JConsole to View Payara Server Monitoring Data

Java SE provides tools to connect to an MBean Server and view the MBeans registered with the server. JConsole is one such popular JMX Connector Client and is available as part of the standard Java SE distribution.When you configure JConsole for use with Payara Server, Payara Server becomes the JMX Connector's server end and JConsole becomes the JMX connector's client end.

To Connect JConsole to Payara Server

Java SE 6 enhances management and monitoring of the virtual machine by including a Platform MBean Server and by including managed beans (MBeans) to configure the virtual machine.

To view all MBeans, Payara Server provides a configuration of the standard JMX connector server called System JMX Connector Server. As part of Payara Server startup, an instance of this JMX Connector Server is started. Any compliant JMX connector client can connect to the server using the JMX Connector Server.

By default, Payara Server is configured with a non-secure System JMX Connector Server. If this is an issue, the JMX connector can be removed. However, access can be restricted to a specific IP address (for example, the loopback address) by setting `address` to `locahost`.

- Start the domain. For instructions, see To Start a Domain.
- Start JConsole using this format: JDK_HOME`/bin/jconsole`. For example:

  ```
  /usr/java/bin/jconsole
  ```

  The JConsole Connect to Agent window is displayed.
- Click the Remote tab and type the host name and port.
  Always connect remotely with JConsole, otherwise MBeans will not load automatically.
- Click Connect.
- In the Remote Process text box, specify the JMX Service URL.
  For example:

```
service:jmx:rmi:///jndi/rmi://localhost:8686/jmxrmi
```

The JMX Service URL is emitted by the server at startup, looking something like this:

```
[#|2009-12-03T10:25:17.737-0800|INFO|glassfishv3.0|
x..system.tools.admin.org.glassfish.server|_ThreadID=20;
_ThreadName=Thread-26;|JMXStartupService: Started JMXConnector, JMXService
URL = service:jmx:rmi://localhost:8686/jndi/rmi://localhost:8686/jmxrmi|#]
```

However, in most cases, simply entering `host:port` is fine, such as, 192.168.1.150:8686. The long Service URL is not needed.

Another host name can be substituted for `localhost`. The default port number (8686) could change if the `jmx-connector` configuration has been modified.

- Click Connect.
  In the JConsole window you will see all your MBeans, JVM information, and so on, in various tabs. Most of the useful MBeans are to be found in the `amx` and `java.lang` domains.

For more information about JConsole, see http://docs.oracle.com/javase/8/docs/technotes/guides/management/jconsole.html.

JMX Monitoring

Payara Server offers a customized JMX Monitoring Service. Once configured, Payara Server will monitor and log the values of all MBean attributes that have been added for explicit monitoring.

The metrics are logged together in a single log message as a series of key-value pairs prefixed by the string `JMX-MONITORING:`.

The default JMX listener is unauthenticated and open for local access.
In an unsecure environment, open JMX ports should be disabled to prevent unwanted access.

To see a non-exhaustive inventory of existing MBeans that are currently available for Payara Server, see here.

Enabling JMX Monitoring

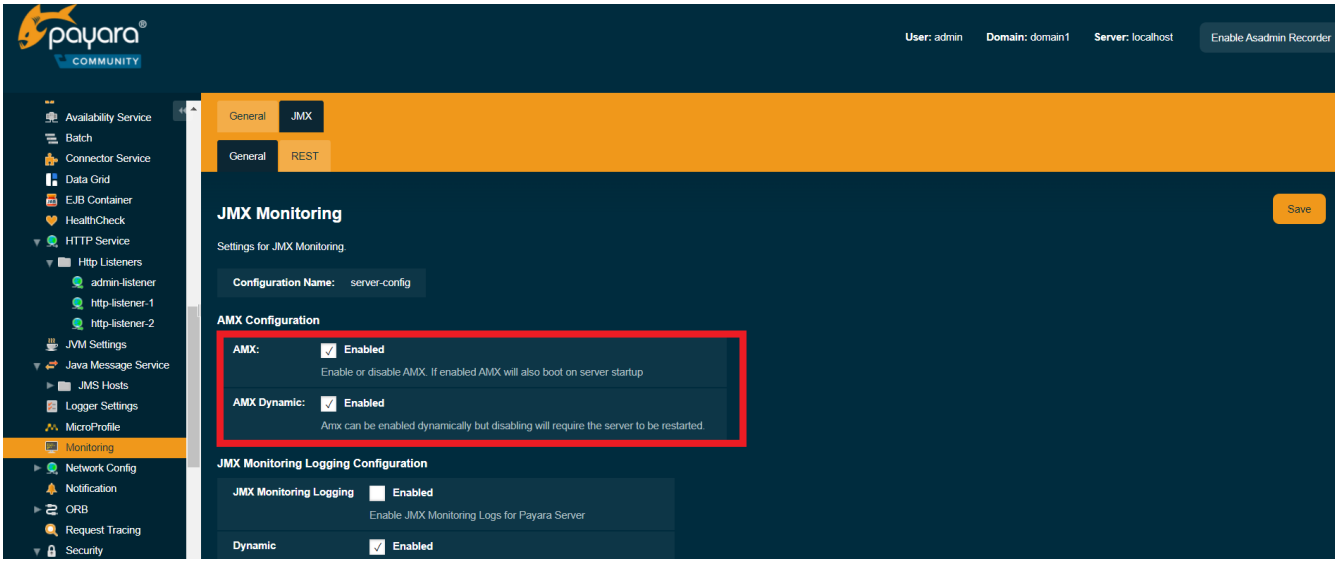
Payara Server uses the AMX API for working with *JMX MBeans*. AMX is not fully exposed by default and as such needs to be loaded to access most *JMX MBean* objects.
The JMX Monitoring Service can be used without AMX but there is a limit to what can be monitored without it.

Boot AMX

To boot AMX at startup or independently of the JMX Monitoring service, run the command below:

```
asadmin set-amx-enabled --enabled true --dynamic true --target server
```

Boot AMX Using the Admin Console



Configure JMX Monitoring

You can enable JMX Monitoring using the `set-jmx-monitoring-configuration` asadmin command

JMX Monitoring can either be enabled for next startup or the service can be dynamically enabled on a running instance of Payara Server (provided a non-empty configuration exists at server startup).

To enable the service dynamically on the default server instance run the following command:

```
asadmin> set-jmx-monitoring-configuration --dynamic true --enabled true
```

Setting The JMX Monitoring Configuration

You can configure JMX Monitoring using the `set-jmx-monitoring-configuration` asadmin command.

Adding a monitoring attribute

To add the `HeapMemoryUsage` attribute to the list of MBean attributes to monitor using the service the following command can be used:

```
asadmin set-jmx-monitoring-configuration --addattribute 'attributeName=HeapMemoryUsage
objectName=java.lang:type=Memory' --enabled false
```

Breaking this command down, two arguments have been used:

- `--addattribute`
- `--enabled`

Passing `--addattribute` to `set-jmx-monitoring-configuration` provides a way to add a new **MBean** attribute to monitor using the service. This argument takes in a string of space-delimited key-value pairs corresponding to the values listed earlier.

The `attributeName` and `objectName` fields are required, but `description` is not. Providing

`attributeName=HeapMemoryUsage` denotes that the name of the **MBean** attribute to log is `HeapMemoryUsage`, while `objectName=java.lang:type=Memory` denotes the `ObjectName` of the **MBean** to look for the attribute on is `java.lang:type=Memory`.

The second argument, `--enabled`, is the only required option for the `asadmin` command. The only valid values to give this option are `true` or `false`. Passing `false` to the option will disable the logging service on next startup if it is currently enabled, but will otherwise do nothing.

Under this scenario the monitoring service has not been configured yet so `false` was passed.

Dealing with composite MBean attributes

The **MBean** attribute added, `HeapMemoryUsage`, is a composite attribute.

It has metrics for the `commited`, `init`, `max` and `used` attributes. The monitoring service will by default monitor each metric and log it as `{$metric}{$attribute_name}:{$attribute_value}`.

If this is not the desired result, it is possible to monitor a single metric for a composite **MBean** attribute.

To monitor a single metric for the attribute the value of `attributeName` passed to the `--addattribute` option should be modified like so:

```
attributeName=HeapMemoryUsage.metric
```

So to log only the used heap memory the asadmin command would be:

```
asadmin set-jmx-monitoring-configuration --addattribute
'attributeName=HeapMemoryUsage.used objectName=java.lang:type=Memory' --enabled false
```

Setting Logging frequency

There are two configuration attributes related to the frequency at which log messages are written: `logfrequency` and `logfrequencyunit`. The first is a numerical value used for the rate, while the second is the unit for the rate. The default configuration is set to have a message logged every *15 seconds*.

If the value of `logfrequencyunit` is the default of `SECONDS` then to have the monitoring service log messages every one minute execute the following command:

```
asadmin set-jmx-monitoring-configuration --logfrequency 60 --enabled false
```

Rest Monitoring

This section covers how to use the REST monitoring functionality in Payara Server. The REST monitoring is implemented through an internal application that functions similarly to Jolokia, as it exposes MBeans over HTTP with a REST API to stop JMX monitoring requiring RMI.

The REST monitoring is hosted on the admin-listener (port `4848`) on the default context root, `/rest-`

`monitoring`.

Configuring REST monitoring

REST monitoring is configurable through several Asadmin CLI commands.

The `set-rest-monitoring-configuration` asadmin command is used to configure REST monitoring. This command requires the server to be running. Each configuration property can be configured individually or all together.

To enable REST monitoring, run the command like this:

```
asadmin set-rest-monitoring-configuration --enabled true
```

Getting REST monitoring Configuration

```
asadmin> get-rest-monitoring-configuration
```

The `get-rest-monitoring-configuration` asadmin command is used to get the configuration of the REST monitoring. This command requires the server to be running.

If no target is specified, the command will get the REST monitoring configuration from the domain configuration (`server-config`). The `--target` option retrieves the REST monitoring from another instance or cluster.

Here's an example of how to use the command:

```
asadmin> get-rest-monitoring-configuration --target server-config

Enabled    Rest Monitoring Application Name    Context Root       Security Enabled
true       __restmonitoring                    /rest-monitoring   false
```

Rest Monitoring Security

To enable security for the REST Monitoring application, you'll have to enable secure administration first.

```
asadmin set-rest-monitoring-configuration --securityEnabled=true
```

The `securityEnabled` property defines whether the REST monitoring application is available over HTTPS. Since the REST monitoring application is hosted on the `admin-listener`.

Enabling secure admin can be done by first configuring the admin password with the `change-admin-password` command, then using the `enable-secure-admin` command.

Remember that enabling secure admin requires a server restart.

When `securityenabled` is set to true, a username and password is required to use REST monitoring.

The default username is set to `payara` and the default password is set to `rest`. The user `payara` is defined in the `file` realm.

The password can be changed with the following command:

```
asadmin update-file-user --groups=rest --target=server-config --authrealmname=file
payara
```

This updates the `payara` user, which is part of the `rest` group. Any users who are able to log in to the REST monitoring must also be defined in the `file` realm and be part of the `rest` group.

New users can be created by using the following command:

```
asadmin create-file-user --groups=rest --target=server-config --authRealmName=file
<username>
```

Performing READ Operations

REST Monitoring supports a subset of operations in the Jolokia API.

The `read` operation reads the details of the requested MBean. The `read` operation accepts GET requests on URLs in the following format:

```
<REST_API_URL>/read/${mbean-name}/${attribute-name}
```

A list of attribute names can be found in the request of an empty attribute name under `value`.

Example Execution

To read the MBean `java.lang:type=Memory` using the default configuration, you would make a GET request to: `http://localhost:4848/rest-monitoring/rest/read/java.lang:type=Memory`.

Example Output

```
{
  "request": {
    "mbean": "java.lang:type=Memory",
    "type": "read"
  },
  "value": {
    "HeapMemoryUsage": {
      "committed": 450363392,
```

```
      "init": 264241152,
      "max": 477626368,
      "used": 97480984
    },
    "ObjectPendingFinalizationCount": 0,
    "NonHeapMemoryUsage": {
      "committed": 139460608,
      "init": 2555904,
      "max": -1,
      "used": 122389432
    },
    "Verbose": false,
    "ObjectName": "java.lang:type=Memory"
  },
  "timestamp": 1502799650273,
  "status": 200
}
```

Performing Bulk READ Operations

It is possible to execute bulk operations using the REST monitoring API. To do this, issue a POST request to the REST API URL with the following JSON structure as the body payload.

The payload is a JSON array consisting of objects of type, MBean, and attribute JSON objects. You may send a single operation request instead of an array also.

```
[
  {
    "type" : "<OPERATION_TYPE>",
    "mbean" : "<MBEAN_NAME>",
    "attribute" : "<ATTRIBUTE_NAME>"
  },
  {
    "type" : "<OPERATION_TYPE>",
    "mbean" : "<MBEAN_NAME>",
    "attribute" : "<ATTRIBUTE_NAME>"
  }
]
```

- **type** - The 'type' of operation to execute, e.g. read, search, write, etc.
- **mbean** - The MBean attribute which the operation will be executed on.
- **attribute** - The MBean attribute upon which the operation will be executed. If omitted, all attributes of the MBean will be involved in the operation.

Example Execution

Using `curl` and a sample REST API URL of `http://localhost:4848/rest-monitoring/rest`

```
curl -X POST http://localhost:4848/rest-monitoring/rest/ \
  -H 'Content-Type: application/json' \
  -d '[
    {
        "mbean": "java.lang:type=Compilation",
        "type": "read"
    },{
        "mbean": "java.lang:type=Runtime",
        "attribute" : "Uptime",
        "type": "read"
    }
]'
```

Example Output

```
[
    {
        "request": {
            "mbean": "java.lang:type=Compilation",
            "type": "read"
        },
        "value": {
            "Name": "HotSpot 64-Bit Tiered Compilers",
            "CompilationTimeMonitoringSupported": true,
            "TotalCompilationTime": 106363,
            "ObjectName": "java.lang:type=Compilation"
        },
        "timestamp": 1529353755633,
        "status": 200
    },
    {
        "request": {
            "mbean": "java.lang:type=Runtime",
            "attribute": "Uptime",
            "type": "read"
        },
        "value": 8541422,
        "timestamp": 1529353755636,
        "status": 200
    }
]
```

Administering the HealthCheck Service

Payara Server includes a HealthCheck Service that is disabled by default. When enabled it can periodically check the following performance metrics:

- Host CPU Usage

- Host Memory Usage
- Payara Server's JVM Garbage Collections
- Payara Server's JVM Heap Usage
- CPU Usage of individual threads
- Detects stuck threads
- Monitors metrics exposed by MicroProfile Metrics

If there is a problem with any of these metrics, and they exceed a configurable threshold then a `GOOD`, `WARNING` or `CRITICAL` event notification is sent to the Notification Service.

This allows operations teams to rapidly detect problems or work out what happened after these problems have occurred.

It is possible to display metrics produced by HealthCheck service on MicroProfile Health REST endpoints.

The Host Memory Usage currently only works on Linux and BSD operating system derivatives.

If the Log Notifier is enabled, such events will be presented in the server's log file like in the following sample:

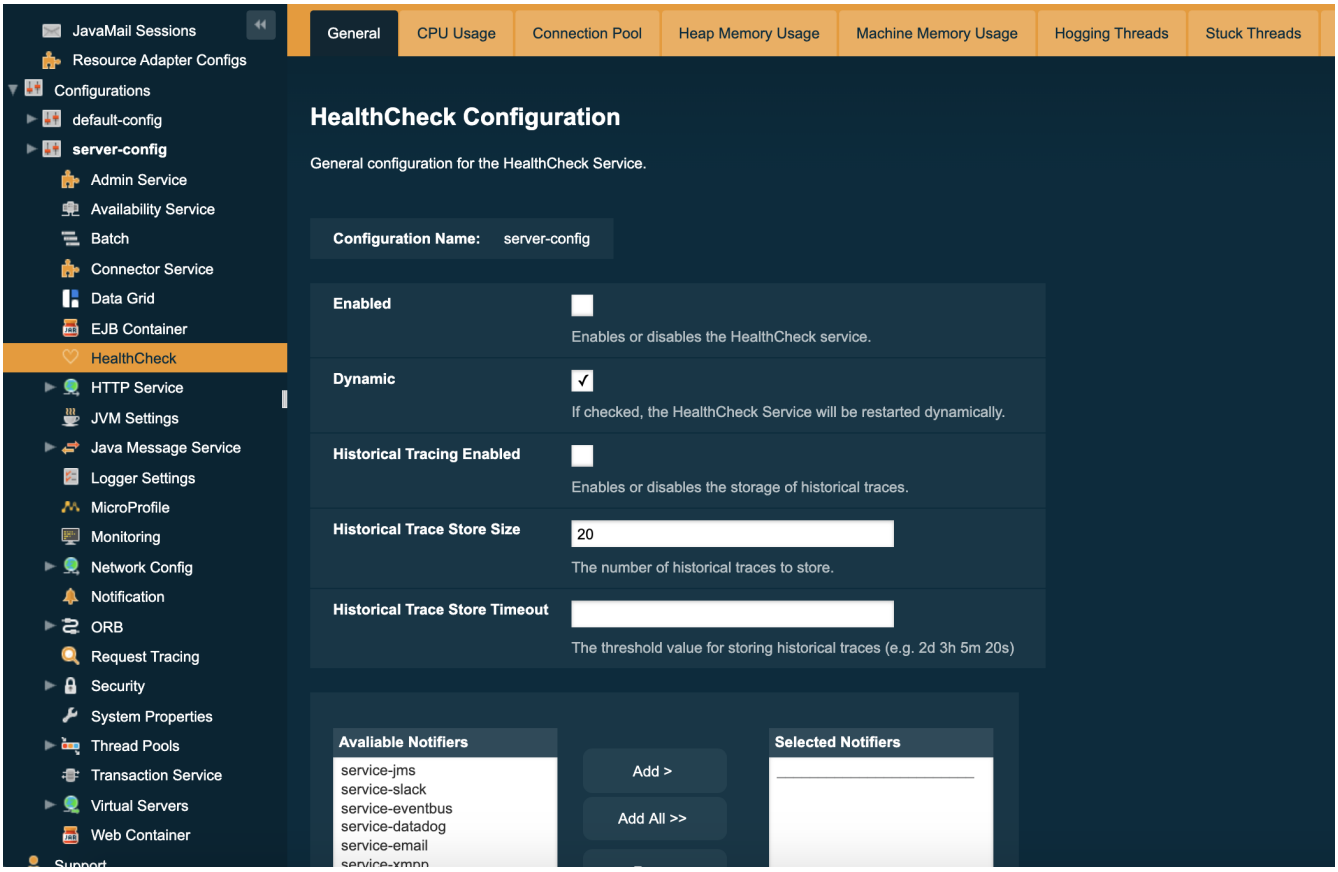
```
[2016-05-24T03:52:28.690+0000] [Payara main-7] [INFO]
[fish.payara.nucleus.healthcheck.HealthCheckService] [tid: _ThreadID=72
_ThreadName=healthcheck-service-3 [timeMillis: 1464061948690] [levelValue: 800] [[
CPUC:Health Check Result:[[status=WARNING, message='CPU%: 75.6, Time CPU used: 267
milliseconds'']']]]  [2016-05-24T21:11:36.579+0000] [Payara 4.1] [SEVERE]
[fish.payara.nucleus.healthcheck.HealthCheckService] [tid: _ThreadID=71
_ThreadName=healthcheck-service-3] [timeMillis: 1464124296579] [levelValue: 1000] [[
HOGT:Health Check Result:[[status=CRITICAL, message='Thread with <id-name>: 145-
testing-thread-1 is a hogging thread for the last 59 seconds 999 milliseconds'']']]]
```

HealthCheck Service Configuration

As with any other services available in Payara Server, the HealthCheck service can be configured by using the web console or by using administration commands.

Using the Web Administration Console

To configure the HealthCheck Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Healthcheck*:



Check the **Enabled** box (and the **Dynamic** box too if you don't want to restart the domain) to switch the HealthCheck service on.

The general settings of the service are:

Threshold Unit

This defines the time duration per unit. The accepted options are any valid java.util.concurrent.TimeUnit values.

The default value is *SECONDS*.

Threshold Value

This defines the number of units beyond which a request will be traced.

Store Historic Traces

When present, enables the storage of the slowest historical request trace events.

Historic Trace Store Size

Determines the number of historical trace events that can be stored in memory when historical storing is enabled. The default value is **20** records

Aside from this configuration settings, you can also define which notifiers will be used to relay the HealthCheck events by moving them to the **Active Notifiers** box.

Keep in mind that for HealthCheck events to be relayed to the active notifiers, both the Notification Service and each respective notifier must be enabled first.

You don't need to manually add each notifier on this screen. When enabling a notifier on its configuration screen, the server will **automatically** add it to the list of active notifiers for the HealthCheck service.
This same result occurs when enabling the notifier using the appropriate `asadmin` command.

Configuring the Available Checkers

Each of the available checkers that are used to determine the server's health can also be configured separately from each other on the admin console. The list of the available checkers is as follows:

CPU Usage

Calculates the CPU usage and prints out the percentage along with the usage time.

Connection Pool

Calculates the ratio of free/used connections available for all JDBC connections pool and prints the percentage of used connections for each active pool.

Heap Memory Usage

Calculates the heap memory usage and prints out the percentage along with initial and committed heap sizes.

Machine Memory Usage

Calculates the machine memory usage and prints out the percentage along with the total and used physical memory size.

Hogging Threads

Identifies the threads that are hogging the CPU.

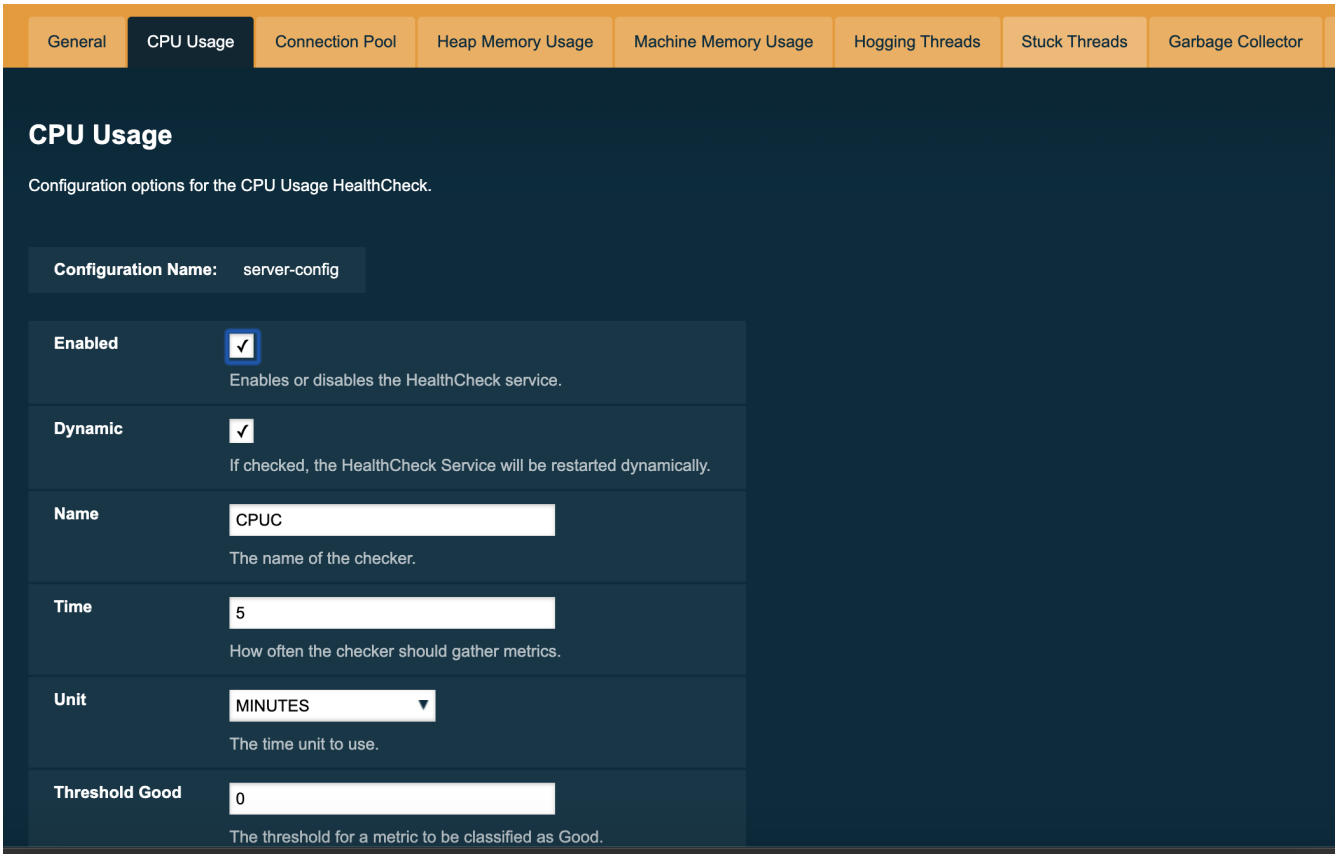
Stuck Threads

Identifies the threads that are stuck for a specified period of time.

Garbage Collector

Calculates and prints out how many times GC is executed with its elapsed time. The percentage is the ratio of time spent in GC and total time passed.

You can configure the settings for each checker on the respective tab in the web console. Here's a sample image with the current configuration for the **CPU Usage** checker:



Common HealthCheck Service Checkers Configuration

The following are the configurable attributes available to **ALL** the HealthCheck Service performance metric checkers:

Enabled

Determines whether the checker is enabled.

Dynamic

Determine whether the changes done to the checker's configuration are applied immediately or after the server/instance's restart.

Name

The name or label that the checker will use to identify itself on the notification events. The default names for all checkers are the following:

Checker	Default name
CPU Usage	`CPUC`
Connection Pool	`CONP`
Heap Memory Usage	`HEAP`
Machine Memory Usage	`MEMM`
Hogging Threads	`HOGT`
Stuck Threads	`STUCK`
Garbage Collector	`GBGC`

Time

The time interval value (as an `Integer`) specified in given unit to execute the checker for the metric. The default value is **5**.

Unit

This defines the time duration per unit. The accepted options are any valid java.util.concurrent.TimeUnit values.

The default value is **MINUTES**.

Threshold Range Configuration for HealthCheck Service Checkers

The following attributes are available to the **CPU Usage**, **Connection Pool**, **Heap Memory Usage**, **Machine Memory Usage** and **Garbage Collector** checkers:

Threshold Good

The upper numeric boundary (valid `Integer`) of the metric used by the checker for the notification event to be classified as **GOOD**. It has **0** as default value.

Threshold Warning

The upper numeric boundary (valid `Integer`) of the metric used by the checker for the notification event to be classified as **WARNING**. It has **50** as default value.

Threshold Critical

The upper numeric boundary (valid `Integer`) of the metric used by the checker for the notification event to be classified as **CRITICAL**. It has **80** as default value.

The threshold values range (GOOD - WARNING - CRITICAL) are used to correctly warn users of the health of a specific metric depending on their value when they are measured based on the checking frequency.

For example, if the **CPU Usage** checker is configured with the default threshold values, and at measuring time, the CPU is performing at `76,8%`. Then this notification event would be generated:

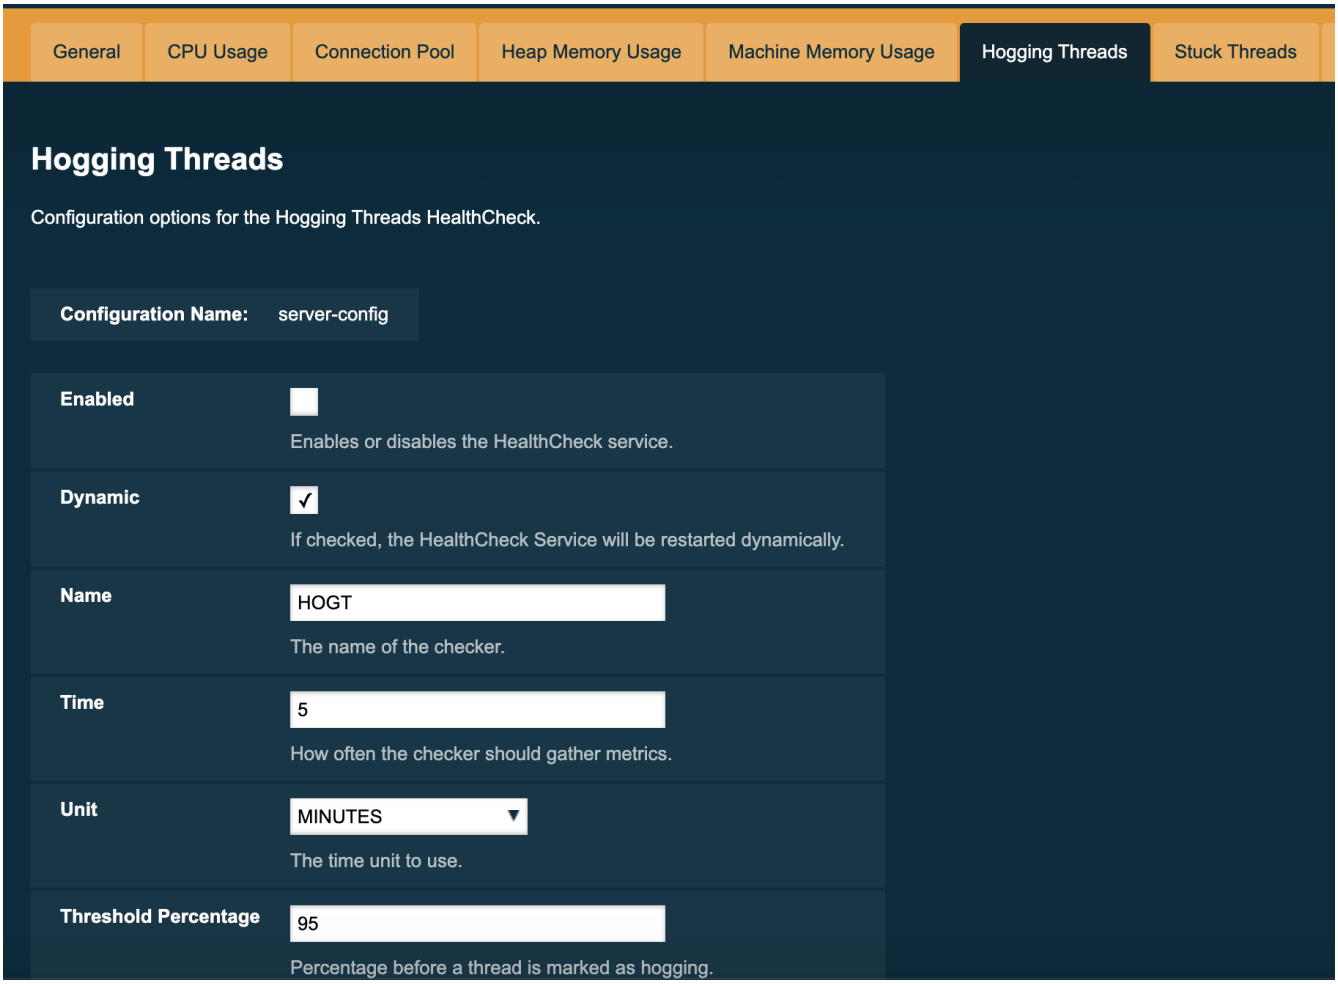
```
Health Check notification with severity level: WARNING - CPUC:Health Check
Result:[[status=WARNING, message='CPU%: 76.8, Time CPU used: 171 milliseconds'']']
```

Special HealthCheck Service Checkers Configuration

The **Hogging Threads** and the **Stuck Threads** checkers are special on their configuration.

They do not have a threshold range configuration, instead opting for different attributes.

Here's a configuration sample of the **Hogging Threads** checker:



The following are the attributes used to configure this checker:

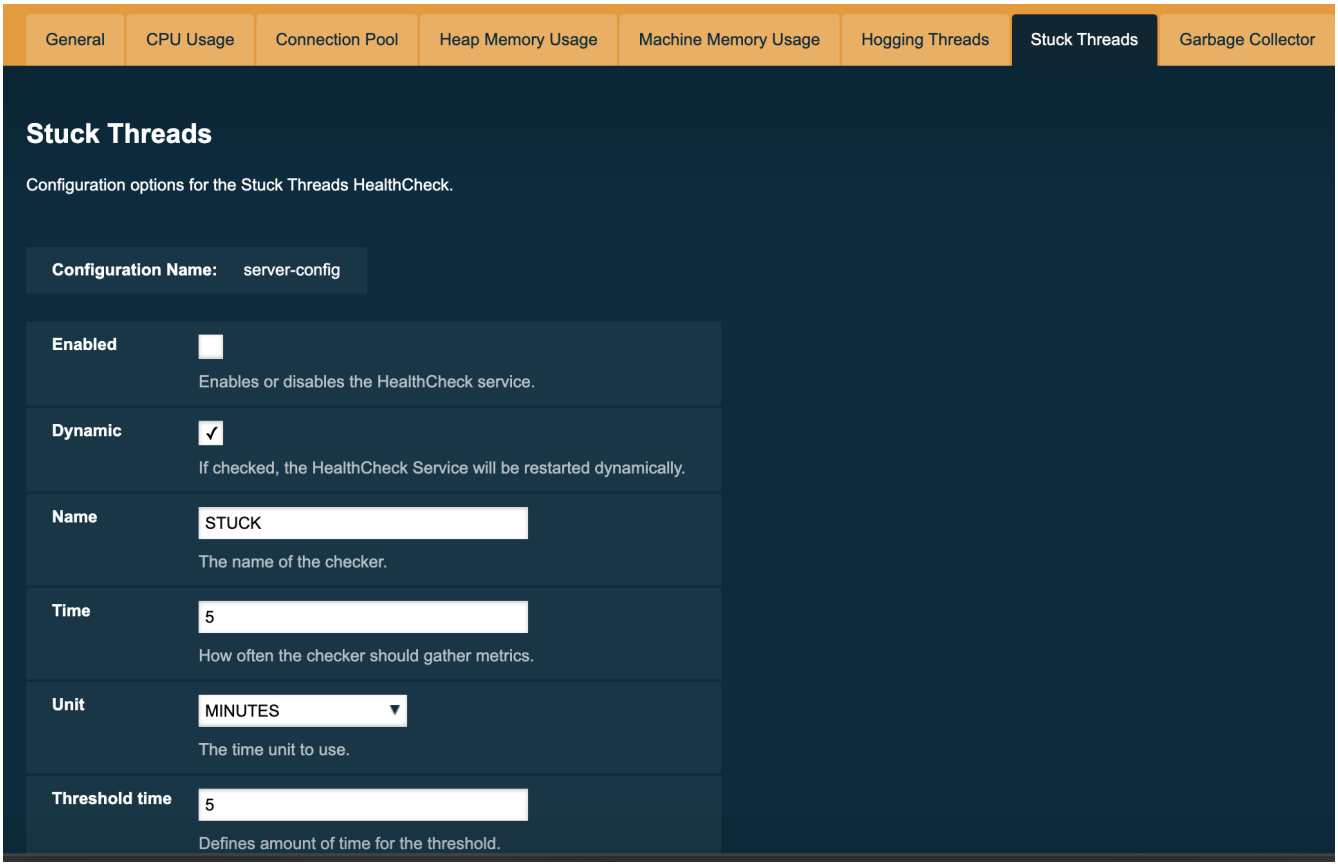
Threshold Percentage

Defines the minimum percentage needed to decide if the thread is hogged CPU-wise. The percentage is calculated with the ratio of elapsed CPU time to checker execution interval. Its default value is **95**.

Retry Count

Represents the count value that should be reached by the hogged thread in order for the service to send notifications. Its default value is **3**

And here's a configuration sample for the **Stuck Threads** checker:



The following are the attributes used to configure this checker:

Threshold Time

Defines the time value for which a thread can be non-responsive before it is considered stuck. It's default value is **5**.

Threshold Unit

Defines the time unit for the value of the **Threshold Time** field. It's default value is **Minutes**.

From the Command Line

You can configure the HealthCheck Service by using the corresponding Asadmin CLI commands.

To enable and configure the general settings of the Healthcheck service, use the `set-healthcheck-configuration` command. For example, to enable the service such that it will only activate from the next time the server is restarted and to configure the historic trace settings and notifiers used by it run the following command:

```
asadmin set-healthcheck-configuration --enabled=true --dynamic=true --historic-trace
-enabled=true --historic-trace-store-size=20 --set-notifiers=log-notifier,jms
-notifiers
```

To configure specific settings of the various performance metric service checkers, use the `set-healthcheck-service-configuration`. This command has multiple settings to configure a specific checker's sampling frequency, threshold values (where applicable) and other specific criteria to each checker service.

As an example, the following command will enable the Garbage Collector checker service and activate it without needing a server restart would be as follows:

```
asadmin set-healthcheck-service-configuration --enabled=true --service=gc
--dynamic=true
```

A more complex example would be the following command that configures the stuck threads checker to check every 30 seconds for any threads which have been stuck for more than 5 minutes:

```
asadmin set-healthcheck-service-configuration --service=st --enabled=true
--dynamic=true --time=30 --time-unit=SECONDS --stuck-threads-threshold=5 --stuck
-threads-threshold-unit=MINUTES
```

For more information and examples for how to use these Asadmin CLI commands, see the `set-healthcheck-configuration` and `set-healthcheck-service-configuration` entries in the Command Reference section.

Administering the Request Tracing Service

The Request Tracing Service provides tracing facilities for multiple protocols and process communications done by the components of deployed applications.

The service helps users to detect application slowness and performance degradation by logging requests that exceed a given threshold. The trace data from long-running requests gives insight to solving bottlenecks and other performance issues.

The following types of requests are traced if the service is enabled:

- JAX-RS endpoints (*)
- JAX-RS client calls (*)
- MicroProfile REST Client calls (*)
- Servlets (HTTP requests)
- SOAP Web Services (*)
- WebSockets
- EJB timers execution
- Inbound JMS messages received by an MDB
- JBatch jobs creation
- Tasks executed by injected Managed Executors.
- Remote Invocations of EJBs (*)

Traces of request types marked in (*) are using higher-level APIs and are also available as OpenTelemetry Spans.

Traces have form of nested spans following the model found in modern tracing APIs such as **OpenTelemetry** and **OpenTracing**.

The OpenTracing specification, found here, gives a more detailed description of what Spans are and the general trace format. Alternatively you can view a short summary here

The Request Tracing service has the concept of sample rates, affording you extra options to limit the amount of traces processed. The Payara Platform offers two options:

- **Flat probability sampling**, which simply applies a percentage chance that a trace will not be traced.
- An **adaptive solution**, which allows you to configure a target number of traces to sample over a given time period (e.g. sample 6 traces every 10 minutes).

An option to perform this sampling before or after the threshold checks is offered, allowing you to either determine if a trace should be sampled at its inception, or only after determining that a trace has breached your configured thresholds respectively.

OpenTelemetry Support

As Payara Platform offers support for MicroProfile Telemetry, it is possible to manually instrument your application code for creating spans.

For the full details, see the OpenTelemetry support in the Payara Platform Application Development section.

OpenTracing Support

In-line with Payara Platform's support for link:/Technical Documentation/MicroProfile/OpenTracing.adoc[MicroProfile OpenTracing,role=unresolved], there's added support for OpenTracing.io code instrumentation.

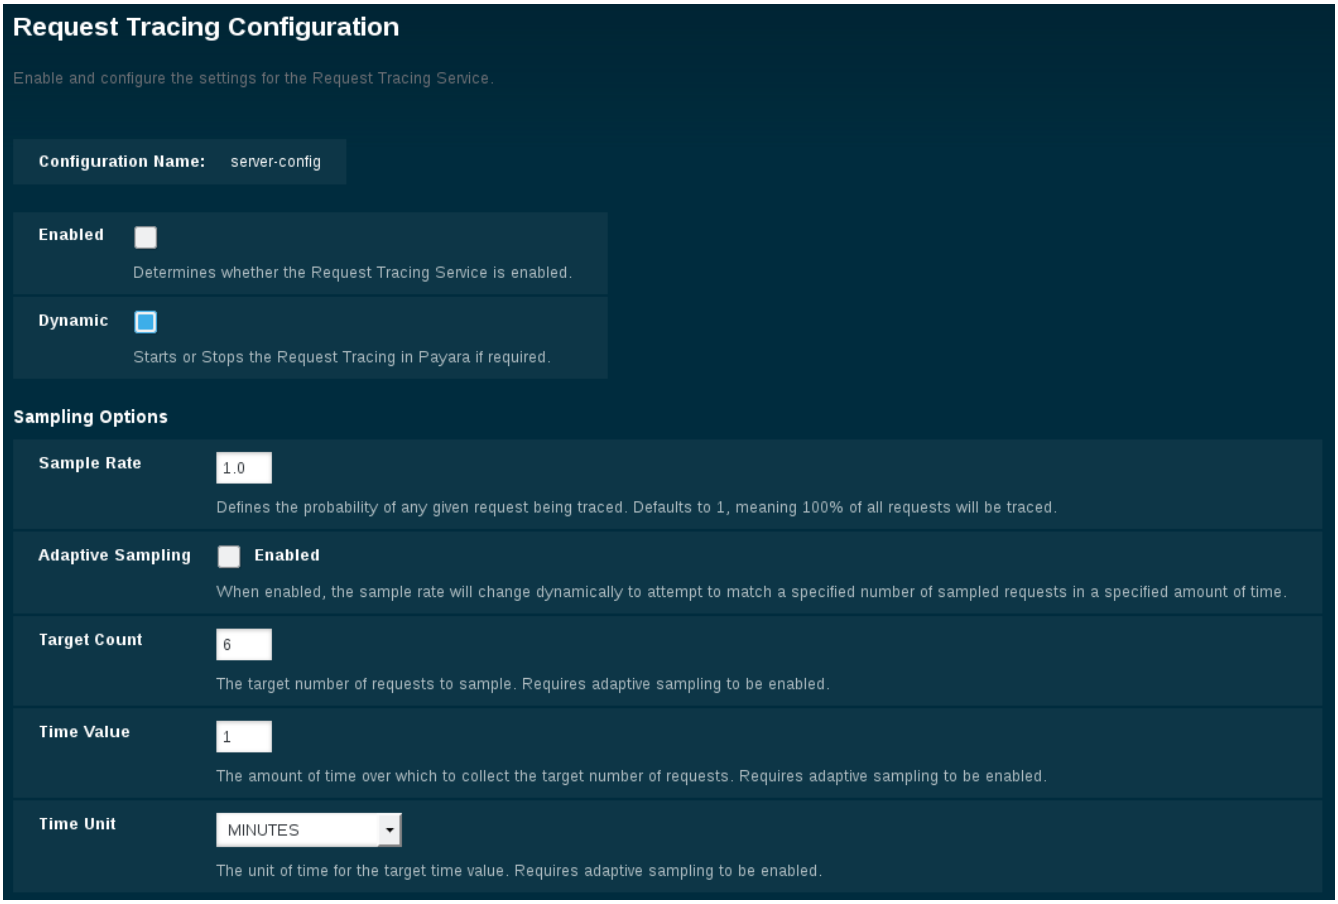
Since OpenTracing is just a wrapper around OpenTelemetry, it is advised to use OpenTelemetry APIs instead.

Configuration

As with any other services available in Payara Server, the Request Tracing service can be configured by using the Admin Console or via the Asadmin CLI.

Using the Web Administration Console

To configure the Request Tracing Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Request Tracing*:



Check the **Enabled** box (and the **Dynamic** box too if you don't want to restart the domain) to switch the request tracing service on.

You can configure the request tracing service settings using the following attributes:

Sample Rate

This defines the percentage chance of a trace being sampled (as in, not discarded). This accepts a value between 0 and 1, with a value of 1 meaning 100% of traces are sampled.

Adaptive Sampling

This option is an alternative to using Sample Rate, allowing the sample rate to change in accordance with how many traces are being sampled over a period of time.

Target Count

This defines the number of sampled traces that the adaptive sampling shall attempt to hit over a period of time.

Time Value

This defines the period of time that the adaptive sampling will try to hit the *Target Count* in.

Time Unit

This defines the time unit of the *Time Value* attribute.

Applications Only

When enabled, traces that originate from outside deployed applications (e.g. the Admin Console) will not be sampled.

Threshold Value

This defines the number of units beyond which a request will be traced.

Threshold Unit

This defines the time duration per unit. The accepted options are any valid java.util.concurrent.TimeUnit values. The default value is *SECONDS*.

Sample Rate First

When enabled, the sample rate will be checked as a trace begins, meaning that traces that would have broken the thresholds are potentially discarded. When disabled, the sample rate is checked after a trace has completed, meaning that you're only sampling traces that have breached your threshold values. Having this disabled will potentially give more accurate trace data, at the expense of a small extra performance overhead.

Reservoir Sampling

When disabled, the trace stores will contain the longest request traces. When enabled, the chance of any sampled request being in the trace stores becomes constant. Note that this applies to both trace stores in most circumstances it doesn't make sense to have this enabled if *Store Historic Traces* is also enabled.

Trace Store Size

The maximum number of traces to be stored in the local rolling trace store. A store shared in a cluster uses the maximum setting of this property of any instance in the cluster with request tracing enabled.

Trace Store Timeout

The timeout value for when traces will be removed from the rolling trace store. This is ignored when reservoir sampling is enabled.

Store Historic Traces

When enabled, a second trace store is created to store the longest historical request traces.

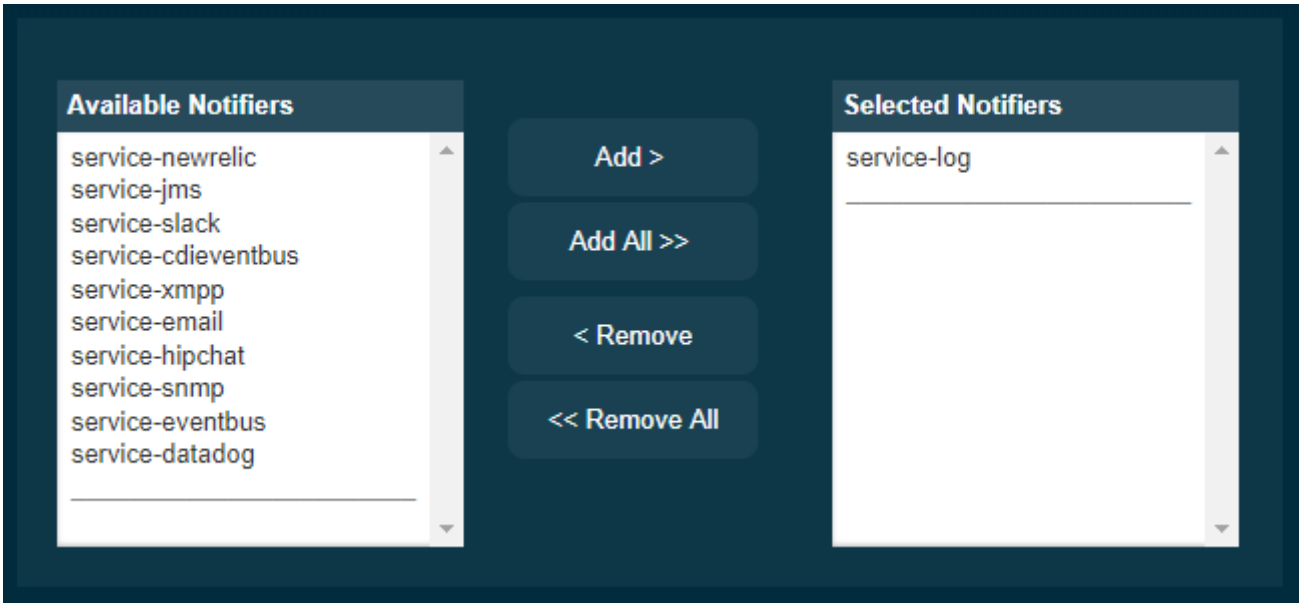
Historic Trace Store Size

Determines the number of historical trace events that can be stored in memory when historical storing is enabled. The default value is **20** records. A store shared in a cluster uses the maximum setting of this property of any instance in the cluster with request tracing enabled.

Historic Trace Store Timeout

Determines how long before Request Tracing messages are removed. This field is specified in the format "%d %h %m %s" where % is an integer. Any of the units can also be omitted.

Aside from this configuration settings, you can also define which notifiers will be used to relay the request tracing events by moving them to the **Selected Notifiers** box.



Keep in mind that for request tracing events to be relayed to the selected notifiers, both the Notification Service and each respective notifier must be enabled first.

You don't need to manually add each notifier on this screen. When enabling a notifier on its configuration screen, the server will **automatically** add it to the list of selected notifiers for the Request Tracing service. This same result occurs when enabling the notifier using the appropriate *asadmin* command.

From the Command Line

You can configure the Request Tracing Service by using these administrations commands:

- `get-requesttracing-configuration`
- `set-requesttracing-configuration`

Administering the Notification Service

Payara Server comes with a general Notification service that can be used to log events which come from other services, such as the Monitoring Service, the HealthCheck service or the Request Tracing Service.

Notification Service Configuration Commands

The following Asadmin CLI subcommands can be used to configure the notification service in general:

- `notification-configure`
- `list-notifiers`
- `get-notification-configuration`
- `set-notification-configuration`

Notifiers

The Notification service provides the ability to disseminate notification events through various channels or **notifiers**, which relay them to different destinations.

Filtering

All notifiers make use of a filtering system to accept or ignore notification events. Events are emitted with a severity level of `INFO`, `WARNING`, or `SEVERE`. Notifiers may be individually configured to filter out events which are below a certain severity level.

A notifier with a filter level of `WARNING` (the default) will disregard events at the `INFO` level, and accept event at the `WARNING` and `SEVERE` levels.

The following is a list of the default set of notifiers available in Payara Server.

Log Notifier

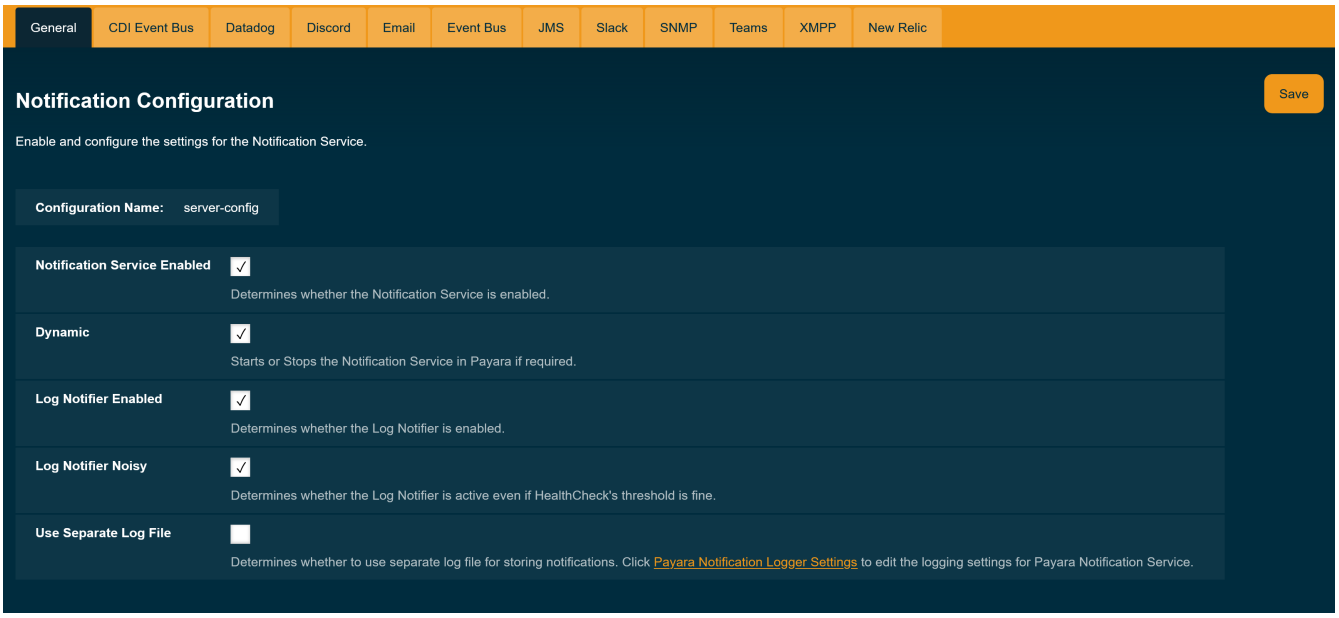
The log notifier is the only notifier that is enabled by default when the notification service is activated.

The default output for the log notifier is the configured instance's log file, which is either the *server.log* file or *cluster.log* file, depending on the instance configuration.

The log notifier only handles the output of notifications from the notification service sent to the log and is not responsible for any other log output.

Configuration

Because the log notifier is the default notifier for the notification service it can be configured on the same page as the notification service, as shown in the image below:



For any new domain, the notification service will be disabled by default. It can be enabled through the admin console as shown above, or via the Asadmin CLI.

To configure the log notifier through the Asadmin CLI, use the `set-log-notifier-configuration` subcommand:

```
asadmin> set-log-notifier-configuration --enabled=true --dynamic=true
```

To get the current configuration of the log notifier, use the `get-log-notifier-configuration` subcommand:

```
asadmin> get-log-notifier-configuration

Enabled  Filter   Use Separate Log File
true     WARNING  false
Command get-log-notifier-configuration executed successfully.
```

See Notification Logging for more information on how to configure specific details of the server logging settings.

JMS Notifier

The JMS notifier makes use of a JMS queue to send notification events via standard Java messages. These messages can then be consumed by a Message Driven Bean or any other JMS compatible client implementation.

Requirements

To use JMS as a notification target, you will need the following a JMS-compatible message broker.

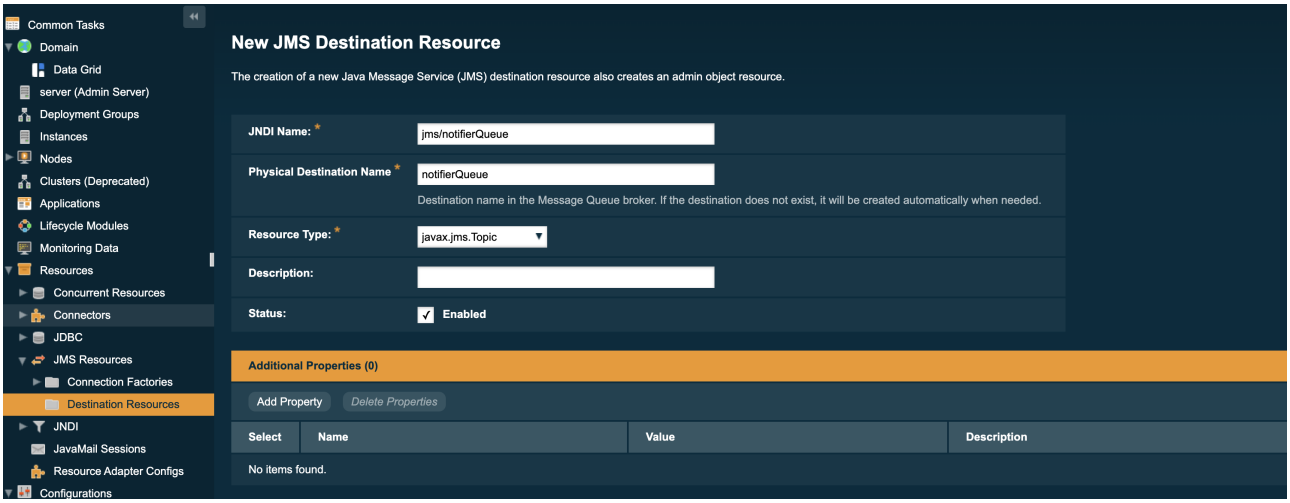
The Payara Server Web Profile distribution does not come with JMS capabilities, so this notifier isn't supported in this profile.

The easiest way to configure the JMS notifier is to use the embedded OpenMQ broker, since Payara Server already comes with it by default.

JMS Notifier Configuration

The notifier configuration requires following a few steps:

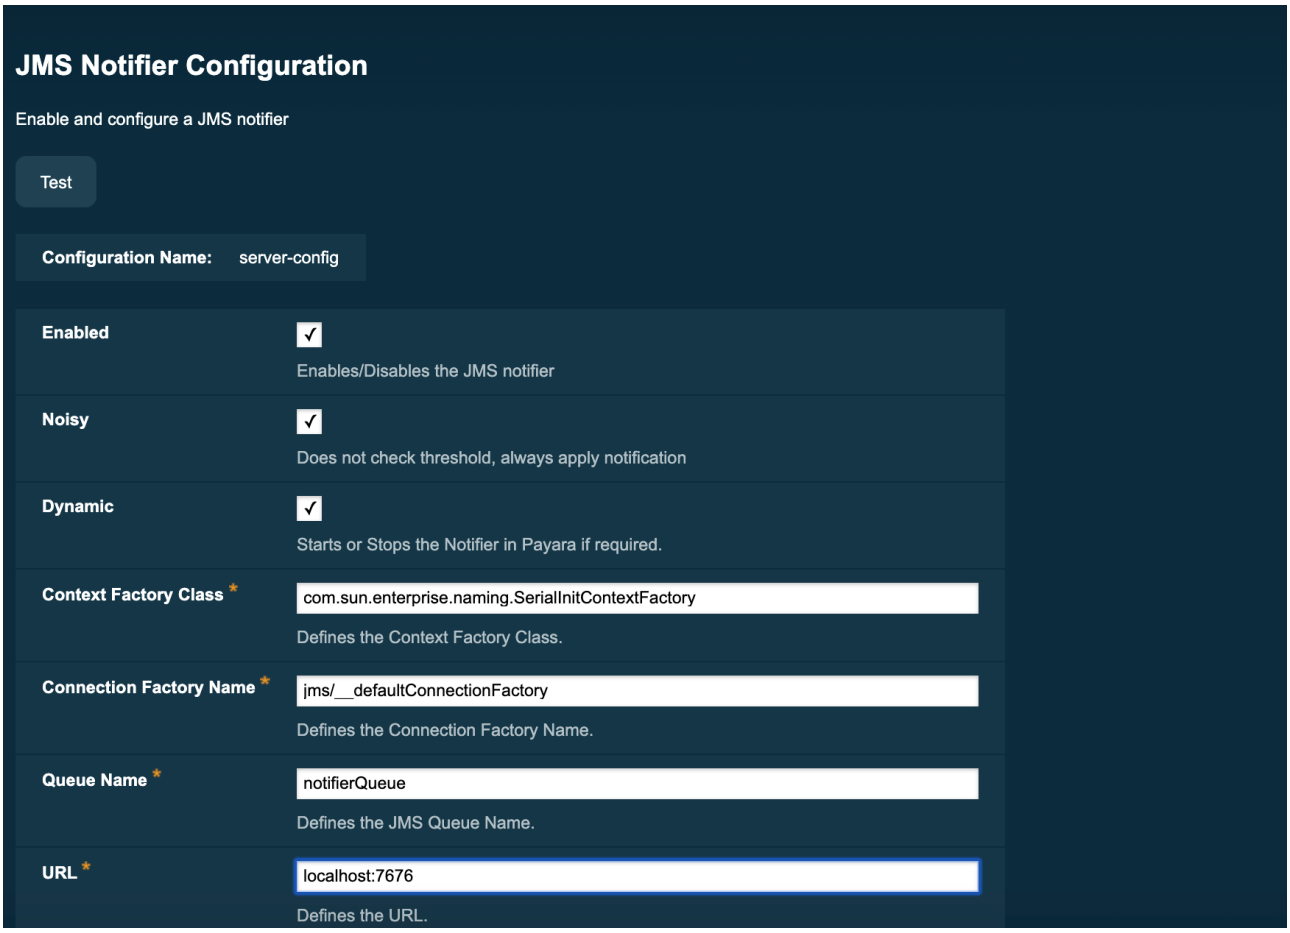
1. Create a new **JMS Queue** to receive the notification messages from the notifier:



To make this change via the Asadmin CLI, use the following subcommand which mirrors the above screenshot:

```
asadmin create-jms-resource --enabled=true --property=Name=notifierQueue
--restype=jakarta.jms.queue jms/notifierQueue
```

2. Set the JMS Notifier settings:



The above example uses the embedded OpenMQ broker's default configuration.

To make this change via the Asadmin CLI, use the following command which mirrors the above screenshot:

```
asadmin set-jms-notifier-configuration --dynamic=true --enabled=true
--contextFactoryClass=com.sun.enterprise.naming.SerialInitContextFactory
--target=server-config --queueName=notifierQueue --url=localhost:7676
--connectionFactoryName=jms/_defaultConnectionFactory
```

Verifying the Configuration

For verification purposes, it may be useful to enable a service to push notifications through the JMS notifier to demonstrate that it is working. To do this, you will also need to set up a Message-Driven Bean (MDB) to consume the notifications and demonstrate that they are being stored in the queue.

1. To consume the messages using a Jakarta Messaging compliant MDB, the following class will work for a pre-configured queue named `notifierQueue`:

```
@MessageDriven(activationConfig = {
    @ActivationConfigProperty(propertyName = "destinationLookup", propertyValue =
"jms/notifierQueue"),
    @ActivationConfigProperty(propertyName = "destinationType", propertyValue =
"jakarta.jms.Queue"),
    @ActivationConfigProperty(propertyName = "destination", propertyValue =
"notifierQueue"),
})
public class NotificationConsumer implements MessageListener {

    @Override
    public void onMessage(Message message) {
        try {
            System.out.println("Message received: " +
message.getBody(String.class));
        } catch (JMSException ex) {}
    }
}
```

2. View the result of the MessageDrivenBean's `onMessage()` command. In this example, the CPU metric of the health check service was configured to notify every *5 seconds*, so the result of simply printing to `System.out` is following log entries:

```
[2017-02-24T14:25:02.019+0000] [INFO] []
[fish.payara.nucleus.healthcheck.HealthCheckService] [tid: _ThreadID=151
_ThreadName=admin-thread-pool::admin-listener(9)] [timeMillis: 1487946302019]
[levelValue: 800] [[Scheduling Health Check for task: CPUC]]

[2017-02-24T14:25:02.019+0000] [INFO] []
[fish.payara.nucleus.healthcheck.HealthCheckService] [tid: _ThreadID=151
_ThreadName=admin-thread-pool::admin-listener(9)] [timeMillis: 1487946302019]
[levelValue: 800] [[Payara Health Check Service Started.]]

[2017-02-24T14:25:02.376+0000] [INFO] [] [] [tid: _ThreadID=48 _ThreadName=p:
```

```
thread-pool-1; w: 3] [timeMillis: 1487946302376] [levelValue: 800] [[Message
received: Health Check notification with severity level: INFO. (host:mike-payara,
server:server, domain:domain1,instance:server) CPUC:Health Check
Result:[[status=GOOD, message='CPU%: 1.45, Time CPU used: 3 seconds 797
milliseconds'']']]]

[2017-02-24T14:25:02.380+0000] [INFO] [] [] [tid: _ThreadID=50 _ThreadName=p:
thread-pool-1; w: 5] [timeMillis: 1487946302380] [levelValue: 800] [[Message
received: Health Check notification with severity level: SEVERE. (host:mike-payara,
server:server, domain:domain1,instance:server) CPUC:Health Check
Result:[[status=CRITICAL, message='CPU%: 109.71, Time CPU used: 7
milliseconds'']']]]
```

Asadmin Commands

Set the JMS notifier configuration

To set the JMS notifier configuration, the following asadmin command will reflect the configuration done in the previous section:

```
asadmin set-jms-notifier-configuration --dynamic=true --enabled=true
  --contextFactoryClass=com.sun.enterprise.naming.SerialInitContextFactory
  --connectionFactoryName=jms/__defaultConnectionFactory
  --queueName=notifierQueue
  --url=localhost:7676
  --username=****
  --password=****
  --target=server-config
```

Get the JMS notifier configuration

To get the JMS notifier configuration using the Asadmin CLI, run the following command:

```
asadmin> get-jms-notifier-configuration

Enabled  Filter   Context Factory Class  Connection Factory Name  Queue Name  URL
Username  Password
true     WARNING  com.sun.enterprise.naming.SerialInitContextFactory
jms/__defaultConnectionFactory  notifierQueue  localhost:7676  myusername  mypassword
Command get-jms-notifier-configuration executed successfully.
```

Troubleshooting

When you have correctly configured the JMS notifier, it can be used to push notifications to your configured queue.

If you do not see any notifications, check the following:

- Is your MDB or other JMS client correctly configured to consume messages from the correct queue? (e.g. check for typos)
- Are the JMS queue details correctly set up in the notifier configuration? (check the server.log for errors)
- Is the JMS queue available? If you have configured your own JMS broker, is it responding? If the broker is remote, check that it is reachable.
- Is the service using the notifier configured to send notifications frequently enough to observe?
- Is the service using the notifier correctly configured and also enabled?

Event Bus Notifier

The Event Bus Notifier provides a way to send notifications from the notification service into the internal Payara Server event bus, which is based on Hazelcast distributed topics.

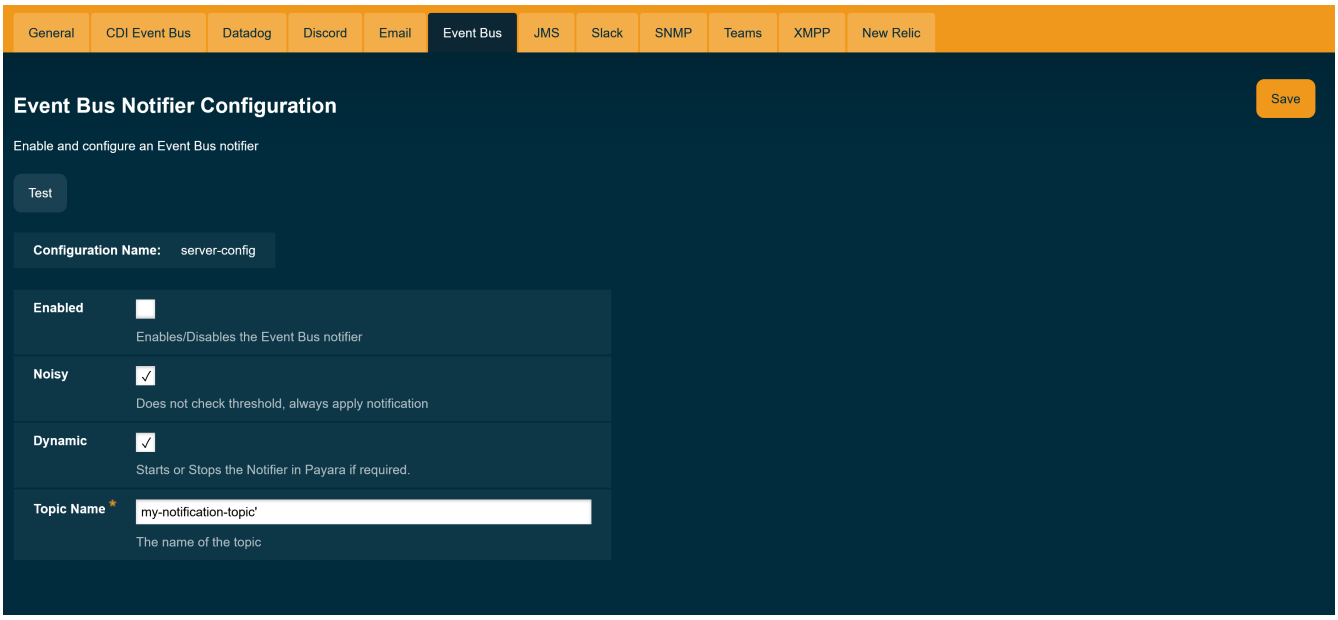
Notifications sent to the internal event bus using this notifier are intended to be received by internal server components and not by user applications.
Currently, no built-in internal components consume event bus notifications yet and there are no available APIs that allow applications to consume these events.

The Data Grid must be enabled for the Event Bus to be available.

Event Bus Notifier Configuration

This notifier provides only one configuration option, the **Topic Name**, which is mandatory.

In the Admin Console, simply set the **Topic Name** to a desired name, which will be used to set up the Hazelcast topic that will receive the notifications.



Make sure that the "Enabled" box is ticked so that the notifier will be used. If you would like the changes to take effect without needing a restart, tick the "Dynamic" box as well.

To make these changes via the Asadmin CLI, use the following subcommand:

```
asadmin set-eventbus-notifier-configuration --topicName=my-topic --dynamic=true
--enabled=true
```

To check the current applied configuration from asadmin, run the command:

```
asadmin get-eventbus-notifier-configuration

Enabled  Filter   Topic Name
false    WARNING  payara.notification.event

Command get-eventbus-notifier-configuration executed successfully.
```

CDI Event Bus Notifier

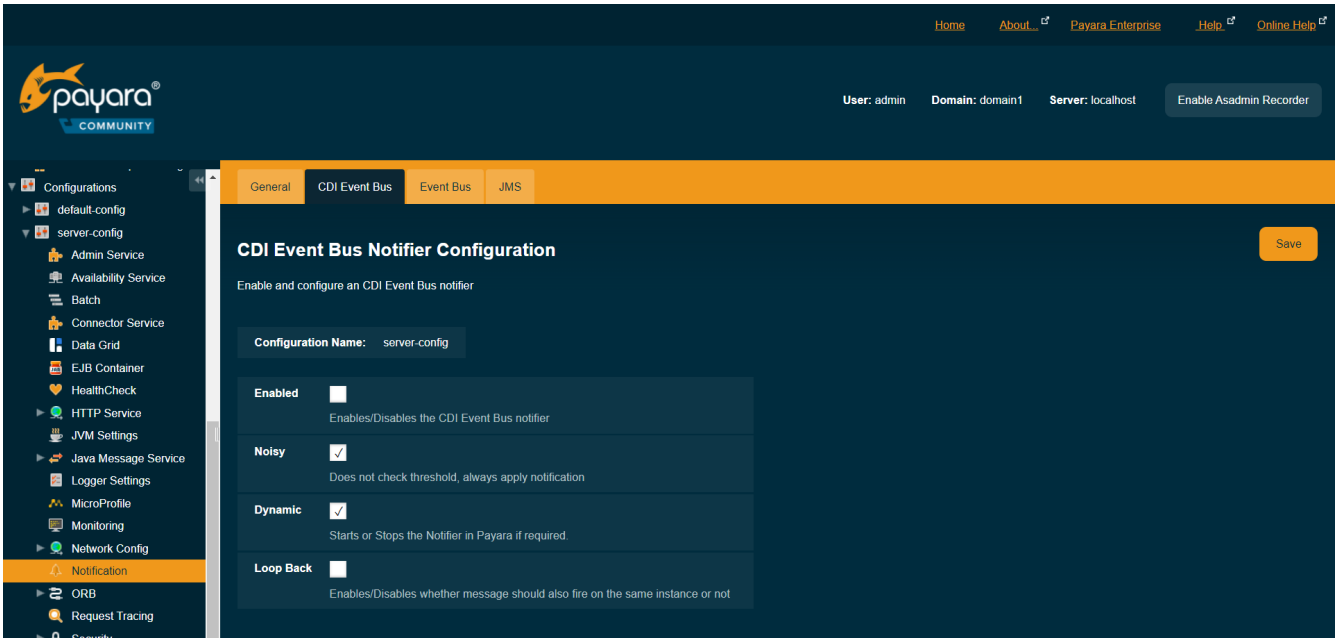
The CDI Event Bus notifier provides a way to send notifications from the notification service into the internal Payara Server's CDI Event bus.

These notifications consist of CDI asynchronous events that can be consumed by user applications with valid CDI beans set up as listeners.

The Data Grid must be enabled for the CDI Event Bus to be available.

CDI Event Bus Notifier Configuration

You can configure the CDI Event Bus notifier from the Admin Console like this:



The following options are available:

`Enabled`

Enables/disables the notifier.

`Dynamic`

Applies changes to the notifier without a server restart.

`Loop Back`

Whether events should also be observed on the same instance that triggered the instance or not.

To make these changes via the Asadmin CLI, use the following subcommand:

```
asadmin> set-cdieventbus-notifier-configuration --loopBack=true --dynamic=true
--enabled=true --hazelcastEnabled=true
```

To check the current applied configuration from asadmin, run the command:

```
asadmin get-cdieventbus-notifier-configuration

Enabled  Filter   Loopback
false    WARNING  false
Command get-cdieventbus-notifier-configuration executed successfully.
```

Observing Notification Events

Any application deployed to any instance in the Data Grid can observe notification events triggered by the CDI Event bus notifier.

Event messages are instances of the `EventbusMessage` class, which provides structured data about the specific event type, such as `HealthCheckNotificationData` or `RequestTracingNotificationData`. It also provides the same information in a String form in the `title` and `message` fields.

Notification events can be observed as a standard `@Inbound` CDI event of type `EventbusMessage` or its super-types:

```
@RequestScoped
public class ObserverBean{

    public void observe(@Observes @Inbound EventbusMessage event) {
        var shortInfo = event.getSubject();
        var detailedMessage = event.getMessage();

        var domainName = event.getDomain();
        var sourceInstanceName = event.getInstance();

        if (event.getData() instanceof HealthCheckNotificationData) {
            Optional<HealthCheckResultEntry> mostCritical = event.getData()
            .as(HealthCheckNotificationData.class).getEntries()
            .stream().sorted().findFirst();
        }
    }
```

```
}
```

For an application to use the `Inbound` annotation and `EventbusMessage` class, it will have to define the link:/Technical Documentation/Public API/Overview.adoc[Payara Public API,role=unresolved] as a project dependency.

Monitoring Service Notifiers Configuration

The Monitoring service can be configured to send notifications using the notification service. This allows you to forward data from exposed MBeans to your configured notifiers.

Configuration

The Monitoring service configuration page can be found under **Configurations** → `<config-name>` → **Monitoring**.

The JMX page allows you to specify the time between notifications, how notifications will be delivered, and the MBeans which will be included within the message.

Enabling Monitoring Service

To configure notification settings for JMX Monitoring, you will need to enable it. Have a look at How To Enable JMX Monitoring

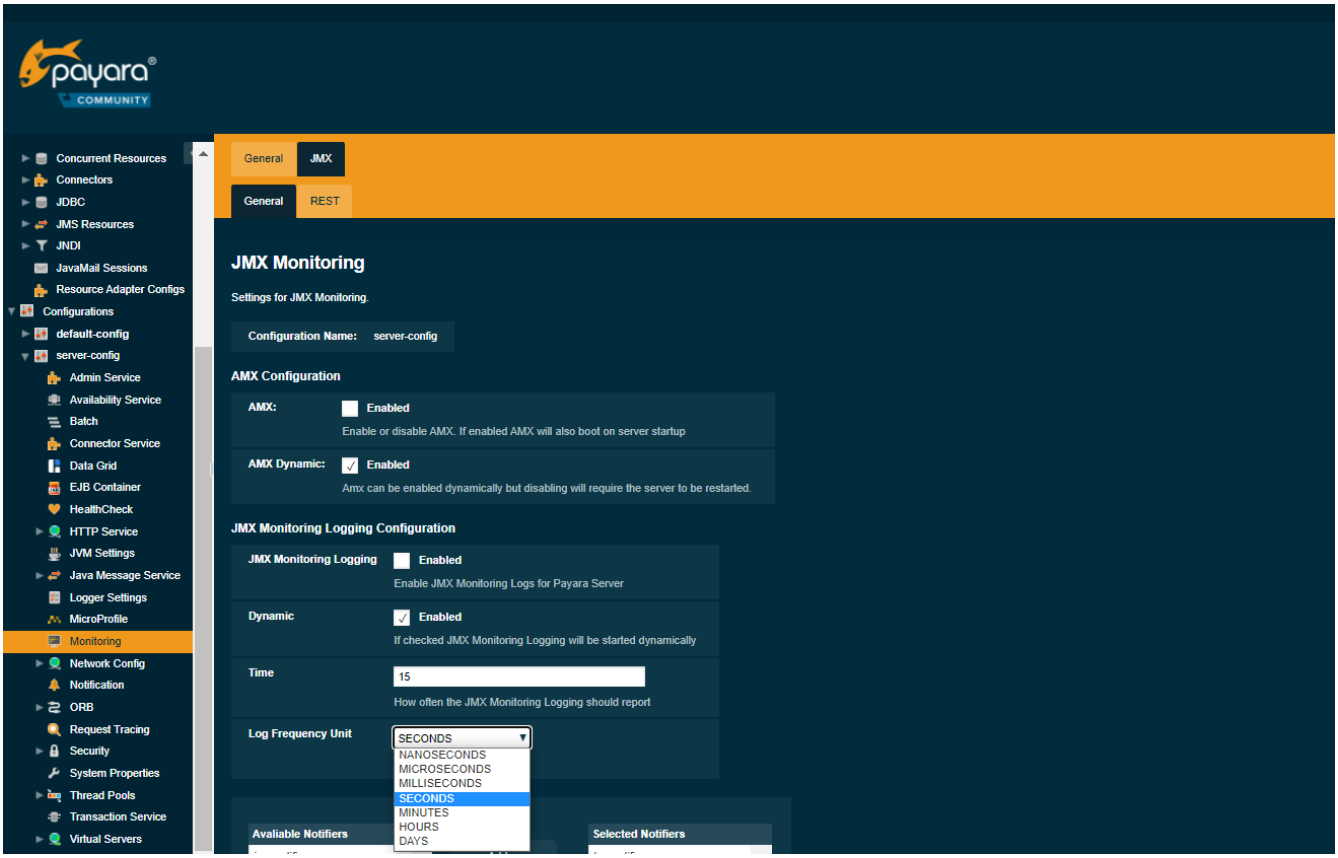
You will need some MBean attributes configured for anything to be logged by the notifiers.

JMX monitoring notifications can be done through the Admin Console or asadmin commands.

Configuring JMX Monitoring Time via the Admin Console

To configure the frequency of logged data, enter both the intended frequency of logs and the unit of time.

For example, to log every 30 milliseconds:



Configuring JMX Monitoring Time via Asadmin CLI

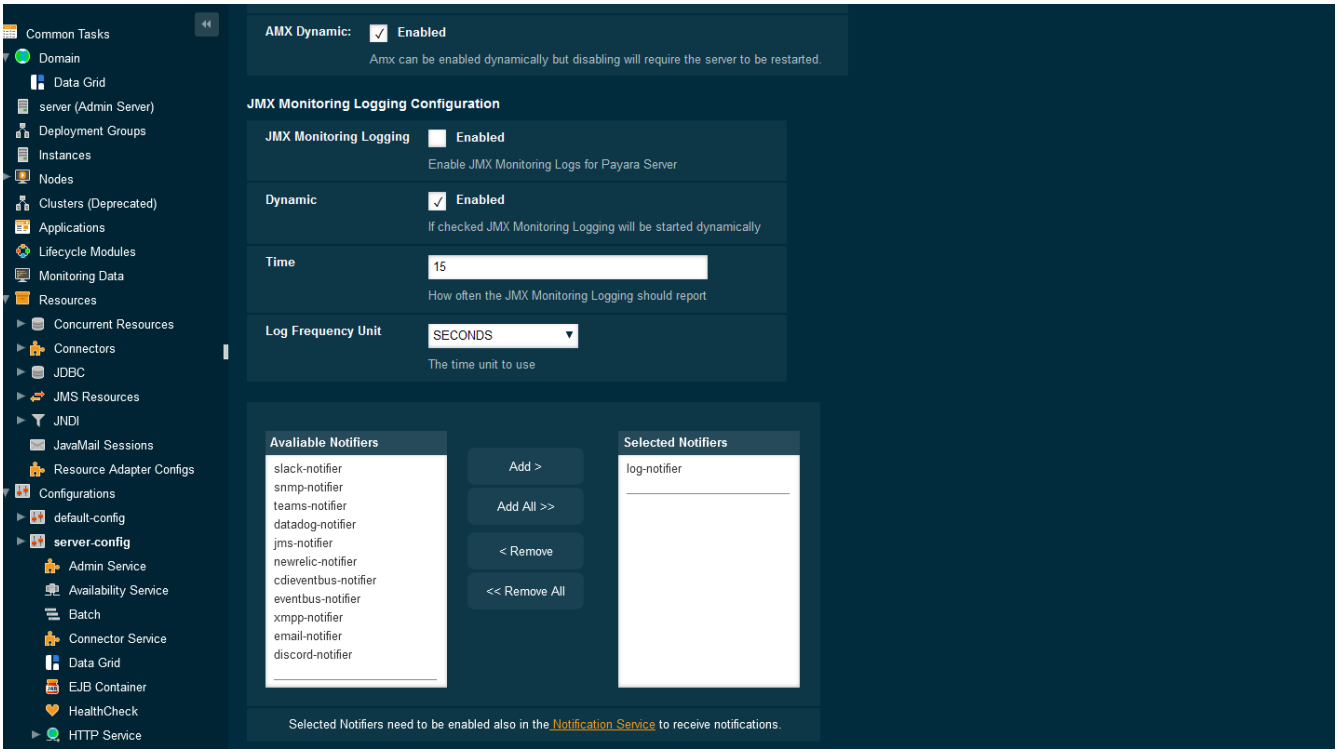
To configure the data logging frequency via asadmin, use the following command:

```
asadmin> set-jmx-monitoring-configuration --logfrequency <frequency>
--logfrequencyunit NANOSECONDS|MICROSECONDS|MILLISECONDS|SECONDS|MINUTES|HOURS|DAYS
```

Adding Notifiers via the Admin Console

Before you receive notifications from your chosen notifier, please ensure that you have configured the notification service beforehand.

To select notifiers to use for JMX Monitoring, hold the `CTRL` or `SHIFT` key to select multiple notifiers, and then click `Add >`.



Adding Notifiers via asadmin

For each notifier you wish to enable use the following command:

```
asadmin set-jmx-monitoring-configuration --setNotifiers=log-notifier,jms
-notifier,cdieventbus-notifier --dynamic=true
```

By using the `setNotifiers` option, you can set the current list of notifiers updated by the Monitoring service.

You can get the list of all available notifiers by using the `list-notifiers` asadmin command.

- Logging Configuration

Extended Notification Service Details

Payara Enterprise has additional notifiers built in and ready for use with your server environment that do not require further installation. These additional notifiers are pre-installed as **extensions** in the server module layout.

If needed, notifiers can be removed from the server's environment to reduce overhead.

Notifier Extension Structure

Each notifier extension is composed of 2 parts:

The Core Module

The core module contains all the code necessary to receive notifications from the notification service and propagate them to their proposed channel. When installing this module, you'll get the admin commands to configure the notifier, as well as the ability to select that notifier in the notification sources such as Request Tracing commands and admin console pages.

The Admin Console Plugin

The admin console plugin contains all the code necessary to configure the notifier in the admin console. This is exclusively the tab in the notification service page. This module is not required for the notifier to function, but makes administrating the notifier easier.

Installing a Notifier

To install a notifier extension: download the artifacts listed on the notifier documentation page and drop them into the `as-install/modules` directory of your Payara Server installation.

You can then restart the server to see your extension activated.

Removing Notifiers

All Payara Server notifiers are included in Payara Enterprise by default, however they are fully pluggable and can be removed from your Payara Server installation.

To remove a notifier from Payara Enterprise edition, first find the relevant modules to the notifier you want to remove in `as-install/modules`. To fully remove the notifier, you should delete both the core module and the admin console plugin module files, then restart the domain.

If you change your mind in the future, you can just drop both the module files back into the `as-install/modules` directory and restart the domain for the notifier to be re-installed.

Additional Notifiers

The following notifiers are available in Payara Server Enterprise:

Email Notifier

Payara Server is able to direct notifications to a single given email address. The notifier modules are available in these locations:

- Email Notifier Core 2.0-enterprise
- Email Notifier Console Plugin 2.0-enterprise

To use this notifier the following requirements have to be met:

- A valid, configured `JavaMail` session.

Configuration

At a high level, the steps to configure the email notifier are:

1. Create a `JavaMail` Session
2. Create the notifier using the `asadmin` command or through the Admin Console

Using the admin console

You will need a `JavaMail` session to send the notifications; instructions on setting up a `JavaMail` session can be found in this section.

The email notifier is configured in the **Email** tab of the Notification Section of the server's instance configuration.

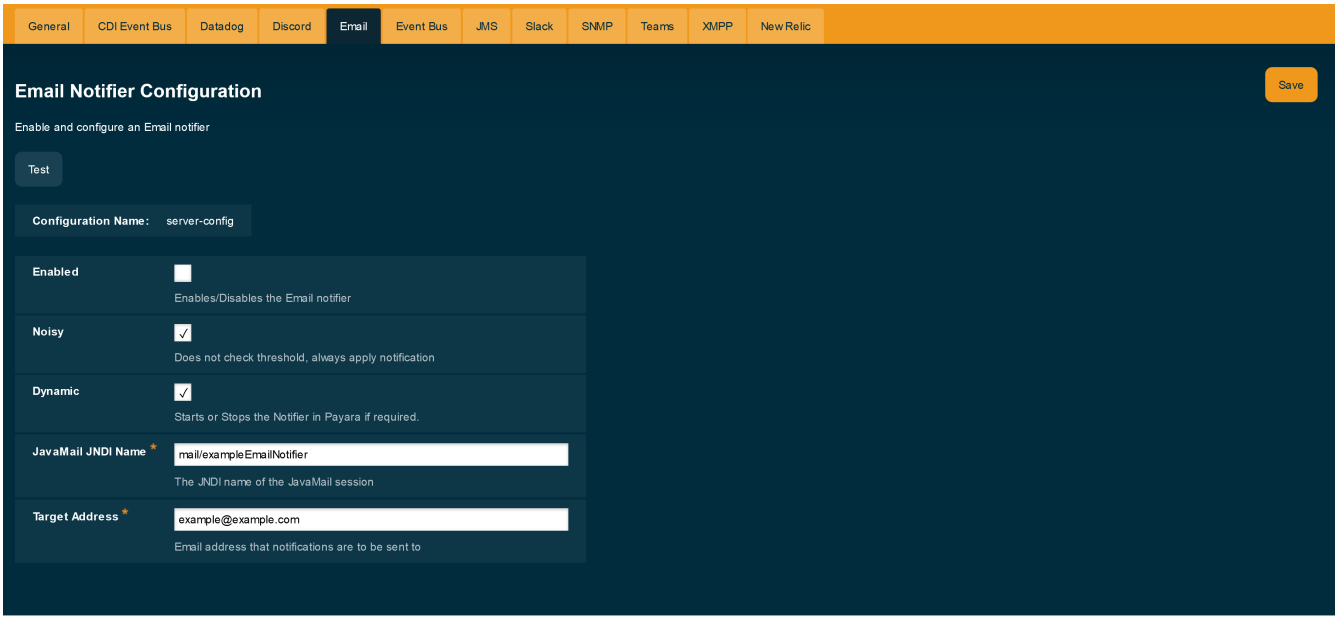
On the Email tab there are four fields:

`Enabled`
: Determines whether the notifier should be activated.

`Dynamic`
: Sets whether the notifier will be enabled without a restart, `true` enables it immediately, while `false` requires a restart.

`JavaMail JNDI Name`
: Sets the name of the Java Naming and Directory Interface (JNDI) of the configured `JavaMail` session. The parameter name is `--jndiName` in the asadmin command.

`Target Address`
: Sets the email address which will receive the email notifications. Currently only one address can be specified. The parameter name is `--recipient` in the asadmin command.



Using the Asadmin CLI

The same configuration can be set using an `asadmin` command, as shown below:

```
asadmin set-email-notifier-configuration --jndiName=mail/exampleEmailNotifier
```

```
--recipient=notifications@example.com --enabled=true --dynamic=true
```

To check the currently applied configuration, you can run the following `asadmin` command:

```
asadmin get-email-notifier-configuration
```

It will return the current configuration of the email notifier in full detail; including whether it is enabled, the recipient address, and the JNDI name of the current JavaMail session in use.

Here is an example output:

```
Enabled  JNDI Name                  Recipient
true     mail/exampleEmailNotifier  example@example.com
```

SNMP Notifier

The **S**imple **N**etwork **M**anagement **P**rotocol is a standard Internet Protocol that was designed to collect and organize information about all managed devices and services that belong to the same network. **SNMP** is supported by a huge variety of devices, including network devices like routers, modems and switches, servers and in the latter years extended to cover IoT devices and specialized equipment connected to the cloud.

The notifier modules are available in these locations:

- SNMP Notifier Core 2.0-enterprise
- SNMP Notifier Console Plugin 2.0-enterprise
- Dependency: SNMP4J 3.7.5

Use the version of SNMP4J 3.7.5 provided above as it has a modified manifest to be compatible with Payara Enterprise.

SNMP Concepts

The basic elements in every SNMP communication are the following:

Managed Component

This is the device or service that is managed and monitored by SNMP, in this specific case, Payara Server.

SNMP Agent

A specialized software that gathers data on the overall status of the managed component and exposes specific instructions over interfaces for its management. In our case, the SNMP Notifier acts as an SNMP agent.

SNMP Manager

A server machine that runs a network management system, which is configured to monitor and

manage all devices and services in a network by *"talking"* to the agents and gathering all relevant information.

The SNMP protocol works using *PDUs (Protocol Data Units)* to allow managers and agents to work with a defined set of instructions.

The notifier currently operates using the **TRAP** PDU to handle notification events.

SNMP Traps

Payara Server notifies network management systems using SNMP traps. An SNMP trap is a special PDU that is used to generate an asynchronous notification from an *agent* to a *manager*. An important point to stress with traps is that they are asynchronous events that can occur at any time, which means that a *manager* expects to receive updates in a **PASSIVE** manner, thus saving resources.

In order to correctly configure Payara Server to send traps to a manager, the following information must be reviewed in tandem with the configuration of the *manager*:

Hostname
: This is the hostname of the server where the manager software resides.

Port
: This is the UDP port where the manager software is receiving SNMP traps. By default, the protocol usually uses port **162**.

Version
: The version used by the SNMP trap.

Community
: This is the community string used to "secure" the communication to the manager

OID
: The object identifier used by the trap in order to allow the manager to correctly interpret the status of the server.

Version

Currently, the SNMP protocol is supported on three versions: **v1**, **v2c** and **v3**. Version 1 is extremely unsecure since authentication is managed only with the community string. Version 2c is an enhanced version of v1 in that improves the message formats and the protocol operations, using stronger authentication guards using the simplistic community string mechanism.

Finally, Version 3 improves security and remote management discarding the use of community strings.

Currently, the notifier configuration only supports **v1** and **v2c**, hence the need to correctly configure a community string as well. By default, all traps are configured to use **v2c**, since it's guaranteed to be supported by almost all network manager systems.

Community

The community string is used to establish trust between managers and agents. The community names are essentially passwords; most vendors ship their equipment with default community strings: `public` for a read-only community (allows reading data values, but doesn't allow modification) and `private` for the read-write community (allowed to read and modify data values). It's important to change these defaults on production environments.

The notifier configures all traps with the `public` community string by default.

OID - Object Identifier

Agents expose management data as variables composed in a structured hierarchy. SNMP does not define which variables are exposed by a managed component. Instead, SNMP uses an extensible design which allows applications and services to define their own hierarchies and other metadata (such as type and description of the variable), which are described in a **Management Information Base (MIB)**.

MIBs describe the structure of the management data of a device subsystem using a hierarchical namespace composed of Object Identifiers (OID). Each OID uniquely identifies a variable sent in the SNMP trap by the agent.

In order for a **network management system** to understand a trap sent to it by an agent, the management system must know what the OID defines. Therefore, it must have the MIB for that trap loaded in its configuration.

The default value used by the notification service is `.1.3.6.1.2.1.1.8`. This OID represents a simple octet string that is used to hold the content of the notification event.

In most cases there is no need to change the default OID, since it's verified by most of the standard MIBs included on SNMP management systems and tools.

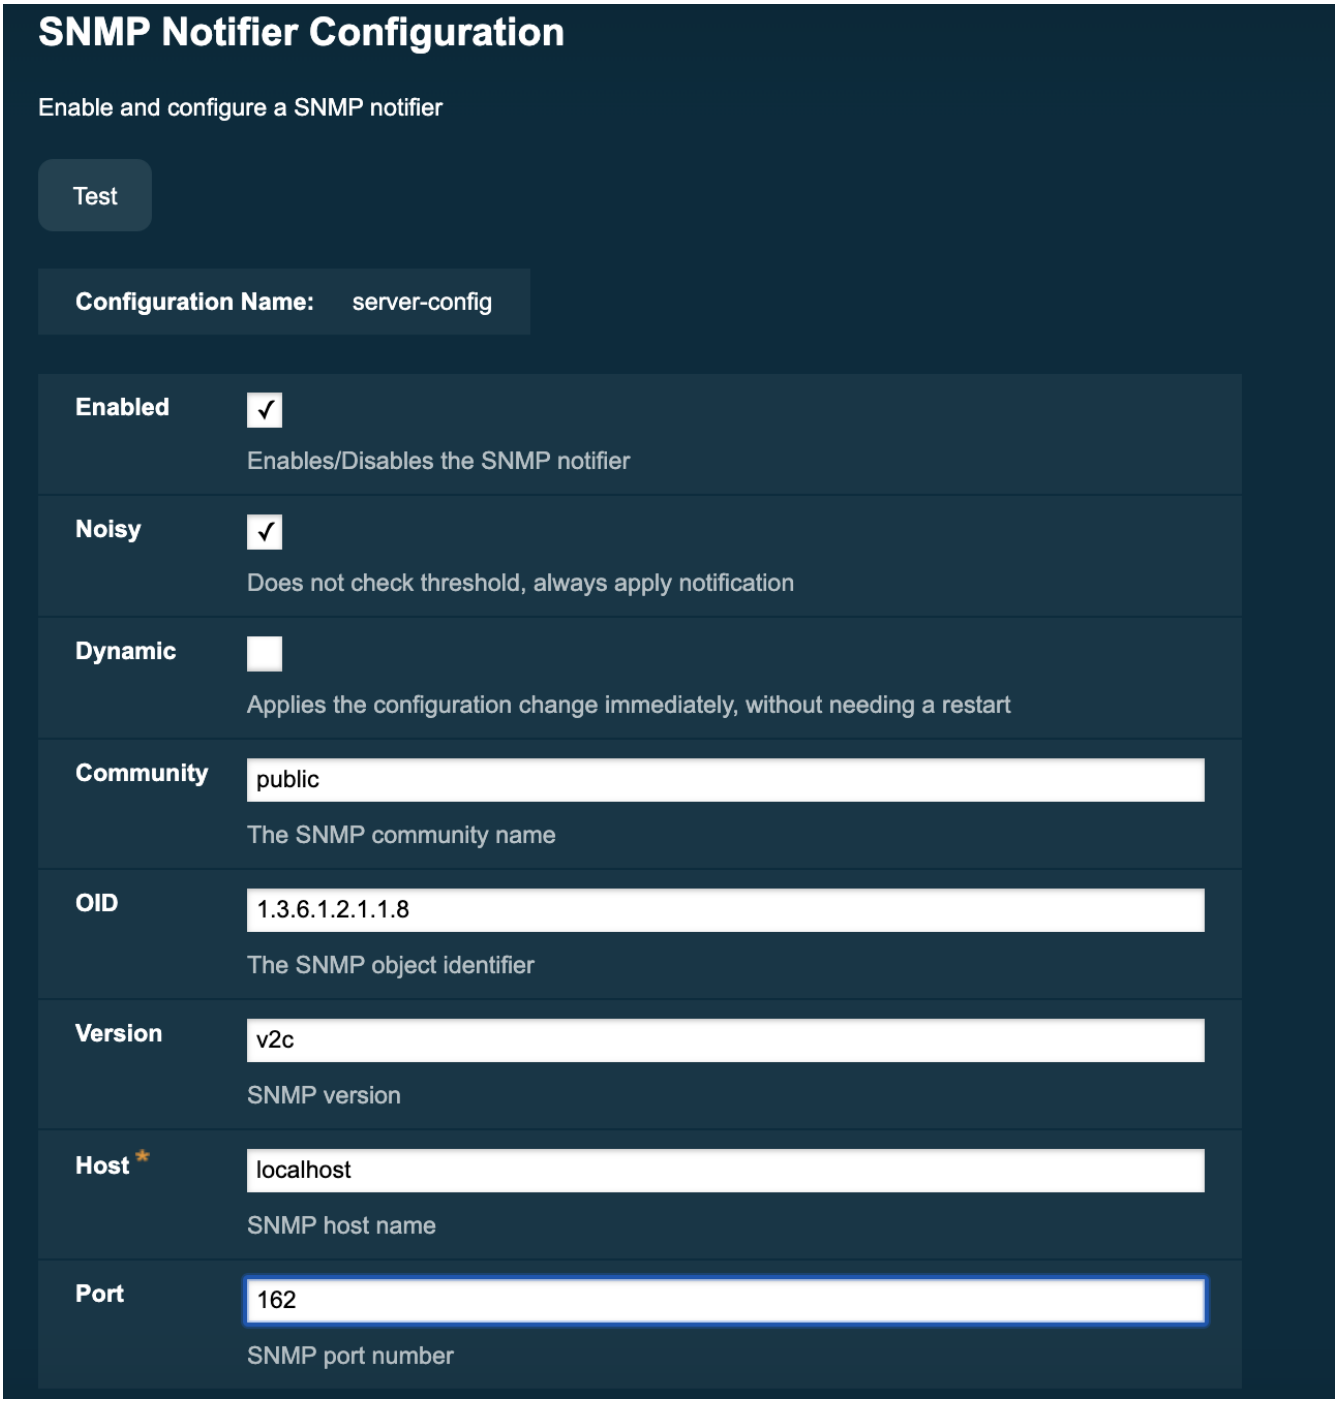
Configuration

To set up the SNMP notifier on Payara Server you need to input the values mentioned earlier in the domain configuration. As usual, you can do this using the administration web console or from the command line.

Keep in mind that the only required value to configure the notifier is the **hostname** of your network management system. All other values will assume the defaults discussed earlier if not configured explicitly.

Using the Admin Console

To configure the Notification Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Notification Service* and click on the **SNMP** tab:



Using the Asadmin CLI

To configure the Notification Service from the command line, use the `set-snmp-notifier-configuration` asadmin command like this:

```
asadmin set-snmp-notifier-configuration --enabled=true --dynamic=true
--hostname=localhost --snmpport=162 --community=public --oid=".1.3.6.1.2.1.1.8"
--version=v2c
```

You can use the `--enabled` and `--dynamic` options to enable or disable the SNMP notifier on demand.

Also, you can retrieve the current configuration for the SNMP notifier using the `get-snmp-notifier-configuration` asadmin command like this:

```
asadmin > get-snmp-notifier-configuration
```

This will return the details of the current SNMP configuration; see below for an example:

```
Enabled  Filter   Community  OID                Version  Host       SNMP Port
true     WARNING  example    .1.3.6.1.2.1.1.8   v2c      127.0.0.1  162
```

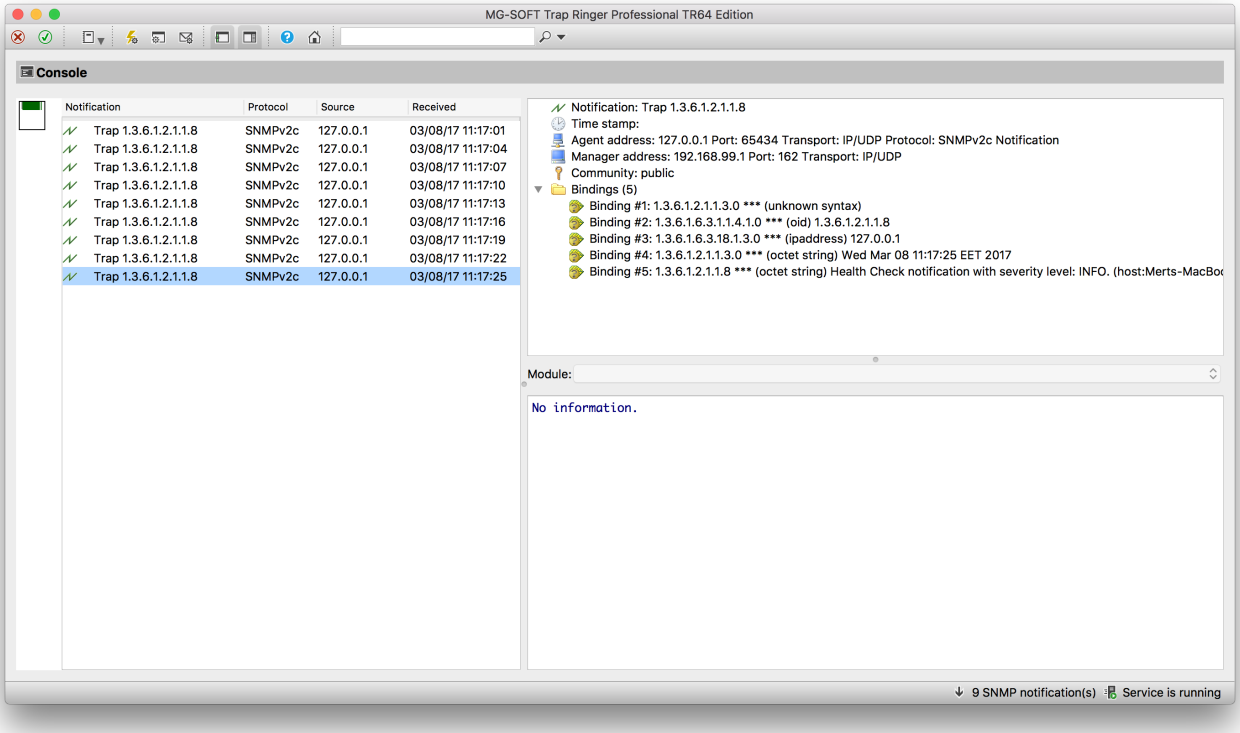
Troubleshooting

When you have correctly configured the SNMP notifier, it can be used to push notifications to your configured server. You can visualize the notification messages on your network management system of your choice.

If you do not see any notification event messages, check the following:

- Is the SNMP notifier enabled?
- Is the Notification Service itself enabled?
- Is there a service configured to use the notifier? (e.g. the HealthCheck service)
- Is the service configured to send notifications frequently enough to observe?
- Have you enabled the service after configuring it?
- Does the SNMP network management supports SNMP traps?
- Does the SNMP network management system support the configured protocol version?
- Is the community string correctly supported by the SNMP network management system?
- Are the SNMP management system's MIB correctly configured to verify traps sent with the configured OID?
- Is there a firewall between Payara Server and the network management system that is correctly configured to allow sending SNMP traps in the respective port?

Here's a sample of how the SNMP traps are visualized using MG-Soft Trap Ringer software:



New Relic Notifier

New Relic is an application performance monitoring (APM) tool that can be used to gather statistics and notify on key critical events generated by different type of applications.

New Relic specializes on integrating Java application servers like GlassFish, JBoss WildFly, etc. and other application frameworks seamlessly.

Payara Server includes a special notifier to send notifications from the Notification service to the New Relic **Insights service** using its remote API.

Custom notification events generated from Payara Server's own monitoring systems like the Request Tracing and Healthcheck services can be automatically identified by this API and gathered correctly to identify performance issues on the application server.

The notifier modules are available in these locations:

- New Relic Notifier Core 2.0-enterprise
- New Relic Notifier Console Plugin 2.0-enterprise

New Relic Configuration

In order for the notifier to work correctly, you must complete the following requirements:

1. Create a New Relic user account. You can sign up for a new account here

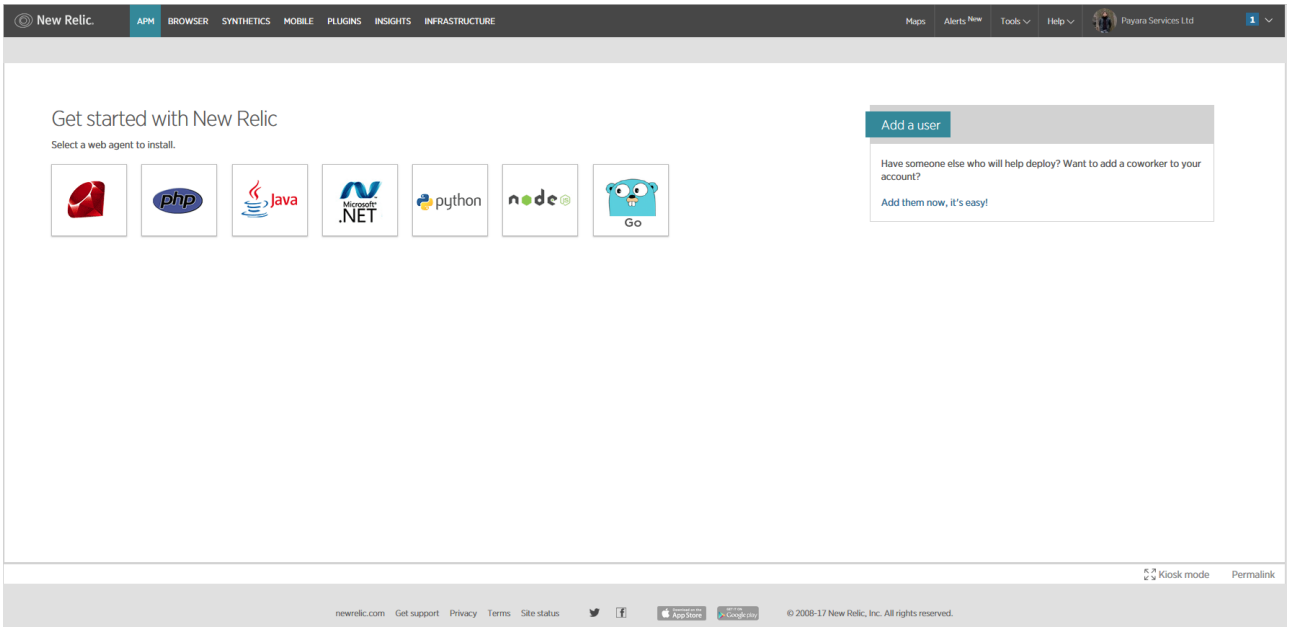
New Relic offers 14-days trial accounts that can be used to test the service for free.

2. Configure application performance monitoring (APM) for a Payara Server instance by installing a New Relic Java agent
3. Configure a New Relic Insights API key that will be used to set up the notifier.

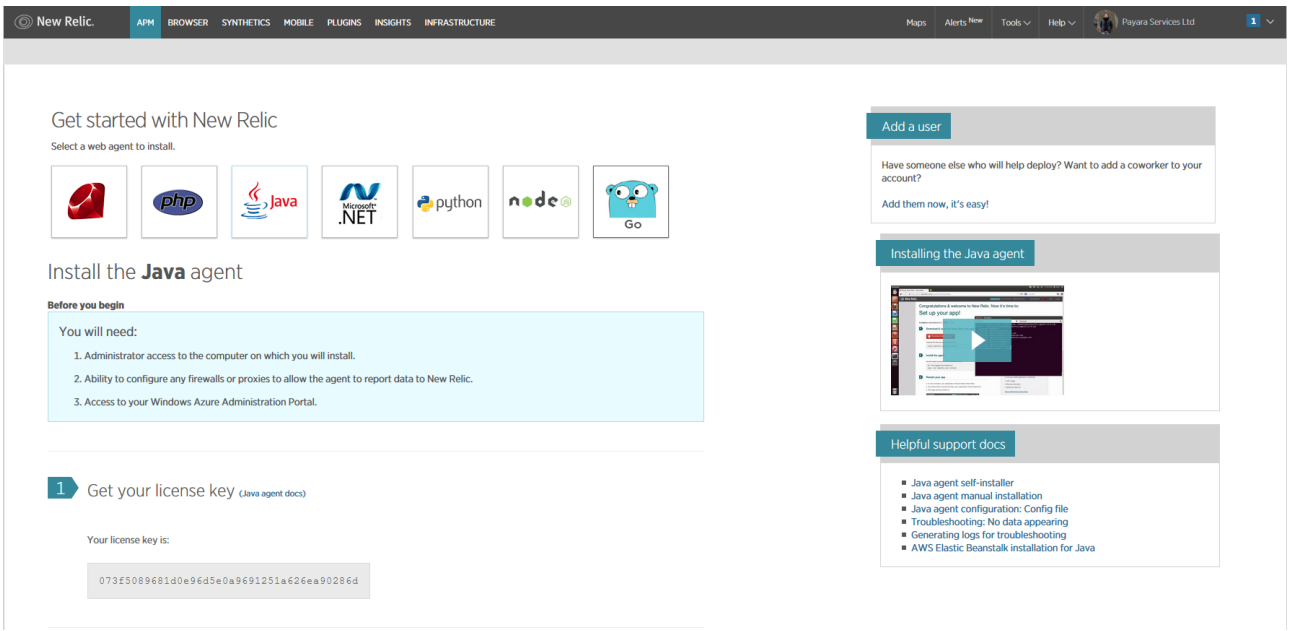
Configure Application Performance Monitoring for Payara Server

The first task is to set up the New Relic Java agent in Payara Server. To do that, follow these steps:

1. Login to New Relic with your account credentials, and if you haven't set up a monitoring agent yet, the following screen will be shown:



2. Select the **Java** option and the agent installation procedure will be shown:



From the screen shown, copy the value of the *License Key* (you need to press the **Reveal License Key** button first) since you will need it later.

3. Now, on the same screen press the **Download the Java Agent**. This will download the Java

agent files to your station. Unzip the files and copy the resulting folder to the root folder of the Payara Server domain you want to monitor.

In the following example we are copying it to the default domain `domain1`:

```
unzip newrelic-java-3.XX.X.zip
mv newrelic as-install/domains/domain1
```

4. Before proceeding to install the agent into the Payara Server domain, we need to configure the License Key we got earlier. To do this, modify the agent's configuration file that's located at `domain-dir/newrelic/newrelic.yml` by using the `license_key` property:

```
  # ...
  # This section is for settings common to all environments.
  # Do not add anything above this next line.
  common: &default_settings

    # ============================== LICENSE KEY ===============================
    # You must specify the license key associated with your New Relic
    # account. ...
    license_key: '073f5089681d0e96d5e0a9691251a626ea90286d'

    # Agent Enabled
    # Use this setting to disable the agent instead of removing it from the startup
command.
    # Default is true.
    agent_enabled: true

    # Set the name of your application as you'd like it to show up in New Relic.
    # ...
    app_name: Payara Server main-7

    # ...
```

We also recommend setting the name of the application under the `app_name` property to correctly identify this server's domain on the APM dashboard

The License Key value must be inserted using single quotes (')

1. Now, proceed to install the agent by running the following command at the root of the domain folder:

```
java -jar newrelic/newrelic.jar install
```

If the installation was successful, the output of the agent's installer will show it like this:

```
***** ( ( o))  New Relic Java Agent Installer
***** Installing version 3.39.1 ...

* Backed up start script to /opt/main-
7/glassfish/domains/domain1/config/domain.xml.20170613_180108
* Added agent switch to start script /opt/main-
7/glassfish/domains/domain1/config/domain.xml

* No need to create New Relic configuration file because:
 A config file already exists: /opt/main-
7/glassfish/domains/domain1/newrelic/newrelic.yml

***** Install successful

***** Next steps:
You\'re almost done! To see performance data for your app:

1) Restart your app server
2) Exercise your app
3) Log into http://rpm.newrelic.com

Within two minutes, your app should show up, ready to monitor and troubleshoot.
If app data doesn\'t appear, check newrelic/logs/newrelic_agent.log for errors.
```

The installer will modify the domain.xml configuration file of your server's domain and add the configuration of the Java agent as a JVM start argument:

```
<java-config classpath-suffix="" debug-options="-
agentlib:jdwp=transport=dt_socket,server=y,suspend=n,address=9009" system-
classpath="">
  <jvm-options>-javaagent:${com.sun.aas.instanceRoot}/newrelic/newrelic.jar</jvm-
options>
  <jvm-options>-server</jvm-options>
  ...
</java-config>
```

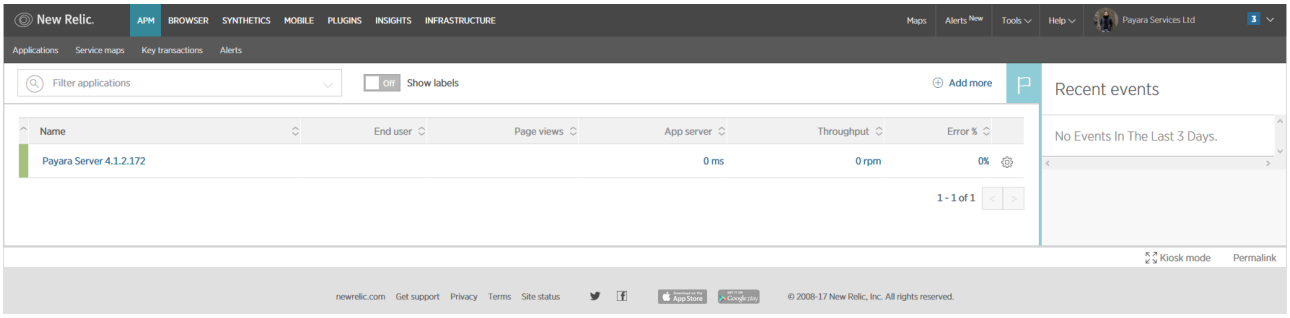
The agent setup page has a different set of instructions for Windows and Linux environments, but they are so similar that the instructions mentioned here should be sufficient.

If you are considering installing the New Relic Java agent on a Payara Server standalone instance or a cluster of multiple instances, you need to manually add the JVM (the installer won't work) option with the `javaagent` configuration to the instance/cluster referenced configuration.
Also, make sure that the directory where the *newrelic.jar* resides also contains the `newrelic.yml` configuration file

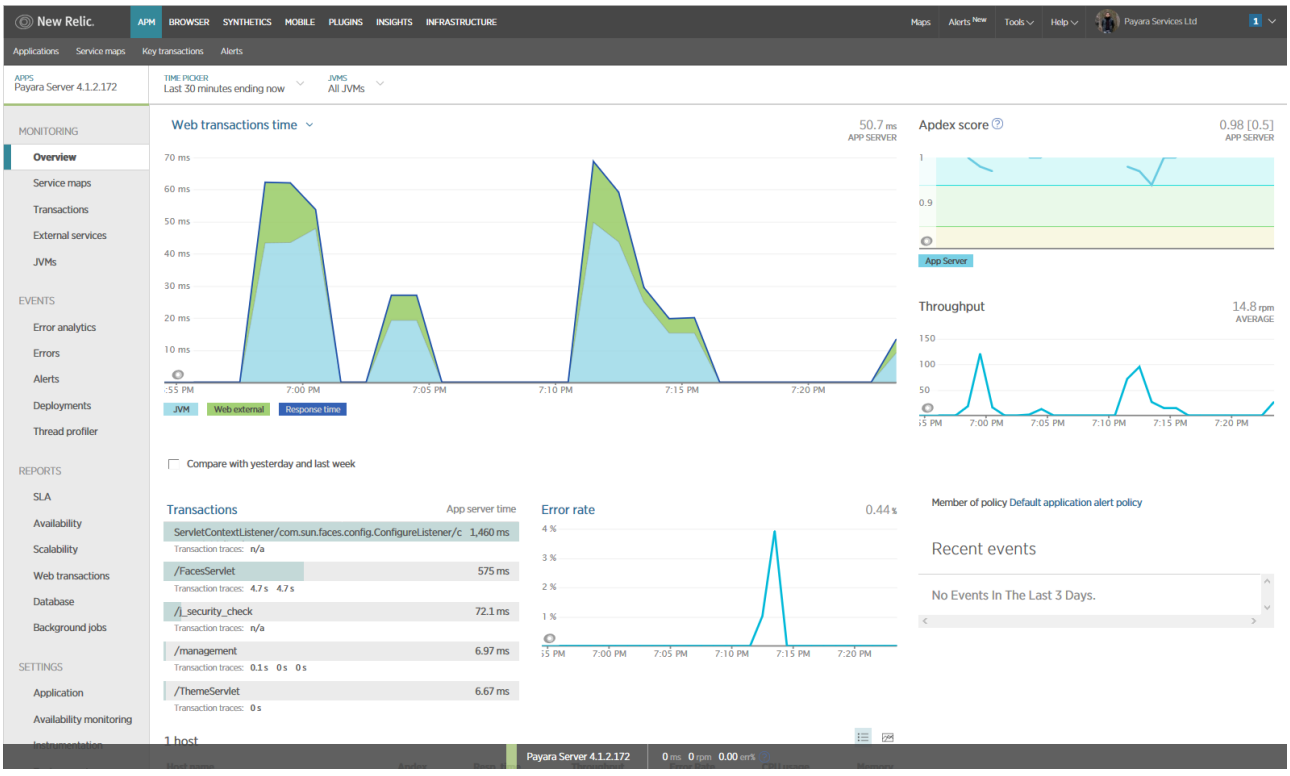
2. Now that the agent has been installed, start the Payara Server domain. You will observe the following messages at the start of the domain's log

```
INFO: New Relic Agent: Loading configuration file "/opt/main-
7/glassfish/domains/domain1/newrelic/newrelic.yml"
INFO: New Relic Agent: Writing to log file: /opt/main-
7/glassfish/domains/domain1/newrelic/logs/newrelic_agent.log
```

3. After some minutes with the server working, you can log in back to the New Relic portal and on the **APM** dashboard you can see a new entry for recently configured server:

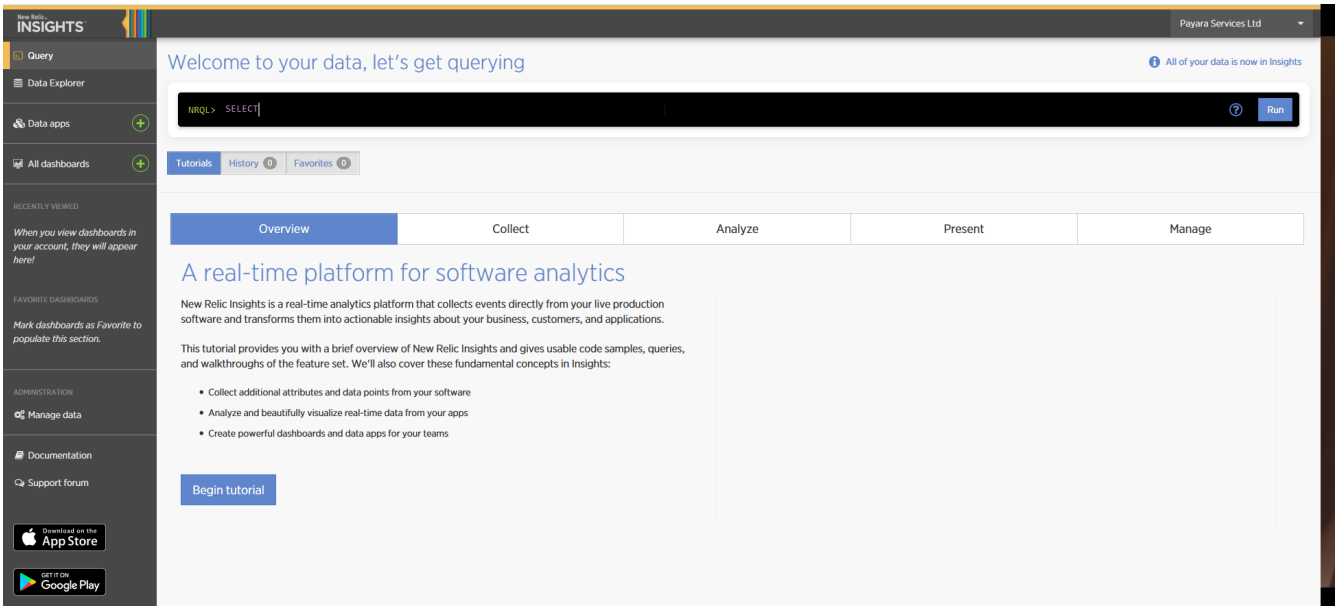


You can also access the latest monitoring statistics:

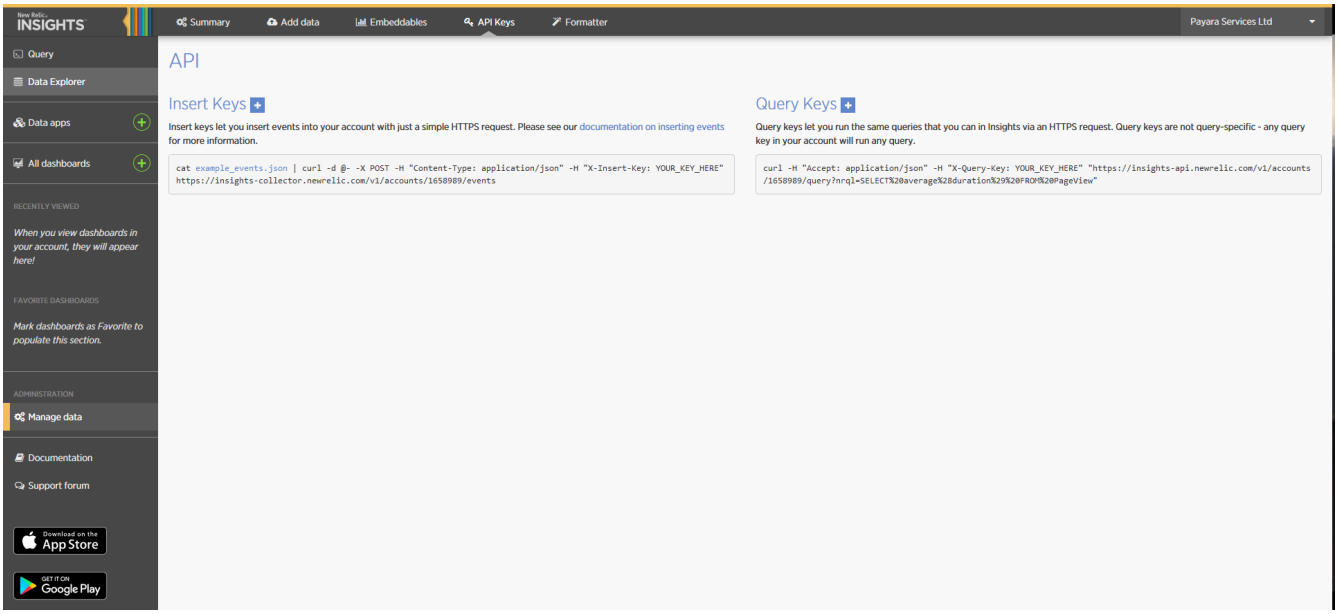


Retrieving the API Key from New Relic Insights

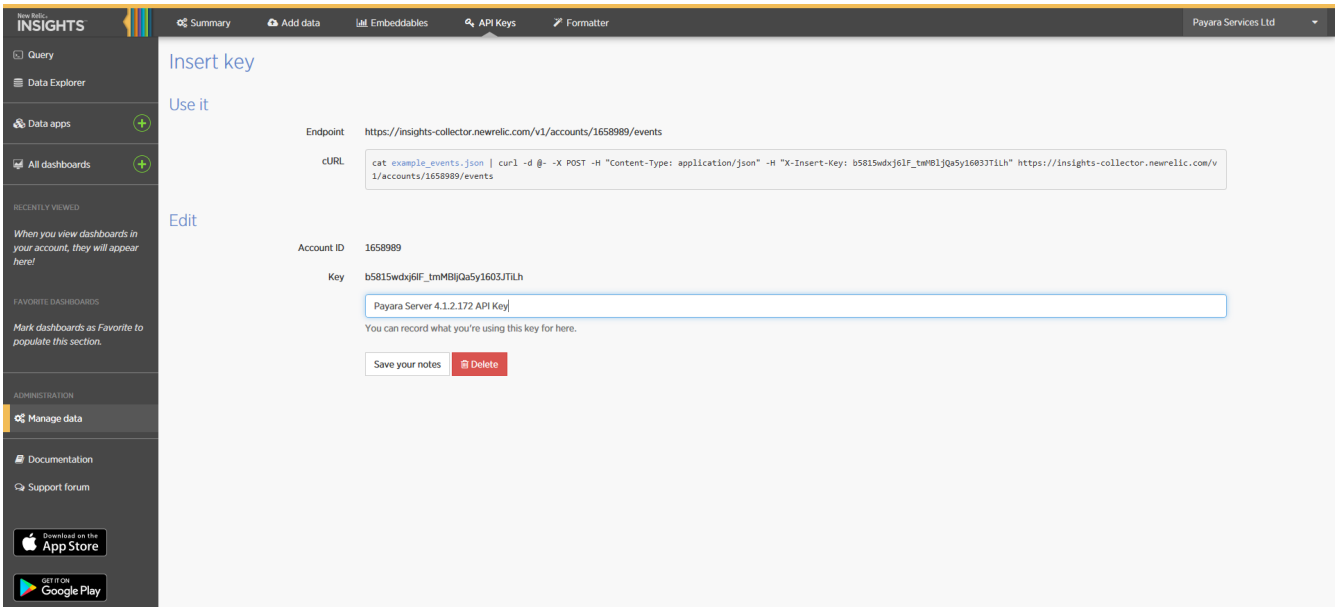
Now that the agent has been correctly installed, login back to your New Relic account portal and head to the **Insights** dashboard:



Access the *Manage Data* option on the side menu, you will be presented the following screen:



Click on the + icon at the side of the **Insert Keys** header. Take note of the *Account ID* and *API Key* value on this screen. Also add a brief description to reference this key on the dashboard:

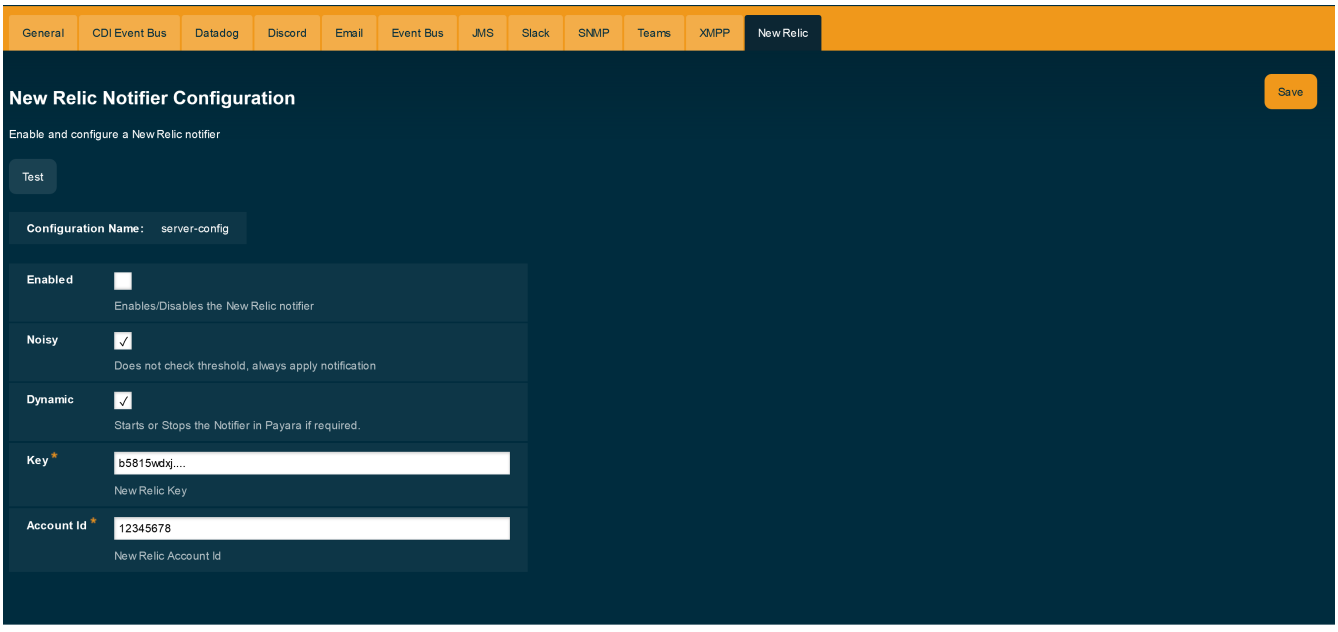


Notifier Configuration

With the New Relic Java agent and Insights API Key correctly configured, you can proceed to configure the New Relic notifier on the Payara Server domain. As usual, you can do this using the administration web console or from the command line.

Using the Administration Web Console

To configure the Notification Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Notification Service* and click on the **New Relic** tab:



Check the **Enabled** box (and the **Dynamic** box too if you don't want to restart the domain) and input the New Relic Account ID and the newly inserted Insights API Key. Hit the **Save** button to preserve the changes.

From the Command Line

To configure the Notification Service from the command line, use the `set-newrelic-notifier-`

`configuration` asadmin command, specifying the tokens like this:

```
asadmin set-newrelic-notifier-configuration --dynamic=true --enabled=true
--accountId=1658989 --key=b5815wdxj6lF_tmMBljQa5y1603JTiLh
```

You can use the `--enabled` and `--dynamic` options to enable or disable the New Relic notifier on demand.

Also, you can retrieve the current configuration for the New Relic notifier using the `get-newrelic-notifier-configuration` asadmin command like this:

```
asadmin get-newrelic-notifier-configuration

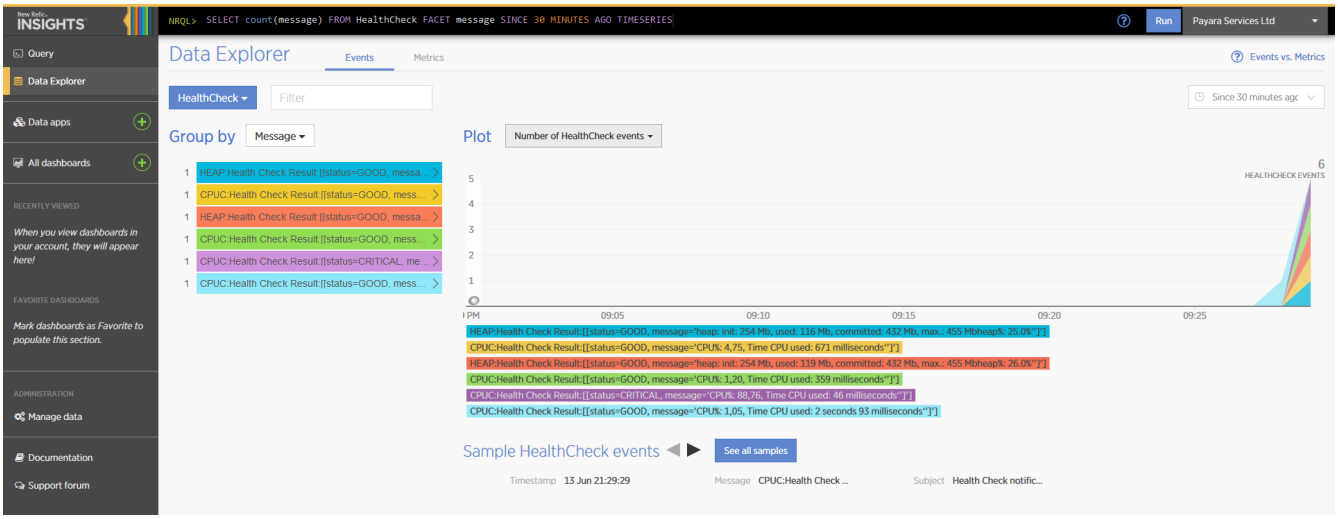
Enabled  Filter  Key                                Account Id
true     WARNING   b5815wdxj6lF_tmMBljQa5y1603JTiLh  1658989
```

Troubleshooting

When you have correctly configured the New Relic notifier, it can be used observe notification events on the New Relic Insights service dashboard. If you do not see any notification event messages on the data explorer, check the following:

- Is the New Relic notifier enabled?
- Is the Notification Service itself enabled?
- Is there a service configured to use the notifier? (e.g. the HealthCheck service)
- Is the service configured to send notifications frequently enough to observe?
- Have you enabled the service after configuring it?
- Is the **Java Agent** for your Payara Server's domain correctly configured?
- Have you created a valid API Key for the Insights service?
- Does your account ID and the Insights API key match the ones configured on the Payara Server notifier?

Here's a sample of how these notifications are visualized on the Data Explorer dashboard for the New Relic Insights service:



You can observe that the events are correctly identified depending on the severity of the notification, and they are correctly grouped by their custom category (in the image only the **Healthcheck** events are shown).

Datadog Notifier

Datadog is a cloud metric aggregator that simplifies the gathering and visualization of multiple platform stacks and services that can be on premises or on the cloud. Datadog also eases browsing through of all this information by implementing combination graphs (multiple graphs that can be configured on a single view) of related metrics.

Datadog supports gathering metrics from the following sources:

- Cloud Providers (Amazon Web Services, Microsoft Azure, Google Cloud Platform)
- Message Queues (Apache Kafka, ActiveMQ, RabbitMQ)
- Code Repositories (GitHub, Bitbucket)
- Clustering and DevOps Tools (Apache Mesos, Kubernetes, Docker)
- Web Servers (Apache HTTP, Nginx, LightHTTP)
- SQL and NoSQL Databases (MySQL, PostgreSQL, MongoDB, CouchBase)
- Monitoring Solutions (New Relic, Nagios, Splunk, Amazon Cloud Trail)

Payara Server includes a special notifier to send notifications from the Notification service to a Datadog account by means of an API key.

Currently, the Payara Datadog notifier only supports the `US1 - East` region.

The notifier modules are available in these locations:

- Datadog Notifier Core 2.0-enterprise
- Datadog Notifier Console Plugin 2.0-enterprise

Datadog Account Integration

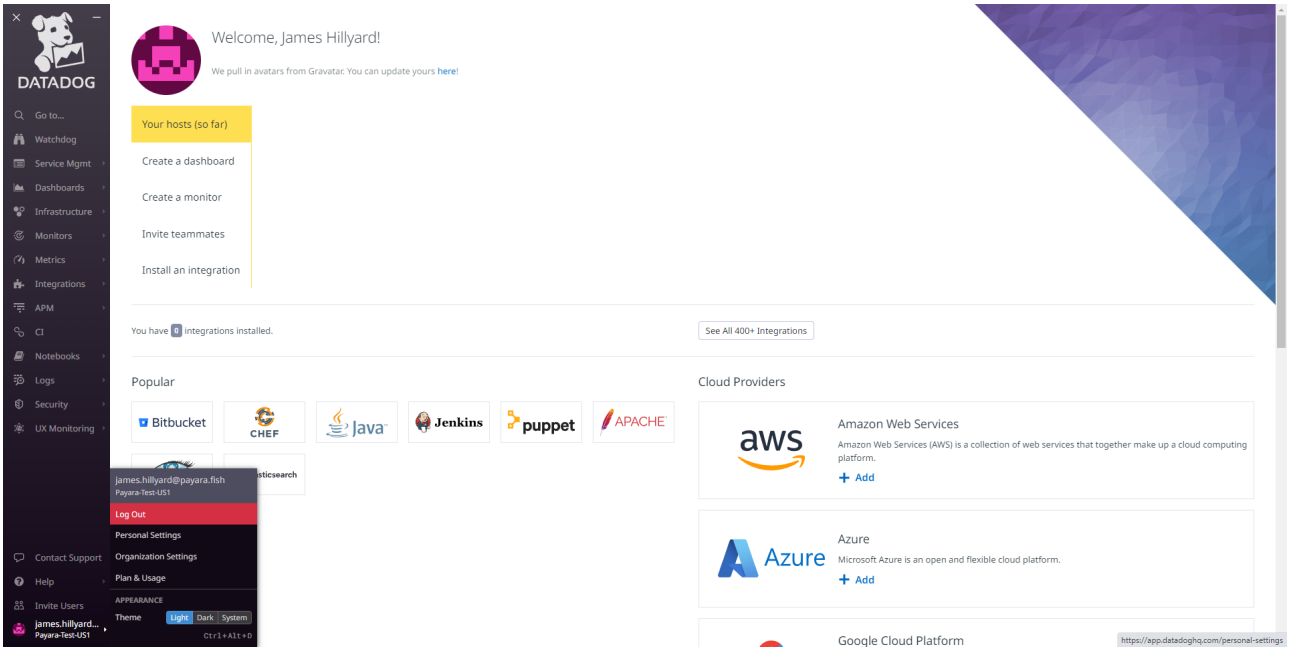
When you create a Datadog account, the service will provide you a default API key that you can use

to integrate Payara Server with your account.

You can sign up for a free trial account (14 days) if you want to test this integration without having to worry about a permanent subscription.

Here are the instructions to retrieve the API keys:

1. First, access the Datadog administration panel located at https://app.datadoghq.com/. Then, in the side menu select your name in the bottom left *Organisation Settings* → *API Keys* option:

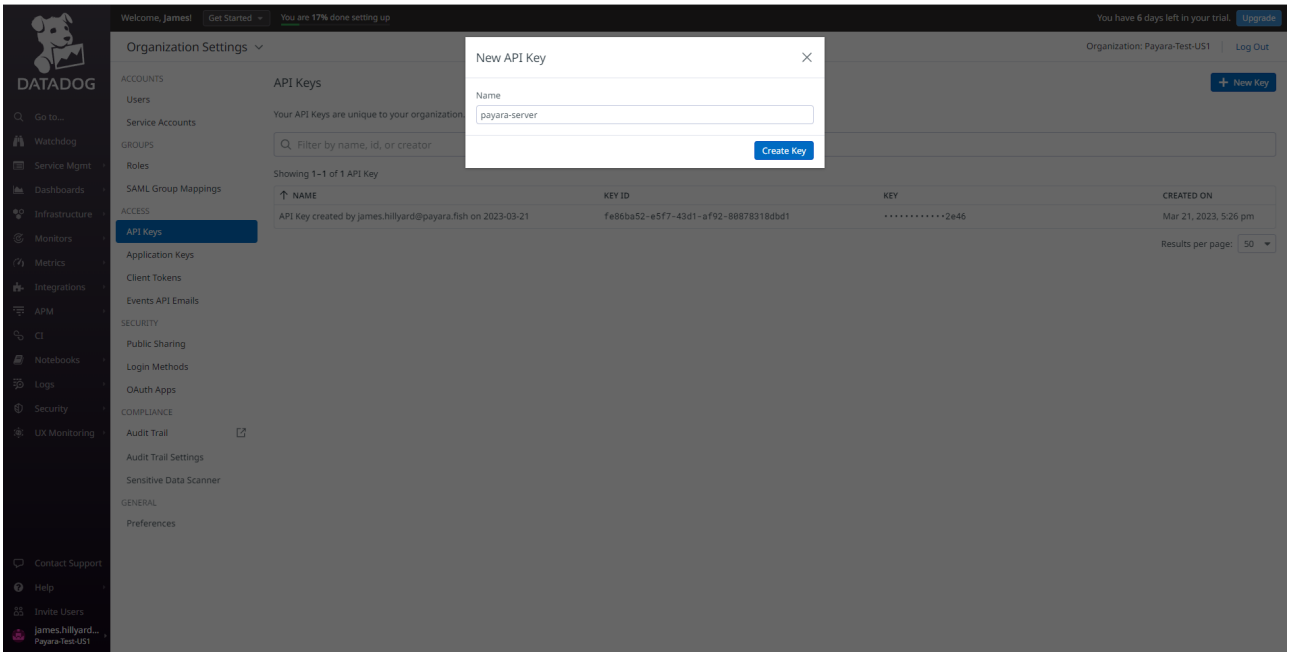


2. On the API Keys tab you will observe the default API Key available for integration:

   You can also create a new API key if you want to use it exclusively for your Payara Server installation.

3. Assign a name to the default API key or a newly created key, so you can identify which services

or platform stacks are integrating with Datadog other than your Payara Server installation:

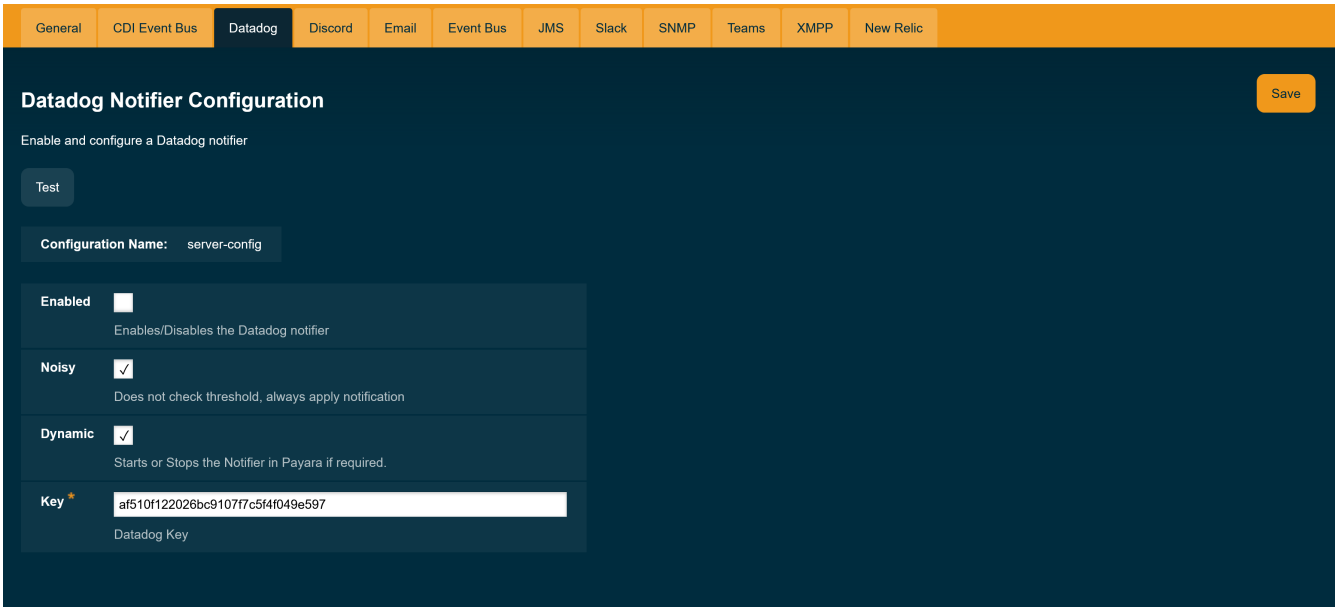


Notifier Configuration

Having retrieved the API key from Datadog's administration panel, it's necessary to configure this key to the notification service on Payara Server. It's possible to do this either by using the administration web console or from the command line using administration commands.

Using the Administration Web Console

To configure the Notification Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Notification Service* and click on the **Datadog** tab:



Check the **Enabled** box (and the **Dynamic** box too if you don't want to restart the domain) and input the three tokens highlighted in the previous section.

Hit the **Save** button to preserve the changes.

From the Command Line

To configure the Notification Service from the command line, use the `set-datadog-notifier-configuration` asadmin command, specifying the tokens like this:

```
asadmin set-datadog-notifier-configuration --dynamic=true
--key=af510f122026bc9107f7c5f4f049e597 --enabled=true
```

You can use the `--enabled` and `--dynamic` options to enable or disable the Datadog notifier on demand.

Also, you can retrieve the current configuration for the Datadog notifier using the `get-datadog-notifier-configuration` asadmin command like this:

```
asadmin get-datadog-notifier-configuration

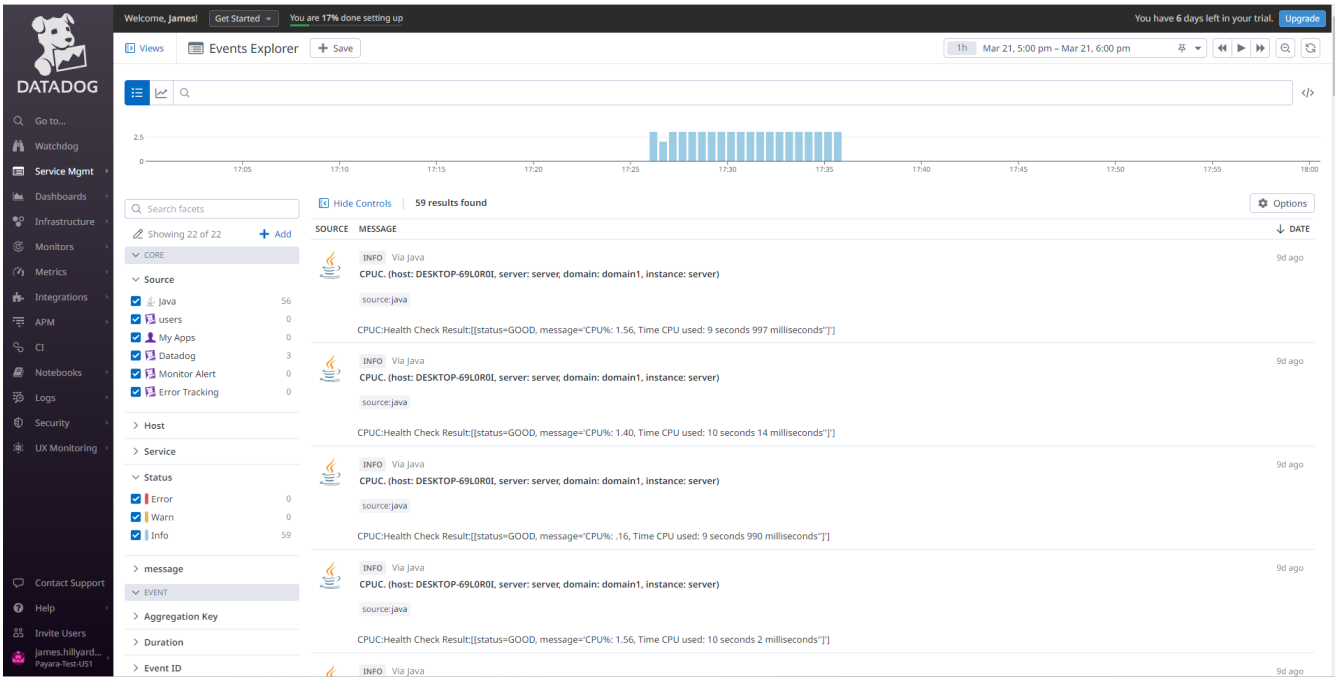
Enabled  Filter   Key
true     WARNING  af510f122026bc9107f7c5f4f049e597
```

Troubleshooting

When you have correctly configured the Datadog notifier, Datadog can gather relevant monitoring events from your Payara Server installation. If you do not see any notification event messages on your Datadog account, check the following:

- Is the Datadog notifier enabled?
- Is the Notification Service itself enabled?
- Is there a service configured to use the notifier? (e.g. the HealthCheck service)
- Is the service configured to send notifications frequently enough to observe?
- Have you enabled the service after configuring it?
- Does the configured API key on Payara Server match one of the API keys configured on your Datadog account?
- Is Datadog running in the US1 region?

Here's a sample of how the notifications are visualized on the Datadog event notification panel (on the side menu select the *ServiceMgmt → Events* option):



MS Teams Notifier

A notifier extension for publishing to a Microsoft Teams channel.

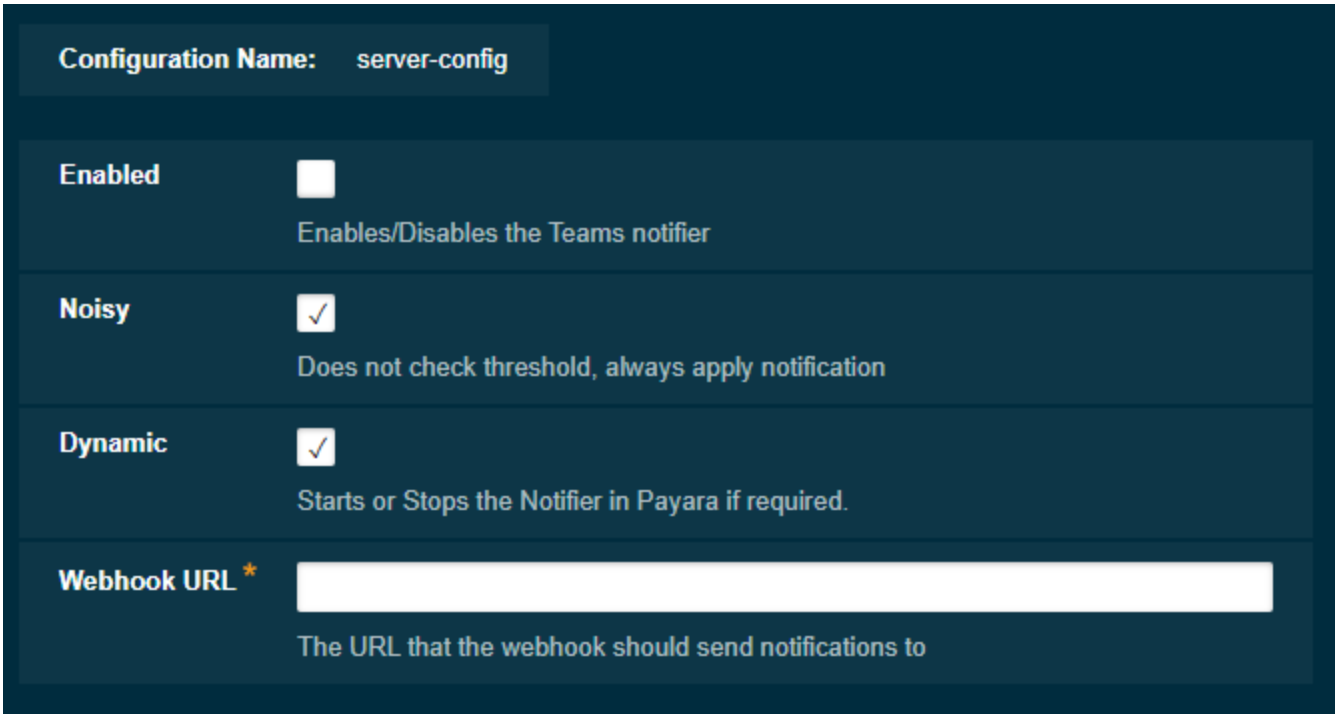
The notifier modules are available in these locations:

- Teams Notifier Core 2.0-enterprise
- Teams Notifier Console Plugin 2.0-enterprise

Notifier Configuration Configuration

Using the Administration Web Console

To configure the Notification Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Notification Service* and click on the **Teams** tab:



From the Command Line

To configure the Notification Service from the command line, use the `set-teams-notifier-configuration` asadmin command like this:

```
asadmin set-teams-notifier-configuration --enabled=true --dynamic=true
https://outlook.office.com/webhook/xyz
```

You can use the `--enabled` and `--dynamic` options to enable or disable the Teams notifier on demand.

You can retrieve the current configuration for the Teams notifier using the `get-teams-notifier-configuration` asadmin command like this:

```
asadmin get-teams-notifier-configuration
```

This will return the details of the current Teams configuration; see below for an example:

```
Enabled  Filter   Webhook URL
true     WARNING  https://outlook.office.com/webhook/xyz
```

Slack Notifier

Slack is a functional enterprise chat and team collaboration tool inspired by IRC. It allows an organisation to create specific **domains** and discuss work topics or subjects in separate **channels** that can either be public or private.

This notifier sends notification events to an organisation's domain channel using Slack API integrations.

The notifier modules are available in these locations:

- Slack Notifier Core 2.0-enterprise
- Slack Notifier Console Plugin 2.0-enterprise

Slack Integration Configuration

In order to allow the notification service to log events on a Slack channel of your choice, you must fulfill the following requirements first:

- Have created a Slack account within your organisation's domain (for example **payara.slack.com**)
- Have a Slack account with granted permissions to create channels and configure API integrations.
- Have created a Slack channel which will be used by the notification service to report notification events.

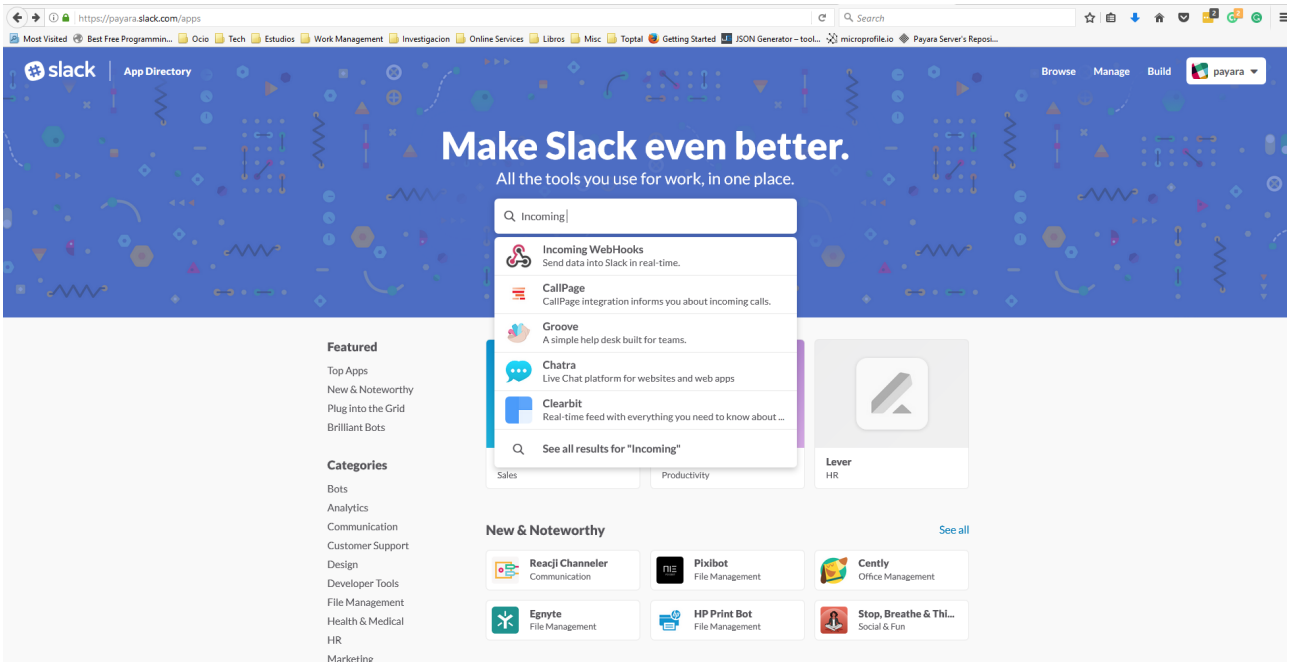
Once you have completed these requirements, you can configure an Incoming Webhook integration for the channel.

An *Incoming Webhook* is the simplest integration mechanism that Slack provides, in that they make use of normal HTTP requests with a *JSON* payload that includes the message text and additional options to format incoming messages to the channel.

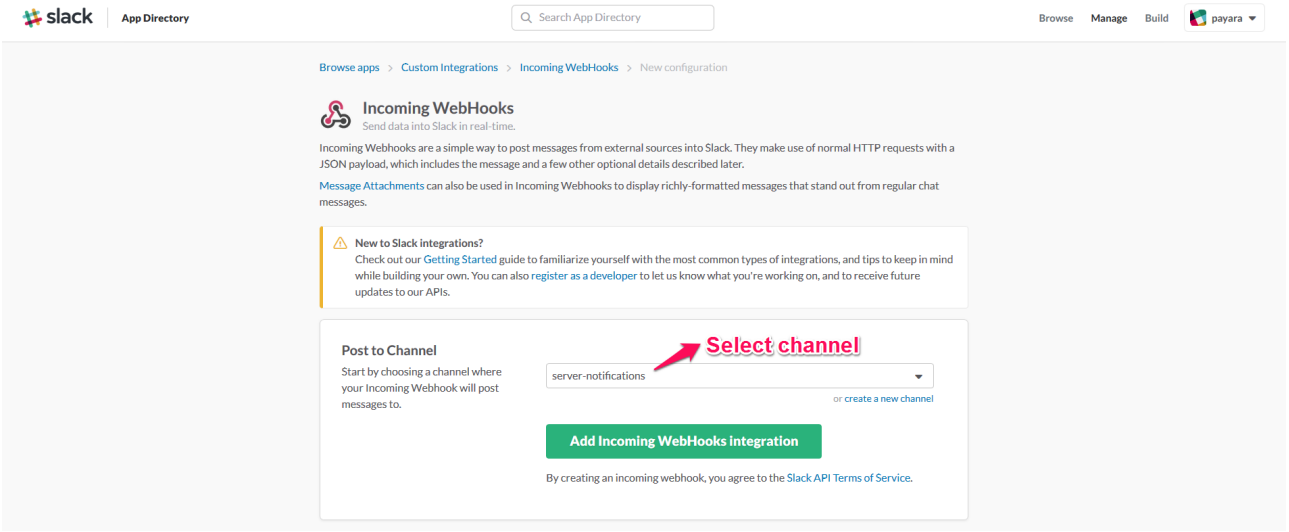
Configure Incoming WebHook

1. First, access the developer portal's application directory located at https://payara.slack.com/apps.

   Then, in the search box type **Incoming Webhooks**. A suggestion will appear in the results display:



2. Now, proceed to select the channel that the WebHook will use to direct the notification events to:



It's recommended to choose a *private* channel, since it will keep these notifications events protected in case of unwanted disclosure, and it won't spam other users of your organisation with unwanted notifications

3. With this, the WebHook configuration is finished. Now, take special attention to the WebHook URL, which is usually follows this structure:

```
https://hooks.slack.com/services/{TOKEN1}/{TOKEN2}/{TOKEN3}
```

Like in the following sample:

We will use these 3 tokens when configuring the server's integration later.

We recommend that you configure the following settings in the channel integration to give better visualization for your notifications:

Descriptive Label

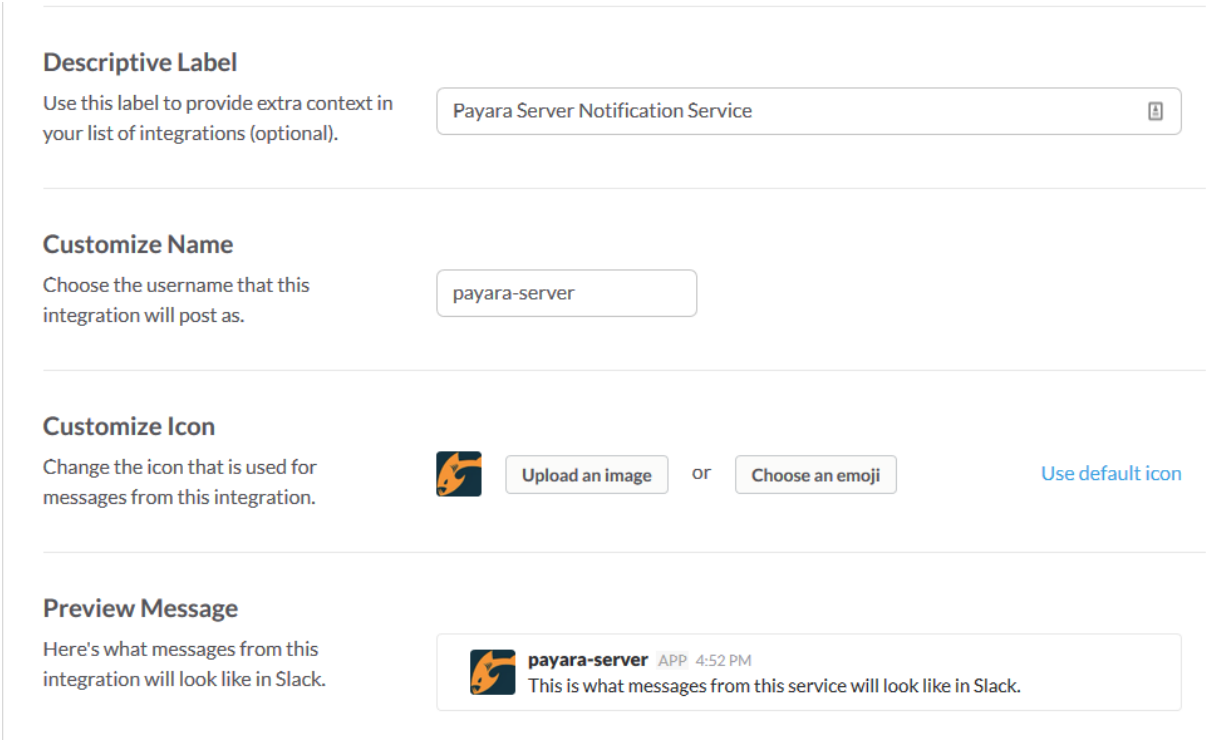
Use a name that's easy to understand to identify this WebHook integration

Customize Name

Insert a name for the "agent" that will report the notification messages

Customize Icon

Insert a custom icon to identify the agent that will be visualized in the messages. We recommend using one of the Payara logos like in this sample:

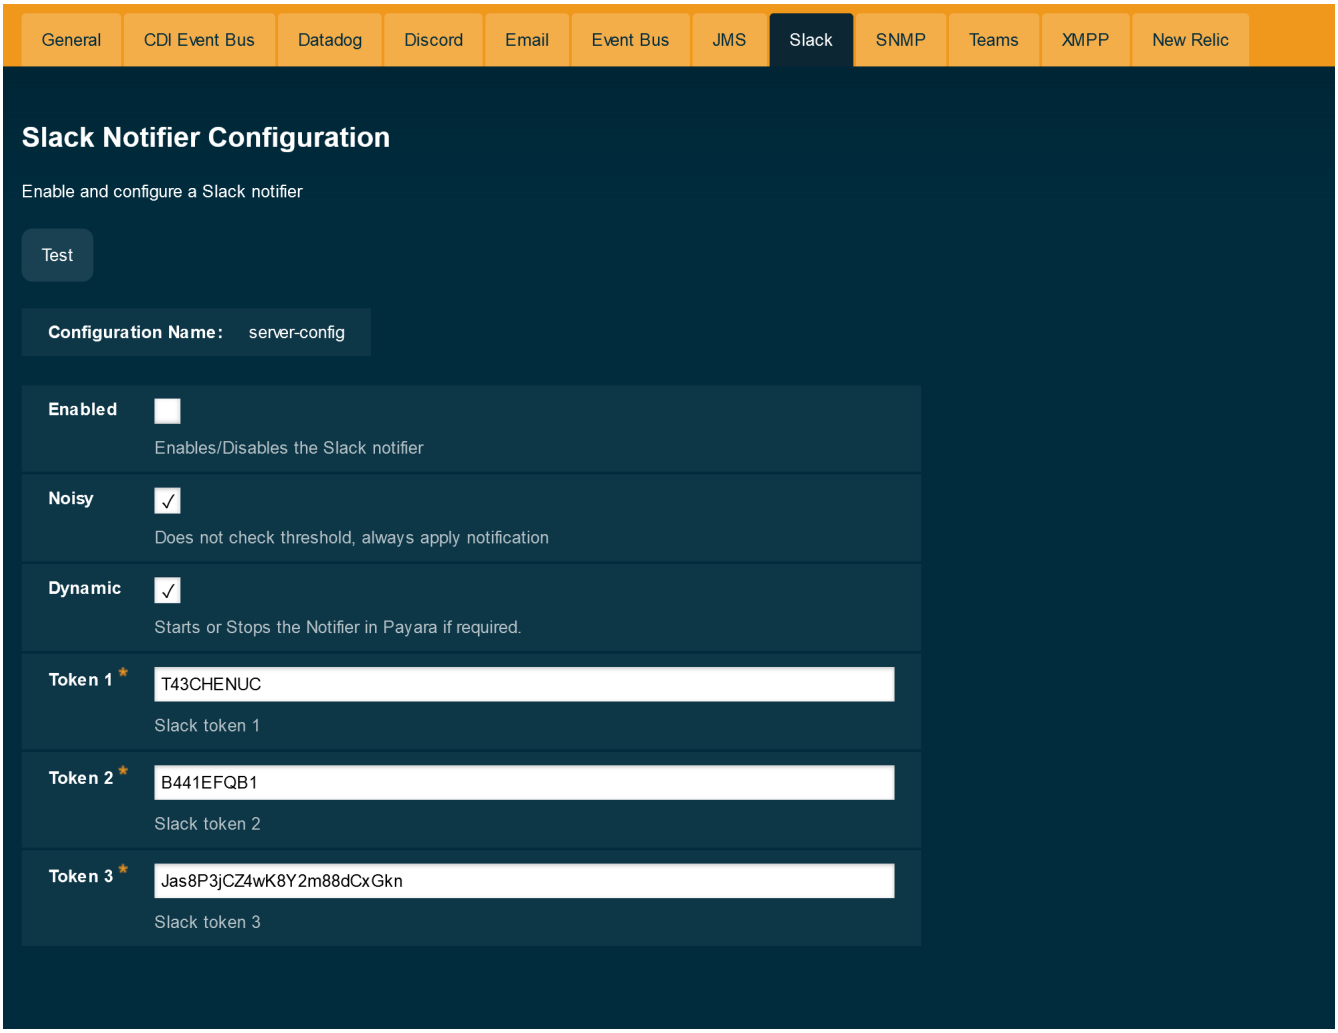


Notifier Configuration

With the Incoming WebHook properly configured, now it's time to set up the Notification Service in the domain configuration. As usual, you can do this using the administration web console or from the command line.

Using the Administration Web Console

To configure the Notification Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Notification Service* and click on the **Slack** tab:



Check the **Enabled** box (and the **Dynamic** box too if you don't want to restart the domain) and input the three tokens highlighted in the previous section. Hit the **Save** button to preserve the changes.

From the Command Line

To configure the Notification Service from the command line, use the `set-slack-notifier-configuration` asadmin command, specifying the tokens like this:

```
asadmin set-slack-notifier-configuration --enabled=true --dynamic=true
--token1=T43CHENUC --token2=B441EFQB1 --token3=Jas8P3jCZ4wK8Y2m88dCxGkn
```

You can use the `--enabled` and `--dynamic` options to enable or disable the Slack notifier on demand.

Also, you can retrieve the current configuration for the Slack notifier using the `get-slack-notifier-configuration` asadmin command like this:

```
asadmin get-slack-notifier-configuration

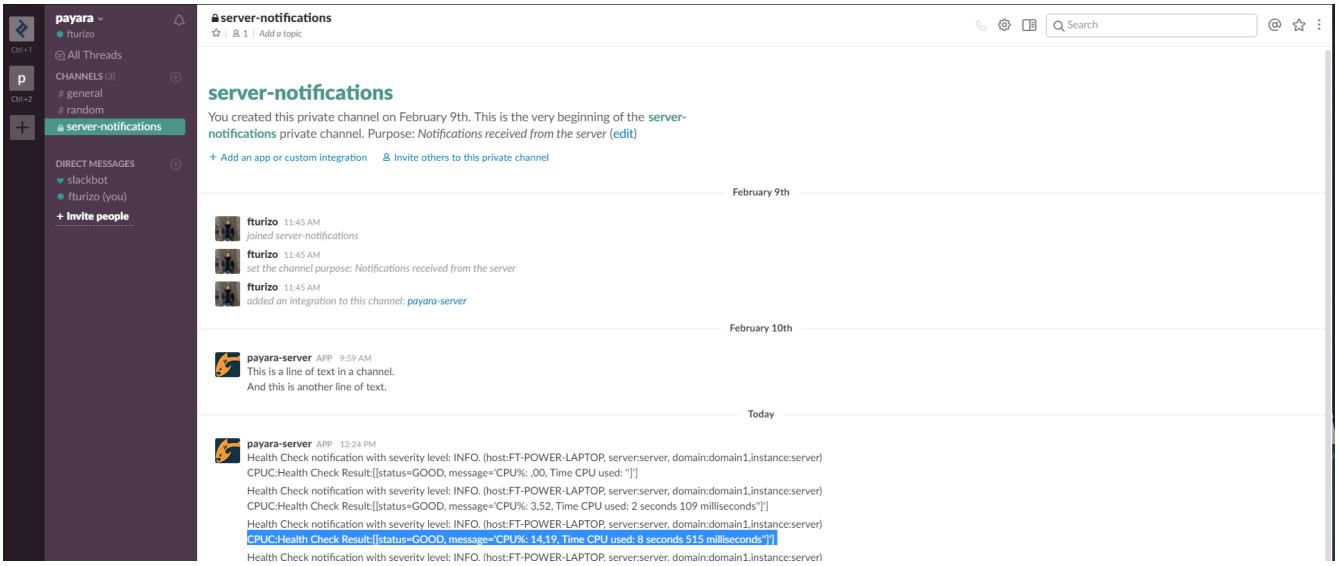
Enabled  Filter   Token 1    Token 2    Token 3
true     WARNING  T43CHENUC  B441EFQB1  Jas8P3jCZ4wK8Y2m88dCxGkn
```

Troubleshooting

When you have correctly configured the Slack notifier, it can be used to push notifications to your configured channel. If you do not see any notification event messages, check the following:

- Is the Slack notifier enabled?
- Is the Notification Service itself enabled?
- Is there a service configured to use the notifier? (e.g. the HealthCheck service)
- Is the service configured to send notifications frequently enough to observe?
- Have you enabled the service after configuring it?
- Is the **Incoming WebHook** correctly configured in the Slack API portal?
- Check that you have not surpassed the current rate limit for the Slack API

Here's a sample of how the notifications are visualized on the Slack Desktop application:



Discord Notifier

A notifier for publishing notifications to a Discord channel.

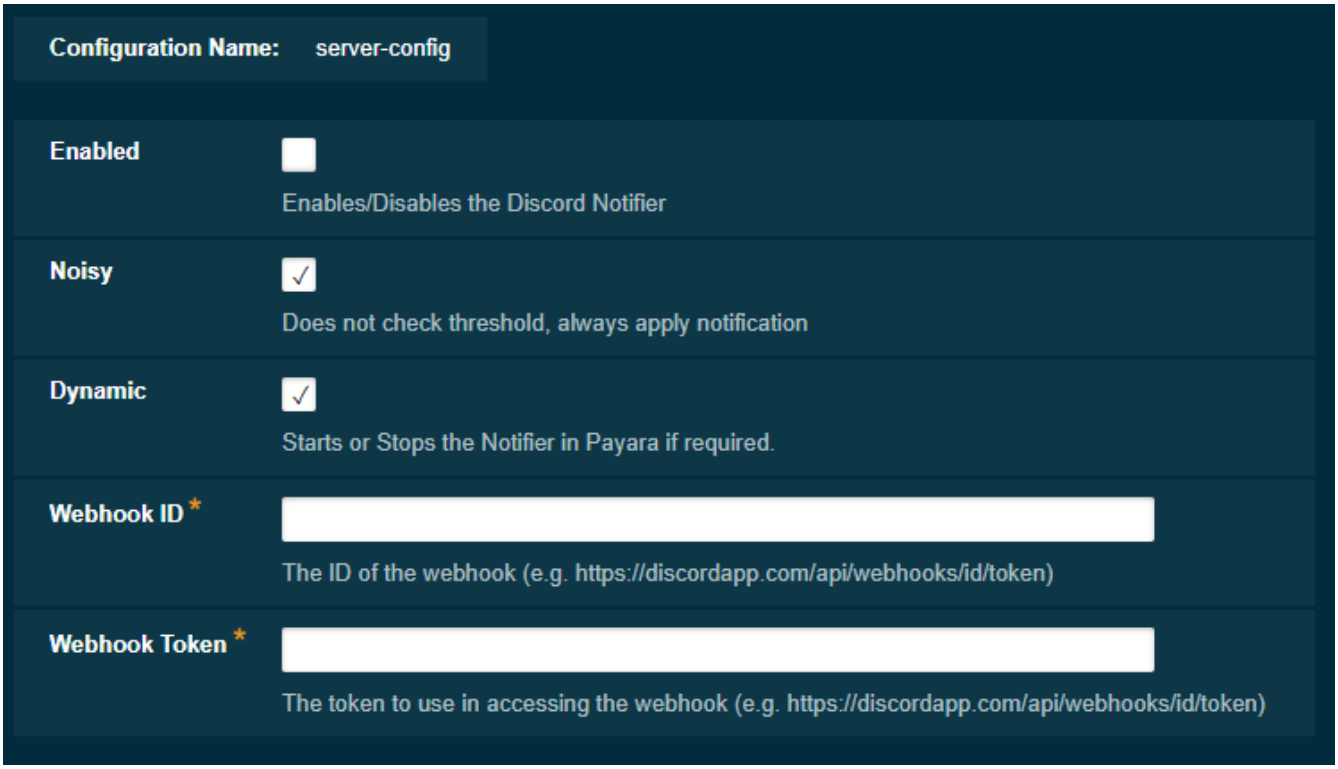
The notifier modules are available in these locations:

- Discord Notifier Core 2.0-enterprise
- Discord Notifier Console Plugin 2.0-enterprise

Notifier Configuration

Using the Administration Web Console

To configure the Notification Service in the Administration Console, go to *Configuration → [instance-configuration (like server-config)] → Notification Service* and click on the **Discord** tab:



From the Command Line

To configure the Notification Service from the command line, use the `set-discord-notifier-configuration` asadmin command like this:

```
asadmin set-discord-notifier-configuration --enabled=true --dynamic=true
--webhookId=xxx --webhookToken=yyy
```

Where the `xxx` and `yyy` are respectively the ID and token for the webhook you have configured within Discord.

You can use the `--enabled` and `--dynamic` options to enable or disable the Discord notifier on demand.

You can retrieve the current configuration for the Discord notifier using the `get-discord-notifier-configuration` asadmin command like this:

```
asadmin get-discord-notifier-configuration
```

This will return the details of the current Discord configuration; see below for an example:

```
Enabled  Filter   Webhook ID  Webhook Token
true     WARNING  xxx         yyy
```

Administering Batch Jobs

This chapter provides procedures for administering batch jobs in the Payara Server environment

by using the `asadmin` command-line utility.

Instructions for accomplishing these tasks by using the Administration Console are contained in the Administration Console online help.

About Batch Jobs

Payara Server provides a batch runtime for the scheduling and execution of batch jobs. Batch jobs are typically long-running, bulk-oriented tasks that contain a series of steps and can be executed without user interaction. Examples include billing, report generation, data format conversion, and image processing.

Batch applications submit jobs to the batch runtime and provide instructions about how and when to execute the steps. The batch runtime processes the steps as directed by job XML documents packaged with the applications and stores information about jobs in a job repository. In Payara Server, the job repository is a database.

For detailed information about batch jobs, batch processing, and the batch processing framework, see "Batch Processing" in The Jakarta Batch specifications. The specification defines the programming model for batch applications and the runtime for scheduling and executing batch jobs.

Viewing Batch Jobs

You can view detailed information about batch jobs, executions, and steps. Users who log in to the `asadmin` utility or to the Administration Console as administrator are the only users who can view details for all batch jobs submitted by all applications in the Payara Server environment.

To List Batch Jobs

Use the `list-batch-jobs` subcommand in remote mode to list batch jobs and job details.

1. Ensure that the server is running.
   Remote subcommands require a running server.
2. List batch jobs by using the list-batch-jobs subcommand.

To List Batch Jobs

This example lists batch jobs for the default server instance, `server`. Use `list-batch-jobs -l` to list additional details.

```
asadmin> list-batch-jobs
JOBNAME  INSTANCECOUNT
payroll  9
bonus    6
Command list-batch-jobs executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-batch-jobs` at the command line.

To List Batch Job Executions

When the batch runtime executes a job, the execution is given a unique execution ID. An execution ID is similar to a process ID. A new execution is created the first time a job is started and every time the existing execution is restarted.

Use the `list-batch-job-executions` subcommand in remote mode to list batch job executions and execution details.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List batch job executions by using the list-batch-job-executions subcommand.

To List Batch Jobs Executions

This example lists batch job executions for the default server instance, `server`, and displays specific details. Use `list-batch-job-executions -l` to list additional details.

```
asadmin> list-batch-job-executions -o=jobname,executionid,batchstatus,exitstatus
JOBNAME  EXECUTIONID  BATCHSTATUS  EXITSTATUS
payroll  9            COMPLETED    COMPLETED
bonus    6            FAILED       FAILED
Command list-batch-job-executions executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-batch-job-executions` at the command line.

To List Batch Job Steps

A batch job consists of one or more steps. A step is an independent and sequential phase of a batch job.

Use the `list-batch-job-steps` subcommand in remote mode to list steps and step details for a specific batch job execution.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the execution ID of an execution by using the `list-batch-job-executions` subcommand.
3. List steps for a specific batch job execution by using the list-batch-job-steps subcommand.

To List Batch Jobs Steps

This example lists batch job steps and specific step details for a job execution with the execution ID of `7`. The target is the default server instance, `server`. Use `list-batch-job-steps -l` to list additional details.

Some lines of output are omitted from this example for readability.

```
asadmin> list-batch-job-steps o=stepname,stepid,batchstatus,stepmetrics 7
STEPNAME   STEPID   BATCHSTATUS   STEPMETRICS
prepare    7        COMPLETED     METRICNAME          VALUE
```

```
                                READ_COUNT          8
                                WRITE_COUNT         8
                                PROCESS_SKIP_COUNT  0
process    8        COMPLETED   METRICNAME          VALUE
                                READ_COUNT          8
                                WRITE_COUNT         8
                                PROCESS_SKIP_COUNT  0
...
Command list-batch-job-steps executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-batch-job-steps` at the command line.

Configuring the Batch Runtime

The batch runtime uses a data source and a managed executor service to execute batch jobs. The data source stores information about current and past jobs, and the managed executor service provides threads to jobs. Batch runtime configuration data is stored in the `config` element in `domain.xml`.

Payara Server provides a default data source and managed executor service for the execution of batch jobs. For the domain administration server (DAS), the default data source is `jdbc/TimerPool` and the default managed executor service is `concurrent/defaultManagedExecutorService`. If you create a standalone server instance or a standalone cluster, the default data source is `jdbc/__default`. You can configure the batch runtime to use different resources.

For more information about data sources, see Administering Database Connectivity. For more information about managed executor services, see Configuring Managed Executor Services.

To List the Batch Runtime Configuration

Use the `list-batch-runtime-configuration` subcommand in remote mode to display the configuration of the batch runtime.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Display the configuration of the batch runtime by using the list-batch-runtime-configuration subcommand.
3. If desired, use the `get` subcommand to view the attributes of the data source and managed executor service resources. For example (output omitted):

```
asdmin> get resources.jdbc-resource.jdbc/__TimerPool.*
...
asdmin> get resources.managed-executor-
service.concurrent/__defaultManagedExecutorService.*
...
```

To List the Batch Job Runtime Configuration

This example lists the configuration of the batch runtime for the default server instance, `server`.

```
asadmin> list-batch-runtime-configuration
DATASOURCELOOKUPNAME     EXECUTORSERVICELOOKUPNAME
jdbc/__TimerPool         concurrent/__defaultManagedExecutorService
Command list-batch-runtime-configuration executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-batch-runtime-configuration` at the command line.

To Configure the Batch Runtime

Use the `set-batch-runtime-configuration` subcommand in remote mode to configure the batch runtime.

Do not change the data source after the first batch job has been submitted to the batch runtime for execution. If the data source must be changed, stop and restart the domain and then make the change before any jobs are started or restarted. However, once the data source has been changed, information stored in the previous data source becomes inaccessible.
The managed executor service can be changed after a batch job has been submitted to the batch runtime without affecting execution of the job.

1. Ensure that the server is running.
   Remote subcommands require a running server.
2. Configure the batch runtime by using the set-batch-runtime-configuration subcommand.

To Set Batch Runtime Configuration

This example configures the batch runtime for the default server instance, `server`, to use an existing managed executor service named `concurrent/Executor1`.

```
asadmin> set-batch-runtime-configuration --executorservicelookupname
concurrent/Executor1
Command set-batch-runtime-configuration executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help set-batch-runtime-configuration` at the command line.

Defining a Schema name

Payara Server allows the ability to define the name of the *database schema* that will hold all batch job tables. This can be set via the Admin Console or using Asadmin CLI commands.

Defining a Schema name through the Admin Console

1. Click on the instance or cluster to move to its configuration page.
2. Select the *Batch* tab, and from there click on the *Configuration* sub-tab.
3. Enter your desired value in the *Database Schema Name* field.
4. Save your changes

Defining a Schema name using the Asadmin CLI

It's possible to set the schema using the `set-batch-runtime-configuration` command.

The command requires you to specify the `Executor` or `DataSource` lookup name, which you can do with the `-x` or `-d` options respectively.

The command defaults to targeting the Admin Server instance (`server`), to target a different instance or cluster, use the `--target` option.

To specify the schema name, use the `--schemaName` option, or its shortcut `-n`.

An example can be seen below:

```
asadmin set-batch-runtime-configuration -d jdbc/__default --target cluster1 -n test
```

Specifying a Blank Schema Name

If you specify a blank schema name, then the schema name will depend on what database vendor is being used:

- On **MySQL**, the *test* schema will be used
- On **H2**, **Derby**, **Oracle**, **DB2** and **PostgreSQL** the schema name will be the username of the JDBC connection pool resource associated with the JDBC resource to which JBatch is configured to use.

This behavior only applies if you explicitly specify the schema name as blank; the schema name will still default to `APP` if not overwritten.

Setting a Table Prefix and/or Suffix

Payara Server allows you to set the prefix and/or the suffix of the batch table name. This can be set via the Admin Console, or using Asadmin CLI commands.

The table prefix and suffix settings may be ignored by non-RDBMS based datastores.

Setting a Table Prefix and/or Suffix on the Admin Console

1. Click on the instance or cluster to move to its configuration page.
2. Select the *Batch* tab, and the *Configuration* sub-tab should load.

3. Enter your desired values in the *Table Prefix* and *Table Suffix* fields.
4. Save your changes

Setting a Table Prefix and/or Suffix using the Asadmin CLI

It's possible to set the table prefix and/or suffix is set using the `set-batch-runtime-configuration` command. The command requires you to specify the `Executor` or `DataSource` lookup name, which you can do with the `-x` or `-d` options respectively.

The command defaults to targeting the Admin Server instance (`server`), to target a different instance or cluster, use the `--target` option.

- To specify the prefix, use the `--tablePrefix` option.
- To specify the table suffix, use the `--tableSuffix` option.

An example can be seen below:

```
asadmin set-batch-runtime-configuration -d jdbc/__default --target cluster1
--tablePrefix PRE --tableSuffix SFX
```

Database Support

You can configure any of the following RDBMS engines in the same way that you would configure it to use H2 (the default database engine used to manage the JBatch data sources):

- MySQL
- PostgreSQL
- Oracle
- IBM DB2

Configuration

On the Admin console:

1. Create a Connection Pool:
    a. Navigate to *Resources* → *JDBC* → *JDBC Connection Pools* and click on *New...*
    b. Give it a name in the *Pool Name* field, select the resource type from the *Resource Type* drop-down, and choose the *Database Driver Vendor* as either **DB2**, **MySQL**, **Oracle**, or **PostgreSQL** from the *Database Driver Vendor* menu.
    c. Set any further configuration options on the next page.
    d. Click *Finish*
2. Create a JDBC Resource:
    a. Navigate to *Resources* → *JDBC* → *JDBC Resources* and click on *New...*
    b. Give it a name in the *JNDI Name* field, and select the data source you just created from the *Pool Name* drop-down.

c. Add any additional properties and select the targets for it to be enabled on.

d. Click *OK*.

3. Navigate to the Batch configuration page of the instance or cluster:
4. Click on the instance or cluster to move to its configuration page.
5. Select the *Batch* tab, and the *Configuration* sub-tab should load.
6. Select the new data source from the *Data Source Lookup Name* drop-down menu.
7. Save the changes.

Usage Restrictions

The Jakarta Batch runtime will not create internally more than one set of JBatch tables per schema. So in your schema if there exists a set of JBatch tables with prefixes and suffixes in the table names and then specify in the JBatch configuration for the same schema above that you wish to use JBatch tables under a different name (for example no table prefix and suffix) then during the JBatch initialization phase, JBatch will attempt to create these tables since they do not exist.

However since the table constraint names already exist for the existing JBatch tables in the same schema, table creation will fail. One can of course run a_SQL_ script to create the relevant JBatch schema objects under different names.

MySQL Specifics

For MySQL (5/8) database use, it is recommended the following additional property be set:

Name	Value	Description
`zeroDateTimeBehavior`	`convertToNull`	Action for `DATETIME` values that are composed entirely of zeros (used by MySQL to represent invalid dates)

Depending on the version of MySQL you may also need to set the server property `sql_mode` to blank as JBatch uses `null` and zero dates.

Administering Database Connectivity

This chapter provides procedures for performing database connectivity tasks in the Payara Server environment.

About Database Connectivity

A database management system (DBMS) provides facilities for storing, organizing, and retrieving data. The information in databases is often described as persistent data because it is saved on disk and exists after the application process ends. Most business applications store data in relational databases. Applications can access database information by using the Java Database Connectivity (JDBC) API.

The key elements of database connectivity are the following:

- Database. The repository where data is stored for an enterprise. Jakarta EE applications access relational databases through the JDBC API. For administration procedures, see Setting Up the Database.
- JDBC Connection Pool. A JDBC connection pool is a group of reusable connections for a particular database. For administration procedures, see Administering JDBC Connection Pools.
- JDBC Resource. A JDBC resource (data source) provides applications with a means of connecting to a database. To create a JDBC resource, specify the connection pool with which it is associated. Multiple JDBC resources can specify a single connection pool. A JDBC resource is identified by its Java Naming and Directory Interface (JNDI) name. For administration procedures, see Administering JDBC Resources.
- JDBC Driver. A database driver is a software component that enables a Java application to interact with a database connectivity API . Each database requires its own driver. For administration procedures, see Integrating the JDBC Driver.

At runtime, the following sequence occurs when an application connects to a database:

1. The application gets the JDBC resource associated with the database by making a call through the JNDI API.
   Using the JNDI name of the resource, the naming and directory service locates the JDBC resource. Each JDBC resource specifies a connection pool.
2. Using the JDBC resource, the application gets a database connection.
   Payara Server retrieves a physical connection from the connection pool that corresponds to the database. The pool defines connection attributes such as the database name (URL), username, and password.
3. After the database connection is established, the application can read, modify, and add data to the database.
   The application accesses the database by making calls to the JDBC API. The JDBC driver translates the application's JDBC calls into the protocol of the database server.
4. When the application is finished accessing the database, the application closes the connection and returns the connection to the connection pool.

Setting Up the Database

Most applications use relational databases to store, organize, and retrieve data. Applications access relational databases through the Java Database Connectivity (JDBC) API.

To Install the Database and Database Driver

1. Install a compatible JDBC relational database product.
2. Install a supported JDBC driver for the database product.

   For a list of drivers supported by Payara Server, see Configuration Specifics for JDBC Drivers.
3. Make the JDBC driver JAR file accessible to the domain administration server (DAS).

   See Integrating the JDBC Driver.

4. Create the database. The application provider usually delivers scripts for creating and populating the database.

Next Steps

You are now ready to create a connection pool for the database, and a JDBC resource that points to the connection pool. See To Create a JDBC Connection Pool and To Create a JDBC Resource. The final step is to integrate the JDBC driver into an administrative domain as described in Integrating the JDBC Driver.

To Start the Database

Payara Server includes an implementation of the H2 Database, however, you can use any JDBC-compliant database. The database is not started automatically when you start Payara Server, so if you have applications that require a database, you need to start H2 database manually by using the local `start-database` subcommand.

Start the database by using the `start-database` subcommand.

When the database server starts, or a client connects to it successfully, the following files are created at the location that is specified by the `--dbhome` option:

- The `h2.log` file contains the database server process log along with its standard output and standard error information.
- The database files contain your schema (for example, database tables).

Example 11-1 To Start a Database

This example starts the H2 database on the host host1 and port 5001.

```
asadmin> start-database --dbhost=localhost --dbport=5001
Starting database in Network Server mode on host localhost and port 5001.
tcp://192.168.0.110:5001
Starting database in the background.
Log redirected to C:\payara-
server\_WORKDIR\7.2025.1\payara7\glassfish\databases\h2.log.
Command start-database executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help start-database` at the command line.

To Stop the Database

Use the local `stop-database` subcommand to stop the H2 database on a specified port. A single host can have multiple database server processes running on different ports.

1. If necessary, notify users that the database is being stopped.
2. Stop the database by using the `stop-database` subcommand.

Example 11-2 To Stop a Database

This example stops the H2 database on port 5001 of `localhost`.

```
asadmin> stop-database --dbhost=localhost --dbport=5001
Command stop-database executed successfully.
```

Troubleshooting

For a laptop that roams between networks, you might have trouble shutting down the database. If you start the H2 database and then change your IP address, you will not be able to stop the H2 database unless you add a specific `--dbhost` argument. For example, if you run `asadmin start-database dbhost = 0.0.0.0`, and then disconnect Ethernet and switch to Wi-Fi, you should run a command similar to the following to stop the database:

```
asadmin> stop-database dbhost localhost
```

You can also view the full syntax and options of the subcommand by typing `asadmin help stop-database` at the command line.

H2 Database documentation

For further details on how to configure the embedded H2 database you can visit the following: H2 Database Documentation.

Configuring Access to the Database

After establishing the database, you are ready to set up access for Payara Server applications. The high-level steps include creating a JDBC connection pool, creating a JDBC resource for the connection pool, and integrating a JDBC driver into an administrative domain.

Administering JDBC Connection Pools

A JDBC connection pool is a group of reusable connections for a particular database. Because creating each new physical connection is time-consuming, Payara Server maintains a pool of available connections. When an application requests a connection, it obtains one from the pool. When an application closes a connection, the connection is returned to the pool. JDBC connection pools can be globally accessible or be scoped to an enterprise application, web module, EJB module, connector module or application client module, as described in "Application-Scoped Resources" in the Payara Server Application Deployment section.

A JDBC resource is created by specifying the connection pool with which the resource is associated. Multiple JDBC resources can specify a single connection pool. The properties of connection pools can vary with different database vendors. Some common properties are the database name (URL), the username, and the password.

To Create a JDBC Connection Pool

It is possible to create a JDBC connection pool using administration commands or on the web

administration console.

Using administration commands

Use the `create-jdbc-connection-pool` subcommand in remote mode to register a new JDBC connection pool with the specified JDBC connection pool name. A JDBC connection pool or a connector connection pool can be created with authentication. You can either use a subcommand option to specify user, password, or other connection information using the `asadmin` utility, or specify the connection information in the XML descriptor file.

One connection pool is needed for each database, possibly more depending on the application. When you are building the connection pool, certain data specific to the JDBC driver and the database vendor is required. You can find some of the following specifics in Configuration Specifics for JDBC Drivers:

- Database vendor name
- Resource type, such as `javax.sql.DataSource` (local transactions only) `javax.sql.XADataSource` (global transactions)
- Data source class name
- Required properties, such as the database name (URL), username, and password

Creating a JDBC connection pool is a dynamic event and does not require server restart. However, there are some parameters that do require server restart. See Configuration Changes That Require Restart.

Before You Begin

Before creating the connection pool, you must first install and integrate the database and its associated JDBC driver. For instructions, see Setting Up the Database.

1. Ensure that the server is running.
   Remote subcommands require a running server.
2. Create the JDBC connection pool by using the `create-jdbc-connection-pool` subcommand.
3. If needed, restart the server. Some parameters require server restart. See Configuration Changes That Require Restart.

Example 11-3 To Create a JDBC Connection Pool

This example creates a JDBC connection pool named `sample_derby_pool` on `localhost`.

```
asadmin> create-jdbc-connection-pool --datasourceclassname
org.apache.derby.jdbc.ClientDataSource --restype javax.sql.XADataSource --property
portNumber=1527:password=APP:user=APP:serverName=localhost:databaseName=sun-appserv-
samples:connectionAttributes=\;create\\=true sample_derby_pool

Command create-jdbc-connection-pool executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-`

`jdbc-connection-pool` at the command line.

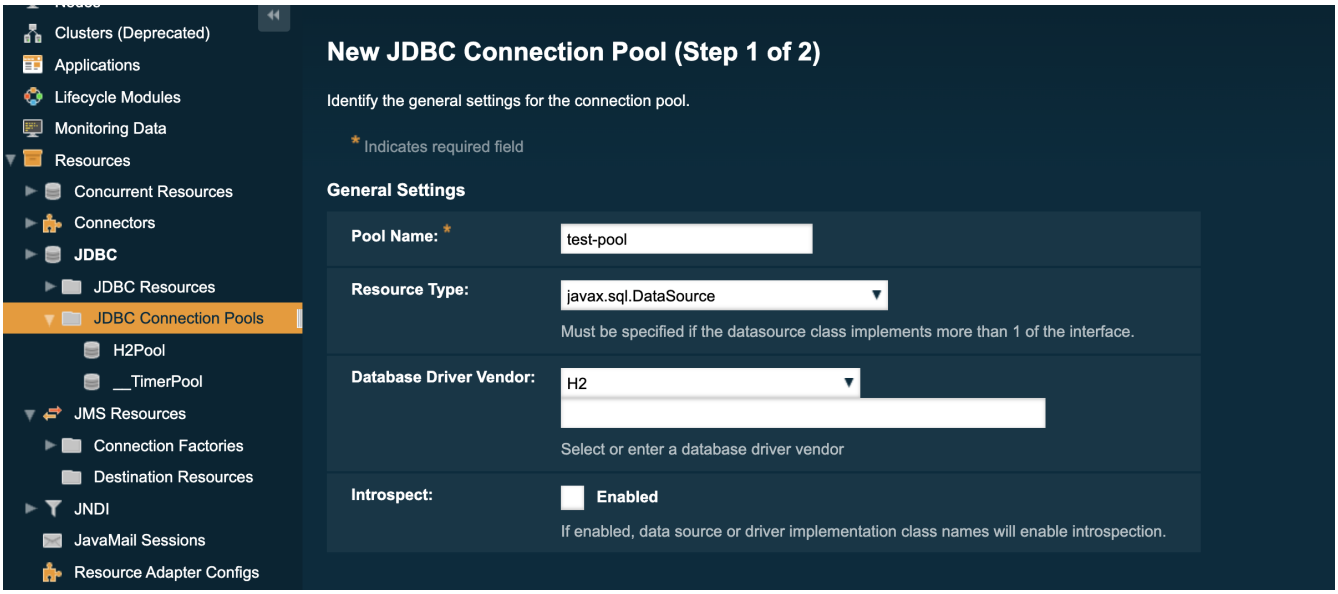
Using Admin Console

In the left hand panel of the Admin console go to *Resources → JDBC → JDBC Connection Pools*

Click the *New* button and enter the following values:

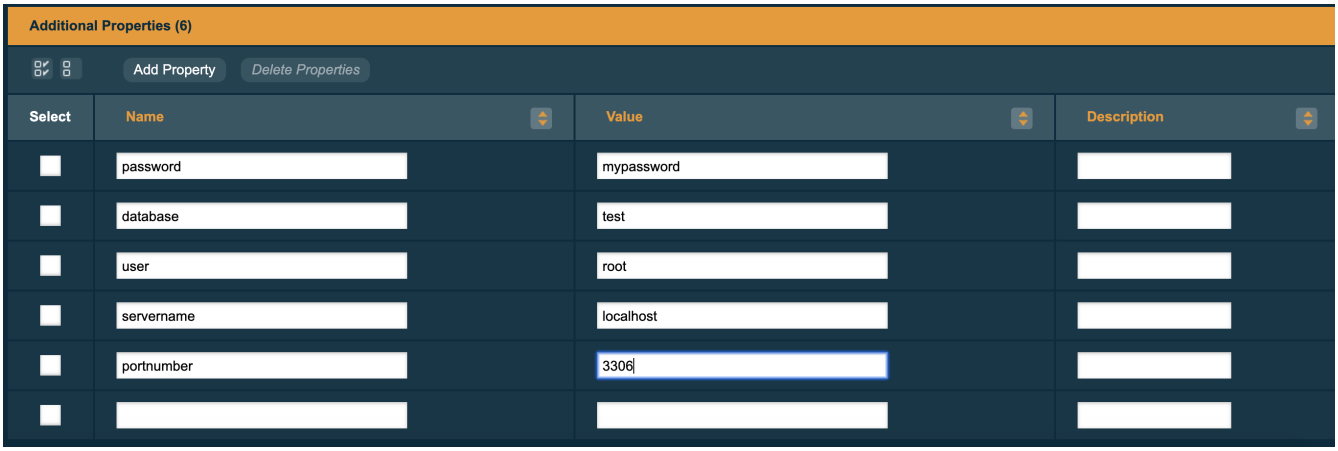
Setting Name	Value
Pool Name	test-pool
Resource Type	`javax.sql.DataSource`
Driver Vendor	(value for the driver, e.g. Derby30 for a Derby DB, MySQL for a MySQL DB)

Click Next and then click Finish on the next screen, accepting the default values.



Add the following properties to the connection pool by going to the *Additional Properties* tab of the connection pool:

Setting name	Value	Description
PortNumber	3306	Database port
Password	`mypassword`	Database password
User	root	Database user
serverName	localhost	Database address
DatabaseName	test	Name of the database
connectionAttributes		Other connection attributes (supported by the JDBC driver)



To test the connection attributes, go back to the *General* tab and click the *Ping* button at the top of the screen. You should see a message stating that the ping succeeded.

To List JDBC Connection Pools

Use the `list-jdbc-connection-pools` subcommand in remote mode to list all existing JDBC connection pools.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the JDBC connection pools by using the `list-jdbc-connection-pools` subcommand.

Example 11-4 To List a JDBC Connection Pool

This example lists the JDBC connection pools that are on `localhost`.

```
asadmin> list-jdbc-connection-pools
sample_derby_pool2
poolA
__TimerPool
H2Pool
sample_derby_pool
Command list-jdbc-connection-pools executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-jdbc-connection-pools` at the command line.

To Contact (Ping) a Connection Pool

Use the `ping-connection-pool` subcommand in remote mode to test if a connection pool is usable. For example, if you create a new JDBC connection pool for an application that is expected to be deployed later, you can test the JDBC pool with this subcommand before the application is deployed.

Running a ping will force the creation of the pool if it hasn't already been created.

Before You Begin

Before you can contact a connection pool, the connection pool must be created with authentication, and the server or database must be running.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Ping a connection pool by using the `ping-connection-pool` subcommand.

Example 11-5 To Contact (Ping) a Connection Pool

This example tests to see if the `DerbyPool` connection pool is usable.

```
asadmin> ping-connection-pool DerbyPool
Command ping-connection-pool executed successfully
```

You can also view the full syntax and options of the subcommand by typing `asadmin help ping-connection-pool` at the command line.

You can also specify that a JDBC connection pool is automatically tested when created or reconfigured by setting its `--ping` option to `true`(the default is `false`). See To Create a JDBC ConnectionPool or To Update a JDBC Connection Pool.

To Reset (Flush) a Connection Pool

Use the `flush-connection-pool` in remote mode to reinitialize all connections established in the specified connection pool without the need for reconfiguring the pool. Connection pool reconfiguration can result in application redeployment, which is a time-consuming operation.

The JDBC connection pool or connector connection pool is reset to its initial state. Any existing live connections are destroyed, which means that the transactions associated with these connections are lost and must be retried. The subcommand then recreates the initial connections for the pool, and restores the pool to its steady pool size.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Reset a connection pool by using the `flush-connection-pool` subcommand.

Example 11-6 Resetting (Flushing) a Connection Pool

This example resets the JDBC connection pool named `__TimerPool` to its steady pool size.

```
asadmin> flush-connection-pool __TimerPool
Command flush-connection-pool executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help flush-connection-pool` at the command line.

To Update a JDBC Connection Pool

You can change all settings for an existing pool except its name. Use the `get` and `set` subcommands to view and change the values of the JDBC connection pool properties.

1. List the JDBC connection pools by using the `list-jdbc-connection-pools` subcommand.
2. View the attributes of the JDBC connection pool by using the get subcommand.

   For example: `asadmin get resources.jdbc-connection-pool.H2Pool.property`

3. Set the attribute of the JDBC connection pool by using the `set` subcommand.

   For example: `asadmin set resources.jdbc-connection-pool.H2Pool.steady-pool-size=9`

4. If needed, restart the server.

Some parameters require server restart. See
Configuration Changes That Require Restart.

Connection pool sizing

Connection pools should be sized to cater for the maximum number of concurrent connections.

The maximum size should be set in accordance with the maximum number of client requests your system or application can process. If your application receives 100 requests and each of those requires a database connection then if your connection pool is anything less than 100 some of those requests will have to wait for a connection to either be created or become available.

The minimum size of the connection pool ensures that a number of connections to the database are always established - this means that if you have a pool with a minimum size of 10, and you receive 10 requests then all can retrieve a database connection without waiting for the pool to create a new connection.

Setting the sizes using the admin console

Click on the connection pool name and under the *Pool Settings* section you will find Initial and Minimum Pool Size and Maximum Pool Size. Set these to your required sizes:

Setting the sizes using administration commands

To set the initial and minimum pool size (to the value of **10** for example), use the following administration commands:

```
asadmin> set resources.jdbc-connection-pool.test-pool.steady-pool-size=10
```

To set the maximum pool size (to the value of **200** for example), use the following administration commands:

```
asadmin> set resources.jdbc-connection-pool.test-pool.max-pool-size=200
```

Connection validation

Connection validation ensures that connections aren't assigned to your application after the connection has already gone stale.

Connection validation is always a trade-off between how sure you want to be that a connection is valid and the performance impact that the validation mechanism can exert into application that use the pool. There will be a negative performance impact by having to return an invalid connection by your application and borrow a new one, so finding the right balance is key.

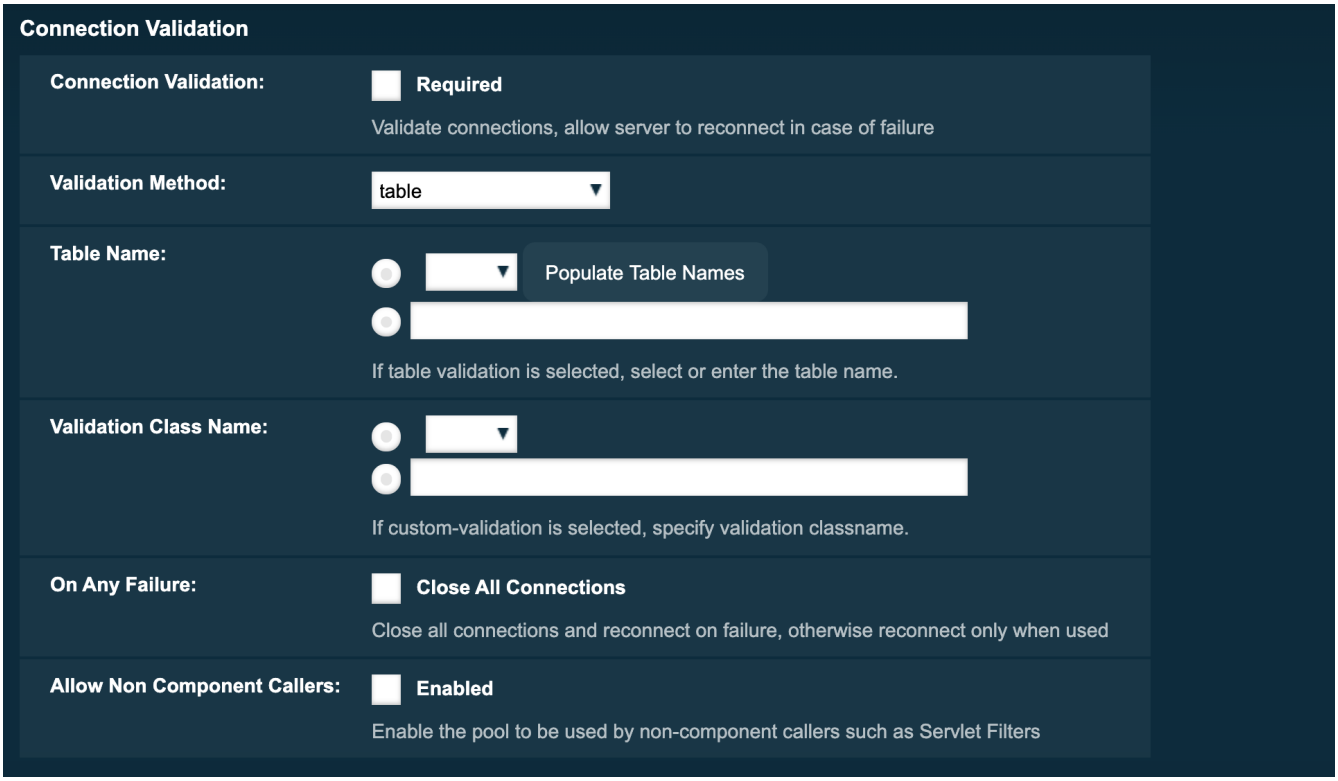
Before using a connection from the pool a simple query is sent to test the connection. If there is an issue with the connection, it is removed from the pool and another one is used. If you have an issue such as the database being down, and you have a large number of connections then each of those connections will be tested and removed.

In order to avoid this, you can set a connection validation so that if a connection fails, all remaining open connections are closed.

Set up the validation using the admin console

1. Click on the name of the connection pool
2. Select the *Advanced* tab
3. Scroll down to the *Connection Validation* section and select the following settings:
    a. *Connection Validation required*
    b. *Validation method* - custom-validation
    c. *Validation class name* – a proper class name for the chosen JDBC driver, such as `org.glassfish.api.jdbc.validation.DerbyConnectionValidation` for a **Derby DB**

From the same screen, you can also set whether to close all connections on failure.



Additional information regarding enabling connection validation through 'asadmin' commands, along with various options, is elaborated in the the `Handling Invalid Connections` section of our Payara Server Application Development JDBC documentation.

To Delete a JDBC Connection Pool

Use the `delete-jdbc-connection-pool` subcommand in remote mode to delete an existing JDBC connection pool. Deleting a JDBC connection pool is a dynamic event and does not require server restart.

Before You Begin

Before deleting a JDBC connection pool, all associations to the resource must be removed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the JDBC connection pools by using the `list-jdbc-connection-pools` subcommand.
3. If necessary, notify users that the JDBC connection pool is being deleted.
4. Delete the connection pool by using the `delete-jdbc-connection-pool` subcommand.

Example 11-7 To Delete a JDBC Connection Pool

This example deletes the JDBC connection pool named `H2Pool`.

```
asadmin> delete-jdbc-connection-pool jdbc/H2Pool
Command delete-jdbc-connection-pool executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-jdbc-connection-pool` at the command line.

Configuring Specific JDBC Connection Pool Features

In Payara Server, JDBC Connection Pools support a variety of features to simplify administration, monitoring and performance tuning.

Transparent Pool Reconfiguration

When the properties or attributes of a JDBC connection pool are changed, the connection pool is destroyed and re-created. Normally, applications using the connection pool must be redeployed as a consequence. This restriction can be avoided by enabling transparent JDBC connection pool reconfiguration. When this feature is enabled, applications do not need to be redeployed. Instead, requests for new connections are blocked until the reconfiguration operation completes. Connection requests from any in-flight transactions are served using the old pool configuration to complete the transaction. Then, connections are created using the pool's new configuration, and any blocked connection requests are served with connections from the re-created pool.

To enable transparent JDBC connection pool reconfiguration, set the `dynamic-reconfiguration-wait-timeout-in-seconds` property of the JDBC connection pool to a positive, nonzero value in one of the following ways:

- Add it as a property in the Edit JDBC Connection Pool Properties page in the Administration Console.
- Specify it using the `--property` option in the `create-jdbc-connection-pool` subcommand. For more information, see `create-jdbc-connection-pool`.
- Set it using the `set` subcommand. For example:

```
asadmin set resources.jdbc-connection-pool.pool-name.property.dynamic-
reconfiguration-wait-timeout-in-seconds=15
```

This property specifies the time in seconds to wait for in-use connections to close and in-flight transactions to complete. Any connections in use or transaction in flight past this time must be retried.

Using an Initialization Statement

You can specify a statement that executes each time a physical connection to the database is created (not reused) from a JDBC connection pool. This is useful for setting request or session specific properties and is suited for homogeneous requests in a single application. Set the *Init SQL* attribute of the JDBC connection pool to the SQL string to be executed in one of the following ways:

- Enter an *Init SQL* value in the Edit Connection Pool Advanced Attributes page in the Administration Console.
- Specify the `--initsql` option in the `asadmin create-jdbc-connection-pool` command. For more information, see `create-jdbc-connection-pool`.
- Specify the `init-sql` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.H2Pool.init-sql="sql-string"
```

Setting a Statement Timeout

An abnormally long-running JDBC query executed by an application may leave it in a hanging state unless a timeout is explicitly set on the statement. Setting a statement timeout guarantees that all queries automatically time out if not completed within the specified period.

When statements are created, the `queryTimeout` is set according to the statement timeout setting. This works only when the underlying JDBC driver supports `queryTimeout` for `Statement`, `PreparedStatement`, `CallableStatement`, and `ResultSet`.

You can specify a statement timeout in the following ways:

- Enter a Statement Timeout value in the Edit Connection Pool Advanced Attributes page in the Administration Console.
- Specify the `--statementtimeout` option in the `asadmin create-jdbc-connection-pool` command. For more information, see `create-jdbc-connection-pool`.

Statement and Connection Leak Detection and Reclamation

This feature allows you to set specific time-outs so that if SQL statements or JDBC connections haven't been closed by an application (potentially leading to a memory leak) they can be logged and/or closed.

If statements are not closed by an application after use, it is possible for the application to run out of cursors. Enabling statement leak detection causes statements to be considered as leaked if they are not closed within a specified period. Additionally, leaked statements can be reclaimed automatically.

By default, these values are set to **0** meaning this detection feature is turned off.

When working on a test or staging environment, it is recommended that leaks are logged after a short timeout but not closed. On production environments, it is recommended that leaks are closed and all logged leaks are monitored instead.

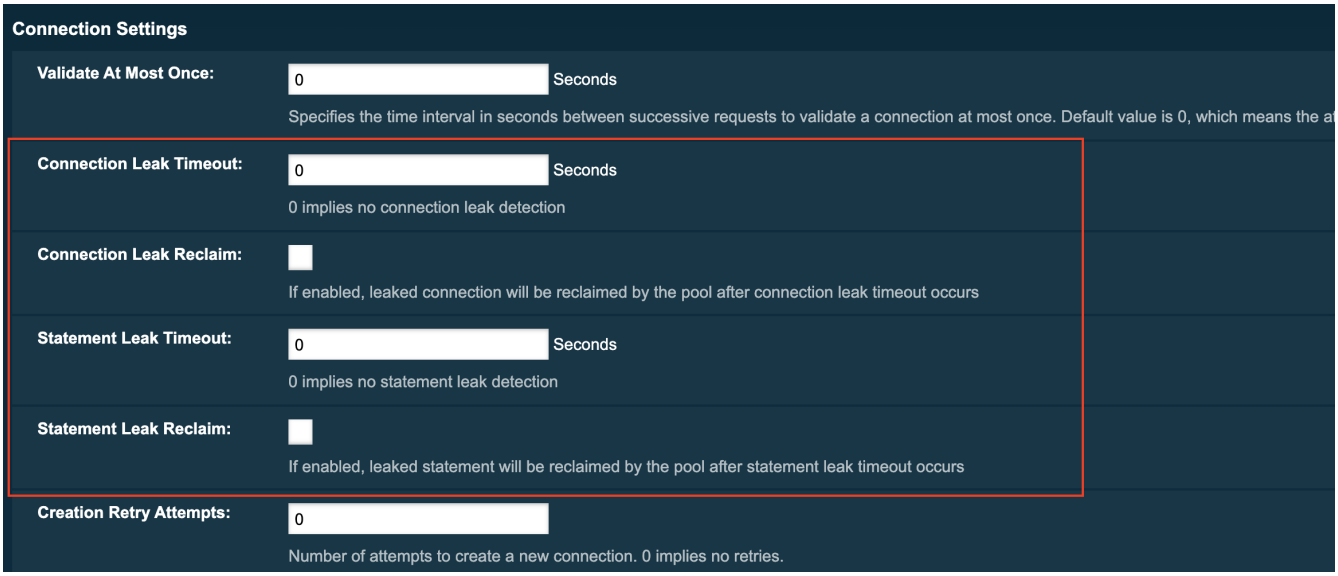
When selecting a value for Statement Leak Timeout In Seconds, make sure that:

- It is less than the Connection Leak Timeout; otherwise, the connection could be closed before the statement leak is recognized.
- It is greater than the Statement Timeout; otherwise, a long-running query could be mistaken as a statement leak.

Configuring Leak Detection using the admin console

1. Click on the name of the JDBC connections pool
2. Select the *Advanced* tab
3. Scroll down to *Connection Settings*

4. Set the *Connection Leak Timeout* and *Statement Leak Timeout* value in seconds



Configuring Leak Detection using administration commands

You also can set the time-out values using the following `asadmin` commands:

```
asadmin> set resources.jdbc-connection-pool.test-pool.statement-leak-timeout-in-
seconds=5
asadmin> set resources.jdbc-connection-pool.test-pool.connection-leak-timeout-in-
seconds=5
```

You can turn on reclaiming of the leaking resources with the following commands:

```
asadmin> set resources.jdbc-connection-pool.DerbyPool.connection-leak-reclaim=true
asadmin> setresources.jdbc-connection-pool.DerbyPool.statement-leak-reclaim=true
```

Once these values are set, if connection or statement leaks are detected, you will see messages similar to the example below in the application log:

```
WARNING: A potential connection leak detected for connection pool test-pool. The stack
trace of the thread is provided below:
 ...
```

Enabling JDBC Call Logging

With **Log JDBC Calls** configured on the connection call each call into the connection pool is timed and logged to the server log at the `FINE` level. A typical log message with Log JDBC Enabled is shown below:

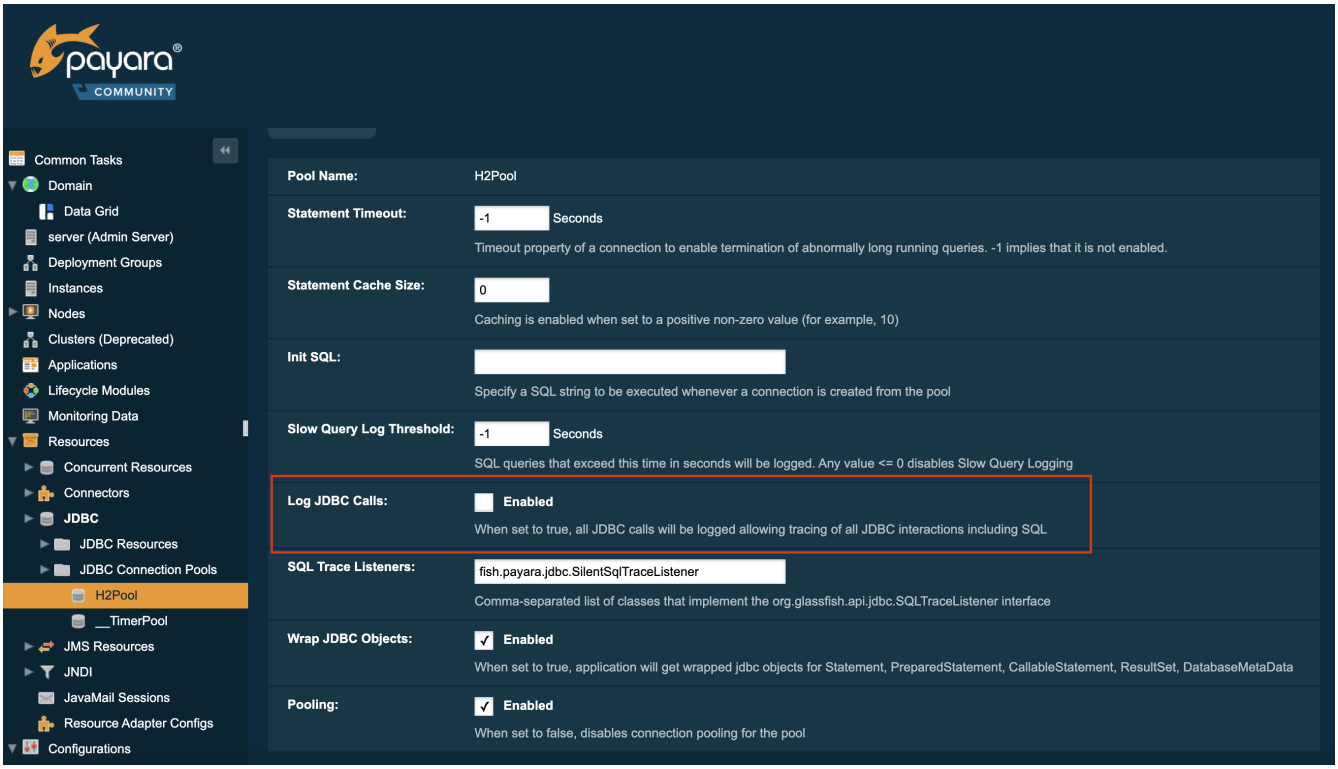
```
[#|2025-11-12T18:51:01.467+0000|FINE|Payara
7.2025.1|javax.enterprise.resource.sqltrace.com.sun.gjc.util|_ThreadID=35;_ThreadName=
http-listener-
```

```
1(5);_TimeMillis=1454611861467;_LevelValue=500;ClassName=com.sun.gjc.util.SQLTraceLogg
er;MethodName=sqlTrace;|
  PoolName=H2Pool | ExecutionTime=1ms |
ClassName=org.apache.derby.client.net.NetConnection40 | MethodName=prepareStatement |
arg[0]=SELECT ID, AGE, BIO, BIRTHDATE, BIRTHDAY, DATEFORMAT, DATEOFBIRTH, DATEOFHIRE,
EMAIL, HIREDATE, HIREDAY, MEMBERAGE, NAME, TODAYSDATE FROM MEMBERENTITY WHERE (NAME =
?) | arg[1]=1003 | arg[2]=1007 | |#]
```

Using the Administration Console

SQL Tracing can be enabled through the Payara Server Web administration console. First, navigate to the advanced table of your JDBC connection pool, then select the *JDBC* > *JDBC Connection pools* > *${Your Connection pool}*.

Then select the **Advanced Tab** in the main window of the administration console. Then select the checkbox next to **Log JDBC Calls** to enable logging of all SQL calls:



Using Asadmin Commands

The **Log JDBC Calls** setting for a JDBC connection pool can also be configured via asadmin using the `set` command to set the `fish.payara.log-jdbc-calls` property of your connection pool to `true`, like in the following example:

```
asadmin set domain.resources.jdbc-connection-pool.__TimerPool.log-jdbc-calls=true
```

Advanced Connection Pool Properties in Deployment Descriptors

Payara Server supports setting advanced JDBC connection pool properties directly on data source definitions made with the `@DataSourceDefinition` annotation or directly on deployment descriptors.

Setting Properties in the Deployment Descriptor

In a Jakarta EE application, a data source definition can be added to a deployment descriptor of an application. For a web application, you would this in the standard *web.xml* deployment descriptor. To set advanced properties just add a `property` element as shown in the following example:

```
<data-source>
    <name>java:global/ExampleDataSource</name>
    <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
    <server-name>localhost</server-name>
    <port-number>3306</port-number>
    <database-name>mysql</database-name>
    <user>test</user>
    <password>test</password>
    <!-- Example of how to use a Payara specific custom connection pool setting -->
    <property>
       <name>fish.payara.is-connection-validation-required</name>
       <value>true</value>
    </property>
</data-source>
```

Setting Properties on the `@DataSourceDefinition` Annotation.

In Jakarta EE applications, a JDBC data source can be deployed by adding the `@DataSourceDefinition` annotation to a managed component (like and `@Stateless` EJB bean for example). To configure advanced JDBC properties, use the `properties` attribute of the annotation to define an array of the properties to configure:

```
@DataSourceDefinition(
    name = "java:app/MyApp/MyDS",
    className = "org.h2.jdbcx.JdbcDataSource",
    url = "jdbc:h2:mem:test",
    properties = {"fish.payara.is-connection-validation-required=true"})
public class ApplicationComponent{
}
```

Full List of Properties

The complete list of configurable properties is the following:

Property	Value Type	Default	Notes
`fish.payara.is-connection-validation-required`	`Boolean`	`false`	`true` - Validate connections, allow server to reconnect in case of failure

Property	Value Type	Default	Notes
`fish.payara.connection-validation-method`	`String`		The method of connection validation table, `auto-commit`, `meta-data`, `custom-validation`
`fish.payara.validation-table-name`	`String`		The name of the table used for validation if the validation method is set to `table`
`fish.payara.validation-classname`	`String`		The name of the custom class used for validation if the `validation-method` is set to `custom-validation`
`fish.payara.fail-all-connections`	`Boolean`	`false`	Close all connections and reconnect on failure, otherwise reconnect only when used
`fish.payara.allow-non-component-callers`	`Boolean`	`false`	Enable the pool to be used by non-component callers such as Servlet Filters
`fish.payara.validate-atmost-once-period-in-seconds`	`Number`	`0`	Specifies the time interval in seconds between successive requests to validate a connection at most once. Default value is `0`, which means the attribute is not enabled.
`fish.payara.connection-leak-timeout-in-seconds`	`Number`	`0`	`0` implies no connection leak detection
`fish.payara.connection-leak-reclaim`	`Boolean`	`false`	If enabled, leaked connection will be reclaimed by the pool after connection leak timeout occurs
`fish.payara.connection-creation-retry-attempts`	`Number`	`0`	Number of attempts to create a new connection. 0 implies no retries

Property	Value Type	Default	Notes
`fish.payara.connection-creation-retry-interval-in-seconds`	`Number`	`10`	Time interval between retries while attempting to create a connection. Effective when Creation Retry Attempts is greater than 0.
`fish.payara.statement-timeout-in-seconds`	`Number`	`-1`	Timeout property of a connection to enable termination of abnormally long-running queries. `-1` implies that it is not enabled.
`fish.payara.lazy-connection-enlistment`	`Boolean`	`false`	Enlist a resource to the transaction only when it is actually used in a method
`fish.payara.lazy-connection-association`	`Boolean`	`false`	Connections are lazily associated when an operation is performed on them
`fish.payara.associate-with-thread`	`Boolean`	`false`	When the same thread is in need of a connection, it can reuse the connection already associated with that thread
`fish.payara.pooling`	`Boolean`	`true`	When set to `false`, disables connection pooling for the pool
`fish.payara.statement-cache-size`	`Number`	`0`	Caching is enabled when set to a positive non-zero value (for example, `10`)
`fish.payara.match-connections`	`Boolean`	`true`	Turns connection matching for the pool ON or OFF

Property	Value Type	Default	Notes
`fish.payara.max-connection-usage-count`	`Number`	`0`	Connections will be reused by the pool for the specified number of times, after which they will be closed. `0` implies the feature is not enabled.
`fish.payara.wrap-jdbc-objects`	`Boolean`	`true`	When set to `true`, application will get wrapped jdbc objects for `Statement`, `PreparedStatement`, `CallableStatement`, `ResultSet`, `DatabaseMetaData`
`fish.payara.sql-trace-listeners`	`String`		Comma-separated list of classes that implement the `org.glassfish.api.jdbc.SQLTraceListener` interface
`fish.payara.ping`	`Boolean`	`false`	When enabled, the pool is pinged during creation or reconfiguration to identify and warn of any erroneous values for its attributes
`fish.payara.init-sql`	`String`		Specify a SQL string to be executed whenever a connection is created from the pool
`fish.payara.statement-leak-timeout-in-seconds`	`Number`	`0`	`0` implies no statement leak detection
`fish.payara.statement-leak-reclaim`	`Boolean`	`false`	If enabled, leaked statement will be reclaimed by the pool after statement leak timeout occurs
`fish.payara.statement-cache-type`	`String`		

Property	Value Type	Default	Notes
`fish.payara.slow-query-threshold-in-seconds`	`Number`	`-1`	SQL queries that exceed this time in seconds will be logged. Any value ⇐ 0 disables Slow Query Logging
`fish.payara.log-jdbc-calls`	`Boolean`	`false`	When set to `true`, all JDBC calls will be logged allowing tracing of all JDBC interactions including SQL
`fish.payara.skip-client-info-validation`	`Boolean`	`false`	When set to `true`, client info will not be validated.

Example Data Source Configuration

An example data source configured on the *web.xml* and deployed with a custom **SQL Trace Listener** is shown below. This data source is configured to also validate all connections returned from the connection pool before giving them to the application using the built-in *MySQL* **Connection Validation** class. The data source is also configured to log any queries that exceed **5** seconds and also logs ALL JDBC statements:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://xmlns.jcp.org/xml/ns/javaee"
     xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
     xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee
http://xmlns.jcp.org/xml/ns/javaee/web-app_3_1.xsd"
     version="3.1">
    <session-config>
        <session-timeout>30</session-timeout>
    </session-config>
    <data-source>
      <name>java:global/ExampleDataSource</name>
      <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
      <server-name>localhost</server-name>
      <port-number>3306</port-number>
      <database-name>mysql</database-name>
      <user>test</user>
      <password>test</password>
      <!-- Example of how to use a Payara specific custom connection pool setting -->
      <property>
          <name>fish.payara.slow-query-threshold-in-seconds</name>
          <value>5</value>
      </property>
      <property>
          <name>fish.payara.log-jdbc-calls</name>
          <value>true</value>
```

```
      </property>
      <property>
          <name>fish.payara.sql-trace-listeners </name>

<value>fish.payara.examples.payaramicro.datasource.example.CustomSQLTracer</value>
      </property>
      <property>
          <name>fish.payara.is-connection-validation-required</name>
          <value>true</value>
      </property>
      <property>
          <name>fish.payara.connection-validation-method</name>
          <value>custom-validation</value>
      </property>
      <property>
          <name>fish.payara.validation-classname</name>
          <value>org.glassfish.api.jdbc.validation.MySQLConnectionValidation</value>
      </property>
    </data-source>
</web-app>
```

Administering JDBC Resources

A JDBC resource, also known as a data source, provides an application with a means of connecting to a database. Typically, you create a JDBC resource for each database that is accessed by the applications deployed in a domain. Multiple JDBC resources can be specified for a database. JDBC resources can be globally accessible or be scoped to an enterprise application, web module, EJB module, connector module or application client module, as described in "Application-Scoped Resources" in the Payara Server Application Deployment section.

A JDBC resource is created by specifying the connection pool with which the resource will be associated. Use a unique Java Naming and Directory Interface (JNDI) name to identify the resource. For example, the JNDI name for the resource of a payroll database might be `java:comp/env/jdbc/payrolldb`.

The Jakarta EE standard specifies that certain default resources be made available to applications, and defines specific JNDI names for these default resources. Payara Server makes these names available through the use of logical JNDI names, which map Jakarta EE standard JNDI names to specific Payara Server resources. For JDBC resources, the Jakarta EE standard name `java:comp/DefaultDataSource` is mapped to the `jdbc/__default` resource.

To Create a JDBC Resource

Use the `create-jdbc-resource` subcommand in remote mode to create a JDBC resource. Creating a JDBC resource is a dynamic event and does not require server restart.

Because all JNDI names are in the `java:comp/env` subcontext, when specifying the JNDI name of a JDBC resource in the Administration Console, use only the `jdbc/`name format. For example, a payrolldatabase might be specified as `jdbc/payrolldb`.

Before You Begin

Before creating a JDBC resource, you must first create a JDBC connection pool. For instructions, see To Create a JDBC Connection Pool.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a JDBC resource by using the `create-jdbc-resource` subcommand.

   Information about properties for the subcommand is included in this help page.
3. If necessary, notify users that the new resource has been created.

Example 11-8 To Create a JDBC Resource

This example creates a JDBC resource named `H2Pool`.

```
asadmin> create-jdbc-resource --connectionpoolid H2Pool jdbc/H2Pool
Command create-jdbc-resource executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-jdbc-resource` at the command line.

To List JDBC Resources

Use the `list-jdbc-resources` subcommand in remote mode to list the existing JDBC resources.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List JDBC resources by using the `list-jdbc-resources` subcommand.

Example 11-9 To List a JDBC Resource

This example lists JDBC resources for `localhost`.

```
asadmin> list-jdbc-resources
jdbc/__TimerPool
jdbc/H2Pool
jdbc/__default
jdbc1
Command list-jdbc-resources executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-jdbc-resources` at the command line.

To Update a JDBC Resource

You can enable or disable a JDBC resource by using the `set` subcommand. The JDBC resource is identified by its dotted name.

1. List JDBC resources by using the `list-jdbc-resources` subcommand.

2. Modify the values for the specified JDBC resource by using the `set` subcommand.

For example:

Example 11-10 To Update a JDBC Resource

This example changes the `res1` enabled setting to `false`.

```
asadmin>set resources.jdbc-resource.res1.enabled=false
```

To Delete a JDBC Resource

Use the `delete-jdbc-resource` subcommand in remote mode to delete an existing JDBC resource. Deleting a JDBC resource is a dynamic event and does not require server restart.

Before You Begin

Before deleting a JDBC resource, all associations with this resource must be removed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List JDBC resources by using the `list-jdbc-resources` subcommand.
3. If necessary, notify users that the JDBC resource is being deleted.
4. Delete a JDBC resource by using the `delete-jdbc-resource` subcommand.

Example 11-11 To Delete a JDBC Resource

This example deletes a JDBC resource named `H2Pool`.

```
asadmin> delete-jdbc-resource jdbc/H2Pool
Command delete-jdbc-resource executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-jdbc-resource` at the command line.

Enabling the `jdbc/__default` Resource in a Clustered Environment

Payara Server includes a preconfigured JDBC resource with the JNDI name `jdbc/default`. This `jdbc/default` resource is not enabled by default in a traditional cluster, so you need to explicitly enable it if you want to use it in a cluster.

To Enable the `jdbc/__default` Resource for a Clustered Environment

Instructions for creating JDBC resources in general are provided in To Create a JDBC Resource. Use the following procedure to enable the preconfigured `jdbc/__default` resource for a clustered Payara Server environment.

1. Create the `jdbc/default resource reference for the cluster. for example: 'asadmin create-resource-ref --target cluster-name jdbc/`default'

2. Enable the resource on the DAS that manages the cluster, for example: 'asadmin set resources.jdbc-connection-pool.DerbyPool.property.serverName=DAS-machine-name'

This step is only required if the cluster includes remote instances. Restart the DAS and the target cluster(s).

```
asadmin stop-cluster cluster-name
asadmin stop-domain domain-name
asadmin start-domain domain-name
asadmin start-cluster cluster-name
```

Integrating the JDBC Driver

To use JDBC features, you must choose a JDBC driver to work with Payara Server, then you must set up the driver.

Supported Database Drivers

For a list of the JDBC drivers currently supported by the Payara Server, see the Payara Release Notes. For configurations of supported and other drivers, see Configuration Specifics for JDBC Drivers.

Because the drivers and databases supported by the Payara Server are constantly being updated, and because database vendors continue to upgrade their products, always check with Oracle technical support for the latest database support information.

Making the JDBC Driver JAR Files Accessible

To integrate the JDBC driver into a Payara Server domain, copy the JAR files into the `domain-dir/lib` directory, then restart the server. This makes classes accessible to all applications or modules deployed on servers that share the same configuration. For more information about Payara Server class loaders, see "Class Loaders" in the Payara Server Application Development section.

Automatic Detection of Installed Drivers

The Administration Console detects installed JDBC Drivers automatically when you create a JDBC connection pool. To create a JDBC connection pool using the Administration Console, open the Resources component, open the JDBC component, select Connection Pools, and click on the New button. This displays the New JDBC Connection Pool page.

Based on the Resource Type and Database Vendor you select on the New JDBC Connection Pool page, data source or driver implementation class names are listed in the Datasource Classname or Driver Classname field when you click on the Next button. When you choose a specific implementation class name on the next page, additional properties relevant to the installed JDBC driver are displayed in the Additional Properties section.

Configuration Specifics for JDBC Drivers

Payara Server is designed to support connectivity to any database management system by using a corresponding JDBC driver.

IBM DB2 Database Type 4 Driver

The JAR file for the DB2 driver is `db2jcc.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: DB2
- DataSource Classname: `com.ibm.db2.jcc.DB2SimpleDataSource`
- Properties:
  - `databaseName` - Set as appropriate.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.
  - `driverType` - Set to `4`.

Apache Derby DB/Derby Type 4 Driver

The JAR file for the Apache Derby DB driver is `derbyclient.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: Apache Derby
- DataSource Classname: Specify one of the following:

```
org.apache.derby.jdbc.ClientDataSource40
org.apache.derby.jdbc.ClientXADataSource40
```

- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server if it is different from the default.
  - `databaseName` - Specify the name of the database.
  - `user` - Specify the database user.
    This is only necessary if the Apache Derby database is configured to use authentication. The Apache Derby database does not use authentication by default. When the user is provided, it is the name of the schema where the tables reside.
  - `password` - Specify the database password.
    This is only necessary if the Apache Derby database is configured to use authentication.

MySQL Server Database Type 4 Driver

The JAR file for the MySQL driver is `mysql-connector-java-5.1.14-bin.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: MySql
- DataSource Classname:

```
com.mysql.jdbc.jdbc2.optional.MysqlDataSource
com.mysql.jdbc.jdbc2.optional.MysqlXADataSource
```

- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `databaseName` - Set as appropriate.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

Oracle 10 Database Driver

The JAR file for the Oracle 10 database driver is `ojdbc14.jar`. Make sure that the shared library is available through `LD_LIBRARY_PATH` and that the `ORACLE_HOME` property is set.

To make the Oracle driver behave in a Jakarta EE-compliant manner, you must define the following JVM property:

```
-Doracle.jdbc.J2EE13Compliant=true
```

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: Oracle
- DataSource Classname: Specify one of the following:

```
oracle.jdbc.pool.OracleDataSource
oracle.jdbc.xa.client.OracleXADataSource
```

- Properties:
  - `user` - Set as appropriate.

- `password` - Set as appropriate.

Oracle 11 Database Driver

The JAR file for the Oracle 11 database driver is `ojdbc6.jar`.

To make the Oracle driver behave in a Jakarta EE-compliant manner, you must define the following JVM property:

```
-Doracle.jdbc.J2EE13Compliant=true
```

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: Oracle
- DataSource Classname: Specify one of the following:

  ```
  oracle.jdbc.pool.OracleDataSource
  oracle.jdbc.xa.client.OracleXADataSource
  ```

- Properties:
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

For this driver, the `XAResource.recover` method repeatedly returns the same set of in-doubt Xids regardless of the input flag. According to the XA specifications, the Transaction Manager initially calls this method with `TMSTARTSCAN` and then with `TMNOFLAGS` repeatedly until no Xids are returned. The `XAResource.commit` method also has some issues.
To disable this Payara Server workaround, the `oracle-xa-recovery-workaround` property value must be set to `false`.
Additionally, in order for the transaction manager to recover transactions, the JDBC connection pool's database user must be given certain Oracle permissions:
SELECT permission on DBA_PENDING_TRANSACTIONS, PENDING_TRANS$, DBA_2PC_PENDING and DBA_2PC_NEIGHBORS. EXECUTE permissions on DBMS_XA and DBMS_SYSTEM.

PostgreSQL Type 4 Driver

The JAR file for the PostgreSQL driver is `postgresql-9.0-801.jdbc4.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.

- Database Vendor: Postgresql
- DataSource Classname: `org.postgresql.ds.PGSimpleDataSource`
- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `databaseName` - Set as appropriate.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

DataDirect Type 4 Driver for IBM DB2 Database

The JAR file for DataDirect driver is `db2.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: DataDirect-DB2
- DataSource Classname: `com.ddtek.jdbcx.db2.DB2DataSource`
- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `databaseName` - Set as appropriate.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

DataDirect Type 4 Driver for IBM Informix

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: DataDirect-Informix
- DataSource Classname: Specify one of the following:

  ```
  com.informix.jdbcx.IfxDataSource
  com.informix.jdbcx.IfxXADataSource
  ```

  DataDirect DataSource Classname: `com.ddtek.jdbcx.informix.InformixDataSourcee`

- Properties:
  - `serverName` - Specify the Informix database server name.

- `portNumber` - Specify the port number of the database server.
- `databaseName` - Set as appropriate. This is optional.
- `user` - Set as appropriate.
- `password` - Set as appropriate.
- `IfxIFXHost` - Specify the host name or IP address of the database server.

DataDirect Type 4 Driver for Microsoft SQL Server Database

The JAR file for the DataDirect driver is `sqlserver.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: DataDirect-Microsoft SQL Server
- DataSource Classname: `com.ddtek.jdbcx.sqlserver.SQLServerDataSource`
- Properties:
  - `serverName` - Specify the host name or IP address and the port of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.
  - `selectMethod` - Set to `cursor`.

DataDirect Type 4 Driver for MySQL Server Database

The JAR file for the DataDirect driver is `mysql.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: DataDirect-MySQL
- DataSource: `com.ddtek.jdbcx.mysql.MySQLDataSource`
- Properties:
  - `serverName` - Specify the host name or IP address and the port of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.
  - `selectMethod` - Set to `cursor`.

DataDirect Type 4 Driver for Oracle 11 Database

The JAR file for the DataDirect driver is `oracle.jar`.

To make the Oracle driver behave in a Jakata EE-compliant manner, you must define the following JVM property:

```
-Doracle.jdbc.J2EE13Compliant=true
```

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: DataDirect-Oracle
- DataSource Classname: `com.ddtek.jdbcx.oracle.OracleDataSource`
- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

DataDirect Type 4 Driver for Sybase Database

The JAR file for the DataDirect driver is `sybase.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: DataDirect-Sybase
- DataSource Classname: `com.ddtek.jdbcx.sybase.SybaseDataSource`
- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `databaseName` - Set as appropriate. This is optional.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

In some situations, using this driver can cause exceptions to be thrown because the driver creates a stored procedure for every parameterized PreparedStatement by default. If this situation arises, add the property `PrepareMethod`, setting its value to `direct`.

Inet Merlia Driver for Microsoft SQL Server Database

The JAR file for the Inet Microsoft SQL Server driver is `Merlia.jar`. Configure the connection pool

using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: MicrosoftSqlServer
- DataSource Classname: `com.inet.tds.TdsDataSource`
- Properties:
  - `serverName` - Specify the host name or IP address and the port of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

Inet Sybelux Driver for Sybase Database

The JAR file for the Inet Sybase driver is `Sybelux.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: Sybase
- DataSource Classname: `com.inet.syb.SybDataSource`
- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `databaseName` - Set as appropriate. Do not specify the complete URL, only the database name.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.

JConnect Type 4 Driver for Sybase ASE 12.5 Database

The JAR file for the Sybase driver is `jconn4.jar`. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: Sybase
- DataSource Classname: Specify one of the following:

```
com.sybase.jdbc4.jdbc.SybDataSource
com.sybase.jdbc4.jdbc.SybXADataSource
```

- Properties:
  - `serverName` - Specify the host name or IP address of the database server.
  - `portNumber` - Specify the port number of the database server.
  - `databaseName` - Set as appropriate. Do not specify the complete URL, only the database name.
  - `user` - Set as appropriate.
  - `password` - Set as appropriate.
  - `BE_AS_JDBC_COMPLIANT_AS_POSSIBLE` - Set to `true`.
  - `FAKE_METADATA` - Set to `true`.

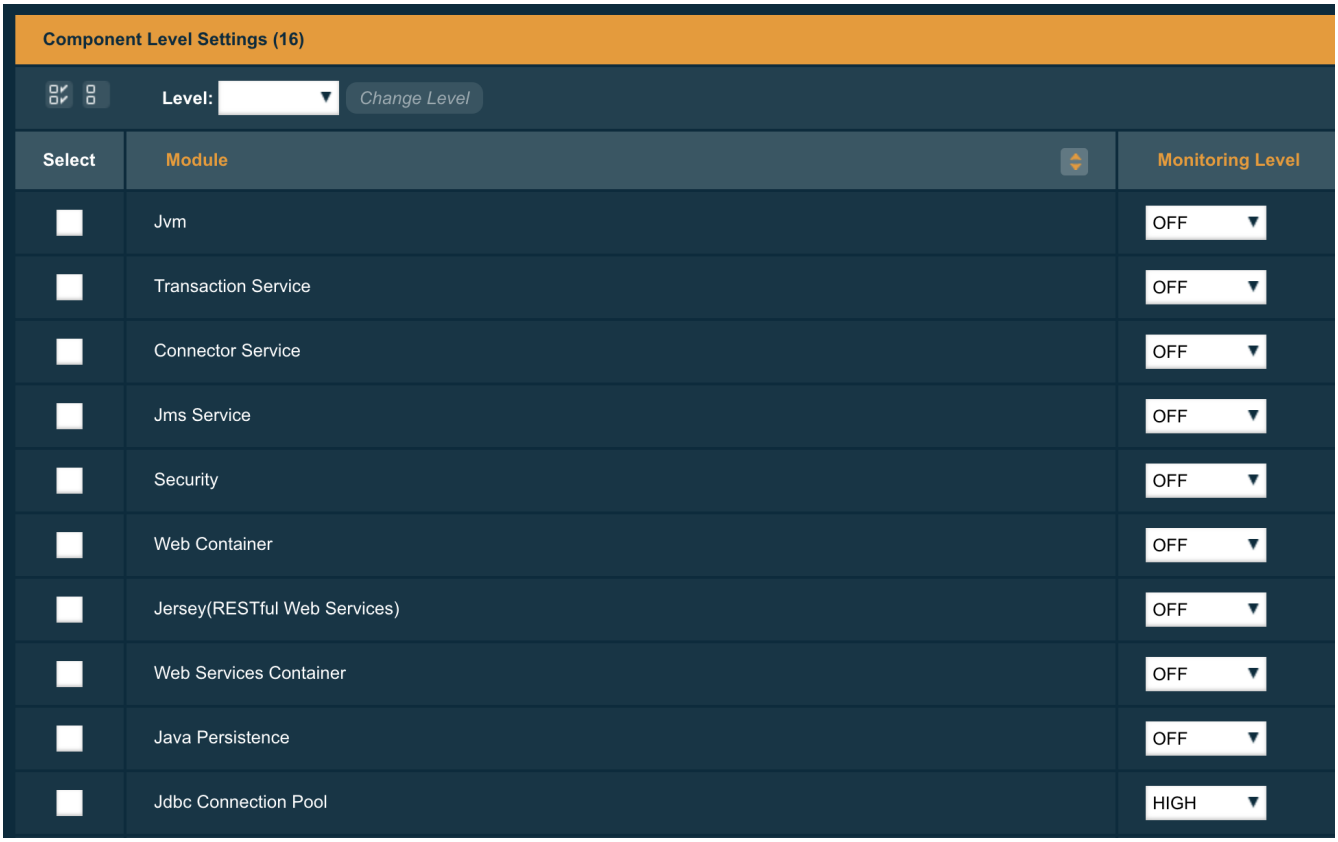
SQL Management in Payara Server

Payara Server keeps track of the recently executed SQL statements for monitoring purposes. This way, one can review which SQL statements are executed, how many times the same statement is executed and how long it took.

Activate Overview

The activation of the collection is controlled by the monitoring service.

When using the Web Administration console, go to *Configuration → [instance-configuration (like server-config)] → Monitoring:* and select the level *High* for the *JDBC Connection pool* component.



When using the *asadmin* CLI, you can execute the following command to set the *Level Value*

```
set configs.config.server-config.monitoring-service.module-monitoring-levels.jdbc-
```

```
connection-pool=HIGH
```

The information can be consulted via the JMX beans or the Rest monitoring interface. These need to be activated also, see jmx monitoring configuration and rest monitoring configuration on how to do this.

Viewing statements

When you want to retrieve the information through the JMX channel, you can find the information in the following MBean:

```
amx:pp=/mon/server-mon[server],type=jdbcra-mon,name=resources/<pool-name>
```

When using the Rest monitoring interface, you can access the following URL

```
http://localhost:4848/monitoring/domain/server/resources/<pool-name>
```

In both cases, the *<pool-name>* is the actual pool name you have created within Payara Server and which you like to retrieve the information for.

The properties we want to highlight here are

`frequsedsqlqueries`
: Contains the list of all SQL statements and their execution count, which are executed during the collection time frame.

`slowSqlQueries`
: Contains again the list of all SQL statements but this time with the maximum execution time they took.

Configuring parameters

The SQL statement collection has a few configuration values which have default values.

- Timeframe: By default, the info about the SQL statements are retained during 5 minutes
- Cache size: The information is kept in a cache which has by default place for 100000 items.

These values can be configured by defining some key-value pairs in the properties for the connection pool. This can be done during the creation or afterward by updating the pool.

- TIME-TO-KEEP-QUERIES-IN-MINUTES: This defines the number of minutes the SQL statement info is retained.
- MAX-CACHE-SIZE: This defines the maximum size of the cache.

Setting the maximum size of the cache to `0` will disable it completely.

When the cache size is too small, you see an information message in the log to indicate that not all

statements could be retained.

Slow SQL Logger

Many performance problems in Enterprise Applications can be traced to slow database access. Payara Server includes capabilities to detect and log slow SQL queries executed via a JDBC Connection pool. The Slow SQL logger monitors all queries executed on the connection pool and if they exceed a configurable execution time in seconds a warning message is logged into the server log.

The warning message (see below) logs the SQL query and the stack trace to the code executing the query. This enables rapid diagnosis by pinpointing the exact lines of code to investigate.

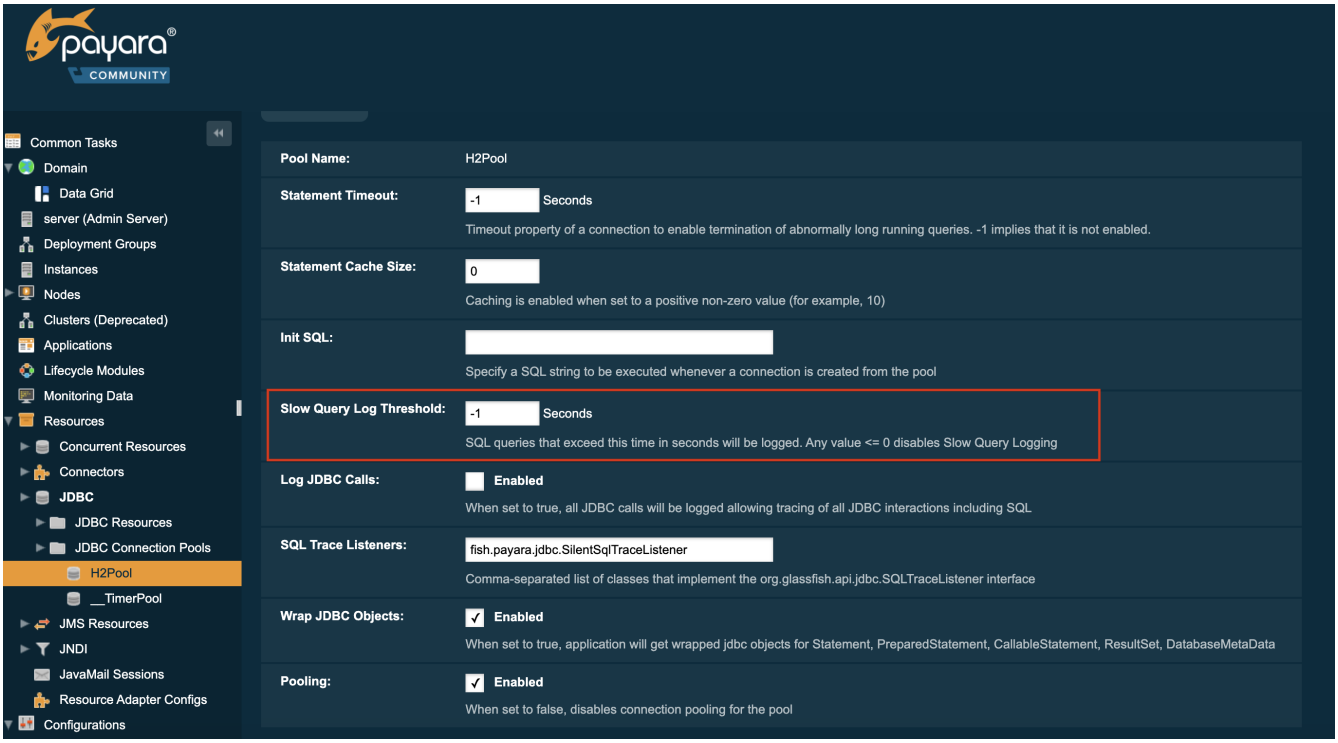
Configuring the Slow SQL Logger

Ensure Wrap JDBC Objects is enabled in your JDBC Connection Pool (enabled by default) for the Slow SQL Logger to function correctly.

There are a number of ways to configure the slow SQL threshold time on a JDBC connection pool.

Using the Administration Console

To configure slow SQL logging on a JDBC connection pool via the administration console, navigate to the Connection Pool's **Advanced Properties** tab. Then specify the **Slow Query Log Threshold** time in seconds or use a decimal value to signify milliseconds.



setting the threshold to -1 will disable the feature

Using Asadmin commands

The **Slow Query Log Threshold** time for a JDBC connection pool can also be configured with an

`asadmin` command, by using the `set` command to set the `slow-query-threshold-in-seconds` property, like in the following example:

```
asadmin set domain.resources.jdbc-connection-pool.__TimerPool.slow-query-threshold-in-seconds=50
```

You can also set the threshold time to milliseconds simply by passing a decimal value. Below is an example of setting the threshold on the `__TimerPool` JDBC connection pool to **200** milliseconds:

```
asadmin set domain.resources.jdbc-connection-pool.__TimerPool.slow-query-threshold-in-seconds=0.2
```

Configuring SQL Trace Listeners

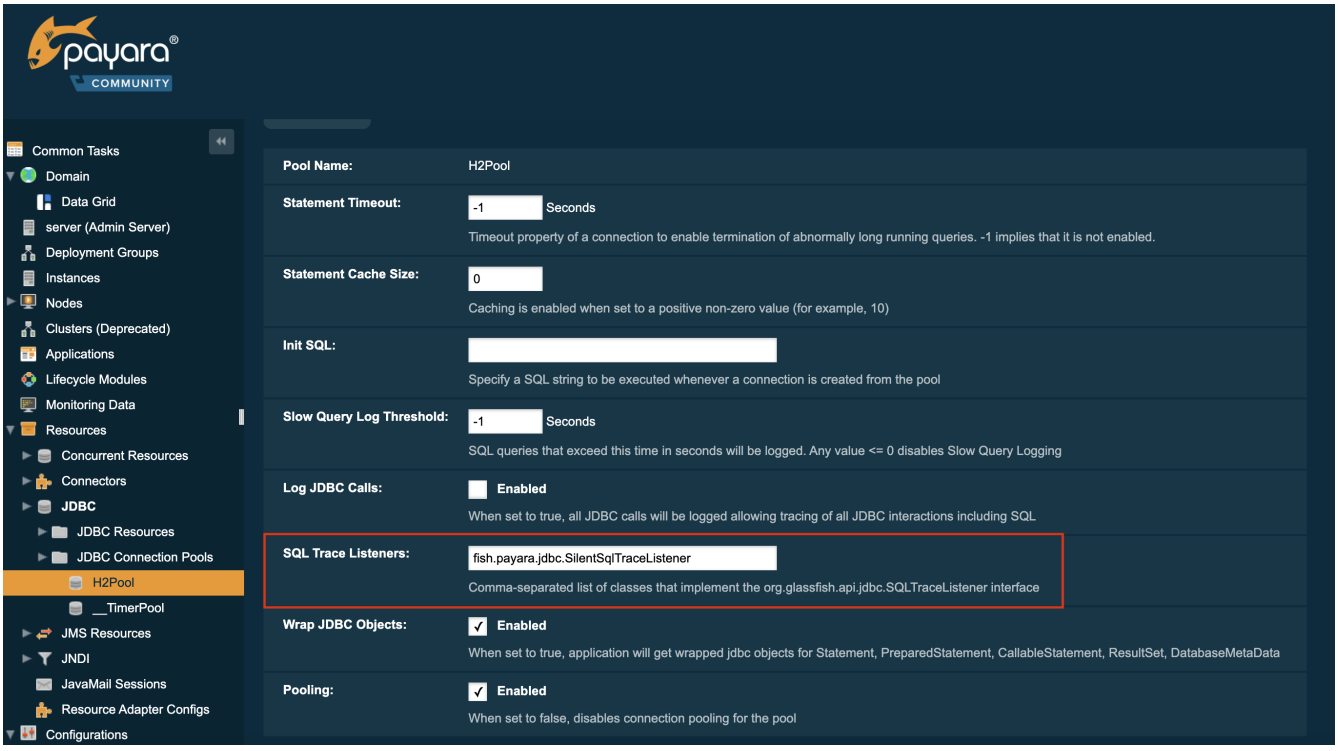
Payara Server provides support for custom SQL Trace Listeners. A **SQL Trace Listener** is registered against a data source and is called after each method call made on the JDBC connection pool.

More information on how to implement a SQL Trace listener can be found in the Application Development section.

Using the Administration Console

SQL Trace Listeners can be enabled on a JDBC connection pool through the administration web console. Navigate to the **Advanced Tab** of your connection pool by selecting the JDBC → JDBC Connection Pools → <**Your Connection pool**>.

Proceed to add the fully qualified class name of your SQL Trace Listener implementation class in the **SQL Trace Listeners** field:



The implementation class must be on the server's *classpath* for it to work correctly.

Using asadmin commands

SQL Trace Listeners can be enabled on a JDBC connection pool using with an `asadmin` commands by using the `set` command to set the `fish.payara.lsql-trace-listeners` to the fully qualified class name of your listener implementation, like on the following example:

```
asadmin set domain.resources.jdbc-connection-pool.__TimerPool.sql-trace-
listeners=fish.payara.examples.payaramicro.datasource.example.CustomSQLTracer
```

Administering EIS Connectivity

This chapter provides information and procedures for administering connections to enterprise information system (EIS) data in the Payara Server environment by using the `asadmin` command-line utility.

If you installed the Web Profile, connector modules that use only outbound communication features and work management that does not involve inbound communication features are supported. Other connector features are supported only in the Full Platform Profile.

Instructions for accomplishing the tasks in this chapter by using the Administration Console are contained in the Administration Console online help.

For information about database connectivity, see Administering Database Connectivity.

About EIS Connectivity

Enterprise information system (EIS) refers to any system that holds the data of an organization. It can be a mainframe, a messaging system, a database system, or an application. Connection resources are used by applications and modules to Create an Administered Object applications and modules to access EIS software.

The key elements of EIS connectivity are the following:

- **Connector Module**. A connector module also called a resource adapter, is a Jakarta EE component that enables applications to interact with EIS software. A connector module is used by Payara Server to implement Java Message Service (JMS). Like other Jakarta EE modules, a connector module is installed when it is deployed. For instructions on creating a connector module, see Developing Connectors in the Payara Server Application Development section.
- **Connector Connection Pool**. A connector connection pool is a group of reusable connections for a particular EIS. A connector connection pool is created when you specify the connector module that is associated with the pool. For administration procedures, see Administering Connector Connection Pools.
- **Connector Resource**. A connector resource is a program object that provides an application with a connection to an EIS. A connector resource is created when you specify its JNDI name

and its associated connection pool. The JNDI name of a connector resource for an EIS is usually in the `java:comp/env/eis-specific` subcontext. For administration procedures, see Administering Connector Resources.

- **Connector Module Configuration**. A connector module configuration is the information that resides in the domain configuration file (`domain.xml`) for the particular connector module (resource adapter). For administration procedures, see Administering the Resource Adapter Configuration.
- **Connector Security Map**. A connector security map associates the caller identity of the application (principal or user group) to a suitable EIS principal or group. For administration procedures, see Administering Connector Security Maps.
- **Connector Work Security Map**. A connector work security map associates the caller identity of the work submitted by the connector module (resource adapter) EIS principal or EIS user group to a suitable principal or user group in the Payara Server security domain. For administration procedures, see Administering Connector Work Security Maps.
- **Administered Object**. An administered object provides specialized functionality for an application, such as providing access to a parser that is specific to the connector module and its associated EIS. For administration procedures, see Administering Administered Objects.

At runtime, the following sequence occurs when an application connects to an EIS:

1. The application gets the connector resource (data source) associated with the EIS by making a call through the JNDI API. Using the JNDI name of the connector resource, the naming and directory service locates the resource. Each EIS resource specifies a connector connection pool.
2. Using the connector resource, the application gets an EIS connection. Payara Server retrieves a physical connection from the connection pool that corresponds to the EIS resource. The pool defines connection attributes such as the EIS name, username, and password.
3. After the EIS connection is established, the application can read, modify, and add data to the EIS. The application accesses the EIS information by making calls to the JMS API.
4. When the application is finished accessing the EIS, the application closes the connection and returns the connection to the connection pool.

You can view the full syntax and options of the subcommand by typing `asadmin help ``subcommand` at the command line. For Example:

```
asadmin help create-connector-connection-pool
```

Administering Connector Connection Pools

After a connector module has been deployed, you are ready to create a connector connection pool for it.

To Create a Connector Connection Pool

Use the `create-connector-connection-pool` subcommand in remote mode to create a connector connection pool for a deployed connector module. When you are building the connector connection

pool, certain data specific to the EIS will be required. The value in the mandatory `--connectiondefintion` option provides the EIS info.

Multiple connector resources can specify a single connection pool.

Creating a connector connection pool is a dynamic event and does not require server restart. However, there are some parameters that do require server restart. See Configuration Changes That Require Restart.

Before creating the connector connection pool, the connector must be installed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create the connector connection pool by using the `create-connector-connection-pool` subcommand. Information about properties for the subcommand is included in this help page.
3. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.
4. You can verify that a connection pool is usable by using the `ping-connection-pool` subcommand. For instructions, see To Contact (Ping) a Connection Pool.

Example 12-1 Creating a Connector Connection Pool

```
asadmin> create-connector-connection-pool --steadypoolsize 20 --maxpoolsize 100
--poolresize 2 --maxwait 60000 --raname jmsra --connectiondefinition
jakarta.jms.QueueConnectionFactory jms/qConnPool

Command create-connector-connection-pool executed successfully
```

To List Connector Connection Pools

Use the `list-connector-connection-pools` subcommand in remote mode to list the pools that have been created.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the connector connection pools by using the `list-connector-connection-pools`) subcommand.

Example 12-2 Listing Connector Connection Pools

```
asadmin> list-connector-connection-pools
jms/qConnPool
Command list-connector-connection-pools executed successfully
```

To Connect to (Ping) or Reset (Flush) a Connector Connection Pool

Use the `ping-connection-pool` or `flush-connection-pool` subcommands in remote mode to perform these tasks on a connection pools. See To Contact (Ping) a Connection Pool or To Reset (Flush) a Connection Pool for instructions.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Connect to or reset a connector connection pool by using the `flush-connection-pool` subcommand or the `ping-connection-pool` subcommand.

To Update a Connector Connection Pool

Use the `get` and `set` subcommands to view and change the values of the connector connection pool properties.

1. List the connector connection pools by using the `list-connector-connection-pools` subcommand.
2. View the properties of the connector connection pool by using the `get` subcommand.

   For example:

   ```
   asadmin> get domain.resources.connector-connection-pool.*
   ```

3. Set the property of the connector connection pool by using the `set` subcommand.

   For example:

   ```
   asadmin> set domain.resources.connector-connection-pool
   .conectionpoolname.validate-atmost-once-period-in-seconds=3
   ```

4. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

To Delete a Connector Connection Pool

Use the `delete-connector-connection-pool` subcommand in remote mode to remove a connector connection pool.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the connector connection pools by using the `list-connector-connection-pools` subcommand.
3. If necessary, notify users that the connector connection pool is being deleted.
4. Delete the connector connection pool by using the `delete-connector-connection-pool` subcommand.

Example 12-3 Deleting a Connector Connection Pool

```
asadmin> delete-connector-connection-pool --cascade=false jms/qConnPool
Command delete-connector-connection-pool executed successfully
```

Administering Connector Resources

A connector resource provides an application or module with the means of connecting to an EIS. Typically, you create a connector resource for each EIS that is accessed by the applications deployed in the domain.

To Create a Connector Resource

Use the `create-connector-resource` subcommand in remote mode to register a new connector resource with its JNDI name.

Creating a connector resource is a dynamic event and does not require server restart. However, there are some parameters that do require server restart. See Configuration Changes That Require Restart.

Before creating a connector resource, you must first create a connector connection pool. For instructions, see To Create a Connector Connection Pool.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create the connector resource by using the `create-connector-resource` subcommand. Information about properties for the subcommand is included in this help page.
3. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 12-4 Creating a Connector Resource

```
asadmin> create-connector-resource --poolname jms/qConnPool
--description "creating sample connector resource" jms/qConnFactory
Command create-connector-resource executed successfully
```

To List Connector Resources

Use the `list-connector-resources` subcommand in remote mode to list the connector resources that have been created.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the connector connection pools by using the `list-connector-resources` subcommand.

Example 12-5 Listing Connector Resources

```
asadmin> list-connector-resources
jms/qConnFactory
Command list-connector-resources executed successfully
```

To Update a Connector Resource

Use the `get` and `set` subcommands to view and change the values of the connector resource properties.

1. List the connector connection pools by using the `list-connector-resources` subcommand.
2. View the properties of the connector resource by using the `get` subcommand.

For example

```
asadmin> get domain.resources.connector-resource.jms/qConnFactory
```

3. Set the property of the connector resource by using the `set` subcommand.

   For example:

   ```
   asadmin> set domain.resources.connector-resource.jms/qConnFactory.enabled=true
   ```

4. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

To Delete a Connector Resource

Use the `delete-connector-resource` subcommand in remote mode to remove a connector resource by specifying the JNDI name.

Before deleting a resource, all associations with the resource must be removed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the connector connection pools by using the `list-connector-resources` subcommand.
3. If necessary, notify users that the connector resource is being deleted.
4. Delete the connector resource by using the `delete-connector-resource` subcommand.

Example 12-6 Deleting a Connector Resource

```
asadmin> delete-connector-resource jms/qConnFactory
Command delete-connector-resources executed successfully
```

Administering the Resource Adapter Configuration

To Create Configuration Information for a Resource Adapter

Use the `create-resource-adapter-config` subcommand in remote mode to create configuration information for a resource adapter, also known as a connector module. You can run the subcommand before deploying a resource adapter, so that the configuration information is available at the time of deployment. The resource adapter configuration can also be created after the resource adapter is deployed. In this situation, the resource adapter is restarted with the new configuration.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create configuration information by using the `create-resource-adapter-config` subcommand. Information about properties for the subcommand is included in this help page.

Example 12-7 Creating a Resource Adapter Configuration

```
asadmin> create-resource-adapter-config --property foo=bar
```

```
--threadpoolid mycustomerthreadpool ra1
Command create-resource-adapter-config executed successfully
```

To List Resource Adapter Configurations

Use the `list-resource-adapter-configs` subcommand in remote mode to list the configuration information contained in the domain configuration file (`domain.xml`) for the specified resource adapter (connector module).

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the configurations for a resource adapter by using the `list-resource-adapter-configs` subcommand.

Example 12-8 Listing Configurations for a Resource Adapter

```
asadmin> list-resource-adapter-configs
ra1
ra2
Command list-resource-adapter-configs executed successfully
```

To Update a Resource Adapter Configuration

Use the `get` and `set` subcommands to view and change the values of the resource adapter configuration properties.

1. List the configurations for a resource adapter by using the `list-resource-adapter-configs` subcommand.
2. View the properties of the connector resource by using the `get` subcommand.

   For example:

   ```
   asadmin>get domain.resources.resource-adapter-config.ra1.*
   ```

3. Set the property of the connector resource by using the `set` subcommand.

   For example:

   ```
   asadmin> set domain.resources.resource-adapter-config.ra1.raSpecificProperty=value
   ```

To Delete a Resource Adapter Configuration

Use the `delete-resource-adapter-config` subcommand in remote mode to delete the configuration information contained in the domain configuration file (`domain.xml`) for a specified resource adapter (connector module).

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the configurations for a resource adapter by using the `list-resource-adapter-configs` subcommand.

3. Delete the configuration for a resource adapter by using the `delete-resource-adapter-config` subcommand.

   Example 12-9 Deleting a Resource Adapter Configuration

   ```
   asadmin> delete-resource-adapter-config ra1
   Command delete-resource-adapter-config executed successfully
   ```

Administering Connector Security Maps

The EIS is any system that holds the data of an organization. It can be a mainframe, a messaging system, a database system, or an application. The connector security map is used to map the application's credentials to the EIS credentials.

A security map applies to a particular connector connection pool. One or more named security maps can be associated with a connector connection pool.

To Create a Connector Security Map

Use the `create-connector-security-map` subcommand in remote mode to create a security map for the specified connector connection pool. If the security map is not present, a new one is created. You can specify back-end EIS principals or back-end EIS user groups. The connector security map configuration supports the use of the wild card asterisk `(*)` to indicate all users or all user groups.

You can also use this subcommand to map the caller identity of the application (principal or user group) to a suitable EIS principal in container-managed authentication scenarios.

For this subcommand to succeed, you must have first created a connector connection pool. For instructions, see To Create a Connector Connection Pool.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a connector security map by using the `create-connector-security-map` subcommand. Information about the options for the subcommand is included in this help page.
3. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 12-10 Creating a Connector Security Map

```
asadmin> create-connector-security-map --poolname connector-pool1
--principals principal1, principal2 --mappedusername backend-username securityMap1
Command create-connector-security-map executed successfully
```

To List Connector Security Maps

Use the `list-connector-security-maps` subcommand in remote mode to list the existing security maps belonging to the specified connector connection pool. You can get a simple listing of the connector security maps for a connector connection pool, or you can get a more comprehensive listing that shows the principals of the map.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List existing connector connection pools by using the `list-connector-connection-pools` subcommand.
3. List the security maps for a specific connector connection pool by using the `list-connector-security-maps` subcommand.

Example 12-11 Listing All Connector Security Maps for a Connector Connection Pool

```
asadmin> list-connector-security-maps connector-Pool1
securityMap1
Command list-connector-security-maps executed successfully.
```

Example 12-12 Listing Principals for a Specific Security Map for a Connector Connection Pool

```
asadmin> list-connector-security-maps --securitymap securityMap1 connector-Pool1
principal1
principal1
Command list-connector-security-maps executed successfully.
```

Example 12-13 Listing Principals of All Connector Security Maps for a Connector Connection Pool

```
asadmin> list-connector-security-maps --verbose connector-Pool1
securityMap1
principal1
principal1
Command list-connector-security-maps executed successfully.
```

To Update a Connector Security Map

Use the `update-connector-security-map` subcommand in remote mode to create or modify a security map for the specified connector connection pool.

1. Ensure that the server is running.
   Remote subcommands require a running server.
2. List existing connector security maps by using the `list-connector-security-maps` subcommand.
3. Modify a security map for a specific connector connection pool by using the `update-connector-security-map` subcommand.
4. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 12-14 Updating a Connector Security Map

```
asadmin> update-connector-security-map --poolname connector-pool1
--addprincipals principal1, principal2 securityMap1
Command update-connector-security-map executed successfully.
```

To Delete a Connector Security Map

Use the `delete-connector-security-map` subcommand in remote mode to delete a security map for the specified connector connection pool.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List existing connector connection pools by using the `list-connector-connection-pools` subcommand.
3. Delete a security map for a specific connector connection pool by `delete-connector-security-map` subcommand. Information about options for this subcommand is included in this help page.

Example 12-15 Deleting a Connector Security Map

```
asadmin> delete-connector-security-map --poolname connector-pool1 securityMap1

Command delete-connector-security-map executed successfully
```

Administering Connector Work Security Maps

The EIS is any system that holds the data of an organization. It can be a mainframe, a messaging system, a database system, or an application. The connector work security map is used to is used to map the EIS credentials to the credentials of Payara Server security domain.

A security map applies to a particular connector connection pool. One or more named security maps can be associated with a connector connection pool.

To Create a Connector Work Security Map

Use the `create-connector-work-security-map` subcommand in remote mode to map the caller identity of the work submitted by the connector module (resource adapter) EIS principal or EIS user group to a suitable principal or user group in the Payara Server security domain. One or more work security maps can be associated with a connector module.

The connector security map configuration supports the use of the wild card asterisk (*) to indicate all users or all user groups.

Before creating a connector work security map, you must first create a connector connection pool. For instructions, see To Create a Connector Connection Pool.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create the connector work security map by using the `create-connector-work-security-map` subcommand. Information about properties for the subcommand is included in this help page.
3. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 12-16 Creating Connector Work Security Maps

```
asadmin> create-connector-work-security-map --raname my-resource-adapter-name
--principalsmap eis-principal-1=server-principal-1,eis-principal-2=server-principal-2,
```

```
eis-principal-3=server-principal-1 workSecurityMap1

asadmin> create-connector-work-security-map --raname my-resource-adapter-name
--groupsmap eis-group-1=server-group-1,eis-group-2=server-group-2,
eis-group-3=server-group-1 workSecurityMap2
Command create-connector-work-security-map executed successfully
```

+ The following examples create `workSecurityMap1` and `workSecurityMap2` for `my-resource-adapter-name`.

To List Connector Work Security Maps

Use the `list-connector-work-security-maps` subcommand in remote mode to list the work security maps that belong to a specific connector module.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the connector work security maps by using the `list-connector-work-security-maps` subcommand.

Example 12-17 Listing the Connector Work Security Maps

```
asadmin> list-connector-work-security-maps generic-ra
generic-ra-groups-map: EIS group=eis-group, mapped group=payara-group
generic-ra-principals-map: EIS principal=eis-bar, mapped principal=bar
generic-ra-principals-map: EIS principal=eis-foo, mapped principal=foo
Command list-connector-work-security-maps executed successfully.
```

To Update a Connector Work Security Map

Use the `update-connector-work-security-map` subcommand in remote to modify a work security map that belongs to a specific resource adapter (connector module).

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the connector work security maps by using the `list-connector-work-security-maps` subcommand.
3. If necessary, notify users that the connector work security map is being modified.
4. Update a connector work security map by using the `update-connector-work-security-map` subcommand.

Example 12-18 Updating a Connector Work Security Map

```
asadmin> update-connector-work-security-map --raname generic-ra
--removeprincipals eis-foo generic-ra-principals-map
Command update-connector-work-security-map executed successfully.
```

To Delete a Connector Work Security Map

Use the `delete-connector-work-security-map` subcommand in remote mode to delete a work security

map that belongs to a specific connector module (resource adapter).

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the connector work security maps by using the `list-connector-work-security-maps` subcommand.
3. Delete a connector work security map by using the `delete-connector-work-security-map` subcommand.

Example 12-19 Deleting a Connector Work Security Map

```
asadmin> delete-connector-work-security-map --raname my_ra worksecuritymap1
Command delete-connector-work-security-map executed successfully.
```

Administering Administered Objects

Packaged within a connector module, an administered object provides specialized functionality for an application. For example, an administered object might provide access to a parser that is specific to the connector module and its associated EIS.

To Create an Administered Object

Use the `create-admin-object` subcommand to create an administered object resource. When creating an administered object resource, name-value pairs are created, and the object is associated to a JNDI name.

Before You Begin The resource adapter must be deployed before running this subcommand (`jmsrar.rar`).

1. Create an administered object by using the `create-admin-object` subcommand. Information about properties for the subcommand is included in this help page.
2. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 12-20 Creating an Administered Object

```
asadmin> create-admin-object --restype jakarta.jms.Queue --raname jmsra
--description "sample administered object" --property Name=sample_jmsqueue
jms/samplequeue
Command create-admin-object executed successfully
```

To List Administered Objects

Use the `list-admin-object` subcommand in remote mode to list the existing administered objects.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the administered objects by using the `list-admin-objects` subcommand.

Example 12-21 Listing Administered Objects

```
asadmin> list-admin-objects
jms/samplequeue
Command list-admin-objects executed successfully
```

To Update an Administered Object

Use the `get` and `set` subcommands to view and change the values of the administered objects properties.

1. List the administered objects by using the `list-admin-objects` subcommand.
2. View the properties of the administered object by using the `get` subcommand.

   For example:

   ```
   asadmin> get domain.resources.admin-object-resource.jms/samplequeue.*
   ```

3. Set the property of the administered object by using the `set` subcommand.

   For example:

   ```
   asadmin> set domain.resources.admin-object-resource.jms/samplequeue.enabled=false
   ```

4. If needed, restart the server. Some properties require server restart. See see Configuration Changes That Require Restart. If your server needs to be restarted, see see To Restart a Domain.

To Delete an Administered Object

Use the `delete-admin-object` subcommand to delete an administered objects.

1. List the administered objects by using the `list-admin-objects` subcommand.
2. If necessary, notify users that the administered object is being deleted.
3. Delete an administered object by using the `delete-admin-object` subcommand.

Example 12-22 Deleting an Administered Object

```
asadmin> delete-admin-object jms/samplequeue
Command delete-admin-object executed successfully
```

Administering HTTP Connectivity

This chapter provides procedures for performing HTTP connectivity tasks in the Payara Server environment by using the `asadmin` command-line utility.

Instructions for accomplishing the tasks in this chapter by using the Administration Console are contained in the Administration Console online help.

About Internet Connectivity

The HTTP service provides functionality for deploying web applications and for making deployed web applications accessible by Internet clients, either in a single application server instance or in a cluster of multiple server instances. HTTP services are provided by two kinds of related objects: listeners and virtual servers.

For more information about clusters, see the Payara Server High Availability section.

About HTTP Network Listeners

An HTTP listener, also known as a network listener, is a listen socket that has an Internet Protocol (IP) address, a port number, a server name, and a default virtual server. Each virtual server provides connections between the server and clients through one or more listeners. Each listener must have a unique combination of port number and IP address. For example, an HTTP listener can listen for a host on all configured IP addresses on a given port by specifying the IP address `0.0.0.0`.

A listener can listen on a specific port on all network interfaces by using the IP `0.0.0.0`, and a configured port. Alternatively, the listener can specify a unique IP address for each listener while using the same port.

A virtual server will then be used to select a combination of network listeners to use for an application. For example, Payara Server has two default network listeners for user deployed applications: an insecure listener on port 8080 (`http-listener-1`), and a secure listener on port 8181 (`http-listener-2`).

Because an HTTP listener is a combination of IP address and port number, you can have multiple HTTP listeners with the same IP address and different port numbers, or with different IP addresses and the same port number (if your host was configured to respond to these addresses). However, if an HTTP listener uses the `0.0.0.0` IP address, which listens on all IP addresses on a port, you cannot create HTTP listeners for additional IP addresses that listen on the same port for a specific IP address. For example, if an HTTP listener uses `0.0.0.0:8080` (all IP addresses on port 8080), another HTTP listener cannot use `1.2.3.4:8080`.

The host running the Payara Server typically has access to only one IP address. HTTP listeners typically use the `0.0.0.0` IP address and different port numbers, with each port number serving a different purpose. However, if the host does have access to more than one IP address, each address can serve a different purpose.

To access a web application deployed on Payara Server, use the URL `http://localhost:8080/` (or `https://localhost:8081/` for a secure application), along with the context root specified for the web application.

To access the Administration Console, use the URL `https://localhost:4848/` or `http://localhost:4848/asadmin/` (console default context root).

About Virtual Servers

A virtual server, sometimes called a virtual host, is an object that allows the same physical server to host multiple Internet domain names.

All virtual servers hosted on the same physical server share the IP address of that physical server. A virtual server associates a domain name for a server (such as `www.aaa.com`) with the particular server on which Payara Server is running. Each virtual server must be registered with the DNS server for your network.

Do not confuse an Internet domain with the administrative domain of Payara Server.

For example, assume that you want to host the following domains on your physical server: `www.aaa.com`, `www.bbb.com`, and `www.ccc.com`. Assume that these domains are respectively associated with web modules `web1`, `web2`, and `web3`. This means that the following URLs are handled by your physical server:

```
http://www.aaa.com:8080/web1
http://www.bbb.com:8080/web2
http://www.ccc.com:8080/web3
```

The first URL is mapped to virtual server `www.aaa.com`, the second URL is mapped to virtual server `www.bbb.com`, and the third is mapped to virtual server `www.ccc.com`. For this mapping to work, `www.aaa.com`, `www.bbb.com`, and `www.ccc.com` must all resolve to your physical server's IP address and each virtual server must be registered with the DNS server for your network. In addition, on a UNIX system, add these domains to your `/etc/hosts` file (if the setting for `hosts` in your `/etc/nsswitch.conf` file includes `files`).

Administering HTTP Network Listeners

By default, when Payara Server starts, the following HTTP listeners are started automatically:

- HTTP listeners associated with the virtual server named `server`:
  - The listener named `http-listener-1` does not have security enabled.
  - The listener named `http-listener-2` has security enabled
- An HTTP listener named `admin-listener`, associated with the virtual server named `__asadmin`. For this listener, security is not enabled.

The following table describes the Payara Server default ports for the listeners that use ports.

Table 2. Default Ports for Listeners

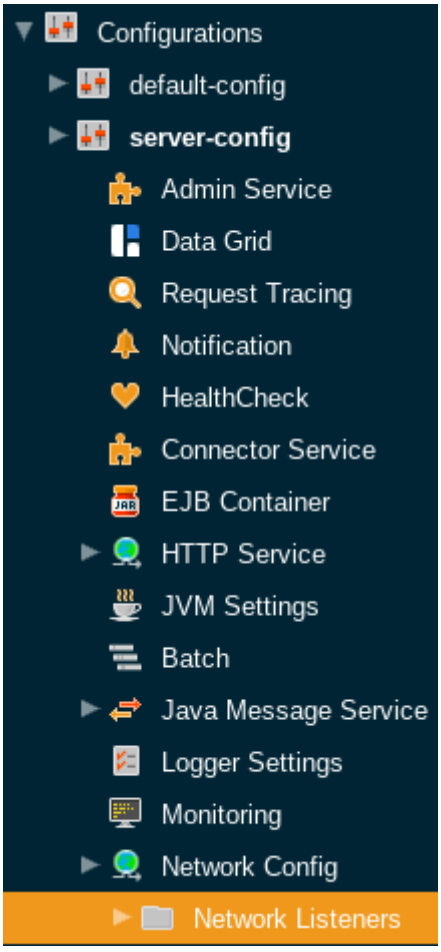
Listener	Default Port	Description
Administrative server	4848	A domain's administrative server is accessed by the Administration Console and the `asadmin` utility. For the Administration Console, specify the port number in the URL of the browser. When running an `asadmin` subcommand remotely, specify the port number by using the `--port` option.

Listener	Default Port	Description
HTTP	8080	The web server listens for HTTP requests on a port. To access deployed web applications and services, clients connect to this port.
HTTPS	8181	Web applications configured for secure communications listen on a separate port.

Network Listeners Configuration

When configuring network listeners from the admin console, there are some visible configuration options that transparently configure the protocol being used. If a configuration property isn't shown here but is visible in the admin console, see Protocols.

Existing network listeners can be configured from the admin console or with asadmin commands. The network listener configurations can be found in the admin console under **Configurations** → **your-config** → **Network Config** → **Network Listeners**.



The following fields can be configured for network listeners:

Table 3. Network Listeners Configuration

configuration settings	Description	Asadmin Command
Name	The unique name of the network listener. This cannot be edited from the admin console.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.name=value`
Protocol	The protocol used by the network listener. This cannot be edited from the admin console.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.protocol=${protocol-name}`
Status	The status of the network listener. This determines whether the listener will be actively listening for requests.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.enabled=[true/false]`
JK Enabled	Whether mod_jk support should be enabled for this listener. Should only be enabled if mod_jk is being explicitly configured on an Apache Web Server in conjunction with Payara Server.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.jk-enabled=[true/false]`
JK Configuration File	The location of the mod_jk configuration file. Defaults to ${com.sun.aas.instanceRoot}/config/glassfish-jk.properties.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.jk-configuration-file=/location/to/file`
Port	The port used by the network listener. The selected port will be used to listen for requests.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.port=value`
Address	The address used by the network listener. 0.0.0.0 corresponds to all addresses.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.address=value`
Transport	The transport used by the network listener. This cannot be edited from the admin console. Defaults to tcp.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.transport=${transport-name}`
Thread Pool	The thread pool used by the network listener. This determines the pool of threads used to service requests.	`set configs.config.server-config.network-config.network-listeners.network-listener.${network-listener-name}.thread-pool=${thread-pool-name}`

To Create an Internet Connection

Use the subcommands in this procedure to create an internet connection with the full range of listener options. A network listener is created behind the scenes. For the shortcut version of this process , see To Create an HTTP Network Listener.

1. Ensure that the server is running.

Remote subcommands require a running server.

2. Create an HTTP or HTTPS protocol by using the `create-protocol` subcommand with the `--securityenabled` option.

   To use the built-in `http-listener-1` HTTP protocol, or `http-listener-2` HTTPS protocol, skip this step.

3. Create an HTTP configuration by using the `create-http` subcommand.

   To use a built-in protocol, skip this step.

4. Create a transport by using the `create-transport` subcommand.

   To use the built-in `tcp` transport, skip this step.

5. Create a thread pool by using the `create-threadpool` subcommand.

   To avoid using a thread pool, or to use the built-in `http-thread-pool` thread pool, skip this step.

   For additional thread pool information, see Administering Thread Pools.

6. Create an HTTP listener by using the `create-network-listener` subcommand.

   Specify a protocol and transport, optionally a thread pool.

7. To apply your changes, restart Payara Server.

   See To Restart a Domain.

To Create an HTTP Network Listener

Use the `create-http-listener` subcommand or the `create-network-listener` subcommand in remote mode to create a listener. These subcommands provide backward compatibility and also provide a shortcut for creating network listeners that use the HTTP protocol.

Behind the scenes, a network listener is created as well as its associated protocol, transport, and HTTP configuration. This method is a convenient shortcut, but it gives access to only a limited number of options. If you want to specify the full range of listener options, follow the instructions in To Create an Internet Connection.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create an HTTP network listener by using the `create-network-listener` subcommand or the `create-http-listener` subcommand.
3. If needed, restart the server. If you edit the special HTTP network listener named `admin-listener`, you must restart the server for changes to take effect.

   See To Restart a Domain.

Example - Creating an HTTP Listener

This example creates an HTTP listener named `sampleListener` that uses a non-default number of acceptor threads. Security is not enabled at runtime.

```
asadmin create-http-listener --listeneraddress `0.0.0.0` --listenerport 7272 --default
-virtual-server server --servername host1.sun.com --acceptorthreads 100
--securityenabled=false --enabled=false sampleListener
Command create-http-listener executed successfully.
```

Example - Creating a Network Listener

This example a network listener named `sampleListener` that is not enabled at runtime:

```
asadmin create-network-listener --listenerport 7272 protocol http-1 --enabled=false
sampleListener
Command create-network-listener executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-http-listener` or `asadmin help create-network-listener` at the command line.

To List HTTP Network Listeners

Use the `list-http-listeners` subcommand or the `list-network-listeners` subcommand in remote mode to list the existing HTTP listeners.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List HTTP listeners by using the `list-http-listeners` or `list-network-listeners` subcommand.

Example - Listing HTTP Listeners*

This example lists the HTTP listeners. The same output is given if you use the `list-network-listeners` subcommand.

```
asadmin list-http-listeners
admin-listener
http-listener-2
http-listener-1
Command list-http-listeners executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-http-listeners` or `asadmin help list-network-listeners` at the command line.

To Update an HTTP Network Listener

1. List HTTP listeners by using the `list-http-listeners` or `list-network-listeners` subcommand.
2. Modify the values for the specified listener by using the `set` subcommand.

The listener is identified by its dotted name.

Example - Updating an HTTP Network Listener

This example changes `security-enabled` to `false` on `http-listener-2`.

```
asadmin set server.network-config.protocols.protocol.http-listener-2.security-
enabled=false
Command set executed successfully.
```

To Restart an HTTP Network Listener

The `restart-http-listeners` commands restarts all HTTP listeners but the `admin-listener` of the targeted instance(s). It is either used with the `--all` flag to target all instances or with a particular target instance, deployment group or cluster following the `--target` parameter.

When `target` and `all` parameters are both omitted the default target is the DAS.

This command only restarts all HTTP listeners except the `admin-listener`. IIOP listeners are not affected and may require a server restart to make changes take effect.

Example - Restarting an HTTP Network Listener

This example restarts the instance named `FlyingFish`:

```
asadmin restart-http-listeners --target FlyingFish
Command restart-http-listeners executed successfully.
```

To Delete an HTTP Network Listener

Use the `delete-http-listener` subcommand or the `delete-network-listener` subcommand in remote mode to delete an existing HTTP listener. This disables secure communications for the listener.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List HTTP listeners by using the `list-http-listeners` subcommand.
3. Delete an HTTP listener by using the `delete-http-listener` or `delete-network-listener` subcommand.
4. To apply your changes, restart Payara Server. See To Restart a Domain.

Example - Deleting an HTTP Listener

This example deletes the HTTP listener named `sampleListener`:

```
asadmin delete-http-listener sampleListener
Command delete-http-listener executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-http-listener` or `asadmin help delete-network-listener` at the command line.

Configure an HTTP Listener for SSL

Use the `create-ssl` subcommand in remote mode to create and configure an SSL element in the specified listener. This enables secure communication for the listener.

1. Ensure that the server is running.

   Remote subcommands require a running server.

2. Configure an HTTP listener by using the `create-ssl` subcommand.
3. To apply your changes, restart Payara Server.

   See To Restart a Domain.

Example - Configuring an HTTP Listener for SSL

This example enables the HTTP listener named `http-listener-1` for SSL:

```
asadmin create-ssl --type http-listener --certname sampleCert http-listener-1
Command create-ssl executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-ssl` at the command line.

Configure SNI for HTTP Listeners

Server Name Indication, SNI for short, allows you to use multiple SSL certificates with the same IP address. When enabled, the server will look for a certificate in the configured keystore using a nickname that matches the host name requested.

SNI can be enabled by configuring a network listener. Existing network listeners can be configured from the admin console or with asadmin commands. The network listener configurations can be found in the admin console under **Configurations** → **<your-config>** → **Network Config** → **Network Listeners**.

From here, click on the SSL tab, and make sure that the **SNI Support** checkbox is ticked.

For SNI to take effect, the network listener must have security enabled by providing a default keypair and certificate, and by checking the **Security** box on the **HTTP** tab.

Configure Optional Client Authentication for SSL

In Payara Server, you can configure the SSL protocol of an HTTP listener such that it requests a certificate before permitting a client connection, but does not refuse a connection if the client does not provide one. To enable this feature, set the `client-auth` property of the SSL protocol to the value

want. For example:

```
asadmin set configs.config.config-name.network-config.protocols.protocol.listener-
name.ssl.client-auth=want
```

Configure a Custom SSL Implementation

In Payara Server, you can configure the SSL protocol an HTTP listener such that it uses a custom implementation of SSL. To enable this feature, set the `classname` property of the SSL protocol to the name of a class that implements the `com.sun.grizzly.util.net.SSLImplementation` interface. For example:

```
asadmin> set configs.config.config-name.network-config.protocols.protocol.listener-
name.ssl.classname=SSLImplementation-class-name
```

By default, Payara Server uses the implementation `com.sun.enterprise.security.ssl.GlassfishSSLImpl` for the SSL protocol.

Delete SSL From an HTTP Listener

Use the `delete-ssl` subcommand in remote mode to delete the SSL element in the specified listener. This disables secure communications for the listener.

1. Ensure that the server is running.

   Remote subcommands require a running server.

2. Delete SSL from an HTTP listener by using the `delete-ssl` subcommand.
3. To apply your changes, restart Payara Server.

   See To Restart a Domain.

Example - Deleting SSL From an HTTP Listener

This example disables SSL for the HTTP listener named `http-listener-1`:

```
asadmin delete-ssl --type http-listener http-listener-1
Command delete-ssl executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-ssl` at the command line.

Assign a Default Virtual Server to an HTTP Listener

1. In the Administration Console, open the HTTP Service component under the relevant configuration.
2. Open the HTTP Listeners component under the HTTP Service component.

3. Select or create a new HTTP listener.
4. Select from the Default Virtual Server drop-down list. For more information, see:

   To Assign a Default Web Module to a Virtual Server.

For details, click the Help button in the Administration Console from the HTTP Listeners page.

Administering HTTP Protocols

A protocol is used by a network listener to determine the nature of the communication expected by the listener. For example, a protocol determines the timeout of a request, as well as whether HTTPS should be used. The reason the protocol is separate to the listener is so that the same protocol configuration can be used to listen on multiple ports.

Existing protocols can be configured from the admin console or with asadmin commands. The protocol configurations can be found in the Admin Console under **Configurations → your-config → Network Config → Protocols**.

Each HTTP listener has an HTTP protocol, which is created either by using the `create-protocol` subcommand or by using the built-in protocols that are applied when you follow the instructions in To Create an HTTP Network Listener.

Protocol Configurations

Table 4. Security

configuration settings	Description	Asadmin Command
Security	Whether security is enabled for the protocol. When disabled, all the SSL/TLS options are ignored.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.security-enabled=[true|false]`

Table 5. HTTP Settings

configuration settings	Description	Asadmin Command
Server Name	The name of the server. This will be sent as the `Server` header in responses.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.server-name-enabled=value`
Default Virtual Server	The default virtual server used for the protocol. Establishes the request priority when multiple virtual servers are configured.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.default-virtual-server=value`
Redirect Port	The port used for SSL transport redirection.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.redirect-port=value`

configuration settings	Description	Asadmin Command
Max Connections	The maximum number of requests per connection to keep in keep-alive mode.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.max-connections=value`
Timeout	The amount of time in seconds before a connection is deemed as idle. After this, the connection will no longer be in keep-alive state.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.timeout-seconds=value`
Upload Timeout Enabled	Enables closing a connection that is reading bytes slowly after the `configuration-http-upload-timeout-millis` setting is reached.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.upload-timeout-enabled=value`
Connection Upload Timeout	The timeout, in milliseconds, for uploads. To disable this timeout, set the value to `-1`.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.connection-upload-timeout-millis=value`
Request Timeout	The timeout, in seconds, for requests. To disable this timeout, set the value to `-1`.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.request-timeout-seconds=value`
Send Buffer Size	The size, in bytes, of the send buffer.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.send-buffer-size-bytes=value`
Header Buffer Length	The size, in bytes, of the buffer used to read the request data.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.header-buffer-length-bytes=value`
Max Post Size	The maximum size, in bytes, of POST actions.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.max-post-size-bytes=value`
Max Form Post Size	The maximum size, in bytes, of a POST form.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.max-form-post-size-bytes=value`
Max Save Post Size	The maximum size, in bytes, of a POST request that will be saved during authentication.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.max-save-post-size-bytes=value`
URI Encoding	The character set used to decode the request URIs received.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.uri-encoding=value`

configuration settings	Description	Asadmin Command
Compression	Whether to enable HTTP/1.1 GZIP compression to save server bandwidth. Will be ignored when HTTP/2 is used.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.compression=[off/on/force]`
Compression Level	The level of compression to be used: • `-1` corresponds to the default level • `0` is no compression • `1` is the best speed • `9` is the best compression	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.compression-level=[-1-9]`
Compression Strategy	Sets the strategy to be used during HTTP compression.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.compression-strategy=[Default/Filtered/Huffman Only]`
Compressible Mime Types	Comma separated list of MIME types for which HTTP compression is used.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.compressable-mime-type=value`
Compression Minimum Size	The minimum size of a file that determines whether compression is applied.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.compression-min-size-bytes=value`
No-Compression User Agents	Comma separated list of regular expressions matching user agents for which compression should not be used.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.no-compression-user-agents=value`
Restricted User Agents	List of restricted user agents for which HTTP compression is applied.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.restricted-user-agents=value`
Default Response Type	The default response type if none are matched. Specified as a semicolon delimited string consisting of content type, encoding, language, charset.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.default-response-type=value`
Adapter	The class name of the static resources adapter.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.adapter=value`
Comet Support	Whether comet support is enabled or not.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.comet-support-enabled=[true|false]`

configuration settings	Description	Asadmin Command
DNS Lookup	Enables Domain Name System lookups.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.dns-lookup-enabled=[true|false]`
Trace Enabled	Enables the TRACE operation Setting this to false helps prevent cross-site scripting attacks.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.trace-enabled=[true|false]`
Auth Pass Through	Enable this if the network listener receives traffic from an SSL terminating proxy server.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.auth-pass-through-enabled=[`true|false]`
Chunking Enabled	Enables HTTP response chunking.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.chunking-enabled=[true|false]`
XFrame Options	When enabled, the `X-Frame-Options` header will be set to `SAMEORIGIN`. This can still be overridden by a deployed application.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.xframe-options=[true|false]`
Encoded Slash	Allow encoded slashes (e.g. `%2F`) in URIs.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.encoded-slash-enabled=[true|false]`
Websockets Support Enabled	Allows Websockets to be used.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.websockets-support-enabled=[true|false]`
Scheme Mapping	HTTP header name used for identifying the originating protocol of an HTTP request.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.scheme-mapping=value`
Remote User Mapping	HTTP header name used for identifying the originating user of an HTTP request.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.remote-user-mapping=value`
Enable Cookie SameSite	Enabling to set all cookies to use the SameSite value.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.cookie-same-site-enabled=[true|false]`

configuration settings	Description	Asadmin Command

Cookie SameSite Value	The values to be used:
	• `Lax`: Cookies are not sent on normal cross-site sub-requests
	• `Strict`: Cookies will only be sent in a first-party context
	• `None`: Cookies will be sent in all contexts
	
	Users can set up the SameSite Cookie attribute at the **application level** by using the `payara-web.xml` deployment descriptor.
	
	Set this attribute by using the `cookie-properties` tag with a child property named `cookieSameSite`:
	
	`<payara-web-app>`
	`<cookie-properties>`
	`<property name="cookieSameSite" value="Strict" />`
	`</cookie-properties>`
	`</payara-web-app>`
		`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.cookie-same-site-value=[`Lax|Strict|None]`

Table 6. HTTP/2 Settings

configuration settings	Description	Asadmin Command
HTTP/2 Enabled	Whether to enable HTTP/2 support. HTTP/2 support can only be enabled on a secure network listener	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-enabled=[true|false]`
Disable HTTP/2 Cipher Check	Whether TLS connections can be established using insecure cipher suites.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-disable-cipher-check=[true|false]`

configuration settings	Description	Asadmin Command
HTTP/2 Max Concurrent Streams	The number of maximum concurrent streams allowed per HTTP/2 connection.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-max-concurrent-streams=value`
HTTP/2 Initial Window Size	The initial window size in bytes.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-initial-window-size-in-bytes=value`
HTTP/2 Max Frame Payload Size	The maximum size of the HTTP/2 frame payload to be accepted.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-max-frame-payload-size-in-bytes=value`
HTTP/2 Max Header List Size	The maximum size, in bytes, of the header list.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-max-header-list-size-in-bytes=value`
Streams High Watermark	The maximum number of streams that are allowed. Excess streams will be cleaned out periodically in proportion to the maximum number of streams.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-streams-high-water-mark=value`
Streams Clean Percentage	The number of streams to process when the high watermark is exceeded. Only closed streams will be removed.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-clean-percentage=value`
Streams Clean Frequency Check	The number of streams that must be closed before checking if the number of streams exceeds the high watermark.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-clean-frequency-check=value`
HTTP/2 Push	Enables server push. This is enabled by default.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.http.http2-push-enabled=[true|false]`

Table 7. HTTP/2 Settings

configuration settings	Description	Asadmin Command
TLS V1.2 Enabled	Whether to enable TLS V1.2 or not. Will be ignored if TLS is disabled.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.tls12-enabled=[true|false]`

configuration settings	Description	Asadmin Command
TLS V1.3 Enabled	Whether to enable TLS V1.3 or not. Will be ignored if TLS is disabled. Support for TLS 1.3 is available with JDK 8 versions after JDK 1.8.0u261, unless you're using Zulu JDK 1.8.0u222 - 1.8.0u252, in which case you'll also need to use the Java option -XX:+UseOpenJSSE. This option makes OpenJSSE default TLS provider. OpenJSEE is a JSEE provider created by Azul to support TLS 1.3 on JDK 8. See TLS 1.3 Support in Zulu 8 with OpenJSSE for more information. Also note that this flag can cause problems with the HTTP/2 support. If you're using a lower version than 1.8.0u222, checkbox to enable TLS 1.3 will not be visible on the web administration console. You will need to add the following Java Option: -Dfish.payara.clientHttpsProtocol=TLSv1.3 to the asadmin script for TLS 1.3 to work	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.tls13-enabled=[true|false]`

configuration settings	Description	Asadmin Command
Client Authentication	When enabled, clients will be required to authenticate themselves to the server.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.client-auth-enabled=[true|false]`
Certificate Nickname	The alias of the certificate to be supplied on secure requests. The certificate should be present in the server keystore.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.cert-nickname=value`
Key Store	The name of the keystore file used to secure communication handled by this network listener.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.key-store=value`
Trust Store	The name of the trust store file where trusted certificates are stored.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.trust-store=value`
Trust Algorithm	The name of the trust management algorithm (e.g. PKIX) to use for certification path validation.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.trust-algorithm=value`
Max Certificate Length	Maximum number of non self-issued intermediate certificates that can exist in a certification path. Only used if the trust algorithm is set to PKIX.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.trust-max-cert-length=value`
Enabled Ciphers	A list of the server enabled ciphers. This string is stores as a comma separated list of the enabled ciphers with a `+` or a `-` at the start of each, depending on whether the cipher is enabled or disabled. E.g. `+TLS_RSA_WITH_AES_256_CBC_SHA,+SSL_RSA_WITH_3DES_EDE_CBC_SHA`.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.ssl3-tls-ciphers=value`
Handshake Timeout	The timeout, in milliseconds, for a handshake. After this timeout the handshake will be aborted.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.handshake-timeout-millis=value`
TLS Rollback	Whether TLS rollback is enabled or not.	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.tls-rollback-enabled=[true|false]`

configuration settings	Description	Asadmin Command
HSTS Enabled	Whether HSTS is enabled. When enabled, the server will respond to requests with the `Strict-Transport-Security` header. While these requests often return a 301 directing the client to the secure site, this header instructs the requester to make all connections to this site secure for the next year. The header takes the following form: `Strict-Transport-Security: max-age=31536000; includeSubDomains; preload` The last 2 attributes are added based on the other HSTS configuration options. HSTS can be enabled on any HTTP listener. However, it's meant to be enabled on a secure HTTP listener if an insecure HTTP listener redirects to the secure listener. When browsers receive the `Strict-Transport-Security` header over HTTPS, they will use HTTPS immediately for all future connections requested over plain HTTP. If the header is retrieved over HTTP, it is ignored by browsers due to	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.hsts-enabled=[true|false]` When the configuration value is set to true, the HSTS header is added with a max-age property value of 31536000. The max-age property is not configurable.

configuration settings	Description	Asadmin Command
HSTS Subdomains	When enabled in combination with HSTS, `Strict-Transport-Security` headers will include the includeSubDomains attribute. When this is configured, the client will also assume subdomains of the targeted resource require secure connections. The subdomains property is not enabled by default and has to be enabled with the following command:	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.hsts-sub-domains=[true|false]`
HSTS Preload	When enabled in combination with HSTS, `Strict-Transport-Security` headers will include the `preload` attribute. When this is configured, the domain of the target resource will be added to the browser `preload` list, meaning that initial requests to this resource in future won't be insecure. The `preload` property is not enabled by default and has to be enabled with the following command:	`set configs.config.server-config.network-config.protocols.protocol.${protocol-name}.ssl.hsts-preload=[true|false]`

Create a Protocol

Use the `create-protocol` subcommand in remote mode to create a protocol.

1. Ensure that the server is running.

   Remote subcommands require a running server.

2. Create a protocol by using the `create-protocol`

   Information about options and properties for the subcommand are included in this help page.

Example - Creating an HTTP Protocol

This example creates a protocol named `http-1` with security enabled.

```
asadmin> create-protocol --securityenabled=true http-1
Command create-protocol executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-protocol` at the command line.

List Protocols

Use the `list-protocols` subcommand in remote mode to list the existing HTTP protocols.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the existing protocols by using the `list-protocols` subcommand.

Example - Listing the Protocols

This example lists the existing protocols.

```
asadmin list-protocols
admin-listener
http-1
http-listener-1
http-listener-2
Command list-protocols executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-protocols` at the command line.

Delete a Protocol

Use the `delete-protocol` subcommand in remote mode to remove a protocol.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Delete a protocol by using the `delete-protocol` subcommand

Example - Deleting a Protocol

This example deletes the protocol named `http-1`.

```
asadmin delete-protocol http-1
Command delete-protocol executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-protocol` at the command line.

Administering HTTP Configurations

Each HTTP listener has an HTTP configuration, which is created either by using the `create-http` subcommand or by using the built-in configurations that are applied when you follow the instructions in To Create an HTTP Network Listener.

Create an HTTP Configuration

Use the `create-http` subcommand in remote mode to create a set of HTTP parameters for a protocol. This set of parameters configures one or more network listeners,

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create an HTTP configuration by using the `create-http` subcommand.

   Information about options and properties for the subcommand are included in this help page.

Example - Creating an HTTP Configuration

This example creates an HTTP parameter set for the protocol named `http-1`.

```
asadmin create-http --timeout-seconds 60 --default-virtual-server server http-1
Command create-http executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-http` at the command line.

Delete an HTTP Configuration

Use the `delete-http` subcommand in remote mode to remove HTTP parameters from a protocol.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Delete the HTTP parameters from a protocol by using the `delete-http` subcommand.

Example - Deleting an HTTP Configuration

This example deletes the HTTP parameter set from a protocol named `http-1`.

```
asadmin delete-http http-1
Command delete-http executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-http` at the command line.

Administering HTTP Transports

Each HTTP listener has an HTTP transport, which is created either by using the `create-transport` subcommand or by using the built-in transports that are applied when you follow the instructions in To Create an HTTP Network Listener.

Create a Transport

Use the `create-transport` subcommand in remote mode to create a transport for a network listener,

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a transport by using the `create-transport` subcommand.

   Information about options and properties for the subcommand are included in this help page.

Example - Creating a Transport

This example creates a transport named `http1-trans` that uses a non-default number of acceptor threads.

```
asadmin create-transport --acceptorthreads 100 http1-trans
Command create-transport executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-transport` at the command line.

List Transports

Use the `list-transports` subcommand in remote mode to list the existing HTTP transports.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the existing transports by using the `list-transports` subcommand.

Example - Listing HTTP Transports

This example lists the existing transports.

```
asadmin list-transports
Enter the value for the target operand> server
http1-trans
tcp
Command list-transports executed successfully.
```

The values for target operand are as follows:

target

Restricts the listing to transports for a specified target. Valid values are as follows:

`server`

Lists the transports for the default server instance. This is the default value.

configuration-name

Lists the transports for the specified configuration.

cluster-name

Lists the transports for all server instances in the specified cluster.

instance-name

Lists the transports for the specified server instance. You can also view the full syntax and options of the subcommand by typing `asadmin help list-transports` at the command line.

Delete a Transport

Use the `delete-transport` subcommand in remote mode to remove a transport.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Delete a transport by using the `delete-transport` subcommand.

Example - Deleting a Transport

This example deletes the transport named `http1-trans`.

```
asadmin delete-transport http1-trans
Command delete-transport executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-transport` at the command line.

Administering Virtual Servers

A virtual server is a virtual web server that serves content targeted for a specific URL. Multiple virtual servers can serve content using the same or different host names, port numbers, or IP addresses. The HTTP service directs incoming web requests to different virtual servers based on the URL.

Just as multiple network cards in a single PC make the network see them as separate hosts, virtual servers allow one physical server instance to appear as many, enabling multiple domain names to be associated with the same server.

When you first install Payara Server, a default virtual server is created. You can assign a default virtual server to each new HTTP listener you create.

Web applications and Jakarta EE applications containing web components (web modules) can be assigned to virtual servers during deployment. A web module can be assigned to more than one virtual server, and a virtual server can have more than one web module assigned to it. If you deploy a web application and don't specify any assigned virtual servers, the web application is assigned to all currently defined virtual servers.

If you then create additional virtual servers and want to assign existing web applications to them, you must redeploy the web applications. For more information about deployment, see the Payara Server Application Deployment section.

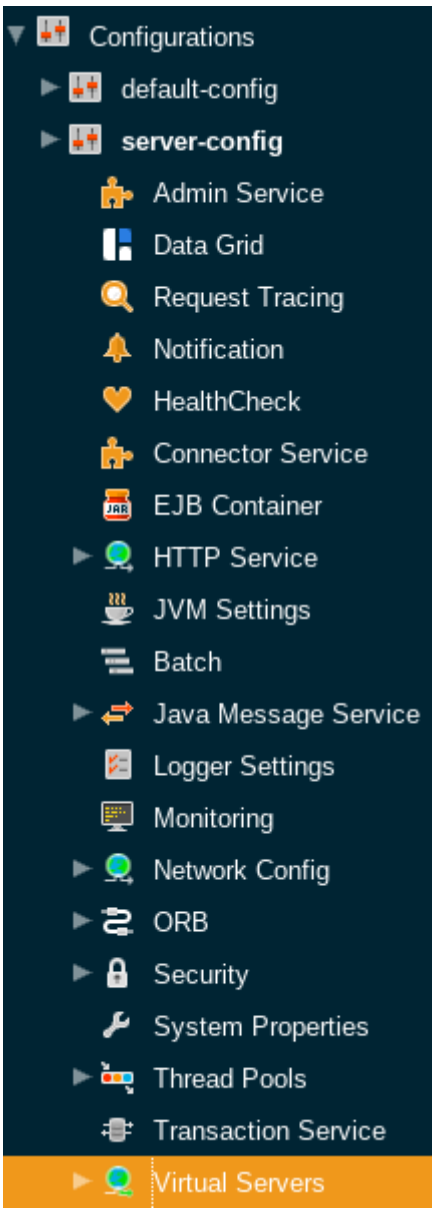
You can define virtual server properties using the `asadmin set` command. For example:

```
asadmin set server-config.http-service.virtual-server.MyVS.property.sso-enabled="true"
```

Some virtual server properties can be set for a specific web application. For details, see "payara-web-app" in the Payara Server Application Deployment section.

Virtual Server Configuration

Existing virtual servers can be configured from the admin console or with `set` asadmin commands. The virtual server configurations can be found in the admin console under **Configurations** → **your-config** → **Virtual Servers**.



The following fields can be configured:

Table 8. Virtual Server Configuration

configuration settings	Description	Asadmin Command
ID	The unique ID for the virtual server. The only field which cannot be altered from the admin console. The ID cannot begin with a number.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.id=value`

configuration settings	Description	Asadmin Command
Hosts	A comma separated list of values allowed in the host request header to select this virtual server. Each virtual server with the same connection group must have a unique host for that group.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.hosts=value,value2`
State	The enabled state of the virtual server. There are 3 options for this property: • **On** → This means that the virtual server is active and will be ready to serve requests. • **Off** → This means that the virtual server is inactive, and will return a 404 error for all requests made through it. This will look from the outside as if no applications are deployed to this server. • **Disabled** → This means that the virtual server is inactive, and will return a 403 error for all requests made through it. This will look from the outside as if the server is intentionally down for maintenance.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.state=on/off/disabled`

configuration settings	Description	Asadmin Command
SSO	Allows multiple web applications deployed to the same virtual server to share the user authentication state. This would mean that signing in to one application would implicitly sign you into all others. There are 3 options for this property: • **True** (enabled) → This enables SSO for applications on the same virtual server. • **False** (disabled) → This disables SSO for applications on the same virtual server. • **Inherit** (controlled by HTTP service) → This will inherit from the value specified in the **HTTP Service**.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.sso-enabled=true/false/inherit`
SSO Cookie Http Only	Determines whether to add the `HttpOnly` flag to the `JSESSIONIDSSO` cookie. In practice, this disallows JavaScript access to the cookie in the browser. This prevents malicious XSS attacks hijacking a Java session. It is enabled by default.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.sso-cookie-http-only=true/false`
Session Cookie Http Only	Determines whether to add the `HttpOnly` flag to the `JSESSIONID` cookie. In practice, this disallows JavaScript access to the cookie in the browser. This prevents malicious XSS attacks hijacking a Java session. It is enabled by default.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.session-cookie-http-only=true/false`

configuration settings	Description	Asadmin Command
Session Cookie Secure	Determines whether to add the `Secure` flag to the `JSESSIONID` cookie. In practice, this specifies that the cookie may only be transmitted using HTTPS connections.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.session-cookie-secure=true/false/dynamic`
Network Listeners	Comma separated list of network listeners which applications deployed to this virtual server are available on.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.network-listeners=listener-1,listener-2`
Default Web Module	This defines which application deployed to this virtual server will be requested if no modules are resolved in the request. For example if `app1` and `app2` have context roots of `/app1` and `/app2` respectively, `app1` will be returned when the user requests `/`.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.default-web-module=app1`
Log File	This defines a file where log messages coming from this virtual server are redirected to. This allows you to separate application logs from server logs.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.log-file=/dir/to/logs/file.log`
Docroot	This defines the directory used as the document root for this virtual server. A document root is a directory where static files can be placed and served from. For example, if you have a web application deployed to `http://localhost:8080/app1` and the corresponding virtual server has a docroot value of `/opt/server/docs`, then requesting `http://localhost:8080/app1/img.jpg` will fetch the file at `/opt/server/docs/img.jpg`.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.docroot=/dir/to/docs/`

configuration settings	Description	Asadmin Command
Access Logging	Enables access logging for this virtual server. Access logging logs all requests made to that virtual server. There are 3 options for this property: • **True** (enabled) → This enables access logging for applications on the same virtual server. • **False** (disabled) → This disables access logging for applications on the same virtual server. • **Inherit** (controlled by HTTP service) → This will inherit from the value specified in the **HTTP Service**.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.access-logging=true/false/inherit`
Access Log Directory	Defines the directory used for access logs.	`set configs.config.server-config.http-service.virtual-server.${virtual-server-name}.access-log=/dir/to/logs`

Additional properties

Defines additional properties for the configuration of a virtual server.

Key	Description	Default Value
sso-max-inactive-seconds	The number of seconds of no activity after which a user's SSO record becomes eligible for purging.	`300`
sso-reap-interval-seconds	The number of seconds between purges of SSO records.	`60`
setCacheControl	Comma separated list of Cache-Control response directives (See section 14.9 of: https://www.ietf.org/rfc/rfc2616.txt).	none

Key	Description	Default Value

allowLinking	If set to `true`, resources that are symbolic links will be served for all applications deployed to this virtual server.
	
	Can be overridden for an individual application in the `glassfish-web.xml`/`payara-web.xml` deployment descriptor with:
	
	`<payara-web-app>`
	`  <property name="allowLinking" value="false" />`
	`</payara-web-app>`
	
	glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.
	
	Setting this property to `true` on Windows systems exposes JSP source code.
		false

accessLogWriteInterval	The number of seconds between each time the log is written to disk. The access log is written when the buffer is full or when the interval expires. If the value is 0, the buffer is always written even if it's not full.	300
accessLogBufferSize	The size, in bytes, of the buffer where access log calls are stored.	32768
allowRemoteAddress	Comma separated list of regular expression patterns to which the remote client's IP address is compared. The IP must match one of the patterns to be accepted.	none
denyRemoteAddress	Comma separated list of regular expression patterns to which the remote client's IP address is compared. The IP must not match any of the patterns to be accepted.	none
allowRemoteHost	Comma separated list of regular expression patterns to which the remote client's host name is compared. The host name must match one of the patterns to be accepted.	none
denyRemoteHost	Comma separated list of regular expression patterns to which the remote client's host name is compared. The host name must not match any of the patterns to be accepted.	none
authRealm	Specifies the name attribute of a security realm, which overrides the server's default realm for standalone web applications deployed to this virtual server. Can be overridden for an individual application with a realm defined in the web.xml.	none

Key	Description	Default Value
securePagesWithPragma	Set this property to `false` to ensure that for all web applications on this server file downloads using SSL work properly in Internet Explorer.	true
contextXmlDefault	Sets the directory of the `context.xml` used for this virtual server, if one is used.	none
alternatedocroot_n	Specifies an alternate document root, where n is a positive integer that allows specification of more than one.	none
send-error_n	Specifies custom error page mappings for the virtual server, which are inherited by all web applications deployed on the virtual server, unless overridden in the web.xml. The value is a string, composed of three values: • code → The HTTP response status code for the custom error page. • path → The path of the file to be returned, relative to the `/config` directory. • reason (optional) → The text of the reason string. E.g. `send-error_1="code=404 path=/dir/of/file/error.html reason=UNAUTHORIZED"`.	none
redirect_n	Specifies a redirect from an old url to a new one. The value is a string, composed of two values: • `from` → The prefix of the requested URI to match. • `url-prefix` → The prefix of the new URI to return to the client. The **from** prefix is replaced by this value. E.g. `redirect_1="from=/fake url-prefix=http://another"`.	none
listener_n	Specifies the fully qualified class name of a custom Catalina listener, where n is a positive integer that allows the specification of more than one. The listener class must implement the `org.apache.catalina.ContainerListener` or `org.apache.catalina.LifecycleListener` interface.	none
errorReportValve	Specifies the fully qualified class name of a custom valve that produces default error pages for applications on this virtual server. Specify an empty string to disable the default error page mechanism for this virtual server.	`org.apache.catalina.valves.ErrorReportValve`
cacheTTL	Specifies the time to live (TTL), expressed in milliseconds, for the virtual server cache used to serve files.	5000

Create a Virtual Server

By default, when Payara Server starts, the following virtual servers are started automatically:

- A virtual server named `server`, which hosts all user-defined web modules. For development, testing, and deployment of web services in a non-production environment, `server` is often the only virtual server required.
- A virtual server named `__asadmin`, which hosts all administration-related web modules (specifically, the Administration Console). This server is restricted, which means that you cannot deploy web modules to this virtual server.

In a production environment, additional virtual servers provide hosting facilities for users and customers so that each appears to have its own web server, even though there is only one physical server.

Use the `create-virtual-server` subcommand in remote mode to create the named virtual server.

Before You Begin

A virtual server must specify an existing HTTP listener. Because the virtual server cannot specify an HTTP listener that is already being used by another virtual server, create at least one HTTP listener before creating a new virtual server.

1. Ensure that the server is running.

   Remote subcommands require a running server.

2. Create a virtual server by using the `create-virtual-server` subcommand.

   Information about properties for this subcommand is included in this help page.

3. To apply your changes, restart Payara Server.

   See To Restart a Domain.

Example - Creating a Virtual Server

This example creates a virtual server named `sampleServer` on `localhost`.

```
asadmin create-virtual-server --hosts pigeon,localhost --property authRealm=ldap
sampleServer
Command create-virtual-server executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-virutal-server` at the command line.

To List Virtual Servers

Use the `list-virtual-servers` subcommand in remote mode to list the existing virtual servers.

1. Ensure that the server is running. Remote subcommands require a running server.

2. List virtual servers by using the `list-virtual-servers` subcommand.

Example - Listing Virtual Servers

This example lists the virtual servers for `localhost`.

```
asadmin list-virtual-servers

sampleListener
admin-listener
http-listener-2
http-listener-1
Command list-http-listeners executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-virutal-servers` at the command line.

Update a Virtual Server

1. List virtual servers by using the `list-virtual-servers` subcommand.
2. Modify the values for the specified virtual server by using the `set` subcommand.

   The virtual server is identified by its dotted name.

Delete a Virtual Server

Use the `delete-virtual-server` subcommand in remote mode to delete an existing virtual server.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List virtual servers by using the `list-virtual-servers` subcommand.
3. If necessary, notify users that the virtual server is being deleted.
4. Delete a virtual server by using the `delete-virtual-server` subcommand.
5. To apply your changes, restart Payara Server. See To Restart a Domain.

Example - Deleting a Virtual Server

This example deletes the virtual server named `sampleServer` from `localhost`.

```
asadmin> delete-virtual-server sampleServer
Command delete-virtual-server executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-virutal-server` at the command line.

To Assign a Default Web Module to a Virtual Server

A default web module can be assigned to the default virtual server and to each new virtual server.

To access the default web module for a virtual server, point the browser to the URL for the virtual server, but do not supply a context root.

For example:

```
http://myvserver:3184/
```

A virtual server with no default web module assigned serves HTML or JavaServer Pages (JSP) content from its document root, which is usually `domain-dir/docroot`.

To access this HTML or JSP content, point your browser to the URL for the virtual server, do not supply a context root, but specify the target file.

For example:

```
http://myvserver:3184/hellothere.jsp
```

Assign a Virtual Server to an Application or Module

You can assign a virtual server to a deployed application or web module.

Before You Begin

The application or module must already be deployed.

1. In the Administration Console, open the HTTP Service component under the relevant configuration.
2. Open the Virtual Servers component under the HTTP Service component.
3. Select the virtual server to which you want to assign a default web module.
4. Select the application or web module from the Default Web Module drop-down list.

To Set `JSESSIONIDSSO` Cookie Attributes

Use the `sso-cookie-http-only` and `sso-cookie-secure` virtual server attributes to set the `HttpOnly` and `Secure` attributes of any `JSESSIONIDSSO` cookies associated with web applications deployed to the virtual server.

Use the `set` subcommand to set the value of the `sso-cookie-http-only` and `sso-cookie-secure` virtual server attributes.

The values supported for these attributes are as follows:

`sso-cookie-http-only`
: A boolean value that specifies whether the `HttpOnly` attribute is included in `JSESSIONIDSSO` cookies.

  When set to `true`, which is the default, the `HttpOnly` attribute is included. When set to `false`, the `HttpOnly` attribute is not included.

`sso-cookie-secure`

A string value that specifies whether the `Secure` attribute is included in `JSESSIONIDSSO` cookies. Allowed values are as follows:

- `true` — The `Secure` attribute is included.
- `false` — The `Secure` attribute is not included.
- `dynamic` — The `Secure` attribute setting is inherited from the default ports table for all HTTP listeners first session participating in SSO. This is the default value.

To Set `JSESSIONID` Cookie Attributes

Use the `session-cookie-http-only` and `session-cookie-secure` virtual server attributes to set the `HttpOnly` and `Secure` attributes of any `JSESSIONID` cookies associated with web applications deployed to the virtual server.

Use the `set` subcommand to set the value of the `session-cookie-http-only` and `session-cookie-secure` virtual server attributes.

The values supported for these attributes are as follows:

`session-cookie-http-only`

A boolean value that specifies whether the `HttpOnly` attribute is included in `JSESSIONID` cookies.

When set to `true`, which is the default, the `HttpOnly` attribute is included. When set to `false`, the `HttpOnly` attribute is not included.

`session-cookie-secure`

A string value that specifies whether the `Secure` attribute is included in `JSESSIONID` cookies. Allowed values are as follows:

- `true` — The `Secure` attribute is included.
- `false` — The `Secure` attribute is not included.
- `dynamic` — The `Secure` attribute setting depends on whether the HTTP connection is secure. This is the default value.

HTTP Header Fields Validation

By default, The following characters are stipulated to be dangerous to parse in both the name and value of all headers passed down on an HTTP request:

Character	Representation
NUL character	This character is expressed in the following forms on a literal value: `\0` `\x00` review explanation here
LF Character (new line)	This character is expressed in the following forms on a literal value: `\n` `\x0A` review explanation here

Character	Representation
CR Character (carriage return)	This character is expressed in the following forms on a literal value: `\r` `\x0D` review explanation here

As stipulated in section 5.5 Field Values of the RFC-9110 specification, these characters are deemed invalid and as such the server, as recipient of the request WILL reject it automatically upon detecting the presence of these characters.

On previous RFC specifications that detailed HTTP 1.1 semantics, these characters were considered **acceptable**, however from RFC-9110 onwards, the use of these characters is no longer acceptable for header fields names and values.

In some cases, to support backwards compatibility it might be necessary to allow these characters to be processed by the server runtime. In these instances, the following Grizzly (HTTP) system properties allow header fields character validation to be turned on/off:

Table 9. Grizzly Header Field Validation Properties

Property	Description
`org.glassfish.grizzly.http.STRICT_HEADER_NAME_VALIDATION_RFC_9110`	This property enables the validation of all header field names on incoming HTTP requests to prevent any usage of invalid characters on it. When set to `true`, the presence of these characters will trigger the server to invalidate the request with a `400 - Bad Request` response. The default value is `true`.
`org.glassfish.grizzly.http.STRICT_HEADER_VALUE_VALIDATION_RFC_9110`	This property enables the validation of all header field values on incoming HTTP requests to prevent any usage of invalid characters on it. When set to `true`, the presence of these characters will trigger the server to invalidate the request with a `400 - Bad Request` response. The default value is `true`.

Administering Concurrent Resources

This chapter provides procedures for administering concurrent resources in the Payara Server environment by using the `asadmin` command-line utility.

Instructions for accomplishing these tasks by using the Administration Console are contained in the Administration Console online help.

About Concurrent Resources

Concurrent resources are managed objects that provide concurrency capabilities to Jakarta EE applications. In Payara Server, you configure concurrent resources and make them available for use by application components such as servlets and EJBs. Concurrent resources are accessed through JNDI lookup or resource injection.

Concurrent resources are resources of the following types:

- Context services
- Managed thread factories
- Managed executor services
- Managed scheduled executor services

For detailed information about concurrent resources, see "Concurrency Specs" in the Jakarta EE specifications.

Default Concurrent Resources

When you create a concurrent resource, you specify a unique JNDI name for the resource. Applications use this name to access the resource.

The Jakarta EE standard specifies that certain default resources be made available to applications, and defines specific JNDI names for these default resources. Payara Server makes these names available through the use of logical JNDI names, which map Jakarta EE standard JNDI names to specific Payara Server resources. For concurrent resources, the mappings are as follows:

java:comp/DefaultContextService

This Jakarta EE standard name is mapped to the `concurrent/__defaultContextService` resource.

java:comp/DefaultManagedThreadFactory

This Jakarta EE standard name is mapped to the `concurrent/__defaultManagedThreadFactory` resource.

java:comp/DefaultManagedExecutorService

This Jakarta EE standard name is mapped to the `concurrent/__defaultManagedExecutorService` resource.

java:comp/DefaultManagedScheduledExecutorService

This Jakarta EE standard name is mapped to the `concurrent/__defaultManagedScheduledExecutorService` resource.

Configuring Context Services

Context services are used to create dynamic proxy objects that capture the context of a container and enable applications to run within that context at a later time. The context of the container is propagated to the thread executing the task.

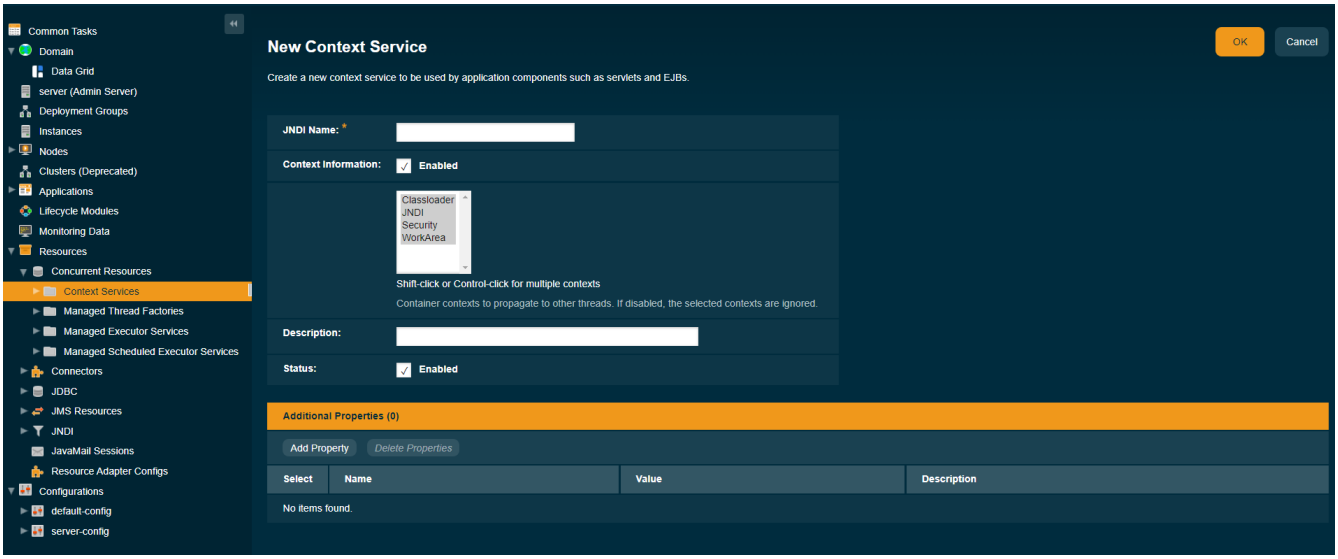
Jakarta Concurrency specifies that certain default resources be made available to

applications, and defines specific JNDI names for these default resources. Payara Server makes these names available through the use of logical JNDI names, which map Jakarta EE JNDI names to specific Payara Server resources. For context services, the mapping is as follows:
java:comp/DefaultContextService
This Jakarta Concurrency standard name is mapped to the concurrent/__defaultContextService resource

To Create a Context Service

Context services can be created by using Admin Console or Asadmin commands.

To create a new Context Service in the Admin Console, go to Resources → Concurrent Resources → Context Services → New:



Alternatively, you can use the `create-context-service` asadmin command to create a context service resource.

Because all JNDI names are in the `java:comp/env` subcontext, when specifying the JNDI name of a context service, use only the `concurrent/`name format. For example, `concurrent/Context1`.

Creating a context service resource is a dynamic event and typically does not require server restart. Applications can use a resource as soon as it is created. However, if an application tried to use a resource before it was created, and that resource is created later, the application or the server must be restarted. Otherwise, the application will not be able to locate the resource.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a context service by using the `create-context-service` subcommand.
3. If necessary, notify users that the new resource has been created.

Example 14-1 To Create a Context Service

This example creates a context service resource named `concurrent/Context1`.

```
asadmin> create-context-service concurrent/Context1
Context service concurrent/Context1 created successfully.
Command create-context-service executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-context-service` at the command line.

To List Context Services

Use the `list-context-services` subcommand in remote mode to list the existing context service resources.

1. Ensure that the server is running.
   Remote subcommands require a running server.
2. List context service resources by using the `list-context-services` subcommand.

Example 14-2 To List a Context Service

This example lists context service resources on the default server instance, `server`.

```
asadmin> list-context-services
concurrent/__defaultContextService
concurrent/Context1
concurrent/Context2
Command list-context-services executed successfully.
```

To Update a Context Service

You can change all of the settings for an existing context service resource except its JNDI name. Use the `get` and `set` subcommands to view and change the values of the context service attributes.

When a resource is updated, the existing resource is shut down and recreated. If an application used the resource prior to the update, the application or the server must be restarted.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the context service resources by using the `list-context-services` subcommand.
3. View the attributes of a specific context service by using the `get` subcommand.
   For example:

   ```
   asdmin> get resources.context-service.concurrent/Context1.*
   ```

4. Set an attribute of the context service by using the `set` subcommand.
   For example:

```
asdmin> set resources.context-service.concurrent/Context1.deployment-order=120
```

To Delete a Context Service

Use the `delete-context-service` subcommand in remote mode to delete an existing context service. Deleting a context service is a dynamic event and does not require server restart.

Before deleting a context service resource, all associations to the resource must be removed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the context service resources by using the `list-context-services` subcommand.
3. If necessary, notify users that the context service is being deleted.
4. Delete the context service by using the `delete-context-service` subcommand.

Example 14-3 To Delete a Context Service

This example deletes the context service resource named `concurrent/Context1`.

```
asadmin> delete-context-service concurrent/Context1
Context service concurrent/Context1 deleted successfully.
Command delete-context-service executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-context-service` at the command line.

Configuring Managed Thread Factories

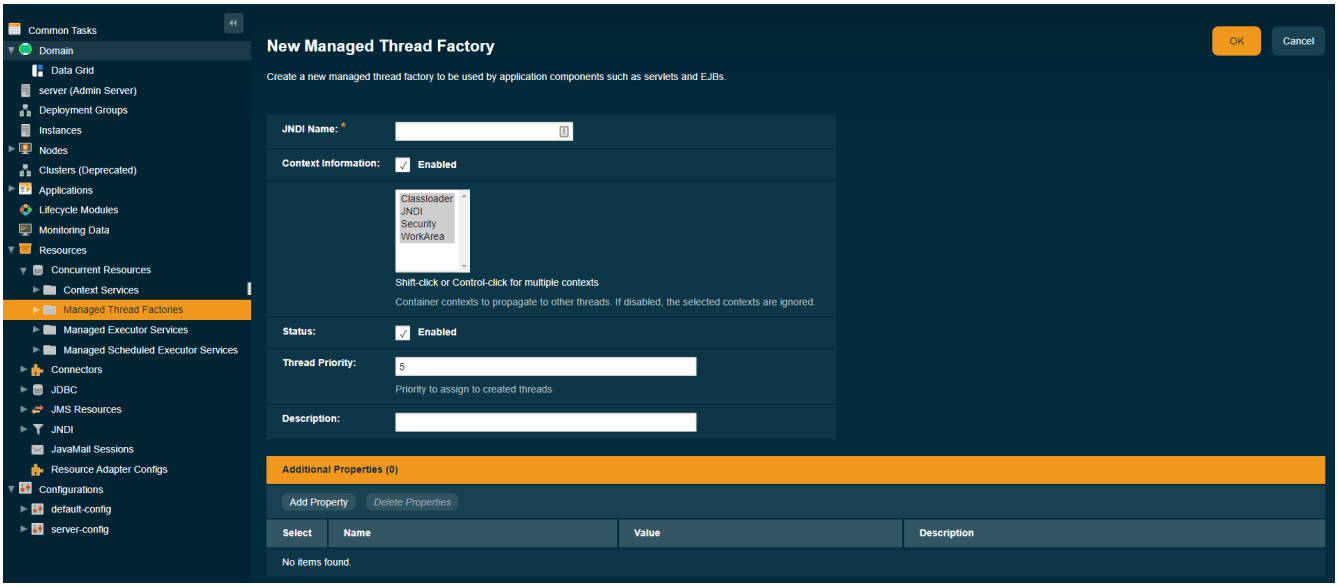
Managed thread factories are used by applications to create managed threads on demand. The threads are started and managed by the container. The context of the container is propagated to the thread executing the task.

Jakarta Concurrency specifies that certain default resources be made available to applications, and defines specific JNDI names for these default resources. Payara Server makes these names available through the use of logical JNDI names, which map Jakarta EE JNDI names to specific Payara Server resources. For managed thread factories, the mapping is as follows:
java:comp/DefaultManagedThreadFactory
This Jakarta Concurrency standard name is mapped to the concurrent/__defaultManagedThreadFactory resource.

To Create a Managed Thread Factory

Managed Thread Factories can be created by using Admin Console or Asadmin commands.

To create a new Managed Thread Factory in the Admin Console, go to Resources → Concurrent Resources → Managed Thread Factories → New:



Because all JNDI names are in the `java:comp/env` subcontext, when specifying the JNDI name of a managed thread factory, use only the `concurrent/` name format. For example, `concurrent/Factory1`.

For more information about the default managed thread factory resource included with Payara Server, see Default Concurrent Resources.

Creating a managed thread factory resource is a dynamic event and typically does not require server restart. Applications can use a resource as soon as it is created. However, if an application tried to use a resource before it was created, and that resource is created later, the application or the server must be restarted. Otherwise, the application will not be able to locate the resource.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a managed thread factory by using the `create-managed-thread-factory` subcommand.
3. If necessary, notify users that the new resource has been created.

Example 14-4 To Create a Managed Thread Factory

This example creates a managed thread factory resource named `concurrent/Factory1`.

```
asadmin> create-managed-thread-factory concurrent/Factory1
Managed thread factory concurrent/Factory1 created successfully.
Command create-managed-thread-factory executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-managed-thread-factory` at the command line.

To List Managed Thread Factories

Use the `list-managed-thread-factories` subcommand in remote mode to list the existing managed thread factory resources.

1. Ensure that the server is running. Remote subcommands require a running server.

2. List managed thread factory resources by using the `list-managed-thread-factories` subcommand.

Example 14-5 To List a Managed Thread Factory

This example lists managed thread factory resources on the default server instance, `server`.

```
asadmin> list-managed-thread-factories
concurrent/__defaultManagedThreadFactory
concurrent/Factory1
concurrent/Factory2
Command list-managed-thread-factories executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-managed-thread-factories` at the command line.

To Update a Managed Thread Factory

You can change all of the settings for an existing managed thread factory resource except its JNDI name. Use the `get` and `set` subcommands to view and change the values of the managed thread factory attributes.

When a resource is updated, the existing resource is shut down and recreated. If applications used the resource prior to the update, the application or the server must be restarted.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the managed thread factory resources by using the `list-managed-thread-factories` subcommand.
3. View the attributes of a managed thread factory by using the `get` subcommand.
   For example:

   ```
   asdmin> get resources.managed-thread-factory.{resource-JNDI-name}.*
   ```

4. Set an attribute of the managed thread factory by using the `set` subcommand.
   For example:

   ```
   asdmin> set resources.managed-thread-factory.{resource-JNDI-name}.deployment-
   order=120
   ```

To Delete a Managed Thread Factory

The `delete-managed-thread-factory` asadmin command can be used to delete an existing managed thread factory. Deleting a managed thread factory is a dynamic event and does not require server restart. Before deleting a managed thread factory resource, all associations to the resource must be removed.

Before deleting a managed thread factory resource, all associations to the resource must be removed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the managed thread factory resources by using the `list-managed-thread-factories` subcommand.
3. If necessary, notify users that the managed thread factory is being deleted.
4. Delete the managed thread factory by using the `delete-managed-thread-factory` subcommand.

Example 14-6 To Delete a Managed Thread Factory

This example deletes the managed thread factory resource named `concurrent/Factory1`.

```
asadmin> delete-managed-thread-factory concurrent/Factory1
Managed thread factory concurrent/Factory1 deleted successfully.
Command delete-managed-thread-factory executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-managed-thread-factory` at the command line.

Configuring Managed Executor Services

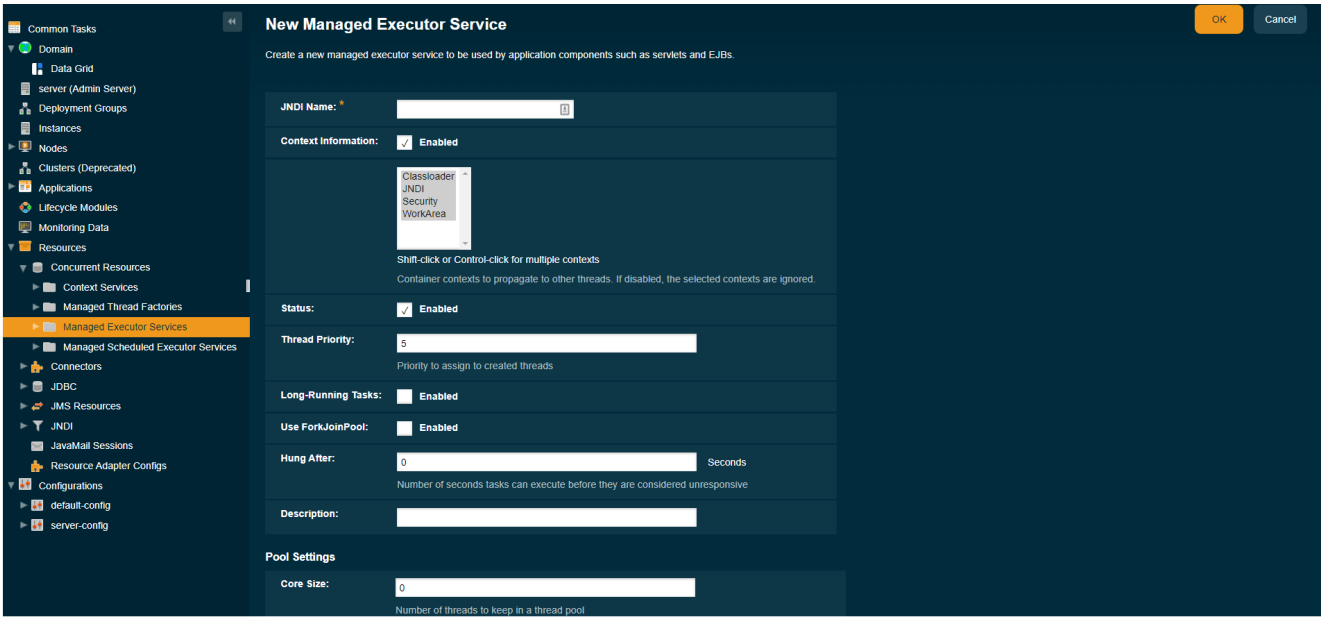
Managed executor services are used by applications to execute submitted tasks asynchronously. Tasks are executed on threads that are started and managed by the container. The context of the container is propagated to the thread executing the task.

Jakarta Concurrency specifies that certain default resources be made available to applications, and defines specific JNDI names for these default resources. Payara Server makes these names available through the use of logical JNDI names, which map Jakarta EE JNDI names to specific Payara Server resources. For managed executor services, the mapping is as follows:
java:comp/DefaultManagedExecutorService
This Jakarta Concurrency standard name is mapped to the concurrent/__defaultManagedExecutorService resource.

To Create a Managed Executor Service

Managed Executor Services can be created by using Admin Console or Asadmin commands.

To create a new Managed Executor Service in the Admin Console, go to Resources → Concurrent Resources → Managed Executor Services → New:



Use the `create-managed-executor-service` subcommand in remote mode to create a managed executor service resource.

Because all JNDI names are in the `java:comp/env` subcontext, when specifying the JNDI name of a managed executor service, use only the `concurrent/`name format. For example, `concurrent/Executor1`.

For more information about the default managed executor service resource included with Payara Server, see Default Concurrent Resources.

Creating a managed executor service resource is a dynamic event and typically does not require server restart. Applications can use a resource as soon as it is created. However, if an application tried to use a resource before it was created, and that resource is created later, the application or the server must be restarted. Otherwise, the application will not be able to locate the resource.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a managed executor service by using the `create-managed-executor-service` subcommand.
3. If necessary, notify users that the new resource has been created.

Example 14-7 To Create a Managed Executor Service

This example creates a managed executor service resource named `concurrent/Executor1`.

```
asadmin> create-managed-executor-service concurrent/Executor1
Managed executor service concurrent/Executor1 created successfully.
Command create-managed-executor-service executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-managed-executor-service` at the command line.

To List Managed Executor Services

The `list-managed-executor-services` asadmin command can be used to list the existing managed executor service resources.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List managed executor service resources by using the `list-managed-executor-services` subcommand.

Example 14-8 To List a Managed Executor Service

This example lists managed executor service resources on the default server instance, `server`.

```
asadmin> list-managed-executor-services
concurrent/__defaultManagedExecutorService
concurrent/Executor1
concurrent/Executor2
Command list-managed-executor-services executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-managed-executor-services` at the command line.

To Update a Managed Executor Service

You can change all of the settings for an existing managed executor service resource except its JNDI name. Use the `get` and `set` subcommands to view and change the values of the managed executor service attributes respectively.

When a resource is updated, the existing resource is shut down and recreated. If applications used the resource prior to the update, the application or the server must be restarted.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the managed executor service resources by using the `list-managed-executor-services` subcommand.
3. View the attributes of a managed executor service by using the `get` subcommand.
   For example:

   ```
   asdmin> get resources.managed-executor-service.{resource-JNDI-name}.*
   ```

4. Set an attribute of the managed executor service by using the `set` subcommand.
   For example:

   ```
   asdmin>  set resources.managed-executor-service.{resource-JNDI-name}.deployment-
   order=120
   ```

To Delete a Managed Executor Service

Use the `delete-managed-executor-service` subcommand in remote mode to delete an existing managed executor service. Deleting a managed executor service is a dynamic event and does not require server restart.

Before deleting a managed executor service resource, all associations to the resource must be removed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the managed executor service resources by using the `list-managed-executor-services` subcommand.
3. If necessary, notify users that the managed executor service is being deleted.
4. Delete the managed executor service by using the `delete-managed-executor-service` subcommand.

Example 14-9 To Delete a Managed Executor Service

This example deletes the managed executor service resource named `concurrent/Executor1`.

```
asadmin> delete-managed-executor-service concurrent/Executor1
Managed executor service concurrent/Executor1 deleted successfully.
Command delete-managed-executor-service executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-managed-executor-service` at the command line.

Configuring Managed Scheduled Executor Services

Managed scheduled executor services are used by applications to execute submitted tasks asynchronously at specific times. Tasks are executed on threads that are started and managed by the container. The context of the container is propagated to the thread executing the task.

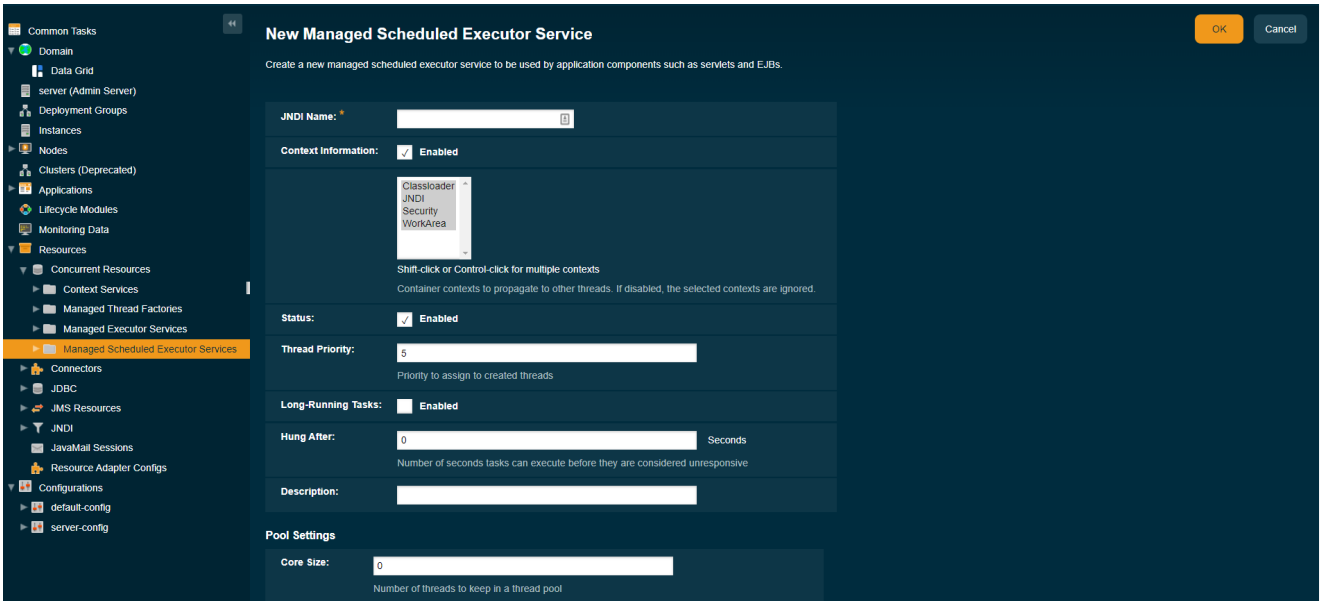
Jakarta Concurrency specifies that certain default resources be made available to applications, and defines specific JNDI names for these default resources. Payara Server makes these names available through the use of logical JNDI names, which map Jakarta EE JNDI names to specific Payara Server resources. For managed scheduled executor services, the mapping is as follows:
java:comp/DefaultManagedScheduledExecutorService
This Jakarta Concurrency standard name is mapped to the concurrent/__defaultManagedScheduledExecutorService resource.

To Create a Managed Scheduled Executor Service

Managed Scheduled Executor Services can be created by using Admin Console or Asadmin commands.

To create a new Managed Scheduled Executor Service in the Admin Console, go to Resources →

Concurrent Resources → Managed Scheduled Executor Services → New:



Alternatively, the `create-managed-scheduled-executor-service` asadmin command can be used to create a managed scheduled executor service resource.

Because all JNDI names are in the `java:comp/env` subcontext, when specifying the JNDI name of a managed scheduled executor service, use only the `concurrent/`name format. For example, `concurrent/ScheduledExecutor1`.

For more information about the default managed scheduled executor service resource included with Payara Server, see Default Concurrent Resources.

Creating a managed scheduled executor service resource is a dynamic event and typically does not require server restart. Applications can use a resource as soon as it is created. However, if an application tried to use a resource before it was created, and that resource is created later, the application or the server must be restarted. Otherwise, the application will not be able to locate the resource.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a managed scheduled executor service by using the `create-managed-scheduled-executor-service` subcommand.
3. If necessary, notify users that the new resource has been created.

Example 14-10 To Create a Managed Scheduled Executor Service

This example creates a managed scheduled executor service resource named `concurrent/ScheduledExecutor1`.

```
asadmin> create-managed-scheduled-executor-service concurrent/ScheduledExecutor1
Managed scheduled executor service concurrent/ScheduledExecutor1 created successfully.
Command create-managed-scheduled-executor-service executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-managed-scheduled-executor-service` at the command line.

To List Managed Scheduled Executor Services

Use the `list-managed-scheduled-executor-services` subcommand in remote mode to list the existing managed scheduled executor service resources.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List managed scheduled executor service resources by using the `list-managed-scheduled-executor-services` subcommand.

Example 14-11 To List a Managed Scheduled Executor Service

This example lists managed scheduled executor service resources on the default server instance, `server`.

```
asadmin> list-managed-scheduled-executor-services
concurrent/__defaultManagedScheduledExecutorService
concurrent/ScheduledExecutor1
concurrent/ScheduledExecutor2
Command list-managed-scheduled-executor-services executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-managed-scheduled-executor-services` at the command line.

To Update a Managed Scheduled Executor Service

You can change all of the settings for an existing managed scheduled executor service resource except its JNDI name. Use the `get` and `set` subcommands to view and change the values of the managed scheduled executor service attributes.

When a resource is updated, the existing resource is shut down and recreated. If applications used the resource prior to the update, the application or the server must be restarted.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the managed scheduled executor service resources by using the `list-managed-scheduled-executor-services` subcommand.
3. View the attributes of a managed scheduled executor service by using the `get` subcommand.
   For example:

   ```
   asdmin>get resources.managed-scheduled-executor-service.{resource-JNDI-name}.*
   ```

4. Set an attribute of the managed scheduled executor service by using the `set` subcommand.
   For example:

```
asdmin> set resources.managed-scheduled-executor-service.{resource-JNDI-
name}.deployment-order=120
```

To Delete a Managed Scheduled Executor Service

Use the `delete-managed-scheduled-executor-service` subcommand in remote mode to delete an existing managed scheduled executor service. Deleting a managed scheduled executor service is a dynamic event and does not require server restart.

Before deleting a managed scheduled executor service resource, all associations to the resource must be removed.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the managed scheduled executor service resources by using the `list-managed-scheduled-executor-service` subcommand.
3. If necessary, notify users that the managed scheduled executor service is being deleted.
4. Delete the managed scheduled executor service by using the `delete-managed-scheduled-executor-service` subcommand.

Example 14-12 To Delete a Managed Scheduled Executor Service

This example deletes the managed scheduled executor service resource named `concurrent/ScheduledExecutor1`.

```
asadmin> delete-managed-scheduled-executor-service concurrent/ScheduledExecutor1
Managed scheduled executor service concurrent/ScheduledExecutor1 deleted successfully.
Command delete-managed-scheduled-executor-service executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help delete-managed-scheduled-executor-service` at the command line.

Administering the ORB

Payara Server supports a standard set of protocols and formats that ensure interoperability. Among these protocols are those defined by CORBA. The Object Request Broker (ORB) is the central component of CORBA. The ORB provides the required infrastructure to identify and locate objects, handle connection management, deliver data, and request communication. This chapter describes how to configure the ORB and the IIOP listeners.

Instructions for accomplishing the tasks in this chapter by using the Administration Console are contained in the Administration Console online help.

About the ORB

The Common Object Request Broker Architecture (CORBA) model is based on clients requesting services from distributed objects or servers through a well-defined interface by issuing requests to the objects in the form of remote method requests. A remote method request carries information

about the operation that needs to be performed, including the object name (called an object reference) of the service provider and parameters, if any, for the invoked method. CORBA automatically handles network programming tasks such as object registration, object location, object activation, request de-multiplexing, error-handling, marshalling, and operation dispatching.

Configuring the ORB

A CORBA object never talks directly with another. Instead, the object makes requests through a remote stub to the Internet Inter-Orb Protocol (IIOP) running on the local host. The local ORB then passes the request to an ORB on the other host using IIOP. The remote ORB then locates the appropriate object, processes the request, and returns the results.

IIOP can be used as a Remote Method Invocation (RMI) protocol by applications or objects using RMI-IIOP. Remote clients of enterprise beans (EJB modules) communicate with Payara Server by using RMI-IIOP.

Administering IIOP Listeners

An IIOP listener is a listen socket that accepts incoming connections from the remote clients of enterprise beans and from other CORBA-based clients. Multiple IIOP listeners can be configured for Payara Server. For each listener, specify a port number (optional; default 1072), a network address, and security attributes (optional). If you create multiple listeners, you must assign a different port number for each listener.

To Create an IIOP Listener

Use the `create-iiop-listener` subcommand in remote mode to create an IIOP listener.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create an IIOP listener by using the `create-iiop-listener` subcommand. Information about the properties for the subcommand is included in this help page.
3. To apply your changes, restart Payara Server. See To Restart a Domain.

Example 15-1 Creating an IIOP Listener

```
asadmin> create-iiop-listener --listeneraddress 192.168.1.100
--iiopport 1400 sample_iiop_listener
Command create-iiop-listener executed successfully.
```

This example creates an IIOP listener named `sample_iiop_listener`.

To List IIOP Listeners

Use the `list-iiop-listeners` subcommand in remote mode to list the existing IIOP listeners.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the IIOP listeners by using the `list-iiop-listeners` subcommand.

Example 15-2 Listing IIOP Listeners

```
asadmin> list-iiop-listeners
orb-listener-1
SSL
SSL_MUTUALAUTH
sample_iiop_listener
Command list-iiop-listeners executed successfully.
```

This example lists all the IIOP listeners for the server instance.

To Update an IIOP Listener

1. List the IIOP listeners by using the `list-iiop-listeners` subcommand.
2. Modify the values for the specified IIOP listener by using the `set` subcommand. The listener is identified by its dotted name.

Example 15-3 Updating an IIOP Listener

```
asadmin> set "server.iiop-service.iiop-listener.SSL.enabled"
server.iiop-service.iiop-listener.SSL.enabled=false
Command set executed successfully.
```

This example changes SSL from enabled to disabled.

To Delete an IIOP Listener

Use the `delete-iiop-listener` subcommand in remote mode to delete an IIOP listener.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the IIOP listeners by using the `list-iiop-listeners` subcommand.
3. Delete an IIOP listener by using the `delete-iiop-listener` subcommand.
4. To apply your changes, restart Payara Server. See To Restart a Domain.

Example 15-4 Deleting an IIOP Listener

```
asadmin> delete-iiop-listener sample_iiop_listener
 Command delete-iiop-listener executed successfully.
```

This example deletes the IIOP listener named `sample_iiop_listener`.

Configuring the New ORB Fragment Processing

The aim of this functionality is to enhance the concurrency mechanism through a new implementation that uses the Lock API. The advantages of this approach instead over relying on synchronized code blocks (default) are:

- Fine-grained control: it uses explicit locking and unlocking, delivering higher accuracy and efficiency.
- Use of condition variables: threads await the fulfillment of specific conditions prior to advancing.
- Multiple object locking: a lock can be shared among various class instances, facilitating more flexible management of synchronization between these instances.

The Fragment processing happens when a big message is processed by the ORB. If the ORB message exceeds the default size of 1024 bytes, then the internal fragmentation of the message starts.

To configure the new functionality use the following properties:

Table 10. New ORB Fragment Processing Properties

Property	Description
`com.sun.corba.ee.protocol.enableNewFragmentProcess`	This property enables the new fragment processing. By default, this property is set as `false` to support the default implementation based on synchronized blocks of code.
`com.sun.corba.ee.protocol.newFragmentEmptyConditionTimeout`	You can use this property to change the wait timeout for fragments of a request. By default, the timeout is 10000 milliseconds. This property only takes effect if the `com.sun.corba.ee.protocol.enableNewFragmentProcess` is enabled. The property value is expressed in milliseconds.

Administering the Jakarta Mail Service

Payara Server includes the Jakarta Mail API along with Jakarta Mail service providers that allow an application component to send email notifications over the Internet and to read email from IMAP and POP3 mail servers.

Instructions for accomplishing the tasks in this chapter by using the Administration Console are contained in the Administration Console online help.

About Jakarta Mail

The Jakarta Mail API is a set of abstract APIs that model a mail system. The Jakarta Mail API provides a platform-independent and protocol-independent framework to build mail and messaging applications and provide facilities for reading and sending electronic messages. Service providers implement particular protocols.

Using the API you can add email capabilities to your applications. Jakarta Mail provides access from Java applications to Internet Message Access Protocol (IMAP) and Simple Mail Transfer Protocol (SMTP) capable mail servers on your network or the Internet.

The API does not provide mail server functionality; you must have access to a mail server to use Jakarta Mail.

The Jakarta Mail API is implemented as an optional package in the Jakarta platform and is also available as part of the Jakarta EE platform.

To learn more about the Jakarta Mail API, consult the Jakarta Mail specification.

Administering Jakarta Mail Resources

When you create a mail session, the server-side components and applications are enabled to access Jakarta Mail services with JNDI, using the session properties you assign for them. When creating a mail session, you can designate the mail hosts, the transport and store protocols, and the default mail user so that components that use Jakarta Mail do not have to set these properties. Applications that are heavy email users benefit because Payara Server creates a single session object and makes the session available to any component that needs it.

Table 11. Jakarta Mail's settings such as the following can be specified:

Jakarta Mail settings	Description
JNDI Name	The unique name for the mail session. Use the naming sub-context prefix mail/ for Jakarta Mail resources. For example: `mail/MySession`
Mail Host	The host name of the default mail server. The connect methods of the store and transport objects use this value if a protocol-specific host property is not supplied. + The name must be resolvable to an actual host name.
Default User	The default username to provide when connecting to a mail server. The connect methods of the store and transport objects use this value if a protocol-specific username property is not supplied.
Default Return Address	The email address of the default user, in the form: `username@host.domain`.
Description	A descriptive statement for the component.
Session	Indicates whether the mail session is enabled or disabled at this time

To Create a Jakarta Mail Resource

Use the `create-javamail-resource` subcommand in remote mode to create a Jakarta Mail session resource. The JNDI name for a Jakarta Mail session resource customarily includes the mail/ naming subcontext, For example: `mail/MyMailSession.`

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a Jakarta Mail resource by using the `create-javamail-resource` subcommand. Information about the properties for the subcommand is included in this help page.
3. To apply your changes, restart Payara Server. See To Restart a Domain.

Example - Creating a Jakarta Mail Resource

```
asadmin> create-javamail-resource --mailhost localhost
--mailuser sample --fromaddress sample\@sun\.com mail/MyMailSession
Command create-javamail-resource executed successfully.
```

This example creates a Jakarta Mail resource named `mail/MyMailSession`. The escape character (\) is used in the `--fromaddress` option to distinguish the dot (.) and at sign (@).

To List JavaMail Resources

Use the `list-javamail-resources` subcommand in remote mode to list the existing JavaMail session resources.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the Jakarta Mail resources by using the `list-javamail-resources` subcommand.

Example - Listing Jakarta Mail Resources

```
asadmin> list-javamail-resources
mail/MyMailSession
Command list-javamail-resources executed successfuly.
```

This example lists the Jakarta Mail resources on `localhost`.

To Update a Jakarta Mail Resource

1. List the Jakarta Mail resources by using the `list-javamail-resources` subcommand.
2. Modify the values for the specified Jakarta Mail source by using the `set` subcommand. The resource is identified by its dotted name.

Example - Updating a Jakarta Mail Resource

```
asadmin> set server.resources.mail-resource.mail/
MyMailSession.user=joeserver.resources.mail-resource.mail/
MyMailSession.user=joe
Command set executed successfully.
```

This example changes `joeserver` to `joe`.

To Delete a Jakarta Mail Resource

Use the `delete-javamail-resource` subcommands in remote mode to delete a Jakarta Mail session resource.

References to the specified resource must be removed before running the `delete-javamail-resource` subcommands.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the Jakarta Mail resources by using the `list-javamail-resources` subcommands.
3. Delete a Jakarta Mail resource by using the `delete-javamail-resource` subcommands.
4. To apply your changes, restart Payara Server. To Restart a Domain.

Example - Deleting a Jakarta Mail Resource

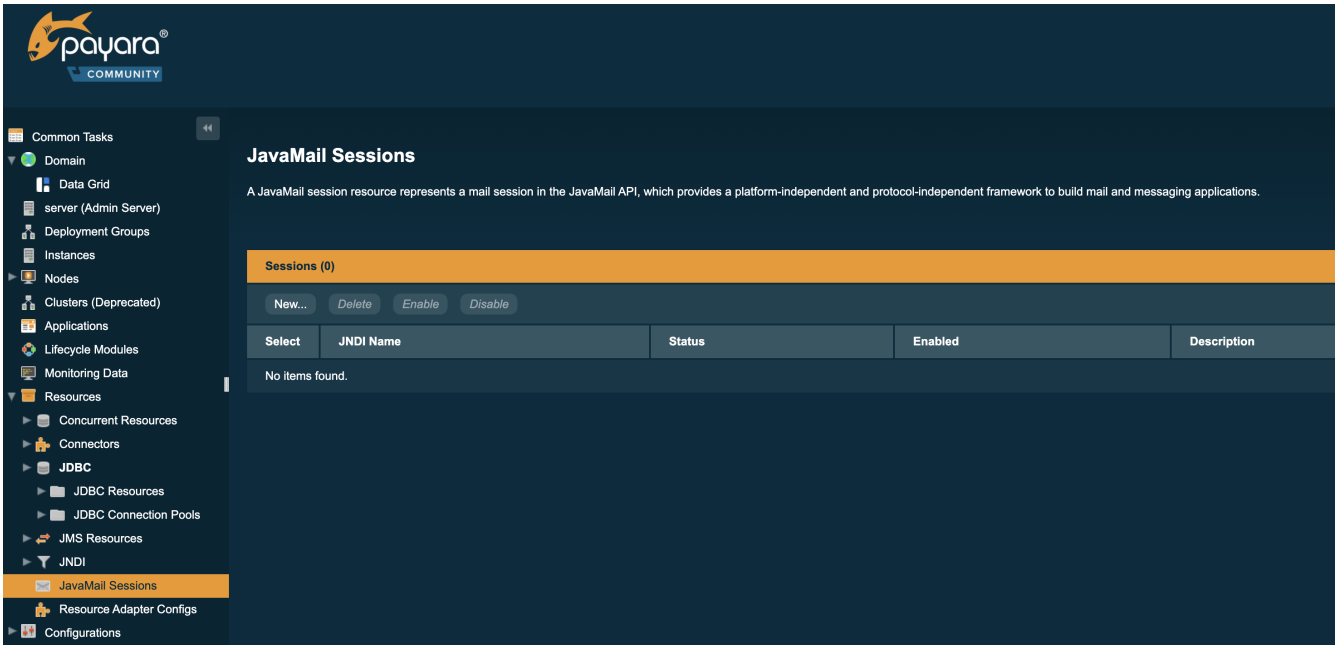
```
asadmin> delete-javamail-resource mail/MyMailSession
Command delete-javamail-resource executed successfully.
```

This example deletes the Jakarta Mail session resource named `mail/MyMailSession`.

Configure a Jakarta Mail session from the Admin Console

Jakarta Mail sessions are added from the `Resources` tab on the left pane of the Admin Console.

Select `New` on the `Sessions` table to create a new Jakarta Mail session:

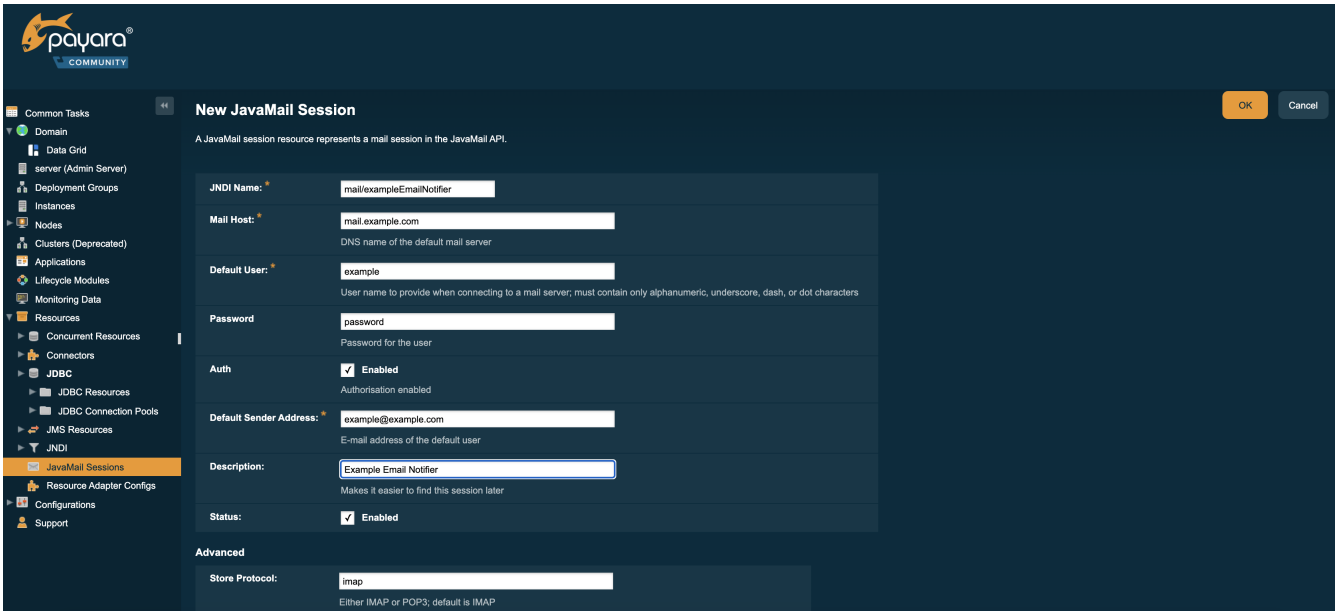


Emails will be sent with a return address of `example@example.com`, using `SMTP` to send mail and `IMAP` to retrieve mail. With the current implementation of the Jakarta Mail API there is no alternative transport protocol provided by default, though as an alternative to the default store protocol of `imap`, `pop3` is available.

Typically, when setting up `SMTP` access, three additional properties must be specified in the Additional Properties table: enabling `startTLS`, enabling authentication, and the password.

These allow for extra security when sending emails and will not always be required - check with your email provider for their specific configuration.

The example below shows the configuration of a mail host:



Administering the Java Message Service

The Java Message Service (JMS) API is a messaging standard that allows Jakarta EE applications and components, including message-driven beans (MDBs), to create, send, receive, and read messages. It enables distributed communication that is loosely coupled, reliable, and asynchronous.

Payara Server supports JMS messaging by communicating with a JMS provider through a Jakarta EE Connector resource adapter. By default, Payara Server provides JMS messaging through its built-in `jmsra` resource adapter communicating with Open Message Queue, which is included with Payara Server. This combination, known as the JMS Service, is tightly integrated with Payara Server, providing a rich set of `asadmin` subcommands and Administration Console pages to simplify JMS messaging administration tasks.

Instructions for accomplishing the task in this chapter by using the Administration Console are contained in the Administration Console online help.

About the JMS Service

To support JMS messaging, the JMS Service provides the following administrative objects:

JMS Service Configuration

The JMS service configuration is part of the overall configuration for a Payara standalone instance or cluster. It specifies how the JMS Service is to create and maintain connections with JMS Hosts.

JMS Hosts

JMS hosts are the message servers that host destinations, store messages, and interact with applications to send and receive messages across connections. In Message Queue, JMS hosts are called brokers.
The JMS service supports these types of JMS hosts:

- Embedded type, in which the JMS host runs in the same JVM as the Payara instance; its configuration and lifecycle are managed by the JMS service

- Local type, in which the JMS host runs separately on the same host as the Payara instance; its configuration and lifecycle are managed by the JMS service
- Remote type, in which the JMS host represents a Message Queue broker or broker cluster that is external to the JMS service; its operation is managed using Message Queue administrative tools
  For more information about JMS host types, see About JMS Host Types.

JMS Connection Factory Resources

JMS connection factory resources house the information that applications use to connect to a JMS provider. For each JMS connection factory, the JMS service automatically maintains a Payara connector resource and a Payara connector connection pool in order to support connection pooling and fail-over.

JMS Destination Resources

JMS destination resources house the information that applications use to specify the target destination of messages they produce and the source destination of messages they consume. For each JMS destination resource, the JMS service automatically maintains a Payara administered object.

JMS Physical Destinations

JMS physical destinations provide a means to create and manage JMS destinations administratively instead of having them created dynamically when needed by an application. While dynamic creation of destinations is often sufficient during application development, administratively created physical destinations are more suitable for production environments.

JMS Service High Availability

Just as Payara Server supports clusters of instances to provide high availability, Message Queue supports clusters of brokers to provide service availability or service and data availability, depending on the type of broker cluster, as described in [Broker Clusters] in Open Message Queue Technical Overview.

The JMS service takes advantage of this Message Queue capability and automatically creates and manages a Message Queue broker cluster when a Payara cluster's configuration specifies Embedded or Local type JMS hosts. Additionally, both Payara clusters and standalone instances can use Message Queue broker clusters as Remote type JMS hosts.

For information about how the JMS service supports Payara clusters and Message Queue broker clusters, see Configuring Java Message Service High Availability in the Payara Server Edition High Availability section.

Updating the JMS Service Configuration

Because the JMS service configuration is part of the overall configuration for a standalone instance or cluster, it is created when the standalone instance or cluster is created. You can then update the JMS service configuration by using the Java Message Service page for the configuration in the Administration Console, or by using a `set` subcommand of the following form:

```
set configs.config.config-name.jms-service.attribute-name=attribute-value
```

The attributes you can set are:

`type`

The JMS host type the service is to use. Available choices are `EMBEDDED`, `LOCAL` and `REMOTE`. See About JMS Host Types for more information.

`init-timeout-in-seconds`

The number of seconds Payara Server waits for the JMS service to start before aborting the startup.

`start-args`

A list of arguments the JMS service passes to Embedded and Local type JMS hosts on startup.

`default-jms-host`

The name of the default JMS host.

`reconnect-enabled`

When set to `true`, the JMS service attempts to reconnect to a JMS host (or one of the JMS hosts in the AddressList) when a connection is lost.

`reconnect-attempts`

The number of attempts to connect (or reconnect) for each JMS host in the AddressList before the JMS service tries the next address in the list. A value of -1 indicates that the number of reconnect attempts is unlimited (the JMS service attempts to connect to the first address until it succeeds).

`reconnect-interval-in-seconds`

The number of seconds between reconnect attempts. This interval applies for attempts on each JMS host in the AddressList and for successive addresses in the list. If it is too short, this time interval does not give a JMS host time to recover. If it is too long, the reconnect might represent an unacceptable delay.

`addresslist-behavior`

The order of connection attempts. Available choices are:

`random`

Select a JMS host from the AddressList randomly. If there are many clients attempting a connection using the same connection factory, specify `random` to prevent them from all being connected to the same JMS host.

`priority`

Always try to connect to the first JMS host in the AddressList and use another one only if the first one is not available.

`addresslist-iterations`

The number of times the JMS service iterates through the AddressList in an effort to establish (or reestablish) a connection. A value of -1 indicates that the number of attempts is unlimited.

`mq-scheme`

`mq-service`

The Message Queue address scheme name and connection service name to use for the AddressList if a non-default scheme or service is to be used.

After making changes to the JMS service configuration, Payara Server instances that use the configuration must be restarted in order for the changes to be propagated.

Setting Message Queue Broker Properties in the JMS Service Configuration

You can specify any Message Queue broker property in the JMS service configuration by adding it by name to the Additional Properties table on the Java Message Service page for the configuration in the Administration Console, or by using a `set` subcommand of the following form:

```
set configs.config.config-name.jms-service.property.broker-property-name=value
```

If the broker property name includes dots, preface the dots with two backslashes (`\\`); for example, to set the `imq.system.max_count` property, specify `imq\\.system\\.max_count` in the `set` subcommand.

You can also set broker properties in the JMS host. If you set the same broker property in both the JMS service configuration and the JMS host, the value specified in the JMS host is used.

Administering JMS Hosts

A JMS host represents a Message Queue broker. JMS contains a JMS hosts list (the `AddressList` property) that contains all the JMS hosts that are used by Payara Server. The JMS hosts list is populated with the hosts and ports of the specified Message Queue brokers and is updated whenever a JMS host configuration changes. When you create JMS resources or deploy message driven beans, the resources or beans inherit the JMS hosts list.

For information about administering JMS hosts that are servicing Payara clusters, see Configuring Payara Clusters to Use Message Queue Broker Clusters in the Payara Server High Availability section.

About JMS Host Types

The JMS service uses Message Queue (MQ) brokers as JMS hosts, integrating them in three ways:

Embedded Type

When the JMS service configuration's `type` attribute is `EMBEDDED`, the MQ broker is co-located in the same JVM as the Payara server instance it services. The JMS service starts it in-process and manages its configuration and lifecycle. For this type, the JMS service uses lazy initialization to

start the broker when the first JMS operation is requested instead of immediately when the Payara instance is started. If necessary, you can force startup of the broker by using the `jms-ping` command. Additionally, if the Payara instance is a standalone instance (not a clustered instance), JMS operations use a Message Queue feature called direct mode to bypass the networking stack, leading to performance optimization.

Local Type

When the JMS service configuration's `type` attribute is `LOCAL`, the JMS service starts the MQ broker specified in the configuration as the default JMS host in a separate process on the same host as the Payara server instance. The JMS service manages its configuration and lifecycle. For this type, the JMS service starts the broker immediately when the Payara instance is started. The JMS service provides the Message Queue broker an additional port to start the RMI registry. This port number is equal to the broker's JMS port plus 100. For example, if the JMS port number is 37676, then the additional port's number will be 37776. Additionally, the `start-args` property of the JMS service configuration can be used to specify Message Queue broker startup options.

Remote Type

When the JMS service configuration's `type` attribute is `REMOTE`, the JMS service uses the information defined by the default JMS host to communicate with an MQ broker or broker cluster that has been configured and started using Message Queue tools. Ongoing administration and tuning of the broker or broker cluster are also performed using Message Queue tools.

Configuring Embedded and Local JMS Hosts

Because the JMS service, not Message Queue, manages Embedded and Local JMS hosts automatically, you should avoid using Message Queue utilities to configure them. Instead, specify broker properties in the JMS service configuration or in the JMS host.

Should the need to use Message Queue utilities arise, you must use the `-varhome` option when running certain Message Queue utilities to specify the `IMQ_VARHOME` location of the Embedded or Local JMS host. This location depends on which Payara instance the JMS host is servicing:

- For `server`, the Domain Administration Server (DAS), the `IMQ_VARHOME` location is:

```
domain-root-dir/domain-dir/imq
```

- For any other Payara instance, the `IMQ_VARHOME` location is:

```
as-install/nodes/node-name/instance-name/imq
```

For example, the broker log file for an Embedded or Local JMS host servicing the DAS is available at `domain-root-dir/domain-dir/imq/instances/imqbroker/log/log.txt`, and the broker log file for an Embedded or Local JMS host servicing any other Payara instance is available at `as-install/nodes/node-name/instance-name/imq/instances/mq-instance-name/log/log.txt`.

When using Message Queue utilities on the Windows platform, you must explicitly use the Windows executable (`.exe`) versions of the utilities, even when running

command shells such as Cygwin. For example, instead of running `imqcmd`, you must run `imqcmd.exe`.

To Create a JMS Host

The default JMS service configuration includes a JMS host, `default_JMS_host`. For most situations, this host is sufficient, so replacing it or creating additional JMS hosts is not often necessary and is a task for advanced users. Use the `create-jms-host` subcommand in remote `asadmin` mode to create an additional JMS host.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Create the JMS host by using the `create-jms-host` subcommand:

```
asadmin> create-jms-host --mqhost hostName --mqport portNumber --mquser adminUser
--mqpassword adminPassword --target glassfishTarget --property mqBrokerPropList
--force trueFalse jms-host-name
```

`--mqhost`
: The host name of the Message Queue broker.

`--mqport`
: The port number of the Message Queue broker.

`--mquser`
: The username of the administrative user of the Message Queue broker.

`--mqpassword`
: The password of the administrative user of the Message Queue broker.

`--target`
: The Payara Server object for which the JMS host is being created. For details, see `create-jms-host`.

`--property`
: A list of one or more Message Queue broker properties to configure the broker. The list is colon-separated (`:`) and has the form:

```
prop1Name=prop1Value:prop2Name=prop2Value:...
```

If a broker property name includes dots, preface the dots with two backslashes (`\\`); for example, to include the `imq.system.max_count` property, specify `imq\\.system\\.max_count` in the `--property` option.

You can also set broker properties in the JMS service configuration. If you set the same broker property in both the JMS host and the JMS service configuration, the value specified in the JMS host is used.

`--force`

Specifies whether the subcommand overwrites the existing JMS host of the same name. The default value is `false`.

jms-host-name

The unique name of the JMS host.

Example 17-1 Creating a JMS Host

This example creates a JMS host named `MyNewHost`.

```
asadmin> create-jms-host --mqhost pigeon --mqport 7677 --mquser admin --mqpassword
admin MyNewHost
Jms Host MyNewHost created.
Command create-jms-host executed successfully.
```

To List JMS Hosts

Use the `list-jms-hosts` subcommand in remote `asadmin` mode to list the existing JMS hosts.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. List the JMS hosts by using the `list-jms-hosts` subcommand.

Example 17-2 Listing JMS Hosts

The following subcommand lists the existing JMS hosts.

```
asadmin> list-jms-hosts
default_JMS_host
MyNewHost
Command list-jmsdest executed successfully
```

To Update a JMS Host

Use the `set` subcommand in remote `asadmin` mode to update an existing JMS host.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Use the `get` subcommand to list the current attribute values of the desired JMS host:

```
asadmin> get configs.config.config-name.jms-service.jms-host.jms-host-name.*
```

For information about JMS host attributes, see `create-jms-host`(1). . Use the `set` subcommand to modify a JMS host attribute:

```
asadmin> set configs.config.config-name.jms-service.jmshost.
```

```
jms-host-name.attribute-name=attribute-value
```

The attributes you can set are

`host`

The host name of the Message Queue broker.

`port`

The port number of the Message Queue broker.

`admin-user-name`

The username of the administrative user of the Message Queue broker.

`admin-password`

The password of the administrative user of the Message Queue broker.

`property.`broker-property-name

A Message Queue broker property. The property and the value assigned to it are used to configure the Message Queue broker.

```
If the broker property name includes dots, preface the dots with two backslashes
(`\\`); for example, to include the `imq.system.max_count` property, specify
`imq\\.system\\.max_count` in the `set` subcommand.
```

You can also set broker properties in the JMS service configuration. If you set the same broker property in both the JMS host and the JMS service configuration, the value specified in the JMS host is used.

Example 17-3 Updating a JMS Host

This example changes the value of the `host` attribute of the JMS host `default_JMS_Host`. By default, this value is `localhost`.

```
asadmin> set configs.config.server-config.jms-service.jms-
host.default_JMS_host.host="server1.middleware.example.com"
```

To Delete a JMS Host

Use the `delete-jms-host` subcommand in remote `asadmin` mode to delete a JMS host from the JMS service. If you delete the only JMS host, the JMS service will not be able to start until you create a new JMS host.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. List the JMS hosts by using the `list-jms-hosts` subcommand.
3. Delete a JMS host by using the `delete-jms-host` subcommand.

Example 17-4 Deleting a JMS Host

This example deletes a JMS host named `MyNewHost`.

```
asadmin> delete-jms-host MyNewHost
Command delete-jms-host executed successfully.
```

Administering JMS Connection Factories and Destinations

The JMS API uses two kinds of administered objects. Connection factory objects allow an application to create other JMS objects programmatically. Destination objects serve as repositories for messages. How these objects are created is specific to each implementation of JMS. In Payara Server, JMS is implemented by performing the following tasks:

- Creating a connection factory
- Creating a destination, which requires creating a physical destination and a destination resource that refers to the physical destination

JMS applications use the Java Naming and Directory Interface (JNDI) API to access the connection factory and destination resources. A JMS application normally uses at least one connection factory and at least one destination. By studying the application or consulting with the application developer, you can determine what resources must be created. The order in which the resources are created does not matter.

The Jakarta EE standard specifies that certain default resources be made available to applications, and defines specific JNDI names for these default resources. Payara Server makes these names available through the use of logical JNDI names, which map Jakarta EE standard JNDI names to specific Payara Server resources. For JMS connection factory resources, the Jakarta EE standard name `java:comp/DefaultJMSConnectionFactory` is mapped to the `jms/__defaultConnectionFactory` resource.

Payara Server provides the following types of connection factory objects:

- `QueueConnectionFactory` objects, used for point-to-point communication
- `TopicConnectionFactory` objects, used for publish-subscribe communication
- `ConnectionFactory` objects, which can be used for both point-to-point and publish-subscribe communications (recommended for new applications)

Payara Server provides the following types of destination objects:

- `Queue` objects, used for point-to-point communication
- `Topic` objects, used for publish-subscribe communication

The subcommands in this section can be used to administer both the connection factory resources and the destination resources. For information on JMS service support of connection pooling and failover, see Connection Failover in the Payara Server High Availability section. For instructions on administering physical destinations, see Administering JMS Physical Destinations.

To Create a Connection Factory or Destination Resource

For each JMS connection factory that you create, Payara Server creates a connector connection pool and connector resource. For each JMS destination that you create, Payara Server creates a connector admin object resource. If you delete a JMS resource, Payara Server automatically deletes the connector resources.

Use the `create-jms-resource` command in remote `asadmin` mode to create a JMS connection factory resource or a destination resource.

To specify the `addresslist` property (in the format `host:mqport,host2:mqport,host3:mqport`) for the `asadmin create-jms-resource` command, escape the : by using `\\`. For example, `host1\\:mqport,host2\\:mqport,host3\\:mpqport`.

To update a JMS connection factory, use the `set` subcommand for the underlying connector connection pool, See To Update a Connector Connection Pool.

To update a destination, use the `set` subcommand for the admin object resource. See To Update an Administered Object.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Create a JMS resource by using the `create-jms-resource` command.
   Information about the properties for the subcommand is included in this help page.
3. If needed, restart the server.
   Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 17-5 Creating a JMS Connection Factory

This example creates a connection factory resource of type `jakarta.jms.ConnectionFactory` whose JNDI name is `jms/DurableConnectionFactory`. The `ClientId` property sets a client ID on the connection factory so that it can be used for durable subscriptions. The JNDI name for a JMS resource customarily includes the `jms/` naming subcontext.

```
asadmin> create-jms-resource --restype jakarta.jms.ConnectionFactory
--description "connection factory for durable subscriptions"
--property ClientId=MyID jms/DurableConnectionFactory
Command create-jms-resource executed successfully.
```

Example 17-6 Creating a JMS Destination

This example creates a destination resource whose JNDI name is `jms/MyQueue`.

```
asadmin> create-jms-resource --restype jakarta.jms.Queue
--property Name=PhysicalQueue jms/MyQueue
Command create-jms-resource executed successfully.
```

To List JMS Resources

Use the `list-jms-resources` subcommand in remote `asadmin` mode to list the existing connection factory and destination resources.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. List the existing JMS resources by using the `list-jms-resources` subcommand.

Example 17-7 Listing All JMS Resources

This example lists all the existing JMS connection factory and destination resources.

```
asadmin> list-jms-resources
jms/Queue
jms/ConnectionFactory
jms/DurableConnectionFactory
jms/Topic
Command list-jms-resources executed successfully
```

Example 17-8 Listing a JMS Resources of a Specific Type

This example lists the resources for the resource type `javax`.

```
asadmin> list-jms-resources --restype jakarta.jms.TopicConnectionFactory
jms/DurableTopicConnectionFactory
jms/TopicConnectionFactory
Command list-jms-resources executed successfully.
```

To Delete a Connection Factory or Destination Resource

Use the `delete-jms-resource` subcommand in remote `asadmin` mode to remove the specified connection factory or destination resource.

Before You Begin

Ensure that you remove all references to the specified JMS resource before running this subcommand.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. List the existing JMS resources by using the `list-jms-resources` subcommand.
3. Delete the JMS resource by using the `delete-jms-resource` subcommand.

Example 17-9 Deleting a JMS Resource

This example deletes the `jms/Queue` resource.

```
asadmin> delete-jms-resource jms/Queue
```

```
Command delete-jms-resource executed successfully
```

Administering JMS Physical Destinations

Messages are delivered for routing and delivery to consumers by using physical destinations in the JMS provider. A physical destination is identified and encapsulated by an administered object (such as a `Topic` or `Queue` destination resource) that an application component uses to specify the destination of messages it is producing and the source of messages it is consuming. For instructions on configuring a destination resource, see To Create a Connection Factory or Destination Resource.

If a message-driven bean is deployed and the physical destination it listens to does not exist, Payara Server automatically creates the physical destination and sets the value of the `maxNumActiveConsumers` property to `-1`. However, it is good practice to create the physical destination beforehand. The first time that an application accesses a destination resource, Message Queue automatically creates the physical destination specified by the Name property of the destination resource. This automatically created physical destination is temporary and expires after a period specified by a Message Queue configuration property, provided that there are no messages in it and no message producers or consumers connected to it.

To Create a JMS Physical Destination

For production purposes, always create physical destinations. During the development and testing phase, however, this step is not required. Use the `create-jmsdest` subcommand in remote `asadmin` mode to create a physical destination.

Because a physical destination is actually a Message Queue object rather than a server object, you use Message Queue broker commands to update properties.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Create a JMS physical destination by using the `create-jmsdest` subcommand. Information about the properties for the subcommand is included in this help page.
3. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 17-10 Creating a JMS Physical Destination

This example creates a queue named `PhysicalQueue`.

```
asadmin> create-jmsdest --desttype queue --property
User=public:Password=public PhysicalQueue
Command create-jmsdest executed successfully.
```

To List JMS Physical Destinations

Use the `list-jmsdest` subcommand in remote `asadmin` mode to list the existing JMS physical destinations.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.

2. List the existing JMS physical destinations by using the `list-jmsdest` subcommand.

Example 17-11 Listing JMS Physical Destinations

```
asadmin> list-jmsdest
PhysicalQueue queue {}
PhysicalTopic topic {}
Command list-jmsdest executed successfully.
```

This example lists the physical destinations for the default server instance.

To Purge Messages From a Physical Destination

Use the `flush-jmsdest` subcommand in remote `asadmin` mode to purge the messages from a physical destination in the specified target's JMS service configuration.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Purge messages from the JMS physical destination by using the `flush-jmsdest` subcommand.
3. If needed, restart the server. Some properties require server restart. See Configuration Changes That Require Restart. If your server needs to be restarted, see To Restart a Domain.

Example 17-12 Flushing Messages From a JMS Physical Destination

```
asadmin> flush-jmsdest --desttype queue PhysicalQueue
Command flush-jmsdest executed successfully
```

This example purges messages from the queue named `PhysicalQueue`.

To Delete a JMS Physical Destination

Use the `delete-jmsdest` subcommand in remote `asadmin` mode to remove the specified JMS physical destination.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. List the existing JMS physical destinations by using the `list-jmsdest` subcommand.
3. Delete the physical resource by using the `delete-jmsdest` subcommand.

Example 17-13 Deleting a Physical Destination

```
asadmin> delete-jmsdest --desttype queue PhysicalQueue
Command delete-jmsdest executed successfully
```

This example deletes the queue named `PhysicalQueue`.

Special Situations When Using the JMS Service

As mentioned earlier, Message Queue, through the built-in `jmsra` resource adapter, is tightly integrated with PayaraServer to provide JMS messaging managed through a rich set of `asadmin` subcommands and Administration Console pages to simplify JMS messaging administration tasks. In most instances, this tight integration is transparent and automatic, requiring no special effort on the part of an administrator. In certain special situations, though, an administrator must perform a task such a setting a Message Queue broker property or a Payara object attribute to enable or disable a capability of the integration.

The topics in this section describe these situations.

Restarting an Embedded or Local Broker That Has Failed

Because the JMS service, not Message Queue, manages the lifecycle of brokers acting as Embedded and Local JMS hosts, do not use the `imqbrokerd` Message Queue utility to start such a broker that has failed. Instead, restart the Payara instance that the broker is servicing.

Changing the Admin User Password for an Embedded or Local Broker

Follow these steps to change the `admin` user password for an Embedded or Local broker:

1. Make sure the broker is running.
2. Use the `imqusermgr` Message Queue utility to change the password of the `admin` user.
3. Edit the configuration of the JMS host, changing the password of the `admin` user to the new password.
4. Restart the Payara instance that the broker is servicing.
   When changing the password for the brokers in a broker cluster, first perform steps 1 and 2 on each broker. Then, perform step 3. Finally, perform step 4 on each broker. Using SSL to Connect to an Oracle Internet Directory (OID) or Oracle

Virtual Directory (OVD) User Respository

When using SSL to connect to an OID or OVD user repository, you must set the `imq.user_repository.ldap.ssl.socketfactory` Message Queue broker property to `com.sun.enterprise.security.auth.realm.ldap.CustomSocketFactory`.

Troubleshooting the JMS Service

If you encounter problems, consider the following:

- Use the `jms-ping` subcommand to confirm that the Message Queue broker is running.
- View the Payara Server log file. For `server`, the DomainAdministrations Server (DAS), the log is available at domain-dir`/logs/server.log`; for other Payara instances, the log is available at as-install`/nodes/node-name/instance-name/logs/server.log`.
  If the log file indicates that a Message Queue broker acting as a Remote JMS host did not respond to a message, stop the broker and then restart it.
- View the broker log. For a broker associated with the Domain Administration Server (DAS), the log is available at domain-dir`/imq/instances/imqbroker/log/log.txt`; for brokers associated with other Payara instances, the log is available at as-install`/nodes/node-name/instance-name/imq/instances/mq-instance-name/log/log.txt`.

- For Remote type JMS hosts, be sure to start Message Queue brokers first, then Payara Server instances.
- If all Message Queue brokers are down, it can take up to 30 minutes for Payara Server to go down or up when you are using the default values in JMS. You can change the default values for this timeout. For example:

```
asadmin set domain1.jms-service.reconnect-interval-in-seconds=5
```

Using ActiveMQ with Payara Server

Payara Server comes with its own message queue broker: OpenMQ. However, ActiveMQ is also an option for a message queue broker. This section describes how to use ActiveMQ with Payara Server.

Installing ActiveMQ

The latest version of ActiveMQ can be downloaded from here: ActiveMQ Downloads

Once downloaded, unzip the file and navigate to /bin folder and run the following command in order to start ActiveMQ:

```
activemq start
```

```
PowerShell 7.3.3
 bin  .\activemq start
Java Runtime: Azul Systems, Inc. 11.0.18 C:\Program Files\Zulu\zulu-11
  Heap sizes: current=1048576k  free=1040894k  max=1048576k
    JVM args: -Dcom.sun.management.jmxremote -Xms1G -Xmx1G -Djava.util.logging.config.file=logging.properties -Djava.sec
urity.auth.login.config=C:\Work\Apps\apache-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\..\conf\login.config -Dactive
mq.classpath=C:\Work\Apps\apache-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\..\conf;C:\Work\Apps\apache-activemq-5.1
7.4-bin\apache-activemq-5.17.4\bin\../conf;C:\Work\Apps\apache-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\../conf; -
Dactivemq.home=C:\Work\Apps\apache-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\.. -Dactivemq.base=C:\Work\Apps\apache
-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\.. -Dactivemq.conf=C:\Work\Apps\apache-activemq-5.17.4-bin\apache-active
mq-5.17.4\bin\..\conf -Dactivemq.data=C:\Work\Apps\apache-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\..\data -Djolok
ia.conf=file:C:\\Work\\Apps\\apache-activemq-5.17.4-bin\\apache-activemq-5.17.4\\bin\\..\\conf\\jolokia-access.xml -Djav
a.io.tmpdir=C:\Work\Apps\apache-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\..\data\tmp
Extensions classpath:

.17.4\bin\..\data\kahadb]
 INFO | Starting KahaDBStore
 INFO | Opening MessageDatabase
 INFO | Page File: C:\Work\Apps\apache-activemq-5.17.4-bin\apache-activemq-5.17.4\bin\..\data\kahadb\db.data. Recovering
```

This is going to start the ActiveMQ broker at http://127.0.0.1:8161

After accessing the web console and logged in with the default credentials (`admin/admin`), you can create a new queue or topic by clicking on the Queues tab, inputting a name to Queue Name text box and clicking on "Create" button. For the purpose of this example we will create a queue named

TESTQ.

Deploy the ActiveMQ RAR to Payara Serve

In order to use ActiveMQ with Payara Server, you need to deploy the ActiveMQ RAR to Payara Server. You can download the ActiveMQ RAR from here: ActiveMQ RAR

The rar needs then to be deployed to Payara Server. This can be done by using the Payara Admin Console or by using the following asadmin command:

```
asadmin deploy --type rar activemq-rar-5.17.4.rar
```

Configuring the ActiveMQ Connector

The first thing to do is to create a new JMS Resource Adapter Config. This can be done by using the Payara Admin Console or by using the following asadmin command:

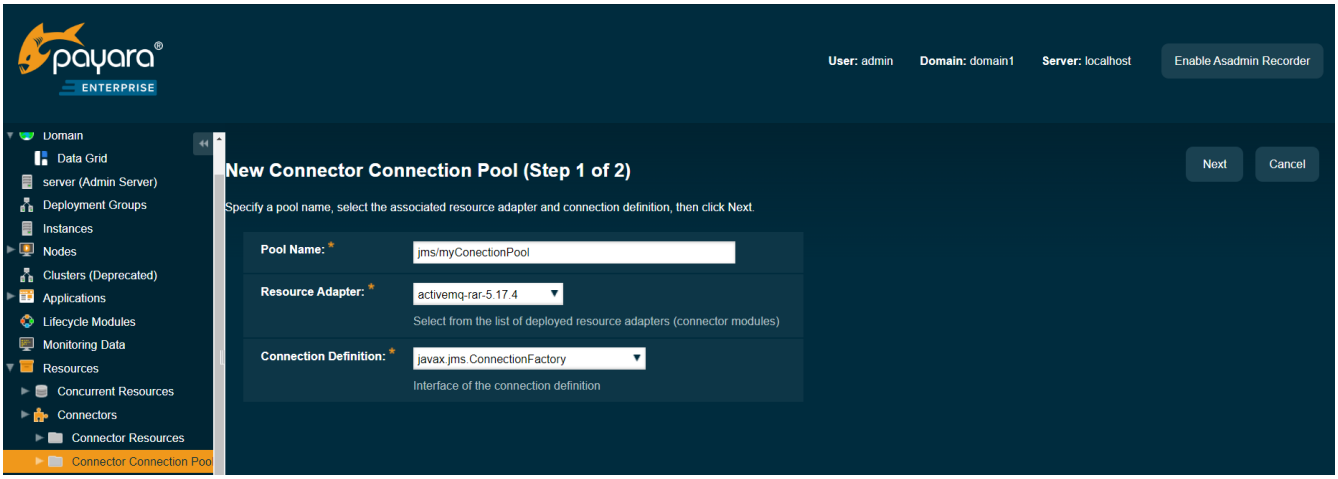
```
asadmin create-resource-adapter-config  --property
ServerUrl=tcp://127.0.0.1:61616:UserName='admin':Password='admin' activemq-rar-5.17.4
```

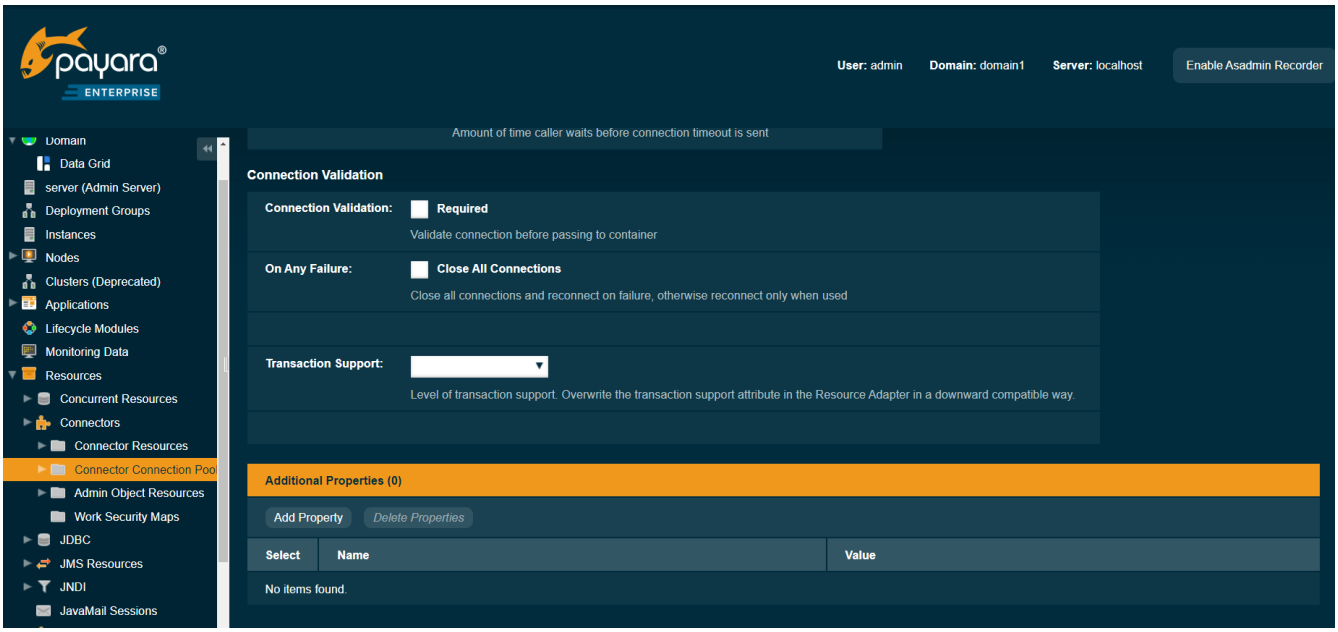
If you chose to use the Payara Admin Console, you will need to create a new JMS Resource Adapter Config by clicking on the "JMS Resource Adapter Configs" link under the "Resources" section of the left menu. The key properties for a default ActiveMQ configuration are:

[[Technical Documentation-Payara Server Documentation-General Administration-Administering the Java Message Service:::table-jms-resource-adapter-config-properties]#Technical Documentation-Payara Server Documentation-General Administration-Administering the Java Message Service:::table-jms-resource-adapter-config-properties]

Property	Value
ServerUrl	tcp://127.0.0.1:61616
UserName	admin
Password	admin

Now we need to create a new JMS Connector Connection Pool as shown in the following screenshots:

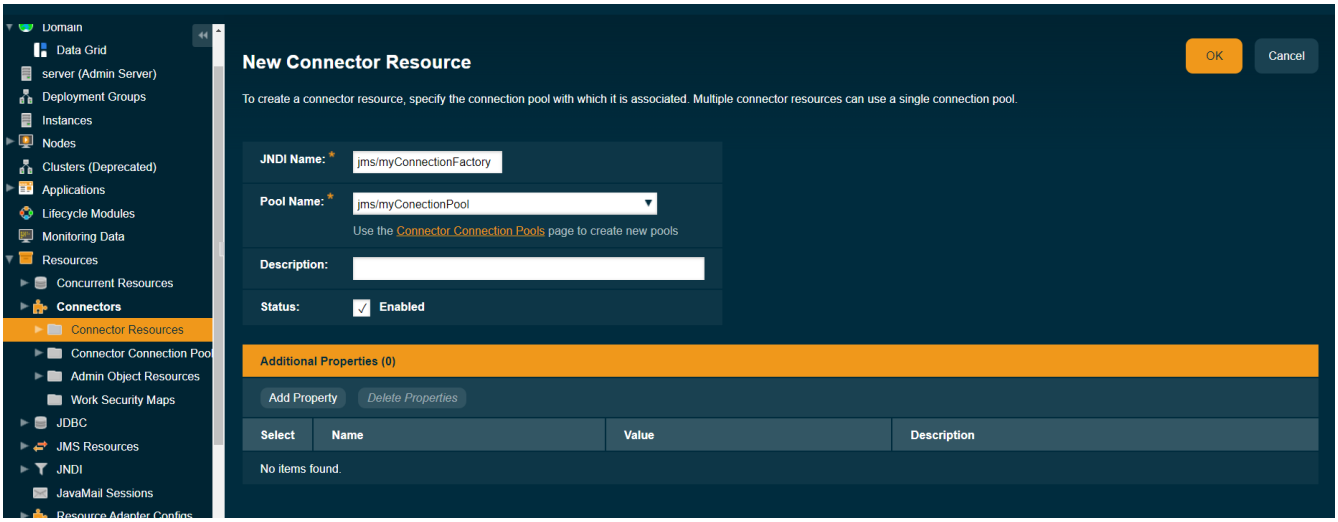




The Connector Connection Pool can also be created by using the following asadmin command:

```
asadmin create-connector-connection-pool --raname activemq-rar-5.17.4
--connectiondefinition javax.jms.ConnectionFactory --ping true --isconnectvalidatereq
true jms/myConnectionPool
```

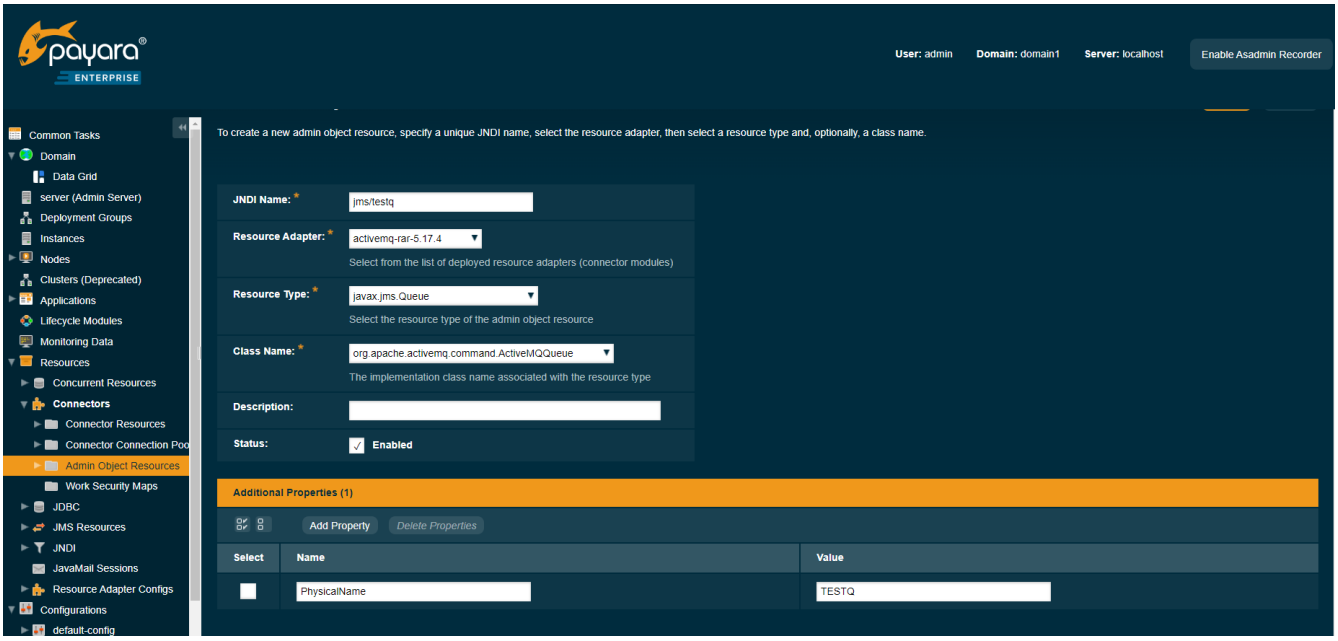
Another configuration needed is the JNDI mapping for te JMS Connector Connection Pool. This can be done by using the Payara Admin Console following this screenshot:



Alternatively you can use the following asadmin command:

```
asadmin create-connector-resource --poolname jms/myConnectionPool
jms/myConnectionFactory
```

Now we have the connection factory configured we can also create a JMS mapping to our Queue. This can be done by using the Payara Admin Console following this screenshot:



Again, if you prefer, you can use the following asadmin command to create the same mapping:

```
asadmin create-admin-object --raname activemq-rar-5.17.4 --restype javax.jms.Queue
--property PhysicalName=TESTQ jms/TESTQ
```

Testing the ActiveMQ Configuration via MDB

Below shows the code for an MDB that listens on the queue configured in this blog within ActiveMQ. We can see that both the resource adapter, the physical name of the queue and the JNDI name are set as Activation Properties of the MDB.

```
package fish.payara.support.activemqtest;

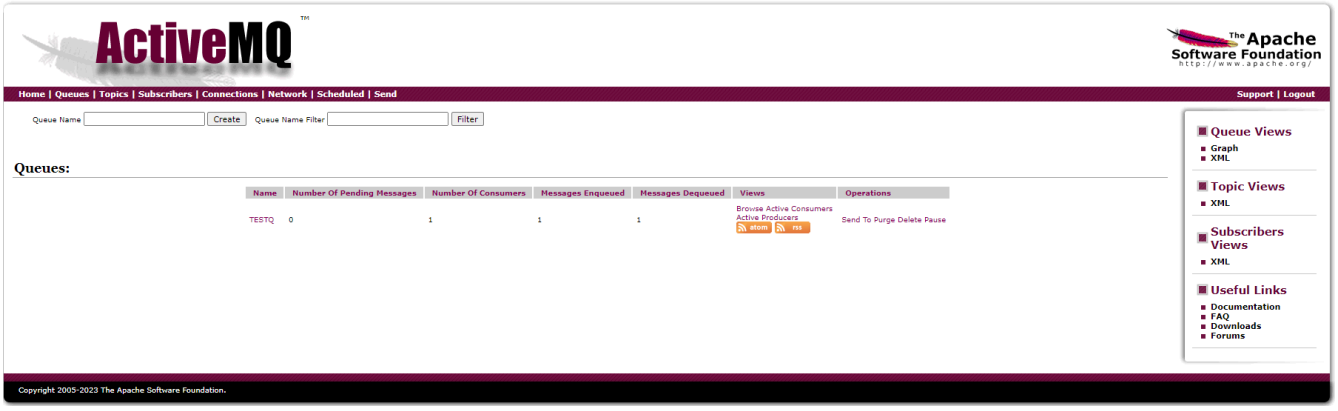
import javax.ejb.ActivationConfigProperty;
import javax.ejb.MessageDriven;
import javax.jms.Message;
import javax.jms.MessageListener;

@MessageDriven(name = "testmdb", activationConfig = {
    @ActivationConfigProperty(propertyName = "destinationLookup", propertyValue =
"jms/TESTQ"),
    @ActivationConfigProperty(propertyName = "destinationType", propertyValue =
"javax.jms.Queue"),
    @ActivationConfigProperty(propertyName = "destination", propertyValue = "TESTQ"),
    @ActivationConfigProperty(propertyName = "resourceAdapter", propertyValue =
"activemq-rar-5.17.4")
})
public class NewMessageBean implements MessageListener {

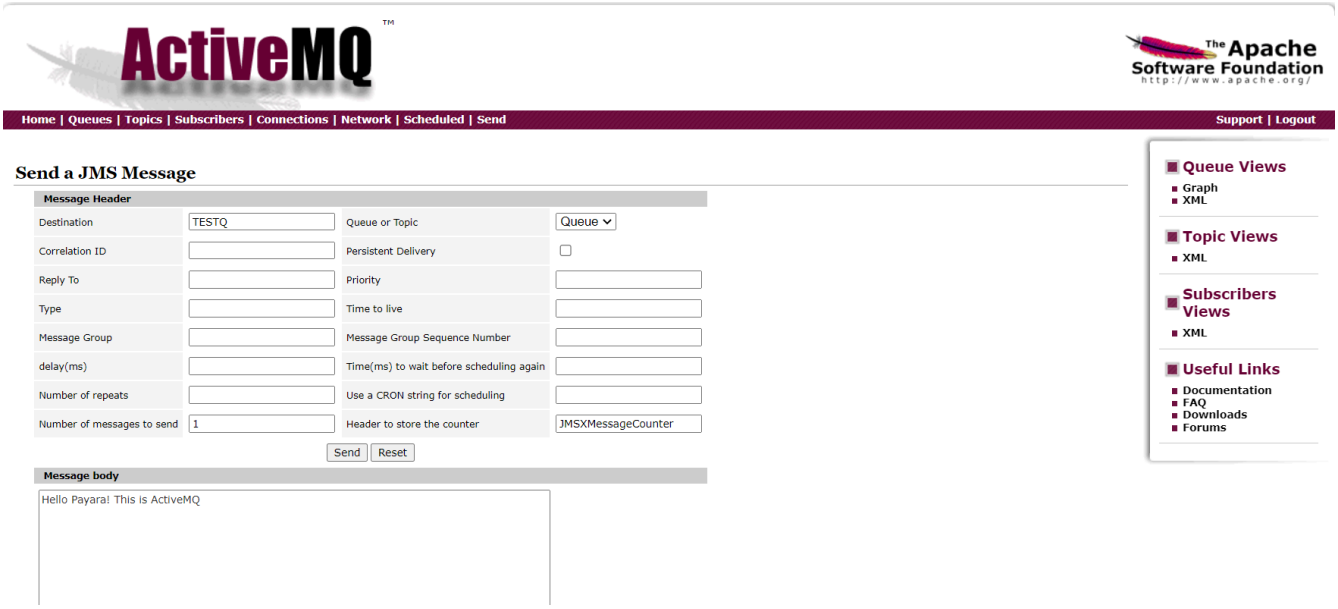
    public NewMessageBean() {
    }

    @Override
    public void onMessage(Message message) {
        System.out.println("Got message " + message);
    }
}
```

If we build and deploy this MDB we will see in the Active MQ console that we have a single consumer on our queue.



We can test the MDB by sending a message using the ActiveMQ console.



Once you have sent the message we can check the server log, the message will be printed out:

```

Administering the JNDI Service

The Java Naming and Directory Interface (JNDI) API is used for accessing different kinds of naming and directory services. Jakarta EE components locate objects by invoking the JNDI lookup method.

Instructions for accomplishing the tasks in this chapter by using the Administration Console are contained in the Administration Console online help.

About JNDI

By making calls to the JNDI API, applications locate resources and other program objects. A resource is a program object that provides connections to systems, such as database servers and

messaging systems. A JDBC resource is sometimes referred to as a data source. Each resource object is identified by a unique, people-friendly name, called the JNDI name. A resource object and its JNDI name are bound together by the naming and directory service, which is included with the Payara Server.

When a new name-object binding is entered into the JNDI, a new resource is created.

Jakarta EE Naming Environment

JNDI names are bound to their objects by the naming and directory service that is provided by a Jakarta EE server. Because Jakarta EE components access this service through the JNDI API, the object usually uses its JNDI name. For example, the JNDI name of the H2 database is `jdbc/_default`. At startup, the Payara Server reads information from the configuration file and automatically adds JNDI database names to the name space, one of which is `jdbc/_default`.

Jakarta EE application clients, enterprise beans, and web components must have access to a JNDI naming environment.

The application component's naming environment is the mechanism that allows customization of the application component's business logic during deployment or assembly. This environment allows you to customize the application component without needing to access or change the source code off the component. A Jakarta EE container implements the provides the environment to the application component instance as a JNDI naming context.

How the Naming Environment and the Container Work Together

The application component's environment is used as follows:

- The application component's business methods access the environment using the JNDI interfaces. In the deployment descriptor, the application component provider declares all the environment entries that the application component expects to be provided in its environment at runtime.
- The container provides an implementation of the JNDI naming context that stores the application component environment. The container also provides the tools that allow the deployer to create and manage the environment of each application component.
- A deployer uses the tools provided by the container to initialize the environment entries that are declared in the application component's deployment descriptor. The deployer sets and modifies the values of the environment entries.
- The container makes the JNDI context available to the application component instances at runtime. These instances use the JNDI interfaces to obtain the values of the environment entries.

Each application component defines its own set of environment entries. All instances of an application component within the same container share the same environment entries. Application component instances are not allowed to modify the environment at runtime.

Naming References and Binding Information

A resource reference is an element in a deployment descriptor that identifies the component's

coded name for the resource. For example, `jdbc/SavingsAccountDB`. More specifically, the coded name references a connection factory for the resource.

The JNDI name of a resource and the resource reference name are not the same. This approach to naming requires that you map the two names before deployment, but it also decouples components from resources. Because of this decoupling, if at a later time the component needs to access a different resource, the name does not need to change. This flexibility makes it easier for you to assemble Jakarta EE applications from preexisting components.

The following table lists JNDI lookups and their associated resource references for the Jakarta EE resources used by the Payara Server.

Table 12. Table 18-1 JNDI Lookup Names and Their Associated References

JNDI Lookup Name	**Associated Resource Reference**	`java:comp/env`	**Application environment entries**
`java:comp/env/jdbc`	JDBC DataSource resource manager connection factories	`java:comp/env/ejb`	EJB References
`java:comp/UserTransaction`	UserTransaction references	`java:comp/env/mail`	JavaMail Session Connection Factories
`java:comp/env/url`	URL Connection Factories	`java:comp/env/jms`	JMS Connection Factories and Destinations

Administering JNDI Resources

Within Payara Server, you can configure your environment for custom and external JNDI resources. A custom resource accesses a local JNDI repository; an external resource accesses an external JNDI repository. Both types of resources need user-specified factory class elements, JNDI name attributes, and so on.

- Administering Custom JNDI Resources
- Administering External JNDI Resources

Administering Custom JNDI Resources

A custom resource specifies a custom server-wide resource object factory that implements the `javax.naming.spi.ObjectFactory` interface.

To Create a Custom JNDI Resource

Use the `create-custom-resource` subcommand in remote mode to create a custom resource.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Create a custom resource by using the `create-custom-resource` subcommand.
   Information on properties for the subcommand is contained in this help page. Restart Payara Server. See To Restart a Domain.

Example 18-1 Creating a Custom Resource

```
asadmin> create-custom-resource --restype topic --factoryclass com.imq.topic
sample_custom_resource
Command create-custom-resource executed successfully.
```

This example creates a custom resource named `sample-custom-resource`.

To List Custom JNDI Resources

Use the `list-custom-resources` subcommand in remote mode to list the existing custom resources.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the custom resources by using the `list-custom-resources` subcommand.

Example 18-2 Listing Custom Resources

```
asadmin> list-custom-resources
sample_custom_resource01
sample_custom_resource02
Command list-custom-resources executed successfully
```

This example lists the existing custom resources.

To Update a Custom JNDI Resource

1. List the custom resources by using the `list-custom-resources` subcommand.
2. Use the `set` subcommand to modify a custom JNDI resource.

Example 18-3 Updating a Custom JNDI Resource

```
asadmin> set server.resources.custom-resource.custom
/my-custom-resource.property.value=2010server.resources.custom-resource.custom
/my-custom-resource.property.value=2010
```

This example modifies a custom resource.

To Delete a Custom JNDI Resource

Use the `delete-custom-resource` subcommand in remote mode to delete a custom resource.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the custom resources by using the `list-custom-resources` subcommand.
3. Delete a custom resource by using the `delete-custom-resource` subcommand.

Example 18-4 Deleting a Custom Resource

```
asadmin> delete-custom-resource sample_custom_resource
```

```
Command delete-custom-resource executed successfully.
```

This example deletes a custom resource named `sample-custom-resource`.

Administering External JNDI Resources

Applications running on Payara Server often require access to resources stored in an external JNDI repository. For example, generic Java objects might be stored in an LDAP server according to the Java schema. External JNDI resource elements let you configure such external resource repositories.

To Register an External JNDI Resource

Use the `create-jndi-resource` subcommand in remote mode to register an external JNDI resource.

Before You Begin

The external JNDI factory must implement the `javax.naming.spi.InitialContextFactory` interface.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Register an external JNDI resource by using the `create-jndi-resource` subcommand. Information on properties for the subcommand is contained in this help page.
3. Restart Payara Server.
   See To Restart a Domain.

Example 18-5 Registering an External JNDI Resource

```
asadmin> create-jndi-resource --jndilookupname sample_jndi
--restype queue --factoryclass sampleClass --description "this is a sample jndi
resource" sample_jndi_resource
Command create-jndi-resource executed successfully
```

In This example `sample_jndi_resource` is registered.

To List External JNDI Resources

Use the `list-jndi-resources` subcommand in remote mode to list all existing JNDI resources.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the existing JNDI resources by using the `list-jndi-resources` subcommand.

Example 18-6 Listing JNDI Resources

```
asadmin> list-jndi-resources
jndi_resource1
jndi_resource2
jndi_resource3
Command list-jndi-resources executed successfully
```

This example lists the JNDI resources.

To List External JNDI Entries

Use the `list-jndi-entries` subcommand in remote mode to browse and list the entries in the JNDI tree. You can either list all entries, or you can specify the JNDI context or subcontext to list specific entries.

1. Ensure that the server is running. Remote subcommands require a running server.
2. List the JNDI entries for a configuration by using the `list-jndi-entries` subcommand.

Example 18-7 Listing JNDI Entries

```
asadmin> list-jndi-entries
jndi_entry03
jndi_entry72
jndi_entry76
Command list-jndi-resources executed successfully
```

This example lists all the JNDI entries for the naming service.

To Update an External JNDI Resource

1. List the existing JNDI resources by using the `list-jndi-resources` subcommand.
2. Use the `set` subcommand to modify an external JNDI resource.

Example 18-8 Updating an External JNDI Resource

```
asadmin> set server.resources.external-jndi-resource.my-jndi-resource.
jndi-lookup-name=bar server.resources.external-jndi-resource.my-jndi-resource.jndi-
lookup-name=bar
```

This example modifies an external resource.

To Delete an External JNDI Resource

Use the `delete-jndi-resource` subcommand in remote mode to remove a JNDI resource.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Remove an external JNDI entry by using the `delete-jndi-resource` subcommand.

Example 18-9 Deleting an External JNDI Resource

```
asadmin> delete-jndi-resource jndi_resource2
Command delete-jndi-resource executed successfully.
```

This example deletes an external JNDI resource:

Example of Using an External JNDI Resource

```
<resources>
 <!-- external-jndi-resource element specifies how to access Jakarta EE
 - resources stored in an external JNDI repository. This example
 - illustrates how to access a java object stored in LDAP.
 - factory-class element specifies the JNDI InitialContext factory that
 - needs to be used to access the resource factory. property element
 - corresponds to the environment applicable to the external JNDI context
 - and jndi-lookup-name refers to the JNDI name to lookup to fetch the
 - designated (in this case the java) object.
 -->
  <external-jndi-resource jndi-name="test/myBean"
      jndi-lookup-name="cn=myBean"
      res-type="test.myBean"
      factory-class="com.sun.jndi.ldap.LdapCtxFactory">
    <property name="PROVIDER-URL" value="ldap://ldapserver:389/o=myObjects" />
    <property name="SECURITY_AUTHENTICATION" value="simple" />
    <property name="SECURITY_PRINCIPAL" value="cn=joeSmith, o=Engineering" />
    <property name="SECURITY_CREDENTIALS" value="changeit" />
  </external-jndi-resource>
</resources>
```

To Disable payara Server v2 Vendor-Specific JNDI Names

The EJB 3.1 specification supported by Payara Server 5.0 defines portable EJB JNDI names. Because of this, there is less need to continue to use older vendor-specific JNDI names.

By default, Payara Server v2-specific JNDI names are applied automatically by Payara Server 5.0 for backward compatibility. However, this can lead to some ease-of-use issues. For example, deploying two different applications containing a Remote EJB component that exposes the same remote interface causes a conflict between the default JNDI names.

The default handling of v2-specific JNDI names in Payara Server can be managed with the `asadmin` command or with the `disable-nonportable-jndi-names` boolean property for the `ejb-container` element in `glassfish-ejb-jar.xml`.

Use the `asadmin` command or directly modify the `glassfish-ejb-jar.xml` file to set the `disable-nonportable-jndi-names` property.

- Using the `asadmin` command:

```
asadmin> set server.ejb-container.property.disable-nonportable-jndi-names="true"
```

- Directly modifying the `glassfish-ejb-jar.xml` file.
  1. Add the `disable-nonportable-jndi-names` property to the `ejb-container` element in `glassfish-ejb-jar.xml`.
  2. Set the value of the `disable-nonportable-jndi-names` boolean, as desired.

`false` - Enables the automatic use of Payara Server v2-specific JNDI names. This is the default setting.
`true` - Disables the automatic use of v2-specific JNDI names. In all cases, 5.0-compatible JNDI names will be used.

3. Save the `glassfish-ejb-jar.xml` file and restart the Payara Server domain. This setting applies to all EJBs deployed to the server.

Administering Transactions

This chapter discusses how to manage the transaction service for the Payara Server environment by using the `asadmin` command-line utility.

Instructions for manually recovering transactions are also included.

Instructions for accomplishing the tasks in this chapter by using the Administration Console are contained in the Administration Console online help.

For more information about the Java Transaction API (JTA) and Java Transaction Service (JTS), see the following sites:

Jakarta Transactions API and Java Transaction Service.

You might also want to read Transactions.

About Transactions

A transaction is a series of discreet actions in an application that must all complete successfully. By enclosing one or more actions in an indivisible unit of work, a transaction ensures data integrity and consistency. If all actions do not complete, the changes are rolled back.

For example, to transfer funds from a checking account to a savings account, the following steps typically occur:

1. Check to see if the checking account has enough money to cover the transfer.
2. Debit the amount from the checking account.
3. Credit the amount to the savings account.
4. Record the transfer to the checking account log.
5. Record the transfer to the savings account log.

These steps together are considered a single transaction.

If all the steps complete successfully, the transaction is committed. If any step fails, all changes from the preceding steps are rolled back, and the checking account and savings account are returned to the states they were in before the transaction started. This type of event is called a `rollback`. A normal transaction ends in either a committed state or a rolled back state.

The following elements contribute to reliable transaction processing by implementing various APIs and functionalities:

- **Transaction Manager**. Provides the services and management functions required to support transaction demarcation, transactional resource management, synchronization, and transaction context propagation.
- **Payara Server**. Provides the infrastructure required to support the application runtime environment that includes transaction state management.
- **Resource Manager**. Through a resource adapter, the resource manager provides the application access to resources. The resource manager participates in distributed transactions by implementing a transaction resource interface used by the transaction manager to communicate transaction association, transaction completion, and recovery work. An example of such a resource manager is a relational database server.
- **Resource Adapter**. A system-level software library is used by Payara Server or a client to connect to a resource manager. A resource adapter is typically specific to a resource manager. The resource adapter is available as a library and is used within the address space of the client using it. An example of such a resource adapter is a Java Database Connectivity (JDBC) driver. For information on supported JDBC drivers, see Configuration Specifics for JDBC Drivers.
- **Transactional User Application**. In the Payara Server environment, the transactional user application uses Java Naming and Directory Interface (JNDI) to look up transactional data sources and, optionally, the user transaction). The application might use declarative transaction attribute settings for enterprise beans, or explicit programmatic transaction demarcation. For more information, see The Transaction Manager, the Transaction Synchronization Registry, and UserTransaction in the Payara Server Application Development section.

Transaction Resource Managers

There are three types of transaction resource managers:

- **Databases** - Use of transactions prevents databases from being left in inconsistent states due to incomplete updates. For information about JDBC transaction isolation levels, see Using JDBC Transaction Isolation Levels in the Payara Server Application Development section.
  The Payara Server supports a variety of JDBC XA drivers. For configurations of supported and other drivers, see Configuration Specifics for JDBC Drivers.
- **Java Message Service (JMS) Providers** - Use of transactions ensures that messages are reliably delivered. The Payara Server is integrated with Open Message Queue, a fully capable JMS provider. For more information about transactions and the JMS API, see Administering the Java Message Service (JMS).
- **J2EE Connector Architecture (CA) components** - Use of transactions prevents legacy EIS systems from being left in inconsistent states due to incomplete updates. For more information about connectors, see Administering EIS Connectivity.

Transaction Scope

A local transaction involves only one non-XA resource and requires that all participating application components execute within one process. Local transaction optimization is specific to the resource manager and is transparent to the Jakarta EE application.

In the Payara Server, a JDBC resource is non-XA if it meets either of the following criteria:

- In the JDBC connection pool configuration, the DataSource class does not implement the javax.sql.XADataSource interface.
- The Resource Type setting is not set to javax.sql.XADataSource.

A transaction remains local if the following conditions remain true:

- One and only one non-XA resource is used. If any additional non-XA resource is used, the transaction is aborted, because the transaction manager must use XA protocol to commit two or more resources.
- No transaction importing or exporting occurs.

Transactions that involve multiple resources or multiple participant processes are distributed or global transactions. A global transaction can involve one non-XA resource if last agent optimization is enabled. Otherwise, all resources must be XA. The `use-last-agent-optimization` property is set to `true` by default. For details about how to set this property, see Configuring the Transaction Service.

If only one XA resource is used in a transaction, one-phase commit occurs, otherwise the transaction is coordinated with a two-phase commit protocol.

A two-phase commit protocol between the transaction manager and all the resources enlisted for a transaction ensures that either all the resource managers commit the transaction or they all abort. When the application requests the commitment of a transaction, the transaction manager issues a `PREPARE_TO_COMMIT` request to all the resource managers involved. Each of these resources can in turn send a reply indicating whether it is ready for commit (`PREPARED`) or not (`NO`). Only when all the resource managers are ready for a commit does the transaction manager issue a commit request (`COMMIT`) to all the resource managers. Otherwise, the transaction manager issues a rollback request (`ABORT`) and the transaction is rolled back.

Configuring the Transaction Service

You can configure the transaction service in the Payara Server in the following ways:

- To configure the transaction service using the Administration Console, open the Transaction Service component under the relevant configuration. For details, click the Help button in the Administration Console.
- To configure the transaction service, use the `set` subcommand to set the following attributes.
  The following examples show the `server-config` configuration, but values for any configuration can be set. For example, if you create a cluster named `cluster1` and a configuration named `cluster1-config` is automatically created for it, you can use `cluster1-config` in the `set` subcommand to get the transaction service settings for that cluster.

```
server-config.transaction-service.automatic-recovery = false
server-config.transaction-service.heuristic-decision = rollback
server-config.transaction-service.keypoint-interval = 2048
server-config.transaction-service.retry-timeout-in-seconds = 600
server-config.transaction-service.timeout-in-seconds = 0
server-config.transaction-service.tx-log-dir = domain-dir/logs
```

You can also set these properties:

```
server-config.transaction-service.property.oracle-xa-recovery-workaround = true
server-config.transaction-service.property.sybase-xa-recovery-workaround = false
server-config.transaction-service.property.disable-distributed-transaction-logging =
false
server-config.transaction-service.property.xaresource-txn-timeout = 0
server-config.transaction-service.property.pending-txn-cleanup-interval = -1
server-config.transaction-service.property.use-last-agent-optimization = true
server-config.transaction-service.property.delegated-recovery = false
server-config.transaction-service.property.wait-time-before-recovery-insec = 60
server-config.transaction-service.property.purge-cancelled-transactions-after = 0
server-config.transaction-service.property.commit-one-phase-during-recovery = false
server-config.transaction-service.property.add-wait-point-during-recovery = 0
server-config.transaction-service.property.db-logging-resource = jdbc/TxnDS
server-config.transaction-service.property.xa-servername = myserver
server-config.transaction-service.property.recover-txn-delay = -1
```

Default property values are shown where they exist. For `db-logging-resource` and `xa-servername`, typical values are shown. Values that are not self-explanatory are as follows:

- The `xaresource-txn-timeout` default of `0` means there is no timeout. The timeout value is expressed in seconds.
- The `pending-txn-cleanup-interval` default of `-1` means the periodic recovery thread doesn't run. The interval value is expressed in seconds.
- The `purge-cancelled-transactions-after` default of `0` means cancelled transactions are not purged. The value is expressed as the number of cancellations between purge attempts.
- The `add-wait-point-during-recovery` property does not have a default value. If this property is unset, recovery does not wait. The wait value is expressed in seconds.
- The `db-logging-resource` property does not have a default value. It is unset by default. However, if you set `db-logging-resource` to an empty value, the value used is `jdbc/TxnDS`.
- The `xa-servername` property does not have a default value. Use this property to override server names that can cause errors.
- The `recover-txn-delay` default of `-1` means that recovery will be attempted upon start of the server if `automatic-recovery` is enabled. Use this property to delay the initial execution of the recovery thread. The delay value is expressed in seconds.

You can use the `get` subcommand to list all the transaction service attributes and the properties that have been set.
Changing `keypoint-interval`, `retry-timeout-in-seconds`, or `timeout-in-seconds` does not require a server restart. Changing other attributes or properties requires a server restart. * You can also set the following system properties:

+

```
ALLOW_MULTIPLE_ENLISTS_DELISTS=false
```

```
JTA_RESOURCE_TABLE_MAX_ENTRIES=8192
JTA_RESOURCE_TABLE_DEFAULT_LOAD_FACTOR=0.75f
```

The `JTA_RESOURCE_TABLE_DEFAULT_LOAD_FACTOR` default is the default `Map` resizing value.

Managing the Transaction Service for Rollbacks

You can roll back a single transaction by using the `asadmin` subcommands described in this section. To do so, the transaction service must be stopped (and later restarted), allowing you to see the active transactions and correctly identify the one that needs to be rolled back.

To Stop the Transaction Service

Use the `freeze-transaction-service` subcommand in remote mode to stop the transaction service. When the transaction service is stopped, all in-flight transactions are immediately suspended. You must stop the transaction service before rolling back any in-flight transactions.

Running this subcommand on a stopped transaction subsystem has no effect. The transaction service remains suspended until you restart it by using the `unfreeze-transaction-service` subcommand.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Stop the transaction service by using the `freeze-transaction-service` subcommand.

Example 19-1 Stopping the Transaction Service

This example stops the transaction service.

```
asadmin> freeze-transaction-service --target instance1
Command freeze-transaction-service executed successfully
```

To Roll Back a Transaction

In some situations, you might want to roll back a particular transaction. Before you can roll back a transaction, you must first stop the transaction service so that transaction operations are suspended. Use the `rollback-transaction` subcommand in remote mode to roll back a specific transaction.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Enable monitoring using the `set` subcommand. For example:

   ```
   asadmin> set cluster1-config.monitoring-service.module-monitoring-
   levels.transaction-service=HIGH
   ```

3. Use the `freeze-transaction-service` subcommand to halt in-process transactions. See To Stop the Transaction Service.
4. Identify the ID of the transaction you want to roll back.

To see a list of IDs of active transactions, use the `get` subcommand with the `--monitor` option to get the monitoring data for the `activeids` statistic. See Transaction Service Statistics. For example:

```
asadmin> get --monitor instance1.server.transaction-service.activeids-current
```

5. Roll back the transaction by using the `rollback-transaction` subcommand.
   The transaction is not rolled back at the time of this command's execution, but only marked for rollback. The transaction is rolled back when it is completed.

Example 19-2 Rolling Back a Transaction

This example rolls back the transaction with transaction ID `0000000000000001_00`.

```
asadmin> rollback-transaction --target instance1 0000000000000001_00
Command rollback-transaction executed successfully
```

To Restart the Transaction Service

Use the `unfreeze-transaction-service` subcommand in remote mote to resume all the suspended in-flight transactions. Run this subcommand to restart the transaction service after it has been frozen.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Restart the suspended transaction service by using the `unfreeze-transaction-service` subcommand.

Example 19-3 Restarting the Transaction Service

This example restarts the transaction service after it has been frozen.

```
asadmin> unfreeze-transaction-service --target instance1
Command unfreeze-transaction-service executed successfully
```

Determining Local Transaction Completion at Shutdown

When you shut down a Payara Server instance, all database connections are closed. When an Oracle JDBC driver-based database connection is closed in the middle of a non-XA transaction, all pending changes are committed. Other databases usually roll back pending changes when a connection is closed without being explicitly committed. To determine the exact behavior for your database, refer to the documentation from your JDBC driver vendor.

To explicitly specify whether Payara Server commits or rolls back non-XA transactions at server shutdown, set the `com.sun.enterprise.in-progress-local-transaction.completion-mode` JVM option to either `commit` or `rollback` using the `create-jvm-options` subcommand. For example:

```
asadmin> create-jvm-options -Dcom.sun.enterprise.in-progress-local
```

```
-transaction.completion-mode=rollback
```

Recovering Transactions

There are some situations where the commit or rollback operations might be interrupted, typically because the server crashed or a resource manager crashed. Crash situations can leave some transactions stranded between steps. Payara Server is designed to recover from these failures. If the failed transaction spans multiple servers, the server that started the transaction can contact the other servers to get the outcome of the transaction. If the other servers are unreachable, the transaction uses heuristic decision information to determine the outcome.

Automatic Transaction Recovery

Payara Server can perform automatic recovery in these ways:

- Pending transactions are completed upon server startup if `automatic-recovery` is set to `true`.
- Periodic automatic recovery is performed by a background thread if the `pending-txn-cleanup-interval` property is set to a positive value.

Changing these settings requires a server restart. For more information about how to change these settings, see Configuring the Transaction Service. If commit fails during recovery, a message is written to the server log.

To Manually Recover Transactions

Use the `recover-transactions` subcommand in remote mode to manually recover transactions that were pending when a resource or a server instance failed.

For a standalone server, do not use manual transaction recovery to recover transactions after a server failure. For a standalone server, manual transaction recovery can recover transactions only when a resource fails, but the server is still running. If a standalone server fails, only the full startup recovery process can recover transactions that were pending when the server failed.

For an installation of multiple server instances, you can use manual transaction recovery from a surviving server instance to recover transactions after a server failure. For manual transaction recovery to work properly, transaction logs must be stored on a shared file system that is accessible to all server instances. See Transaction Logging.

When you execute `recover-transactions` in non-delegated mode, you can recover transactions that didn't complete two-phase commit because of a resource crash. To use manual transaction recovery in this way, the following conditions must be met:

- The `recover-transactions` command should be executed after the resource is restarted.
- Connection validation should be enabled so the connection pool is refreshed when the resource is accessed after the recovery.

If commit fails during recovery, a message is written to the server log.

A JMS resource crash is handled the same way as any other resource.

> You can list in-doubt Open Message Queue transactions using the `imqcmd list txn` subcommand.

1. Ensure that the server is running. Remote subcommands require a running server.
2. Manually recover transactions by using the `recover-transactions` subcommand.

Example 19-4 Manually Recovering Transactions

This example performs manual recovery of transactions on `instance1`, saving them to `instance2`.

```
asadmin recover-transactions --target instance2 instance1
Transaction recovered.
```

Distributed Transaction Recovery

To enable cluster-wide automatic recovery, you must first facilitate storing of transaction logs in a shared file system. See Transaction Logging.

Next, you must set the transaction service's `delegated-recovery` property to `true` (the default is `false`). For information about setting `tx-log-dir` and `delegated-recovery`, see Configuring the Transaction Service.

Recovery Workarounds and Limitations

The Payara Server provides workarounds for some known issues with transaction recovery implementations.

These workarounds do not imply support for any particular JDBC driver.

General Recovery Limitations

The following general limitations apply to transaction recovery:

- Recovery succeeds if there are no exceptions during the process. This is independent of the number of transactions that need to be recovered.
- Only transactions that did not complete the two-phase commit can be recovered (one of the XA resources failed or Payara Server crashed after resources were prepared).
- Manual transaction recovery cannot recover transactions after a server crash on a standalone server instance. Manual operations are intended for cases when a resource dies unexpectedly while the server is running. In case of a server crash, only startup recovery can recover in-doubt transactions.
- It is not possible to list transaction IDs for in-doubt transactions.
- Delegated transaction recovery (by a different server instance in a cluster) is not possible if the failed instance used an `EMBEDDED` Message Queue broker, or if it used a `LOCAL` or `REMOTE` Message Queue broker and the broker also failed. In this case, only automatic recovery on server instance restart is possible. This is because for conventional Message Queue clustering, state information in a failed broker is not available until the broker restarts.

Oracle Setup for Transaction Recovery

You must configure the following `grant` statements in your Oracle database to set up transaction recovery:

```
grant select on SYS.DBA_PENDING_TRANSACTIONS to user;
grant execute on SYS.DBMS_SYSTEM to user;
grant select on SYS.PENDING_TRANS$ to user;
grant select on SYS.DBA_2PC_NEIGHBORS to user;
grant execute on SYS.DBMS_XA to user;
grant select on SYS.DBA_2PC_PENDING to user;
```

The user is the database administrator. On some versions of the Oracle driver the last `grant execute` fails. You can ignore this.

Oracle Thin Driver

In the Oracle thin driver, the `XAResource.recover` method repeatedly returns the same set of in-doubt Xids regardless of the input flag. According to the XA specifications, the Transaction Manager initially calls this method with TMSTARTSCAN and then with TMNOFLAGS repeatedly until no Xids are returned. The `XAResource.commit` method also has some issues.

To disable the Payara Server workaround, set the `oracle-xa-recovery-workaround` property value to `false`. For details about how to set this property, see Configuring the Transaction Service. This workaround is used unless explicitly disabled.

Delegated Recovery After Server Crash Doesn't Work on MySQL

The MySQL database supports XA transaction recovery only when the database crashes. When a Payara Server instance crashes, MySQL rolls back prepared transactions.

Call to `XATeminator.recover()` During `ResourceAdapter.start()` Hangs If Automatic Recovery Is Enabled

Calls to `XATerminator.recover()` from the `ResourceAdapter.start()` method never return because Payara Server deadlocks. This only occurs when automatic recovery is enabled.

It is not advisable to do transactional activities, such as starting a transaction or calling `XATerminator.recover()`, during `ResourceAdapter.start()`. For more information, see `http://markmail.org/message/ogc7qndhaywfkdrp#query:+page:1+mid:kyyzpcexusbnv7ri+state:results`.

Transaction Logging

The transaction service writes transactional activity into transaction logs so that transactions can be recovered. You can control transaction logging in these ways:

- Set the location of the transaction log files in one of these ways:
  - Set the Payara Server's `log-root` setting to a shared file system base directory and set the transaction service's `tx-log-dir` attribute to a relative path.
  - Set `tx-log-dir` to an absolute path to a shared file system directory, in which case `log-root` is

ignored for transaction logs.

- Set a system property called `TX-LOG-DIR` to a shared file system directory. For example:

```
asadmin> create-system-properties --target server TX-LOG-DIR=/inst1/logs
```

For information about setting `log-root` and other general logging settings, see Administering the Logging Service.

- Turn off transaction logging by setting the `disable-distributed-transaction-logging` property to `true` and the `automatic-recovery` attribute to `false`. Do this only if performance is more important than transaction recovery.

All instances in a cluster must be owned by the same user (`uid`), and read/write permissions for that user must be set on the transaction log directories.

Transaction logs should be stored in a high-availability network file system (NFS) to avoid a single point of failure.

To Store Transaction Logs in a Database

For multi-core machines, logging transactions to a database may be more efficient. Transaction logging is designed to work with any JDBC-compliant database. For databases with which transaction logging has been tested, see the Payara Server Release Notes.

1. Create a JDBC connection Pool. To use non-transactional connections to insert log records, you can either set the `non-transactional-connections` attribute to `true` in this step, or you can perform step 5 later.
2. Create a JDBC resource that uses the connection pool and note the JNDI name of the JDBC resource.
3. Automatic table creation for the transaction logs is done by default. However, if you would prefer to create the table manually, name it `txn_log_table` with the following schema:

Column Name	JDBC Type
`LOCALTID`	`VARCHAR`
`INSTANCENAME`	`VARCHAR`
`SERVERNAME`	`VARCHAR(n)`
`GTRID`	`VARBINARY`

   The size of the `SERVERNAME` column should be at least the length of the Payara Server host name plus 10 characters.
   The size of the `GTRID` column should be at least 64 bytes.

4. Add the `db-logging-resource` property to the transaction service. For example:

```
asadmin set server-config.transaction-service.property.db-logging-
```

```
resource="jdbc/TxnDS"
```

The property's value should be the JNDI name of the JDBC resource configured previously.

5. If you didn't set the `non-transactional-connections` attribute to `true` in step 1 and you want to use non-transactional connections to insert log records, use the following `asadmin create-jvm-options` command to reference an existingtransactional resource but use non-transactional connections for the `INSERT` statements:

```
asadmin create-jvm-options
-Dcom.sun.jts.dblogging.use.nontx.connection.for.add=true
```

6. To disable file synchronization, use the following `asadmin create-jvm-options` command:

```
asadmin create-jvm-options -Dcom.sun.appserv.transaction.nofdsync
```

7. Restart the server.

Next Steps

To define the SQL used by the transaction manager when it is storing its transaction logs in the database, use the following flags:

`-Dcom.sun.jts.dblogging.insertquery=sql` statement

`-Dcom.sun.jts.dblogging.deletequery=sql` statement

`-Dcom.sun.jts.dblogging.selectquery=sql` statement

`-Dcom.sun.jts.dblogging.selectservernamequery=sql` statement

The default statements are as follows:

```
-Dcom.sun.jts.dblogging.insertquery=insert into txn_log_table values ( ?, ?, ?, ? )

-Dcom.sun.jts.dblogging.deletequery=delete from txn_log_table where localtid = ? and servername
= ?

-Dcom.sun.jts.dblogging.selectquery=select * from txn_log_table where servername = ?

-Dcom.sun.jts.dblogging.selectservernamequery=select distinct servername from txn_log_table
where instancename = ?
```

To set one of these flags using the `asadmin create-jvm-options` command, you must quote the statement. For example:

```
create-jvm-options '-Dcom.sun.jts.dblogging.deletequery=delete from txn_log_table where gtrid =
?'
```

You can also set JVM options in the Administration Console. Select the JVM Settings component under the relevant configuration. These flags and their statements must also be quoted in the

Administration Console. For example:

```
'-Dcom.sun.jts.dblogging.deletequery=delete from txn_log_table where gtrid = ?'
```

Administering Web Applications

This chapter explains how to administer web applications in the Payara Server environment.

Instructions for accomplishing some of these tasks by using the Administration Console are contained in the Administration Console online help.

Invoking a Servlet by Alternate Means

You can call a servlet deployed to Payara Server by using a URL in a browser or embedded as a link in an HTML or JSP file. The format of a servlet invocation URL is as follows:

```
http://server:port/context-root/servlet-mapping?name=value
```

Table 13. Table 6-1 URL Fields for Servlets Within an Application

URL element	Description
server`:`port	The IP address (or host name) and optional port number. To access the default web module for a virtual server, specify only this URL section. You do not need to specify the context-root or servlet-name unless you also wish to specify name-value parameters.
context-root	For an application, the context root is defined in the `context-root` element of the `application.xml`, `sun-application.xml`, or `payara-web.xml`/`sun-web.xml` (deprecated) file. For an individually deployed web module, the context root is specified during deployment. For both applications and individually deployed web modules, the default context root is the name of the WAR file minus the `.war` suffix.
servlet-mapping	The `servlet-mapping` as configured in the `web.xml` file.
`?`name=value...`	Optional request parameters.

In this example, `localhost` is the host name, `MortPages` is the context root, and `calcMortgage` is the servlet mapping.

Example 6-1 Invoking a Servlet With a URL

```
http://localhost:8080/MortPages/calcMortgage?rate=8.0&per=360&bal=180000
```

To invoke a servlet from within a JSP file, you can use a relative path. For example:

Example 6-2 Invoking a Servlet From Within a JSP File

```
<jsp:forward page="TestServlet"/><jsp:include page="TestServlet"/>
```

Changing Log Output for a Servlet

`ServletContext.log` messages are sent to the server log. By default, the `System.out` and `System.err` output of servlets are sent to the server log. During startup, server log messages are echoed to the `System.err` output. Also by default, there is no Windows-only console for the `System.err` output.

You can change these defaults using the Administration Console Write to System Log box. If this box is checked, `System.out` output is sent to the server log. If it is unchecked, `System.out` output is sent to the system default location only.

Defining Global Features for Web Applications

You can use the `default-web.xml` file to define features such as filters and security constraints that apply to all web applications.

For example, directory listings are disabled by default for added security. To enable directory listings in your domain's `default-web.xml` file, search for the definition of the servlet whose `servlet-name` is equal to `default`, and set the value of the `init-param` named `listings` to `true`. Then restart the server.

```
<init-param>
   <param-name>listings</param-name>
   <param-value>true</param-value>
</init-param>
```

If `listings` is set to `true`, you can also determine how directory listings are sorted. Set the value of the `init-param` named `sortedBy` to `NAME`, `SIZE`, or `LAST_MODIFIED`. Then restart the server.

```
<init-param>
   <param-name>sortedBy</param-name>
   <param-value>LAST_MODIFIED</param-value>
</init-param>
```

The `mime-mapping` elements in `default-web.xml` are global and inherited by all web applications. You can override these mappings or define your own using `mime-mapping` elements in your web application's `web.xml` file. For more information about `mime-mapping` elements, see the Servlet specification.

You can use the Administration Console to edit the `default-web.xml` file, or edit the file directly using the following steps.

To Use the `default-web.xml` File

1. Place the JAR file for the filter, security constraint, or other feature in the domain-dir`/lib` directory.

2. Edit the domain-dir`/config/default-web.xml` file to refer to the JAR file.
3. To apply your changes, restart Payara Server. See To Restart a Domain.

Redirecting a URL

You can specify that a request for an old URL be treated as a request for a new URL. This is called redirecting a URL.

To specify a redirected URL for a virtual server, use the `redirect_n` property, where n is a positive integer that allows specification of more than one. Each of these `redirect_n` properties is inherited by all web applications deployed on the virtual server.

The value of each `redirect_n` property has two components which can be specified in any order:

- The first component, `from`, specifies the prefix of the requested URI to match.
- The second component, `url-prefix`, specifies the new URL prefix to return to the client. The from prefix is replaced by this URL prefix.

This example redirects `from dummy` to `etude`:

Example 6-3 Redirecting a URL

```
<property name="redirect_1" value="from=/dummy url-prefix=http://etude"/>
```

Administering `mod_jk`

The Apache Tomcat Connector `mod_jk` can be used to connect the web container with web servers such as Apache HTTP Server. By using `mod_jk`, which comes with Payara Server, you can front Payara Server with Apache HTTP Server.

You can also use `mod_jk` directly at the JSP/servlet engine for load balancing. For more information about configuring `mod_jk` and Apache HTTP Server for load balancing with Payara Server refer to Configuring HTTP Load Balancing in the Payara Server High Availability section.

To Enable `mod_jk`

You can front Payara Server with Apache HTTP Server by enabling the `mod_jk` protocol for one of Payara Server's network listeners, as described in this procedure. A typical use for `mod_jk` would be to have Apache HTTP Server handle requests for static resources, while having requests for dynamic resources, such as servlets and JavaServer Pages (JSPs), forwarded to, and handled by the Payara Server back-end instance.

When you use the `jk-enabled` attribute of the network listener, you do not need to copy any additional JAR files into the `/lib` directory. You can also create JK connectors under different virtual servers by using the network listener attribute `jk-enabled`.

1. Install Apache HTTP Server and `mod_jk`.
    - For information on installing Apache HTTP Server, see `https://httpd.apache.org/docs/2.4/install.html`.

- For information on installing `mod_jk`, see `http://tomcat.apache.org/connectors-doc/webserver_howto/apache.html`.

2. Configure the following files:
   - `apache2/conf/httpd.conf`, the main Apache configuration file
   - `apache2/conf/workers.properties` Example 6-4 and Example 6-5 provide examples of configuring these two files.
3. Start Apache HTTP Server (`httpd`).
4. Start Payara Server with at least one web application deployed.
   In order for the `mod_jk`-enabled network listener to start listening for requests, the web container must be started. Normally, this is achieved by deploying a web application.
5. Create a jk-enabled network listener by using the `create-network-listener` subcommand.

```
asadmin> create-network-listener --protocol http-listener-1 \
--listenerport 8009 --jkenabled true jk-connector
```

6. If you are using the `glassfish-jk.properties` file to use non-default values of attributes described at `http://tomcat.apache.org/tomcat-5.5-doc/config/ajp.html`), set the `jk-configuration-file` property of the network listener to the fully-qualified file name of the `glassfish-jk.properties` file.

```
asadmin> set server-config.network-config.network-listeners.network-listener.\
jk-connector.jk-configuration-file=domain-dir/config/glassfish-jk.properties
```

7. If you expect to need more than five threads for the listener, increase the maximum threads in the `http-thread-pool` pool:

```
asadmin> set configs.config.server-config.thread-pools.thread-pool.\
http-thread-pool.max-thread-pool-size=value
```

8. To apply your changes, restart Payara Server. See To Restart a Domain.

Example 6-4 `httpd.conf` File for `mod_jk`

This example shows an `httpd.conf` file that is set for `mod_jk`. In this example, `mod_jk` used as a simple pass-through.

```
LoadModule jk_module /usr/lib/httpd/modules/mod_jk.so
JkWorkersFile /etc/httpd/conf/worker.properties
# Where to put jk logs
JkLogFile /var/log/httpd/mod_jk.log
# Set the jk log level [debug/error/info]
JkLogLevel debug
# Select the log format
JkLogStampFormat "[%a %b %d %H:%M:%S %Y] "
```

```
# JkOptions indicate to send SSL KEY SIZE,
JkOptions +ForwardKeySize +ForwardURICompat -ForwardDirectories
# JkRequestLogFormat set the request format
JkRequestLogFormat "%w %V %T"
# Send all jsp requests to GlassFish
JkMount /*.jsp worker1
# Send all glassfish-test requests to GlassFish
JkMount /glassfish-test/* worker1
```

Example 6-5 `workers.properties` File for `mod_jk`

This example shows a `workers.properties` that is set for `mod_jk`. This `workers.properties` file is referenced in the second line of Example 6-4.

```
# Define 1 real worker using ajp13
worker.list=worker1
# Set properties for worker1 (ajp13)
worker.worker1.type=ajp13
worker.worker1.host=localhost
worker.worker1.port=8009
```

- For more information on Apache, see `http://httpd.apache.org/`.
- For more information on Apache Tomcat Connector, see `http://tomcat.apache.org/connectors-doc/index.html`.

To Load Balance Using `mod_jk` and Payara Server

Load balancing is the process of dividing the amount of work that a computer has to do between two or more computers so that more work gets done in the same amount of time. Load balancing can be configured with or without security.

In order to support stickiness, the Apache `mod_jk` load balancer relies on a `jvmRoute` system property that is included in any `JSESSIONID` received by the load balancer. This means that every Payara Server instance that is front-ended by the Apache load balancer must be configured with a unique `jvmRoute` system property.

1. On each of the instances, perform the steps in To Enable `mod_jk`.
   If your instances run on the same machine, you must choose different JK ports. The ports must match `worker.worker*.port` in your `workers.properties` file. See the properties file in Example 6-5.
2. On each of the instances, create the `jvmRoute` system property of Payara Server by using the `create-jvm-options` subcommand.
   Use the following format:

   ```
   asadmin> create-jvm-options "-DjvmRoute=/instance-worker-name"/
   ```

   where instance-worker-name is the name of the worker that you defined to represent the

instance in the `workers.properties` file.

3. To apply your changes, restart Apache HTTP Server and Payara Server.

Example 6-6 `httpd.conf` File for Load Balancing

This example shows an `httpd.conf` file that is set for load balancing.

```
LoadModule jk_module /usr/lib/httpd/modules/mod_jk.so
JkWorkersFile /etc/httpd/conf/worker.properties
# Where to put jk logs
JkLogFile /var/log/httpd/mod_jk.log
# Set the jk log level [debug/error/info]
JkLogLevel debug
# Select the log format
JkLogStampFormat "[%a %b %d %H:%M:%S %Y] "
# JkOptions indicate to send SSL KEY SIZE,
JkOptions +ForwardKeySize +ForwardURICompat -ForwardDirectories
# JkRequestLogFormat set the request format
JkRequestLogFormat "%w %V %T"
# Send all jsp requests to Payara Server
JkMount /*.jsp worker1
# Send all glassfish-test requests to Payara Server
JkMount /glassfish-test/* loadbalancer
```

Example 6-7 `workers.properties` File for Load Balancing

This example shows a `workers.properties` or `glassfish-jk.properties` file that is set for load balancing. The `worker.worker*.port` should match with JK ports you created.

```
worker.list=worker1,worker2,loadbalancer
worker.worker1.type=ajp13
worker.worker1.host=localhost
worker.worker1.port=8009
worker.worker1.lbfactor=1
worker.worker1.socket_keepalive=1
worker.worker1.socket_timeout=300
worker.worker2.type=ajp13
worker.worker2.host=localhost
worker.worker2.port=8010
worker.worker2.lbfactor=1
worker.worker2.socket_keepalive=1
worker.worker2.socket_timeout=300
worker.loadbalancer.type=lb
worker.loadbalancer.balance_workers=worker1,worker2
```

To Enable SSL Between the `mod_jk` Load Balancer and the Browser

To activate security for `mod_jk` on Payara Server, you must first generate a Secure Socket Layer (SSL)

self-signed certificate on the Apache HTTP Server with the mod_ssl module. The tasks include generating a private key, a Certificate Signing Request (CSR), a self-signed certificate, and configuring SSL-enabled virtual hosts.

Before You Begin, The mod_jk connector must be enabled.

1. Generate the private key as follows:

   ```
   openssl genrsa -des3 -rand file1:file2:file3:file4:file5 -out server.key 1024
   ```

   where file1:file2: and so on represents the random compressed files.

2. Remove the pass-phrase from the key as follows:

   ```
   openssl rsa -in server.key -out server.pem
   ```

3. Generate the CSR is as follows:

   ```
   openssl req -new -key server.pem -out server.csr
   ```

   Enter the information you are prompted for.

4. Generate a temporary certificate as follows:

```
openssl x509 -req -days 60 -in server.csr -signkey server.pem -out server.crt
```

This temporary certificate is good for 60 days. . Create the http-ssl.conf file under the /etc/apache2/conf.d directory. . In the http-ssl.conf file, add one of the following redirects: * Redirect a web application, for example, JkMount /hello/* worker1. * Redirect all requests, for example, JkMount /* worker1.

```
# Send all jsp requests to GlassFish
JkMount /*.jsp worker1
# Send all glassfish-test requests to GlassFish
JkMount /glassfish-test/* loadbalancer
```

Example 6-8 http-ssl.conf File for mod_jk Security

A basic SSL-enabled virtual host will appear in the http-ssl.conf file. In this example, all requests are redirected.

```
Listen 443
<VirtualHost _default_:443>
SSLEngine on
SSLCipherSuite ALL:!ADH:!EXP56:RC4+RSA:+HIGH:+MEDIUM:+LOW:+SSLv2:+EXP:+eNULL
```

```
SSLCertificateFile "/etc/apache2/2.2/server.crt"
SSLCertificateKeyFile "/etc/apache2/2.2/server.pem"
JkMount /* worker1
</VirtualHost>
```

To Enable SSL Between the `mod_jk` Load Balancer and Payara Server

This procedure does not enable SSL transfer between `mod_jk` and Payara Server. It enables `mod_jk` to forward SSL-encrypted information from the browser to Payara Server.

Before You Begin, The self-signed certificate must be configured.

1. Perform the steps in To Enable `mod_jk`.
2. Start another Payara Server with at least one web application deployed. In order for the `mod_jk` -enabled network listener to start listening for requests, the web container must be started. Normally, this is achieved by deploying a web application.
3. Follow instructions from To Configure and HTTP Listener for SSL on the `mod_jk` connector.
   Use the following format:

   ```
   asadmin> create-ssl --type http-listener --certname sampleCert new-listener
   ```

4. Add the following directives in the `httpd.conf` file under the `/etc/apache2/conf.d` directory:

   ```
   # Should mod_jk send SSL information (default is On)
   JkExtractSSL On
   # What is the indicator for SSL (default is HTTPS)
   JkHTTPSIndicator HTTPS
   # What is the indicator for SSL session (default is SSL_SESSION_ID)
   JkSESSIONIndicator SSL_SESSION_ID
   # What is the indicator for client SSL cipher suit (default is SSL_CIPHER )
   JkCIPHERIndicator SSL_CIPHER
   # What is the indicator for the client SSL certificated? (default is
   SSL_CLIENT_CERT )
   JkCERTSIndicator SSL_CLIENT_CERT
   ```

5. To apply your changes, restart Apache HTTP Server and Payara Server.

Administering `mod_proxy_ajp`

The Apache Connector `mod_proxy_ajp` can be used to connect the web container with Apache HTTP Server. By using `mod_proxy_ajp`, you can front Payara Server with Apache HTTP Server.

To Enable `mod_proxy_ajp`

You can front Payara Server with Apache HTTP Server and its `mod_proxy_ajp` connector by enabling the AJP protocol for one of Payara Server's network listeners, as described in this procedure. A typical use for `mod_proxy_ajp` would be to have Apache HTTP Server handle requests for static

resources, while having requests for dynamic resources, such as servlets and JavaServer Pages (JSPs), forwarded to, and handled by the Payara Server back-end instance.

1. Install Apache HTTP Server. For information on installing Apache HTTP Server, see https://httpd.apache.org/docs/2.4/install.html.
2. Configure apache2/conf/httpd.conf, the main Apache configuration file. For example:

```
LoadModule proxy_module /usr/lib/httpd/modules/mod_proxy.so
LoadModule proxy_ajp_module /usr/lib/httpd/modules/mod_proxy_ajp.so

Listen 1979
NameVirtualHost *:1979
<VirtualHost *:1979>
   ServerName localhost
   ErrorLog /var/log/apache2/ajp.error.log
   CustomLog /var/log/apache2/ajp.log combined

   <Proxy *>
     AddDefaultCharset Off
     Order deny,allow
     Allow from all
   </Proxy>

   ProxyPass / ajp://localhost:8009/
   ProxyPassReverse / ajp://localhost:8009/
</VirtualHost>
```

3. Start Apache HTTP Server (httpd).
4. Create a jk-enabled network listener by using the create-network-listener subcommand.

```
asadmin> create-network-listener --protocol http-listener-1 \
--listenerport 8009 --jkenabled true jk-connector
```

5. If you expect to need more than five threads for the listener, increase the maximum threads in the http-thread-pool pool:

```
asadmin> set configs.config.server-config.thread-pools.thread-pool.\
http-thread-pool.max-thread-pool-size=value
```

6. To apply your changes, restart Payara Server.
   See To Restart a Domain.
   - For more information on Apache, see http://httpd.apache.org/.
   - For more information on the Apache mod_proxy_ajp Connector, see https://httpd.apache.org/docs/2.4/mod/mod_proxy.html and https://httpd.apache.org/docs/2.4/mod/mod_proxy_ajp.html.

- For more information on the AJP protocol, see http://tomcat.apache.org/connectors-doc/ajp/ajpv13a.html.

To Load Balance Using `mod_proxy_ajp` and Payara Server

Load balancing is the process of dividing the amount of work that a computer has to do between two or more computers so that more work gets done in the same amount of time. In the Payara Server context, load balancing is most frequently used to distribute work among the instances in a Payara Server cluster.

To configure load balancing using `mod_proxy_ajp`, you must use the `mod_proxy_balancer` Apache module in addition to `mod_proxy_ajp`.

In order to support stickiness, the `mod_proxy_balancer` load balancer relies on a `jvmRoute` system property that is included in any `JSESSIONID` received by the load balancer. Consequently, every Payara Server instance that is front-ended by the Apache load balancer must be configured with a unique `jvmRoute` system property.

1. Install Apache HTTP Server. For information on installing Apache HTTP Server, see https://httpd.apache.org/docs/2.4/install.html
2. Configure `apache2/conf/httpd.conf`, the main Apache configuration file. For example:

```
LoadModule proxy_module /usr/lib/httpd/modules/mod_proxy.so
LoadModule proxy_ajp_module /usr/lib/httpd/modules/mod_proxy_ajp.so
LoadModule proxy_balancer_module /usr/lib/httpd/modules/mod_proxy_balancer.so

# Forward proxy needs to be turned off
ProxyRequests Off
# Keep the original Host Header
ProxyPreserveHost On

   <Proxy *>
      Order deny,allow
      Deny from all
      Allow from localhost
   </Proxy>

# Each BalancerMember corresponds to an instance in the Payara Server
# cluster. The port specified for each instance must match the ajp port
# specified for that instance.
<Proxy balancer://localhost>
    BalancerMember ajp://localhost:8009
    BalancerMember ajp://localhost:8010
    BalancerMember ajp://localhost:8011
</Proxy>
```

3. Start Apache HTTP Server (`httpd`).
4. In Payara Server, use the `create-network-listener` subcommand to create a jk-enabled network listener targeted to the cluster. For example:

```
asadmin> create-network-listener --jkenabled true --target cluster1 \
--protocol http-listener-1 --listenerport ${AJP_PORT} jk-listener
```

In this example, `cluster1` is the name of the cluster and `jk-listener` is the name of the new listener.

5. If you expect to need more than five threads for the listener, increase the maximum threads in the `http-thread-pool` pool:

```
asadmin> set configs.config.cluster1-config.thread-pools.thread-pool.\
http-thread-pool.max-thread-pool-size=value
```

6. Use the `create-jvm-options` subcommand to create the `jvmRoute` property targeted to the cluster. For example:

```
asadmin> create-jvm-options --target cluster1 \
"-DjvmRoute=\${AJP_INSTANCE_NAME}"
```

7. Use the `create-system-properties` subcommand to define the `AJP_PORT` and `AJP_INSTANCE_NAME` properties for each of the instances in the cluster, making sure to match the port values you used in Step 2 when specifying the load balancer members. For example:

```
asadmin> create-system-properties --target instance1 AJP_PORT=8009
asadmin> create-system-properties --target instance1 \
AJP_INSTANCE_NAME=instance1
asadmin> create-system-properties --target instance2 AJP_PORT=8010
asadmin> create-system-properties --target instance2 \
AJP_INSTANCE_NAME=instance2
asadmin> create-system-properties --target instance3 AJP_PORT=8011
asadmin> create-system-properties --target instance3 \
AJP_INSTANCE_NAME=instance3
```

In this example, `instance1`, `instance2` and `instance3` are the names of the Payara Server instances in the cluster.

8. To apply your changes, restart Payara Server. See To Restart a Domain.

Configuration Variables Reference

This section outlines how to reference different variable type sources in the configuration of a Payara Server domain.

References to System Properties

Variable references to system properties start with `${`, followed by the name of the variable, and end with `}`. An example of a variable reference that refers to a `java.home` system property is:

```
${java.home}
```

Values of system properties can be specified by:

- the JVM (standard JVM properties like `java.home`)
- Payara Server (a set of predefined variables, such as `com.sun.aas.instanceRoot`)
- the `create-system-properties` asadmin command (or in the Admin console `System properties` section)
- a JVM option prefixed with `-D`

When custom properties are specified, their value can also contain other variable references. It is therefore possible to define a system property using other system properties or environment variables.

References to environment variables

Environment variable references are used like system property references, but contain an extra `ENV` qualifier and equals sign before the variable name. An example of a reference to an environment variable `HOME` then looks like:

```
${ENV=HOME}
${ENV=MAYBE_AVAILABLE:default}
```

Environment variables need to be specified in the environment before a Payara instance is started. By adding a colon after the variable name, you may append a default value if the variable has not been set.

References to password aliases

References to password aliases are used to refer to a password which is stored securely in the domain's keystore. They are treated in a special way and cannot be mixed with other variable references and with other characters in the same configuration value. They are only supposed to be used as a value anywhere a password is expected in the configuration.

Password aliases look like system property references, but contain an extra `ALIAS` qualifier and equals sign before the alias name. Whenever used, the configuration value can only contain a password alias and nothing more.

An example of a reference to a password alias called `cluster-password` for an attribute `admin-password` looks like:

```
admin-password="${ALIAS=cluster-password}"
```

Reference to MicroProfile Config Properties

MicroProfile Configuration variable references can be used exactly like an environment variable

reference, but using the `MPCONFIG` qualifier. An example of a reference to a MicroProfile Configuration variable called `foo` would look like:

```
${MPCONFIG=foo}
${MPCONFIG=bar:default}
```

MicroProfile Configuration variables must be declared in one of the Payara Platform link:/Technical Documentation/MicroProfile/Config/Overview.adoc#config-sources[supported configuration sources,role=unresolved].

By adding a colon (:) after the property name, you may append a default value if the variable has not been set.

Using variable references

A variable can be referenced anywhere inside a string value of a property which supports variable references. Multiple references to system properties and environment variables can be used within the same configuration value, concatenating any number of variable references and plain text chunks. When a reference to a password alias is used, it has to expand to the whole property value and cannot be combined with any other text or variable references.

Variable references in the domain configuration

Variable references can be used inside text values in the following configuration files within the domain directory:

- domain.xml (inside attribute values or inside text nodes that contain a configuration value)
- logging.properties (inside property values)

Variable references in deployed applications

Variable references can be used inside text values also in the following places within deployed applications and modules:

- Package descriptors:
  - web.xml / payara-web.xml / glassfish-web.xml (deprecated)
  - ejb-jar.xml / payara-ejb-jar.xml / glassfish-ejb-jar.xml (deprecated)
  - application.xml / payara-application.xml / glassfish-application.xml (deprecated)
  - payara-resources.xml / glassfish-resources.xml (deprecated)
- Framework descriptors:
  - persistence.xml
  - faces-config.xml
- In the annotations:
  - `@EJB`, `@WebService`, `@Stateless`, `@Stateful`, `@Singleton`, `@ActivationConfigProperty`, `@DataSource`, `@WebServlet`

- In JNDI lookups inside an application
- In pre and post boot command files.
- In JVM Options.
- In the `payara-expression-config.properties` file.

Examples

Here are several examples of where you can use variable references:

Within an annotation

```
@DataSourceDefinition(name="java:global/ExampleDataSource",
      className="com.mysql.jdbc.jdbc2.optional.MysqlXADataSource",
      user="${mysql.user}",
      password="${ALIAS=mysql-db-password}",
      databaseName="${ENV=MYSQL_DBNAME}",
      serverName="localhost"
   )
```

Within a `web.xml` descriptor

```
<data-source>
     <name>java:global/ExampleDataSource</name>
     <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
     <server-name>localhost</server-name>
     <port-number>3306</port-number>
     <database-name>${ENV=MYSQL_DBNAME}</database-name>
     <user>${mysql.user}</user>
     <password>${ALIAS=mysql-db-password}</password>
</data-source>
```

Multiple variable references combined in a single value withing the `domain.xml`

```
<domain log-root="${com.sun.aas.instanceRoot}/${ENV=STAGE_NAME}/logs">
```

Within a pre or post boot command file

```
set configs.config.server-config.http-service.virtual-server.server.default-web-
module=${ENV=deployed-app-name}
set configs.config.server-config.network-config.protocols.protocol.http-listener-
1.security-enabled=${ENV=security-enabled}
```

Within a `logging.properties` file

```
handlers=${ENV=CONSOLE-HANDLER}
handlerServices=${ENV=SYS-LOG-HANDLER}
```

Within a `payara-expression-config.properties` file

The `payara-expression-config.properties` config source is only available in Payara Server

```
fish.payara.example.system=${java.home}
fish.payara.example.env=${ENV=PATH}
fish.payara.example.password=${ALIAS=secret}
fish.payara.example.multiple=property containing both an ${ENV=envProperty} and a
${sysProp}
```

Subcommands for the Asadmin CLI

Subcommands for the `asadmin` Utility

For information and instructions on using the `asadmin` application deployment subcommands, see Application Deployment

Online help for the `asadmin` subcommands can be invoked on the command line, for example, `asadmin create-domain --help`.

General Administration Subcommand

Subcommands	Description
`add-resources`	Creates the resources named in the specified XML file. Supported in remote mode only. For procedural information in this guide. see To Add Resources From an XML File
`asadmin`	Describes how the `asadmin` utility works.
`attach`	Attaches to subcommands that were started using the `asadmin --detach` option or that contain progress information. For procedural information in this guide, see To Run asadmin Subcommands in `--detach ` Mode.
`configure-managed-jobs`	Configures how long information about subcommands (jobs) that were started using the `asadmin --detach` option or that contain progress information is kept. For procedural information in this guide, see To Run asadmin Subcommands in `--detach ` Mode.
`create-module-config`	Adds the default configuration of a module to domain.xml.
`create-service`	Configures the starting of a domain administration server (DAS) on an unattended boot. On Oracle Solaris 10, this subcommand uses the Service Management Facility (SMF). For procedural information in this guide, see To Configure a DAS or an Instance for Automatic Restart on Oracle Solaris.

Subcommands	Description
`create-system-properties`	Creates or updates system properties. Supported in remote mode only. For procedural information in this guide, see To Create System Properties.
`delete-module-config`	Removes the configuration of a module from `domain.xml`.
`delete-system-property`	Deletes system properties of a domain or configuration, or server instance. Supported in remote mode only. For procedural information in this guide, see To Delete a System Property.
`get`	Gets an attribute of an element in the `domain.xml` file. With the `-m` option, gets the names and values of the monitorable or configurable attributes. For procedural information in this guide, see Guidelines for Using the list and get Subcommands for Monitoring.
`get-active-module-config`	Displays the current active configuration of a module.
`list`	Lists the configurable element. On Oracle Solaris, quotes are needed when running subcommands with * as the option value or operand. For procedural information in this guide, see Guidelines for Using the list and get Subcommands for Monitoring.
`list-commands`	Lists all the `asadmin` subcommands, local subcommands first, then remote subcommands. You can specify that only remote subcommands or only local subcommands be displayed. Supported in remote mode only. For procedural information in this guide, see To List Subcommands.
`list-containers`	Lists application containers and the status of each container. Supported in remote mode only. For procedural information in this guide, see To List Containers.
`list-jobs`	Lists information about subcommands that were started using the `asadmin --detach` option or that contain progress information. For procedural information in this guide, see To Run asadmin Subcommands in --detach Mode.
`list-modules`	Lists modules that are accessible to the Payara Server subsystem. The status of each module is included. Supported in remote mode only. For procedural information in this guide, see To List Modules.
`list-system-properties`	Lists the system properties of a domain or configuration. Supported in remote mode only. For procedural information in this guide, see To List System Properties.
`list-timers`	List the timers owned by a specific server instance. Supported in remote mode only. For procedural information in this guide, see To List Timers.
`multimode`	Provides an `asadmin>` prompt for running multiple subcommands while preserving options and environment settings. Supported in local mode only. For procedural information, see Using the asadmin Utility.
`osgi`	Delegates the command line to the Apache Felix Gogo remote shell for the execution of OSGi shell commands. For procedural information in this guide, see To Run Apache Felix Gogo Remote Shell Commands.

Subcommands	Description
`osgi-shell`	Provides interactive access to the Apache Felix Gogo remote shell for the execution of OSGi shell commands. For procedural information in this guide, see To Run Apache Felix Gogo Remote Shell Commands.
`set`	Sets the values of one or more configurable attributes. For procedural information in this guide, see Configuring Monitoring.
`show-component-status`	Lists the status of existing components. Supported in remote mode only. For procedural information in this guide, see To Show Component Status.
`start-database`	Starts the internal H2 database server. Use this subcommand only for working with applications deployed to Payara Server. For procedural information in this guide, see To Start the Database.
`stop-database`	Stops a process of the internal H2 database server. For procedural information in this guide, see To Stop the Database.
`version`	Displays the version information for the option specified in archive or folder format. Supported in remote mode only. For procedural information in this guide, see To Display the Payara Server Version.

Batch Jobs Subcommands

Subcommands	Description
`list-batch-jobs`	Lists batch jobs and job details. For procedural information in this guide, see To List Batch Jobs.
`list-batch-job-executions`	Lists batch job executions and execution details. For procedural information in this guide, see To List Batch Job Executions.
`list-batch-job-steps`	Lists steps for a specific batch job execution. For procedural information in this guide, see To List Batch Job Steps.
`list-batch-runtime-configuration`	Displays the configuration of the batch runtime. For procedural information in this guide, see To List the Batch Runtime Configuration.
`set-batch-runtime-configuration`	Configures the batch runtime. For procedural information in this guide, see To Configure the Batch Runtime.

Concurrent Resources Subcommands

Subcommands	Description
`create-context-service`	Creates a context service resource. For procedural information in this guide, see To Create a Context Service.
`create-managed-executor-service`	Creates a managed executor service resource. For procedural information in this guide, see To Create a Managed Executor Service.
`create-managed-scheduled-executor-service`	Creates a managed scheduled executor service resource. For procedural information in this guide, see To Create a Managed Scheduled Executor Service.

Subcommands	Description
create-managed-thread-factory	Creates a managed thread factory resource. For procedural information in this guide, see To Create a Managed Thread Factory.
list-context-services	Lists context service resources. For procedural information in this guide, see To List Context Services.
list-managed-executor-services	Lists managed executor service resources. For procedural information in this guide, see To List Managed Executor Services.
list-managed-scheduled-executor-services	Lists managed scheduled executor service resources. For procedural information in this guide, see To List Managed Scheduled Executor Services.
list-managed-thread-factories	Lists managed thread factory resources. For procedural information in this guide, see To List Managed Thread Factories.
delete-context-service	Removes a context service resource. For procedural information in this guide, see To Delete a Context Service.
delete-managed-executor-service	Removes a managed executor service resource. For procedural information in this guide, see To Delete a Managed Executor Service.
delete-managed-scheduled-executor-service	Removes a managed scheduled executor service resource. For procedural information in this guide, see To Delete a Managed Scheduled Executor Service.
delete-managed-thread-factory	Removes a managed thread factory resource. For procedural information in this guide, see To Delete a Managed Thread Factory.

Connectivity Subcommands

Subcommands	Description
create-admin-object	Creates an administered object. For procedural information in this guide, see To Create an Administered Object.
create-connector-connection-pool	Adds a new connector connection pool with the specified connection pool name. For procedural information in this guide, see To Create a Connector Connection Pool.
create-connector-resource	Creates a connector resource. For procedural information in this guide, see To Create a Connector Resource.
create-connector-security-map	Creates a connector security map for the specified connector connection pool. For procedural information, see To Create a Connector Security Map.
create-connector-work-security-map	Creates a connector work security map for the specified resource adapter. Supported in remote mode only. For procedural information in this guide, see To Create a Connector Work Security Map.
create-jdbc-resource	Creates a new JDBC resource. Supported in remote mode only. For procedural information in this guide, see To Create a JDBC Resource.
create-jdbc-connection-pool	Registers a new JDBC connection pool with the specified JDBC connection pool name. Supported in remote mode only. For procedural information in this guide, see To Create a JDBC Connection Pool.

Subcommands	Description
`create-resource-adapter-config`	Creates configuration information for the connector module. Supported in remote mode only. For procedural information in this guide, see To Create Configuration Information for a Resource Adapter.
`delete-admin-object`	Deletes an administered object. For procedural information in this guide, see To Delete an Administered Object.
`delete-connector-connection-pool`	Removes the connector connection pool specified using the `connector_connection_pool_name` operand. For procedural information in this guide, see To Delete a Connector Connection Pool.
`delete-connector-resource`	Deletes connector resource. For procedural information in this guide, see To Delete a Connector Resource.
`delete-connector-security-map`	Deletes a specified connector security map. Supported in remote mode only. For procedural information in this guide, see To Delete a Connector Security Map.
`delete-connector-work-security-map`	Deletes a specified connector work security map. Supported in remote mode only. For procedural information in this guide, see To Delete a Connector Work Security Map.
`delete-jdbc-connection-pool`	Deletes the specified JDBC connection pool. Supported in remote mode only. For procedural information in this guide, see To Delete a JDBC Connection Pool.
`delete-jdbc-resource`	Deletes a JDBC resource. The specified JNDI name identifies the resource to be deleted. Supported in remote mode only. For procedural information in this guide, see To Delete a JDBC Resource.
`delete-resource-adapter-config`	Deletes configuration information for the connector module. Supported in remote mode only. For procedural information in this guide, see To Delete a Resource Adapter Configuration.
`flush-connection-pool`	Re-initializes all connections established in the specified connection. For procedural information in this guide, see To Reset (Flush) a Connection Pool.
`list-admin-objects`	Lists administered objects. For procedural information in this guide, see To List Administered Objects.
`list-connector-connection-pools`	Lists the connector connection pools that have been created. For procedural information in this guide, see To List Connector Connection Pools.
`list-connector-resources`	Creates connector resources. For procedural information in this guide, see To List Connector Resources.
`list-connector-security-maps`	Lists the connector security maps belonging to a specified connector connection pool. For procedural information in this guide, see To List Connector Security Maps.
`list-connector-work-security-maps`	Lists the existing connector work security maps for a resource adapter. Supported in remote mode only. For procedural information in this guide, see o List Connector Work Security Maps.

Subcommands	Description
`list-jdbc-connection-pools`	Lists the existing JDBC connection pools. Supported in remote mode only. For procedural information in this guide, see To List JDBC Connection Pools.
`list-jdbc-resources`	Lists the existing JDBC resources. Supported in remote mode only. For procedural information in this guide, see To List JDBC Resources.
`list-resource-adapter-configs`	Lists configuration information for the connector modules. Supported in remote mode only. For procedural information in this guide, see To List Resource Adapter Configurations.
`ping-connection-pool`	Tests if a JDBC connection pool is usable. Supported in remote mode only. For procedural information in this guide, see To Contact (Ping) a Connection Pool.
`update-connector-security-map`	Modifies a security map for the specified connector connection pool. For procedural information in this guide, see To Update a Connector Security Map.
`update-connector-work-security-map`	Modifies a work security map that belongs to a specific resource adapter (connector module). For procedure information in this guide, see To Update a Connector Work Security Map.

Domain Subcommands

Subcommands	Description
`backup-domain`	Describes how to back up a domain. Supported in local mode only. For procedural information in this guide, see To Back Up a Domain.
`create-domain`	Creates the configuration of a domain. A domain can exist independent of other domains. Any user who has access to the `asadmin` utility on a given host can create a domain and store its configuration in a location of choice. For procedural information in this guide, see To Create a Domain.
`delete-domain`	Deletes the specified domain. The domain must be stopped before it can be deleted. For procedural information in this guide, see To Delete a Domain.
`list-backups`	Lists the existing domain backups. Supported in local mode only. For procedural information in this guide, see To List Domain Backups.
`list-domains`	Lists the existing domains and their statuses. If the domain directory is not specified, the domains in the domain-root-dir, the default for which is as-install`/domains`, are displayed. For procedural information in this guide, see To List Domains.
`login`	Allows you to log in to a domain. For procedural information in this guide, see To Log In to a Domain.
`restart-domain`	Restarts the Domain Administration Server (DAS) of the specified domain. Supported in remote mode only. For procedural information in this guide, see To Restart a Domain.
`restore-domain`	Recovers and domain from a backup file. Supported in local mode only. For procedural information in this guide, see To Restore a Domain.

Subcommands	Description
start-domain	Starts a domain. If the domain directory is not specified, the default domain1 in the default domain-root-dir directory is started. If there are two or more domains, the domain_name operand must be specified. For procedural information in this guide, see To Start a Domain.
stop-domain	Stops the domain administration server (DAS) of the specified domain. Supported in remote mode only. For procedural information in this guide, see To Stop a Domain.
uptime	Displays the length of time that the domain administration server (DAS) has been running since the last restart. Supported in remote mode only. For procedural information in this guide, see To Display Domain Uptime.

Internet Connectivity Subcommands

Subcommands	Description
create-http	Creates a set of HTTP parameters for a protocol, which in turn configures one or more network listeners. Supported in remote mode only. For procedural information in this guide, see To Create an HTTP Configuration.
create-http-listener	Creates a new HTTP listener socket. Supported in remote mode only. For procedural information in this guide, see To Create an Internet Connection.
create-network-listener	Creates a new HTTP listener socket. Supported in remote mode only. For procedural information in this guide, see To Create an Internet Connection.
create-protocol	Creates a protocol for a listener. Supported in remote mode only. For procedural information in this guide, see To Create a Protocol.
create-transport	Creates a transport object for a listener. Supported in remote mode only. For procedural information in this guide, see To Create a Transport.
create-virtual-server	Creates the specified virtual server element. Supported in remote mode only. For procedural information in this guide, see To Create a Virtual Server.
create-ssl	Creates and configures the SSL element in the selected HTTP listener to enable secure communication on that listener/service. Supported in remote mode only. For procedural information in this guide, see To Configure an HTTP Listener for SSL.
delete-http	Deletes an existing HTTP configuration. Supported in remote mode only. For procedural information in this guide, see To Delete an HTTP Configuration.
delete-http-listener	Deletes the specified HTTP listener. Supported in remote mode only. For procedural information in this guide, see To Delete an HTTP Network Listener.
delete-network-listener	Deletes the specified HTTP listener. Supported in remote mode only. For procedural information in this guide, see To Delete an HTTP Network Listener.
delete-protocol	Deletes and existing HTTP protocol. Supported in remote mode only. For procedural information in this guide, see To Delete a Protocol.

Subcommands	Description
`delete-ssl`	Deletes the SSL element in the selected HTTP listener. Supported in remote mode only. For procedural information in this guide, see To Delete SSL From an HTTP Listener.
`delete-transport`	Deletes and existing HTTP transport. Supported in remote mode only. For procedural information in this guide, see To Delete a Transport.
`delete-virtual-server`	Deletes the specified virtual server element. Supported in remote mode only. For procedural information in this guide, see To Delete a Virtual Server.
`list-http-listeners`	Lists the existing HTTP listeners. Supported in remote mode only. For procedural information in this guide, see To List HTTP Network Listeners.
`list-network-listeners`	Lists the existing HTTP listeners. Supported in remote mode only. For procedural information in this guide, see To List HTTP Network Listeners.
`list-protocols`	Lists the existing HTTP protocols. Supported in remote mode only. For procedural information in this guide, see To List Protocols.
`list-transports`	Lists the existing HTTP transports. Supported in remote mode only. For procedural information in this guide, see To List Transports.
`list-virtual-servers`	Lists the existing virtual servers. Supported in remote mode only. For procedural information in this guide, see To List Virtual Servers.

JavaMail Subcommands

Subcommands	Description
`create-javamail-resource`	Creates a JavaMail session resource. Supported in remote mode only. For procedural information in this guide, see To Create a JavaMail Resource.
`delete-javamail-resource`	Deletes a JavaMail session resource. Supported in remote mode only. For procedural information in this guide, see To Delete a JavaMail Resource.
`list-javamail-resources`	Creates JavaMail session resources. Supported in remote mode only. For procedural information in this guide, see To List JavaMail Resources.

JMS Subcommands

Subcommands	Description
`create-jmsdest`	Creates a JMS physical destination. Along with the physical destination, you use the `create-jms-resource` subcommand to create a JMS destination resource that has a `Name` property that specifies the physical destination. Supported in remote mode only. For procedural information in this guide, see To Create a JMS Physical Destination.
`create-jms-host`	Creates a JMS host within the JMS service. Supported in remote mode only. For procedural information in this guide, see To Create a JMS Host.

Subcommands	Description
`create-jms-resource`	Creates a JMS connection factory resource or JMS destination resource. Supported in remote mode only. Supported in remote mode only. For procedural information in this guide, see To Create a Connection Factory or Destination Resource.
`delete-jmsdest`	Removes the specified JMS destination. Supported in remote mode only. For procedural information in this guide, see To Delete a JMS Physical Destination.
`delete-jms-host`	Deletes a JMS host within the JMS service. Supported in remote mode only. For procedural information in this guide, see To Delete a JMS Host.
`delete-jms-resource`	Deletes a JMS connection factory resource or JMS destination resource. Supported in remote mode only. For procedural information in this guide, see To Delete a Connection Factory or Destination Resource.
`flush-jmsdest`	Purges the messages from a physical destination in the specified JMS Service configuration of the specified target. Supported in remote mode only. For procedural information in this guide, see To Purge Messages From a Physical Destination.
`jms-ping`	Checks if the JMS service (also known as the JMS provider) is up and running. Supported in remote mode only. For procedural information in this guide, see Troubleshooting the JMS Service.
`list-jmsdest`	Lists the JMS physical destinations. Supported in remote mode only. For procedural information in this guide, see To List JMS Physical Destinations.
`list-jms-hosts`	Lists the existing JMS hosts. Supported in remote mode only. For procedural information in this guide, see To List JMS Hosts.
`list-jms-resources`	Lists the existing JMS connection factory or destination resources. Supported in remote mode only. For procedural information in this guide, see To List JMS Resources.

JNDI Subcommands

Subcommands	Description
`create-custom-resource`	Creates a custom JNDI resource. Supported in remote mode only. For procedural information in this guide, see To Create a Custom JNDI Resource.
`create-jndi-resource`	Creates an external JNDI resource. Supported in remote mode only. For procedural information in this guide, see To Register an External JNDI Resource.
`delete-custom-resource`	Deletes a custom JNDI resource. Supported in remote mode only. For procedural information in this guide, see To Delete a Custom JNDI Resource.
`delete-jndi-resource`	Deletes an external JNDI resource. Supported in remote mode only. For procedural information in this guide, see To Delete an External JNDI Resource.
`list-custom-resources`	Lists the existing custom JNDI resources. Supported in remote mode only. For procedural information in this guide, see To List Custom JNDI Resources.

Subcommands	Description
`list-jndi-entries`	Lists the entries in the JNDI tree. Supported in remote mode only. For procedural information in this guide, see To List External JNDI Entries.
`list-jndi-resources`	Lists the existing external JNDI resources. Supported in remote mode only. For procedural information in this guide, see To List External JNDI Resources.

JVM Subcommands

Subcommands	Description
`create-jvm-options`	Creates a JVM option in the Java configuration element of the `domain.xml` file. Supported in remote mode only. For procedural information in this guide, see To Create JVM Options.
`delete-jvm-options`	Deletes the specified JVM option from the Java configuration element of the `domain.xml` file. Supported in remote mode only. For procedural information in this guide, see To Delete JVM Options.
`generate-jvm-report`	Generates a report showing the threads, classes, and memory for the virtual machine that runs Payara Server. For procedural information in this guide, see To Generate a JVM Report.
`list-jvm-options`	Lists the command-line options that are passed to the Java application launcher when Payara Server is started. Supported in remote mode only. For procedural information in this guide, see To List JVM Options.

Logging and Monitoring Subcommands

Subcommands	Description
`collect-log-files`	Collects all available log files and creates a ZIP archive. Supported in remote mode only. For procedural information in this guide, see To Collect Log Files into a ZIP Archive.
`disable-monitoring`	Disables the monitoring service. Supported in remote mode only. For procedural information in this guide, see To Disable Monitoring.
`enable-monitoring`	Enables the monitoring service. Supported in remote mode only. For procedural information in this guide, see To Enable Monitoring.
`list-log-attributes`	Lists log file attributes. Supported in remote mode only. For procedural information in this guide, see Configuring the Logging Service.
`list-log-levels`	Lists the existing loggers. Supported in remote mode only. For procedural information in this guide, see To List Log Levels.
`list-loggers`	Lists all public loggers in your distribution of Payara Server. Internal loggers are not listed. For procedural information in this guide, see To List Loggers.
`monitor`	Displays monitoring information for the common Payara Server resources. Supported in remote mode only. For procedural information in this guide, see To View Common Monitoring Data.

Subcommands	Description
`rotate-log`	Rotates the `server.log` file and stores the old data in a time-stamped file. Supported in remote mode only. For procedural information in this guide, see To Rotate Log Files Manually.
`set-log-attributes`	Sets log file attributes. Supported in remote mode only. For procedural information in this guide, see Configuring the Logging Service.
`set-log-file-format`	Sets the formatter used to format log records in log files. For procedural information in this guide, see Setting the Log File Format.
`set-log-levels`	Sets the log level for a module. Supported in remote mode only. For procedural information in this guide, see Setting Log Levels.

ORB Subcommands

Subcommands	Description
`create-iiop-listener`	Creates an IIOP listener. Supported in remote mode only. For procedural information in this guide, see To Create an IIOP Listener.
`delete-iiop-listener`	Deletes an IIOP listener. Supported in remote mode only. For procedural information in this guide, see To Delete an IIOP Listener.
`list-iiop-listeners`	Lists the existing IIOP listeners. Supported in remote mode only. For procedural information in this guide, see To List IIOP Listeners.

Thread Pool Subcommands

Subcommands	Description
`create-threadpool`	Creates a new thread pool. Supported in remote mode only. For procedural information in this guide, see To Create a Thread Pool.
`delete-threadpool`	Deletes the specified thread pool. Supported in remote mode only. For procedural information in this guide, see To Delete a Thread Pool.
`list-threadpools`	Lists the existing thread pools. Supported in remote mode only. For procedural information in this guide, see To List Thread Pools.

Transaction Service Subcommands

Subcommands	Description
`freeze-transaction-service`	Freezes the transaction subsystem during which time all the in-flight transactions are suspended. Supported in remote mode only. For procedural information, see To Stop the Transaction Service.
`recover-transactions`	Manually recovers pending transactions. Supported in remote mode only. For procedural information, see To Manually Recover Transactions.
`rollback-transaction`	Rolls back the named transaction. Supported in remote mode only. For procedural information, see To Roll Back a Transaction.

Subcommands	Description
`unfreeze-transaction-service`	Resumes all the suspended in-flight transactions. Invoke this subcommand on an already frozen transaction. Supported in remote mode only. For procedural information, see To Restart the Transaction Service.

MBeans Inventory

Below is a non-exhaustive list of MBeans which are useful to monitor in any Payara Server environment.

Other MBeans not listed show static information or are JDK-specific.

JVM MBeans

Class Loading

In JMX Monitoring logging set the value to `java.lang:type=ClassLoading` to monitor this MBean

Attribute	Description	Comment
`loadedclass-count`	Number of classes currently loaded in the Java virtual machine	
`totalloadedclass-count`	Total number of classes that have been loaded since the Java virtual machine has started execution	
`unloadedclass-count`	Total number of classes unloaded since the Java virtual machine has started execution	Classes are only unloaded from Payara when the application they are in is un-deployed.

Compilation

In JMX Monitoring logging set the value to `java.lang:type=Compilation` to monitor this MBean

Attribute	Description	Comment
`totalcompilationtime-current`	Approximate accumulated elapsed time (in milliseconds) spent in compilation	

Garbage Collectors

In JMX Monitoring logging set the value to `java.lang:type=GarbageCollector,name=collectors-name` to monitor this MBean The garbage collector's name will be one of the following depending on your JDK configuration options:

- Copy
- G1 Young Generation

- G1 Mixed Generation
- MarkSweepCompact
- ParNew
- PS MarkSweep
- PS Scavenge

Attribute	Description	Comment
`collectioncount-count`	Total number of collections that have occurred	The number of times this garbage collector has been called since Payara Server was started
`collectiontime-count`	Approximate accumulated collection elapsed time in milliseconds	How much time has been spent on garbage collection since Payara Server was started

Memory

In JMX Monitoring logging set the value to `java.lang:type=Memory` to monitor this MBean

Attribute	Description	Comment
`ObjectsPendingFinalization`	Approximate number of objects for which finalization is pending	
`UsedHeapSize`	Amount of used memory in bytes	
`UsedNonHeapSize`	Amount of used memory in bytes	

Runtime

In JMX Monitoring logging set the value to `java.lang:type=Runtime` to monitor this MBean.

Attribute	Description	Comment
`uptime-count`	Uptime of the Java virtual machine in milliseconds	

Thread System

In JMX Monitoring logging set the value to `java.lang:type=Threading` to monitor this MBean.

Attribute	Description	Comment
`currentthreadcputime`	Returns the total CPU time for the current thread in nanoseconds	

Attribute	Description	Comment
`currentthreadusertime`	Returns the CPU time that the current thread has executed in user mode in nanoseconds	
`daemonthreadcount`	Returns the current number of live daemon threads	
`deadlockedthreads`	Finds cycles of threads that are in deadlock waiting to acquire object monitors	Is either a list of deadlocked threads or the sentence "None of the threads are monitor deadlocked."
`monitordeadlockedthreads`	Finds cycles of threads that are in deadlock waiting to acquire object monitors	Is either a list of deadlocked threads or the sentence "None of the threads are monitor deadlocked."
`peakthreadcount`	Returns the peak live thread count since the Java virtual machine started or peak was reset	
`threadcount`	Returns the current number of live threads including both daemon and non-daemon threads	
`totalstartedthreadcount`	Returns the total number of threads created and also started since the Java virtual machine started	

Payara Platform MBeans

These MBeans are registered exclusively by Payara Server and provide additional information about current usage.

They are all in the form of `amx:pp=amx:pp=/mon/server-mon[instance-name],type=type-of-mbean,name=MBeanName` where `instance-name` is replaced by the name of the instance i.e. `amx:pp=/mon/server-mon[server],type=web-request-mon,name=web/request`.

See enable JMX Monitoring for how to view all available MBeans.

Payara Platform MBeans are only available when AMX is booted. This is done automatically once a JMX client connects. For all other cases, AMX must be either configured to boot at server startup (through domain config) or booted via a JMX operation `bootAMX` on the `amx-support:type=boot-amx` MBean using a non-JMX client (e.g. over a local socket).
Programmatic activation during application deployment (by means of a Startup EJB singleton for example) will not work.

Connection Queue

Network Connection Queue Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=connection-queue-mon,name=network//connection-queue` to use this MBean.

To monitor a specific network connection set the name value to be `network/name-of-listener/connection-queue` i.e. `name=network/http-listener-1/connection-queue`.

Attribute	Description	Comment
`peakqueued`	Largest number of connections that were in the queue simultaneously	
`countoverflows`	Number of times the queue has been too full to accommodate a connection	
`counttotalconnections`	Total number of connections that have been accepted	
`countopenconnections`	The number of open/active connections	
`countqueued`	Number of connections currently in the queue	
`countqueued1minuteaverage`	Average number of connections queued in the last 1 minute	
`countqueued5minutesaverage`	Average number of connections queued in the last 5 minutes	
`countqueued15minutesaverage`	Average number of connections queued in the last 15 minutes	
`counttotalqueued`	Total number of connections that have been queued	

Connector Service

Connector Container Work Management Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=connector-service-mon,name=jms-service/work-management` to monitor this MBean.

Attribute	Description	Comment
`activeworkcount`	Number of active work objects	
`workrequestwaittime`	Wait time of a work object before it gets executed	

Attribute	Description	Comment
waitqueuelength	Number of work objects waiting in the queue for execution	
rejectedworkcount	Number of work objects rejected by the application server	
submittedworkcount	Number of work objects submitted by a connector module for execution	
completedworkcount	Number of work objects completed execution	

Deployment

Deployment Module Statistics

In JMX Logging set value to amx:pp=/mon/server-mon[server],type=deployment-mon,name=deployment/lifecycle to monitor this MBean.

Attribute	Description	Comment
activeapplicationsdeployedcount	Number of applications deployed	
totalapplicationsdeployedcount	Total number of applications ever deployed	This does not persist across restarts

EJB Security

EJB Security Deployment statistics

In JMX Logging set value to amx:pp=/mon/server-mon[server],type=ejb-security-mon,name=security/ejb to monitor this MBean.

Attribute	Description	Comment
policyconfigurationcount	Count of EJB policy configurations	
securitymanagercount	Count of EJB security managers	

Thread Pool Executor

ThreadPoolExecutor Statistics

In JMX Logging set value to amx:pp=/mon/server-mon[server],type=exec-pool-mon,name=ejb/default-exec-pool to monitor this MBean.

Attribute	Description	Comment
corenumthreads	Core number of threads in the associated pool	
maxnumthreads	Maximum number of threads in the associated pool	
numthreads	Current number of threads in the associated pool	
activenumthreads	Number of active threads in the associated pool	
totaltaskscreated	Number of tasks created in the associated pool	
keepalivetime	Keep-Alive time for threads in the associated pool	
numtaskscompleted	Number of tasks completed in the associated pool	
largestnumthreads	Largest number of simultaneous threads in the associated pool	

JDBC Connection Pool

JDBC Connection Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=jdbc-connection-pool-mon,name=resources/NameOfPool` to monitor this MBean, replacing `NameOfPool` to whatever the actual name of the pool is i.e. **H2Pool**.

Attribute	Description	Comment
numconncreated	The number of physical connections that were created since the last reset	
numconndestroyed	Number of physical connections that were destroyed since the last reset.	
numconnfree	The total number of free connections in the pool as of the last sampling	
numpotentialconnleak	Number of potential connection leaks	

Attribute	Description	Comment
numconnfailedvalidation	The total number of connections in the connection pool that failed validation from the start time until the last sample time	
connrequestwaittime	The longest and shortest wait times of connection requests. The current value indicates the wait time of the last request that was serviced by the pool.	Unit is milliseconds
numconnacquired	Number of logical connections acquired from the pool	
numconnreleased	Number of logical connections released to the pool	
averageconnwaittime	Average wait-time-duration per successful connection request	Unit is milliseconds
numconnsuccessfullymatched	Number of connections successfully matched	
numconnnotsuccessfullymatched	Number of connections rejected during matching	
waitqueuelength	Number of connection requests in the queue waiting to be serviced	
numconntimedout	The total number of connections in the pool that timed out between the start time and the last sample time	

Keep Alive

Keep-Alive Statistics

This MBean is for network connections in keep-alive mode. For more details on `keep-alive` see RFC 7230 6.3.

As of **HTTP 1.1** all connections are `keep-alive` unless declared otherwise.

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=keep-alive-mon,name=network//keep-alive` to use this MBean. To monitor a specific network connection set the name value to be `network/name-of-listener/keep-alive` i.e. `name=network/http-listener-1/keep-alive`.

Attribute	Description	Comment
counttimeouts	Number of keep-alive connections that timed out	
counthits	Number of requests received by connections in keep-alive mode	
countconnections	Number of connections in keep-alive mode	
countflushes	Number of keep-alive connections that were closed	
countrefusals	Number of keep-alive connections that were rejected	

Managed Executor Service

`ManagedExecutorService` Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=managed-executor-service-mon,name=executorService/concurrent/NameOfManagedExecutorService` to use this MBean, replacing `NameOfManagedExecutorService` to whatever the actual name of the service is i.e. `__defaultManagedExecutorService`.

Attribute	Description	Comment
PoolSize	The current number of threads in the pool	
ActiveCount	The approximate number of active threads	
CompletedTaskCount	Number of tasks completed	
LargestPoolSize	The largest number of threads that have ever simultaneously been in the pool	
TaskCount	The number of tasks executed by the executor service	

Message Driven Beans

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=message-driven-bean-mon,name=applicationName/ClassUsingBean` to use this MBean, replacing `applicationName` with the name of your application using JMS and `ClassUsingBean` with the class that has the `@MessageDriven` annotation on it.

Attribute	Description	Comment
createcount	Number of times EJB create method is called	

Attribute	Description	Comment
removecount	Number of times EJB remove method is called	
messagecount	Number of messages received for the message-driven bean	

Request

Web Container HTTP Service Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=request-mon,name=http-service/VirtualServer/request` to use this MBean, replacing `VirtualServer` name of the virtual server it is running on.

This MBean differs from Connection Queue statistics by being selected by virtual server rather than by listener, as well as providing some additional information about responses.

Attribute	Description	Comment
method	The method of the last request serviced	This will be one of `GET`, `HEAD`, `POST`, `PUT`, `DELETE`, `TRACE`, `OPTIONS`, `CONNECT` or `PATCH`
countopenconnections	The number of open connections	Unlike most other attributes with count in the name, this one is the current number rather than total over the server lifetime
countrequests	The number of requests received	The number of requests received since the server was started
uri	The URI of the last request serviced	
maxtime	Longest response time for a request; not a cumulative value, but the largest response time from among the response times	
count200	Number of responses with a status code equal to **200**	This is the total since the server started
count2xx	Number of responses with a status code in the **2xx** range	This is the total since the server started
count302	Number of responses with a status code equal to **302**	This is the total since the server started
count304	Number of responses with a status code equal to **304**	This is the total since the server started

Attribute	Description	Comment
count3xx	Number of responses with a status code in the **3xx** range	This is the total since the server started
count400	Number of responses with a status code equal to **400**	This is the total since the server started
count401	Number of responses with a status code equal to **401**	This is the total since the server started
count403	Number of responses with a status code equal to **403**	This is the total since the server started
count404	Number of responses with a status code equal to **404**	This is the total since the server started
count4xx	Number of responses with a status code in the **4xx** range	This is the total since the server started
count503	Number of responses with a status code in the **5xx** range	This is the total since the server started
countother	Number of responses with a status code outside the **2xx**, **3xx**, **4xx**, and **5xx** range	This is the total since the server started
countbytestransmitted	The number of bytes transmitted	
countbytesreceived	The number of bytes received	
errorcount	Cumulative value of the error count, with error count representing the number of cases where the response code was greater than or equal to **400**	
processingtime	Average request processing time	Unit is milliseconds

Security Realm

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=security-realm-mon,name=security/realm` to use this MBean.

Attribute	Description	Comment
RealmCount	Security Realm Count	

Server

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=server-runtime-mon` to use this MBean.

Attribute	Description	Comment
`state`	state of the server such as **Running**, **Stopped**, **Failed**	
`uptime`	uptime of the Java virtual machine in milliseconds	

Servlet

Web Container Servlet Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=servlet-mon,name=ApplicationName/InstanceName/ServletName` to use this MBean, where `ApplicationName` is the name of your application and `InstanceName` is the instance it is running.

This MBean provides information on all servlets within an application.

Attribute	Description	Comment
`totalservletsloadedcount`	Total number of Servlets ever loaded	
`activeservletsloadedcount`	Number of Servlets loaded	
`servletprocessingtimes`	Cumulative Servlet processing times	Unit is milliseconds

Web Container Servlet Instance Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=servlet-instance-mon,name=ApplicationName/VirtualServerName/ServletName` to use this MBean, where `ApplicationName` is the name of your application, `VirtualServerName` is the virtual server it is running on and `ServletName` is the name of the servlet to access.

If the servlet is annotation with `@WebServlet(name = "ServletName")` then the servlet name will be the name in the annotation, otherwise it is the fully qualified class name.

Attribute	Description	Comment
`errorcount`	Number of error responses (that is, responses with a status code greater than or equal to 400)	
`requestcount`	Number of requests processed	
`processingtime`	Average response time	Unit is milliseconds
`maxtime`	Maximum response time	Unit is milliseconds
`servicetime`	Aggregate response time	

Singleton Bean

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=singleton-bean-mon,name=ApplicationsName/ClassName` where `ApplicationName` is the name of your application and `ClassName` of the name of the Singleton EJB class.

Attribute	Description	Comment
`createcount`	Number of times EJB create method is called	
`removecount`	Number of times EJB remove method is called	

Stateful Bean

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=stateful-bean-mon,name=ApplicationsName/ClassName` where `ApplicationName` is the name of your application and `ClassName` of the name of the Stateful EJB class.

Attribute	Description	Comment
`createcount`	Number of times EJB create method is called	
`removecount`	Number of times EJB remove method is called	
`methodreadycount`	Number of stateful session beans in `MethodReady` state	
`passivecount`	Number of stateful session beans in Passive state	

Stateless Bean

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=stateless-bean-mon,name=ApplicationsName/ClassName` where `ApplicationName` is the name of your application and `ClassName` of the name of the Stateless EJB class.

Attribute	Description	Comment
`createcount`	Number of times EJB create method is called	
`removecount`	Number of times EJB remove method is called	
`methodreadycount`	Number of stateful session beans in `MethodReady` state	

Thread Pool

Thread Pool Statistics

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=thread-pool-mon,name=network/NetworkListenerName/thread-pool` where `NetworkListenerName` is the name of the network listener to monitor.

Alternatively set the value to `amx:pp=/mon/server-mon[server],type=thread-pool-mon,name=network//global-thread-pool-stats` for totals across all thread pools.

Attribute	Description	Comment
`corethreads`	Core number of threads in the thread pool	
`totalexecutedtasks`	Provides the total number of tasks, which were executed by the thread pool	
`maxthreads`	Maximum number of threads allowed in the thread pool	
`currentthreadcount`	Provides the number of request processing threads currently in the listener thread pool	
`currentthreadsbusy`	Provides the number of request processing threads currently in use in the listener thread pool serving requests	

Transaction Service

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=transaction-service-mon,name=transaction-service` to use this MBean.

Attribute	Description	Comment
`activecount`	Provides the number of transactions that are currently active.	
`committedcount`	Provides the number of transactions that have been committed.	
`rolledbackcount`	Provides the number of transactions that have been rolled back.	
`state`	Indicates if the transaction service has been frozen.	Returns `false` if service is working fine

Virtual Server

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=virtualserverinfo-mon,name=http-service/VirtualServerName` where `VirtualServerName` is the name of the virtual server.

Attribute	Description	Comment
`id`	The id of the virtual server	
`hosts`	The host (alias) names of the virtual server"	
`mode`	The mode of the virtual server	Is either active or unknown
`state`	The state of the virtual server	

Web Request

In JMX Logging set value to `amx:pp=/mon/server-mon[server],type=web-request-mon,name=ApplicationName/VirtualServer` where `ApplicationName` is the name of your application and `VirtualServer` is the name of the virtual server it is running on. There is also the special value of `web/request` for all requests to every virtual server and application.

Attribute	Description	Comment
`errorcount`	Cumulative value of the error count, with error count representing the number of cases where the response code was greater than or equal to **400**	
`requestcount`	Cumulative number of requests processed so far	
`processingtime`	Average request processing time	
`maxtime`	Longest response time for a request; not a cumulative value, but the largest response time from among the response times	

OpenMQ MBeans

Payara Server includes OpenMQ as a JMS broker, which includes its own MBeans.Documentation on them can be found in the official Eclipse Open Message Queue Developer's Guide for Java Clients.

Deployment Planning

Overview

This section explains how to build a production deployment of Payara Server.

Product Concepts

Payara Server provides a robust platform for the development, deployment, and management of Jakarta EE applications. Key features include scalable transaction management, web services performance, clustering, security, and integration capabilities.

Jakarta EE Platform Overview

Payara Server implements Jakarta EE technology. The Jakarta EE platform is a set of standard specifications that describe application components, APIs, and the runtime containers and services of an application server.

Jakarta EE Applications

Jakarta EE applications are made up of components such as JavaServer Pages (JSP), Java servlets, and Enterprise JavaBeans (EJB) modules. These components enable software developers to build large-scale, distributed applications. Developers package Jakarta EE applications in Java Archive (JAR) files (similar to zip files), which can be distributed to production sites. Administrators install Jakarta EE applications onto Payara Server by deploying Jakarta EE JAR files onto one or more server instances (or clusters of instances).

Containers

Each server instance includes two containers: web and EJB. A container is a runtime environment that provides services such as security and transaction management to Jakarta EE components. Web components, such as Java Server Pages and servlets, run within the web container. Enterprise JavaBeans run within the EJB container.

Jakarta EE Services

The Jakarta EE platform provides services for applications, including:

- Naming - A naming and directory service binds objects to names. A Jakarta EE application can locate an object by looking up its Java Naming and Directory Interface (JNDI) name.
- Security - The Java Authorization Contract for Containers (JACC) is a set of security contracts defined for the Jakarta EE containers. Based on the client's identity, containers can restrict access to the container's resources and services.
- Transaction management - A transaction is an indivisible unit of work. For example, transferring funds between bank accounts is a transaction. A transaction management service ensures that a transaction is either completed, or is rolled back.
- Message Service - Applications hosted on separate systems can communicate with each other by exchanging messages using the Java Message Service (JMS). JMS is an integral part of the Jakarta EE platform and simplifies the task of integrating heterogeneous enterprise applications.

Web Services

Clients can access a Jakarta EE application as a remote web service in addition to accessing it through HTTP, RMI/IIOP, and JMS. Web services are implemented using the Java API for XML-based web services (JAX-WS). A Jakarta EE application can also act as a client to web services, which

would be typical in network applications.

Web Services Description Language (WSDL) is an XML format that describes web service interfaces. Web service consumers can dynamically parse a WSDL document to determine the operations a web service provides and how to execute them. Payara Server distributes web services interface descriptions using a registry that other applications can access through the Java API for XML Registries (JAX-R).

Client Access

Clients can access Jakarta EE applications in several ways. Browser clients access web applications using hypertext transfer protocol (HTTP). For secure communication, browsers use the HTTP secure (HTTPS) protocol that uses secure sockets layer (SSL).

Rich client applications running in the Application Client Container can directly look up and access Enterprise JavaBeans using an Object Request Broker (ORB), Remote Method Invocation (RMI) and the internet inter-ORB protocol (IIOP), or IIOP/SSL (secure IIOP). They can access applications and web services using HTTP/HTTPS, JMS, and JAX-WS. They can use JMS to send messages to and receive messages from applications and message-driven beans.

Clients that conform to the Web Services-Interoperability (WS-I) Basic Profile can access Jakarta EE web services. WS-I is an integral part of the Jakarta EE standard and defines interoperable web services. It enables clients written in any supporting language to access web services deployed to Payara Server.

The best access mechanism depends on the specific application and the anticipated volume of traffic. Payara Server supports separately configurable listeners for HTTP, HTTPS, JMS, IIOP, and IIOP/SSL. You can set up multiple listeners for each protocol for increased scalability and reliability.

Jakarta EE applications can also act as clients of Jakarta EE components such as Enterprise JavaBeans modules deployed on other servers, and can use any of these access mechanisms.

External Systems and Resources

On the Jakarta EE platform, an external system is called a resource. For example, a database management system is a JDBC resource. Each resource is uniquely identified and by its Java Naming and Directory Interface (JNDI) name. Applications access external systems through the following APIs and components:

- Java Database Connectivity (JDBC) - A database management system (DBMS) provides facilities for storing, organizing, and retrieving data. Most business applications store data in relational databases, which applications access via JDBC. Payara Server includes the Java DB database for use sample applications and application development and prototyping, though it is not suitable for deployment. Payara Server provides certified JDBC drivers for connecting to major relational databases. These drivers are suitable for deployment.
- Java Message Service - Messaging is a method of communication between software components or applications. A messaging client sends messages to, and receives messages from, any other client via a messaging provider that implements the Java Messaging Service (JMS) API. Payara Server includes a high-performance JMS broker, Open Message Queue.

- Jakarta EE Connectors - The Jakarta EE Connector architecture enables integrating Jakarta EE applications and existing Enterprise Information Systems (EIS). An application accesses an EIS through a portable Jakarta EE component called a connector or resource adapter, analogous to using JDBC driver to access an RDBMS. Resource adapters are distributed as standalone Resource Adapter Archive (RAR) modules or included in Jakarta EE application archives. As RARs, they are deployed like other Jakarta EE components. Payara Server includes evaluation resource adapters that integrate with popular EIS.
- JavaMail - Through the JavaMail API, applications can connect to a Simple Mail Transport Protocol (SMTP) server to send email and to an IMAP or POP3 server to receive email.

Payara Server Components

This section describes the components in Payara Server.

The administration tools, such as the browser-based Administration Console, communicate with the domain administration server (DAS), which in turn communicates with the server instances.

Server Instances

A server instance is a Payara Server running in a single Java Virtual Machine (JVM) process. The supported platforms for Payara Server are described in this following article: Supported Platforms.

It is usually sufficient to create a single server instance on a machine, since Payara Server and accompanying JVM are both designed to scale to multiple processors. However, it can be beneficial to create multiple instances on one machine for application isolation and rolling upgrades. In some cases, a large server with multiple instances can be used in more than one administrative domain. The administration tools makes it easy to create, delete, and manage server instances across multiple machines.

Administrative Domains

An administrative domain (or simply domain) is a group of server instances that are administered together. A server instance belongs to a single administrative domain. The instances in a domain can run on different physical hosts.

You can create multiple domains from one installation of Payara Server. By grouping server instances into domains, different organizations and administrators can share a single Payara Server installation. Each domain has its own configuration, log files, and application deployment areas that are independent of other domains. Changing the configuration of one domain does not affect the configurations of other domains. Likewise, deploying an application on one domain does not deploy it or make it visible to any other domain.

All hosts in a domain on which the DAS and Payara Server instances are running must have the same operating system.

Domain Administration Server (DAS)

A domain has one Domain Administration Server (DAS), a specially designated Payara Server instance that hosts the administrative applications. The DAS authenticates the administrator, accepts requests from administration tools, and communicates with server instances in the domain

to carry out the requests.

The administration tools are the `asadmin` command-line tool and the browser-based Administration Console. Payara Server also provides a REST-ful API for server administration. The administrator can view and manage a single domain at a time, thus enforcing secure separation.

The DAS is also sometimes referred to as the admin server or default server. It is referred to as the default server because it is the default target for some administrative operations.

Since the DAS is a Payara Server instance, it can also host Jakarta EE applications for testing purposes. However, do not use it to host production applications. You might want to deploy applications to the DAS, for example, if the clusters and instances that will host the production application have not yet been created.

The DAS keeps a repository containing the configuration of its domain and all the deployed applications. If the DAS is inactive or down, there is no impact on the performance or availability of active server instances, however administrative changes cannot be made. In certain cases, for security purposes, it may be useful to intentionally stop the DAS process, for example to reboot the host operating system to install a kernel patch or a hardware upgrade.

Administrative commands are provided in order to back up and restore the domain configuration and applications. With the standard backup and restore procedures, you can quickly restore working configurations. If the DAS host fails, you must create a new DAS installation to restore the previous domain configuration. For instructions, see "Administering Domains" in the Payara Server General Administration section.

Clusters

A cluster is a named collection of server instances that share the same applications, resources, and configuration information. You can group server instances on different machines into one logical cluster and administer them as one unit. You can easily control the lifecycle of a multi-machine cluster with the DAS.

Clusters enable horizontal scalability, load balancing, and failover protection. By definition, all the instances in a cluster have the same resource and application configuration. When a server instance or a machine in a cluster fails, the load balancer detects the failure, redirects traffic from the failed instance to other instances in the cluster, and recovers the user session state. Since the same applications and resources are on all instances in the cluster, an instance can fail over to any other instance in the cluster.

All hosts in a cluster on which the DAS and Payara Server instances are running must have the same operating system.

Clusters, domains, and instances are related as follows:

- An administrative domain can have zero or more clusters.
- A cluster has one or more server instances.
- A cluster belongs to a single domain.

Named Configurations

A named configuration is an abstraction that encapsulates Payara Server property settings. Clusters and stand-alone server instances reference a named configuration to get their property settings. With named configurations, Jakarta EE container configurations are independent of the physical machine on which they reside, except for particulars such as IP address, port number, and amount of heap memory. Using named configurations provides power and flexibility to Payara Server administration.

To apply configuration changes, you simply change the property settings of the named configuration, and all the clusters and stand-alone instances that reference it pick up the changes. You can only delete a named configuration when all references to it have been removed. A domain can contain multiple named configurations.

Payara Server comes with a default configuration, called `default-config`. The default configuration is optimized for developer productivity.

You can create your own named configuration based on the default configuration that you can customize for your own purposes. Use the Administration Console and `asadmin` command line utility to create and manage named configurations.

Session Persistence

Jakarta EE applications typically have significant amounts of session state data. A web shopping cart is the classic example of a session state. Also, an application can cache frequently-needed data in the session object. In fact, almost all applications with significant user interactions need to maintain a session state. Both HTTP sessions and stateful session beans (SFSBs) have session state data.

While the session state is not as important as the transactional state stored in a database, preserving the session state across server failures can be important to end users.

Payara Server provides the capability to save, or persist, this session state in a repository. If the Payara Server instance that is hosting the user session experiences a failure, the session state can be recovered. The session can continue without loss of information.

Payara Server supports the following session persistence types:

- `memory`
- `hazelcast` (Data Grid)
- `file`

With `memory` persistence, the state is always kept in memory and does not survive failure.

With `hazelcast` persistence, Payara Server stores session data in the Data Grid, implemented internally using a Hazelcast cluster. For SFSBs, if `hazelcast` persistence is not specified, Payara Server stores state information in the `session-store` subdirectory of its corresponding instance.

Checking an SFSB state for changes that need to be saved is called **checkpointing**. When enabled, checkpointing generally occurs after any transaction involving the SFSB is completed, even if the

transaction rolls back. For more information on developing stateful session beans,see "Using Session Beans" in the Payara Server Application Development section. For more information on enabling SFSB failover, see "Stateful Session Bean Failover" in the Payara Server High Availability section.

Apart from the number of requests being served by Payara Server, the session persistence configuration settings also affect the session information in each request.

For more information on configuring session persistence, see "Configuring High Availability Session Persistence and Failover" in the Payara Server High Availability section.

IIOP Load Balancing in a Cluster

With IIOP load balancing, IIOP client requests are distributed to different server instances or name servers. The goal is to spread the load evenly across the cluster, thus providing scalability. IIOP load balancing combined with EJB clustering and availability features in Payara Server provides not only load balancing but also EJB failover.

There are two steps to IIOP failover and load balancing. The first step, bootstrapping, is the process by which the client sets up the initial naming context with one ORB in the cluster. The client attempts to connect to one of the IIOP endpoints. When launching an application client using the `appclient` script, you specify these endpoints using the `-targetserver` option on the command line or `target-server` elements in the `sun-acc.xml` deployment descriptor. The client randomly chooses one of these endpoints and tries to connect to it, trying other endpoints if needed until one works.

The second step concerns sending messages to a specific EJB. By default, all naming look-ups, and therefore all EJB accesses, use the cluster instance chosen during bootstrapping. The client exchanges messages with an EJB through the client ORB and server ORB. As this happens, the server ORB updates the client ORB as servers enter and leave the cluster. Later, if the client loses its connection to the server from the previous step, the client fails over to some other server using its list of currently active members. In particular, this cluster member might have joined the cluster after the client made the initial connection.

When a client performs a JNDI lookup for an object, the Naming Service creates an InitialContext` (IC) object associated with a particular server instance. From then on, all lookup requests made using that IC object are sent to the same server instance. All `EJBHome` objects looked up with that `InitialContext` are hosted on the same target server. Any bean references obtained henceforth are also created on the same target host. This effectively provides load balancing, since all clients randomize the list of live target servers when creating `InitialContext` objects. If the target server instance goes down, the lookup or EJB method invocation will fail over to another server instance.

Adding or deleting new instances to the cluster does not update the existing client's view of the cluster. You must manually update the endpoints list on the client side.

Message Queue and JMS Resources

The Open Message Queue (MQ) software provides reliable, asynchronous messaging for distributed applications. Message Queue is an enterprise messaging system that implements the Java Message Service (JMS) standard. Message Queue provides messaging for Jakarta EE application components such as message-driven beans (MDBs).

Payara Server implements the Java Message Service (JMS) API by integrating Message Queue into Payara Server. Payara Server includes the Enterprise version of Message Queue which has failover, clustering and load balancing features.

For basic JMS administration tasks, use the Administration Console and `asadmin` command-line utility.

For advanced tasks, including administering a Message Queue cluster, use the tools provided in the `as-install/mq/bin` directory.

For information on deploying JMS applications and Message Queue clustering for message failover, see Planning Message Queue Broker Deployment.

Configuration Roadmap for High Availability of Payara Server

The following procedure lists the major tasks for configuring Payara Server for high availability. The procedure also provides cross-references to detailed instructions for performing each task.

To Configure Payara Server for High Availability

1. Determine your requirements and goals for performance and QoS. For more information, see the following documentation:
    - Establishing Performance Goals
    - Planning the Network Configuration
    - Planning for Availability
2. Size your system. For more information, see Design Decisions.
3. Install Payara Server
4. If you plan to administer your clusters centrally, set up secure shell (SSH) for centralized administration.
5. Configure domains, nodes, clusters/deployment groups, instances, and virtual servers as required.

    For more information, see the following documentation:

    - "Administering Domains" in the Payara Server General Administration section
    - "Administering Payara Server Nodes" in the Payara Server High Availability section
    - "Administering Payara Server Clusters" in the Payara Server High Availability section
    - "Administering Payara Server Instances" in the Payara Server High Availability section
    - "Administering Virtual Servers" in the Payara Server General Administration section
6. Configure your load balancer, tentatively, using Apache Mod JK. For more information, see "Administering mod_jk" in the Payara Server General Administration section.
7. Configure the web container and EJB container for replicated session persistence.
   For more information, see "Configuring High Availability Session Persistence and Failover" in the Payara Server High Availability section.

8. If you are using messaging extensively, configure Java Message Service (JMS) clusters for failover.

   For more information, see the following documentation:

   - Planning Message Queue Broker Deployment
   - "Configuring Java Message Service High Availability" in the Payara Server High Availability section

Planning your Deployment

Before deploying Payara Server, first determine the performance and availability goals, and then make decisions about the hardware, network, and storage requirements accordingly.

Establishing Performance Goals

At its simplest, high performance means maximizing throughput and reducing response time. Beyond these basic goals, you can establish specific goals by determining the following:

- What types of applications and services are deployed, and how do clients access them?
- Which applications and services need to be highly available?
- Do the applications have session state or are they stateless?
- What request capacity or throughput must the system support?
- How many concurrent users must the system support?
- What is an acceptable average response time for user requests?
- What is the average think time between requests?

You can calculate some of these metrics using a remote browser emulator (RBE) tool, or website performance and benchmarking software that simulates expected application activity. Typically, RBE and benchmarking products generate concurrent HTTP requests and then report the response time for a given number of requests per minute. You can then use these figures to calculate server activity.

The results of the calculations described in this chapter are not absolute. Treat them as reference points to work against, as you fine-tune the performance of Payara Server and your applications.

Examples of RBEs include: Puppeteer, Apache JMeter, LoadRunner, Selenium etc.

[[Technical Documentation-Payara Server Documentation-Deployment Planning-Planning your Deployment:::establishing-availability-goals]]

Estimating Throughput

In broad terms, throughput measures the amount of work performed by Payara Server. For Payara Server, throughput can be defined as the number of requests processed per minute per server instance.

As described in the next section, Payara Server throughput is a function of many factors, including

the nature and size of user requests, number of users, performance of Payara Server instances and back-end databases. You can estimate throughput on a single machine by benchmarking with simulated workloads.

High availability applications incur additional overhead because they periodically save session data. The amount of overhead depends on the amount of data, how frequently it changes, and how often it is saved. The first two factors depend on the application in question; the latter is also affected by server settings.

Estimating Load on Payara Server Instances

Consider the following factors to estimate the load on Payara Server instances.

Maximum Number of Concurrent Users

Users interact with an application through a client, such as a web browser or Java program. Based on the user's actions, the client periodically sends requests to the Payara Server. A user is considered active as long as the user's session has neither expired nor been terminated. When estimating the number of concurrent users, include all active users.

Initially, as the number of users increases, throughput increases correspondingly. However, as the number of concurrent requests increases, server performance begins to saturate, and throughput begins to decline.

Identify the point at which adding concurrent users reduces the number of requests that can be processed per minute. This point indicates when optimal performance is reached and beyond which throughput starts to degrade. Generally, strive to operate the system at optimal throughput as much as possible. You might need to add processing power to handle additional load and increase throughput.

Think Time

A user does not submit requests continuously. A user submits a request, the server receives and processes the request, and then returns a result, at which point the user spends some time before submitting a new request. The time between one request and the next is called think time.

Think times are dependent on the type of users. For example, machine-to-machine interaction such as for a web service typically has a lower think time than that of a human user. You may have to consider a mix of machine and human interactions to estimate think time.

Determining the average think time is important. You can use this duration to calculate the number of requests that need to be completed per minute, as well as the number of concurrent users the system can support.

Average Response Time

Response time refers to the amount of time Payara Server takes to return the results of a request to the user. The response time is affected by factors such as network bandwidth, number of users, number and type of requests submitted, and the average think time.

In this section, response time refers to the mean, or average, response time. Each type of request

has its own minimal response time. However, when evaluating system performance, base the analysis on the average response time of all requests.

The faster the response time, the more requests per minute are being processed. However, as the number of users on the system increases, the response time starts to increase as well, even though the number of requests per minute declines.

A system performance graph indicates that after a certain point, requests per minute are inversely proportional to response time. The sharper the decline in requests per minute, the steeper the increase in response time.

The point of the peak load is the point at which requests per minute start to decline. Prior to this point, response time calculations are not necessarily accurate because they do not use peak numbers in the formula. After this point, (because of the inversely proportional relationship between requests per minute and response time), the administrator can more accurately calculate response time using maximum number of users and requests per minute.

Use the following formula to determine $T_{response}$, the response time (in seconds) at peak load:

$T_{response} = n/r - T_{think}$

where

- `n` is the number of concurrent users
- `r` is the number requests per second the server receives
- T_{think} is the average think time (in seconds) to obtain an accurate response time result, always include think time in the equation.

Calculation of Response Time

Consider the following example:

- Assume maximum number of concurrent users, n, is 5,000.
- Assume maximum number of requests, r, 1,000 per second.
- Assume average think time, T_{think}, is three seconds per request.

Thus, the calculation of response time is:

$T_{response} = n/r - T_{think} = (5000/ 1000) - 3 \text{ sec.} = 5 - 3 \text{ sec.}$

Therefore, the response time is two seconds.

After the system's response time has been calculated, particularly at peak load, compare it to the acceptable response time for the application. Response time, along with throughput, is one of the main factors critical to Payara Server performance.

Requests Per Minute

If you know the number of concurrent users at any given time, the response time of their requests, and the average user think time, then you can calculate the number of requests per minute.

Typically, start by estimating the number of concurrent users that are on the system.

For example, after running website performance software, the administrator concludes that the average number of concurrent users submitting requests on an online banking website is `3,000`. This number depends on the number of users who have signed up to be members of the online bank, their banking transaction behavior, the time of the day or week they choose to submit requests, and so on.

Therefore, knowing this information enables you to use the requests per minute formula described in this section to calculate how many requests per minute your system can handle for this user base. Since requests per minute and response time become inversely proportional at peak load, decide if fewer requests per minute is acceptable as a trade-off for better response time, or alternatively, if a slower response time is acceptable as a trade-off for more requests per minute.

Experiment with the requests per minute and response time thresholds that are acceptable as a starting point for fine-tuning system performance. Thereafter, decide which areas of the system require adjustment.

Solving for `r` in the equation in the previous section gives:

$r = n/(T_{response} + T_{think})$

Calculation of Requests Per Second

Consider the following example:

- n = 2,800 concurrent users
- $T_{response}$ = 1 (one second per request average response time)
- T_{think} = 3, (three seconds average think time)

The calculation for the number of requests per second is:

```
r = 2800 / (1+3) = 700
```

Therefore, the number of requests per second is 700 and the number of requests per minute is 42000.

Planning the Network Configuration

When planning how to integrate the Payara Server into the network, estimate the bandwidth requirements and plan the network in such a way that it can meet users' performance requirements.

Estimating Bandwidth Requirements

To decide on the desired size and bandwidth of the network, first determine the network traffic and identify its peak. Check if there is a particular hour, day of the week, or day of the month when overall volume peaks, and then determine the duration of that peak.

During peak load times, the number of packets in the network is at its highest level. In general, if you design for peak load, scale your system with the goal of handling 100 percent of peak volume. Bear in mind, however, that any network behaves unpredictably and that despite your scaling efforts, it might not always be able to handle 100 percent of peak volume.

For example, assume that at peak load, five percent of users occasionally do not have immediate network access when accessing applications deployed on Payara Server. Of that five percent, estimate how many users retry access after the first attempt. Again, not all of those users might get through, and of that unsuccessful portion, another percentage will retry. As a result, the peak appears longer because peak use is spread out over time as users continue to attempt access.

Calculating Bandwidth Required

Based on the calculations made in Establishing Performance Goals, determine the additional bandwidth required for deploying Payara Server at your site.

Depending on the method of access (T-1 lines, ADSL, cable modem, and so on), calculate the amount of increased bandwidth required to handle your estimated load. For example, suppose your site uses T-1 or higher-speed T-3 lines. Given their bandwidth, estimate how many lines are needed on the network, based on the average number of requests generated per second at your site and the maximum peak load. Calculate these figures using a website analysis and monitoring tool.

Calculation of Bandwidth Required

A single T-1 line can handle 1.544 Mbps. Therefore, a network of four T-1 lines can handle approximately 6 Mbps of data. Assuming that the average HTML page sent back to a client is 30 kilobytes (KB), this network of four T-1 lines can handle the following traffic per second:

6,176,000 bits/10 bits = 772,000 bytes per second

772,000 bytes per second/30 KB = approximately 25 concurrent response pages per second.

With traffic of 25 pages per second, this system can handle 90,000 pages per hour (25 x 60 seconds x 60 minutes), and therefore 2,160,000 pages per day maximum, assuming an even load throughout the day. If the maximum peak load is greater than this, increase the bandwidth accordingly.

Estimating Peak Load

Having an even load throughout the day is probably not realistic. You need to determine when the peak load occurs, how long it lasts, and what percentage of the total load is the peak load.

Calculation of Peak Load

If the peak load lasts for two hours and takes up 30 percent of the total load of 2,160,000 pages, this implies that 648,000 pages must be carried over the T-1 lines during two hours of the day.

Therefore, to accommodate peak load during those two hours, increase the number of T-1 lines according to the following calculations:

648,000 pages/120 minutes = 5,400 pages per minute

5,400 pages per minute/60 seconds = 90 pages per second

If four lines can handle 25 pages per second, then approximately four times that many pages requires four times that many lines, in this case 16 lines. The 16 lines are meant for handling the realistic maximum of a 30 percent peak load. Obviously, the other 70 percent of the load can be handled throughout the rest of the day by these many lines.

Planning for Availability

Rightsizing Availability

To plan availability of systems and applications, assess the availability needs of the user groups that access different applications. For example, external fee-paying users and business partners often have higher quality of service (QoS) expectations than internal users. Thus, it may be more acceptable to internal users for an application feature, application, or server to be unavailable than it would be for paying external customers.

There is an increasing cost and complexity to mitigating against decreasingly probable events. At one end of the continuum, a simple load-balanced cluster can tolerate localized application, middleware, and hardware failures. At the other end of the scale, geographically distinct clusters can mitigate against major catastrophes affecting the entire data center.

To realize a good return on investment, it often makes sense to identify availability requirements of features within an application. For example, it may not be acceptable for an insurance quotation system to be unavailable (potentially turning away new business), but brief unavailability of the account management function (where existing customers can view their current coverage) is unlikely to turn away existing customers.

Using Clusters to Improve Availability

At the most basic level, a cluster is a group of Payara Server clients as a single instance. This provides horizontal scalability as well as higher availability than a single instance on a single machine. The ORB and integrated JMS brokers also perform load balancing to Payara Server clusters. If an instance fails, becomes unavailable (due to network faults), or becomes unresponsive, requests are redirected only to existing, available machines.

Adding Redundancy to the System

One way to achieve high availability is to add hardware and software redundancy to the system. When one unit fails, the redundant unit takes over. This is also referred to as fault tolerance. In general, to maximize high availability, determine and remove every possible point of failure in the system.

Identifying Failure Classes

The level of redundancy is determined by the failure classes (types of failure) that the system needs to tolerate. Some examples of failure classes are:

- System process
- Machine

- Power supply
- Disk
- Network failures
- Building fires or other preventable disasters
- Unpredictable natural catastrophes

Duplicated system processes tolerate single system process failures, as well as single machine failures. Attaching the duplicated mirrored (paired) machines to different power supplies tolerates single power failures. By keeping the mirrored machines in separate buildings, a single-building fire can be tolerated. By keeping them in separate geographical locations, natural catastrophes like earthquakes can be tolerated.

Planning Failover Capacity

Failover capacity planning implies deciding how many additional servers and processes you need to add to the Payara Server deployment so that in the event of a server or process failure, the system can seamlessly recover data and continue processing. If your system gets overloaded, a process or server failure might result, causing response time degradation or even total loss of service. Preparing for such an occurrence is critical to successful deployment.

To maintain capacity, especially at peak loads, add spare machines running Payara Server instances to the existing deployment.

For example, consider a system with two machines running one Payara Server instance each. Together, these machines handle a peak load of 300 requests per second. If one of these machines becomes unavailable, the system will be able to handle only 150 requests, assuming an even load distribution between the machines. Therefore, half the requests during peak load will not be served.

Design Decisions

Design decisions include whether you are designing the system for peak or steady-state load, the number of machines in various roles and their sizes, and the size of the administration thread pool.

Designing for Peak or Steady State Load

In a typical deployment, there is a difference between steady state and peak workloads:

- If the system is designed to handle peak load, it can sustain the expected maximum load of users and requests without degrading response time. This implies that the system can handle extreme cases of expected system load. If the difference between peak load and steady state load is substantial, designing for peak loads can mean spending money on resources that are often idle.
- If the system is designed to handle steady state load, it does not have all the resources required to handle the expected peak load. Thus, the system has a slower response time when peak load occurs.

How often the system is expected to handle peak load will determine whether you want to design

for peak load or for steady state.

If peak load occurs often (let's say, several times per day), it may be worthwhile to expand capacity to handle it. If the system operates at steady state 90 percent of the time, and at peak only 10 percent of the time, then it may be preferable to deploy a system designed around steady state load. This implies that the system's response time will be slower only 10 percent of the time. Decide if the frequency or duration of time that the system operates at peak justifies the need to add resources to the system.

System Sizing

Based on the load on the Payara Server instances and failover requirements, you can determine the number of applications server instances (hosts) needed. Evaluate your environment on the basis of the factors explained in Estimating Load on Payara Server Instances to each Payara Server instance, although each instance can use more than one Central Processing Unit (CPU).

Sizing the Administration Thread Pool

The default `admin-thread-pool` size of 50 should be adequate for most cluster deployments. If you have unusually large clusters, you may need to increase this thread pool size. In this case, set the `max-thread-pool-size` attribute to the number of instances in your largest cluster, but not larger than the number of incoming synchronization requests that the DAS can handle.

Planning Message Queue Broker Deployment

The Jakarta Messaging (JMS) API is a messaging standard that allows Jakarta EE applications and components to create, send, receive, and read messages. It enables distributed communication that is loosely coupled, reliable, and asynchronous. Message Queue, which implements JMS, is integrated with Payara Server, enabling you to create components that send and receive JMS messages, including message-driven beans (MDBs).

Message Queue is integrated with Payara Server using a resource adapter also known as a connector module. A resource adapter is a Jakarta EE component defined according to the Jakarta Connectors (JCA) Specification. This specification defines a standardized way in which application servers such as Payara Server can integrate with enterprise information systems such as JMS providers. Payara Server includes a resource adapter that integrates with its own JMS provider, Message Queue. To use a different JMS provider, you must obtain and deploy a suitable resource adapter that is designed to integrate with it.

Creating a JMS resource in Payara Server using the Administration Console creates a reconfigured connector resource that uses the Message Queue resource adapter. To create JMS Resources that use any other resource adapter (including `GenericJMSRA`), you must create them under the Connectors node in the Administration Console.

In addition to using resource adapter APIs, Payara Server uses additional Message Queue APIs to provide better integration with Message Queue. This tight integration enables features such as connector failover, load balancing of outbound connections, and load balancing of inbound messages to MDBs. These features enable you to make messaging traffic fault-tolerant and highly available.

Multi-Broker Clusters

Message Queue supports using multiple interconnected broker instances known as a broker cluster. With broker clusters, client connections are distributed across all the brokers in the cluster. Clustering provides horizontal scalability and improves availability.

A single message broker scales to about eight CPUs and provides sufficient throughput for typical applications. If a broker process fails, it is automatically restarted. However, as the number of clients connected to a broker increases, and as the number of messages being delivered increases, a broker will eventually exceed limitations such as number of file descriptors and memory.

Having multiple brokers in a cluster rather than a single broker enables you to:

- Provide messaging services despite hardware failures on a single machine.
- Minimize downtime while performing system maintenance.
- Accommodate workgroups having different user repositories.
- Deal with firewall restrictions.

Message Queue allows you to create conventional or enhanced broker clusters. Conventional broker clusters offer service availability. Enhanced broker clusters offer both service and data availability.

In a conventional cluster, having multiple brokers does not ensure that transactions in progress at the time of a broker failure will continue on the alternate broker. Although Message Queue reestablishes a failed connection with a different broker in a cluster, transactions owned by the failed broker are not available until it restarts. Except for failed in-progress transactions, user applications can continue on the failed-over connection. Service failover is thus ensured.

In an enhanced cluster, transactions and persistent messages owned by the failed broker are taken over by another running broker in the cluster and non-prepared transactions are rolled back. Data failover is ensured for prepared transactions and persisted messages.

Master Broker and Client Synchronization for Conventional Clusters

In a configuration for a conventional broker cluster, each destination is replicated on all the brokers in a cluster. Each broker knows about message consumers that are registered for destinations on all other brokers. Each broker can therefore route messages from its own directly-connected message producers to remote message consumers, and deliver messages from remote producers to its own directly-connected consumers.

In a cluster configuration, the broker to which each message producer is directly connected performs the routing for messages sent to it by that producer. Hence, a persistent message is both stored and routed by the message's home broker.

Whenever an administrator creates or destroys a destination on a broker, this information is automatically propagated to all other brokers in a cluster. Similarly, whenever a message consumer is registered with its home broker, or whenever a consumer is disconnected from its home broker—either explicitly or because of a client or network failure, or because its home broker goes down—the relevant information about the consumer is propagated throughout the cluster. In a

similar fashion, information about durable subscriptions is also propagated to all brokers in a cluster.

A shared database of cluster change records can be configured as an alternative to using a master broker. For more information, "Using Message Queue Broker Clusters With Payara Server" in the Payara Server High Availability section.

Configuring Payara Server to Use Message Queue Brokers

By default, Message Queue brokers (JMS hosts) run in the same JVM as the Payara Server process. However, Message Queue brokers (JMS hosts) can be configured to run in a separate JVM from the Payara Server process. This allows multiple Payara Server instances or clusters to share the same set of Message Queue brokers.

The Payara Server's Java Message Service represents the connector module (resource adapter) for Message Queue. You can manage the Java Message Service through the Administration Console or the `asadmin` command-line utility.

In Payara Server, a JMS host refers to a Message Queue broker. The Payara Server's Java Message Service configuration contains a JMS Host List (also called AddressList) that contains all the JMS hosts that will be used.

Java Message Service Type

There are three types of integration between Payara Server and Message Queue brokers: `embedded`, `local`, and `remote`. You can set this type attribute on the Administration Console's Java Message Service page.

Embedded Java Message Service

If the Type attribute is `EMBEDDED`, Payara Server and the JMS broker are co-located in the same virtual machine. The JMS Service is started in-process and managed by Payara Server. In `EMBEDDED` mode, JMS operations on stand-alone server instances bypass the networking stack, which leads to performance optimization. The `EMBEDDED` type is most suitable for stand-alone Payara Server instances. `EMBEDDED` mode is not supported for enhanced broker clusters and not recommended for production environments.

With the `EMBEDDED` type, use the **Start Arguments** attribute to specify Message Queue broker startup parameters.

With the `EMBEDDED` type, make sure the Java heap size is large enough to allow Payara Server and Message Queue to run in the same virtual machine.

Local Java Message Service

If the Type attribute is `LOCAL`, Payara Server starts and stops the Message Queue broker. When Payara Server starts up, it starts the Message Queue broker specified as the Default JMS host. Likewise, when the Payara Server instance shuts down, it shuts down the Message Queue broker. The `LOCAL` type is most suitable for use with enhanced broker clusters, and for other cases where the administrator prefers the use of separate JVMs.

With the `LOCAL` type, use the **Start Arguments** attribute to specify Message Queue broker startup parameters.

Remote Java Message Service

If the Type attribute is `REMOTE`, Payara Server uses an externally configured broker or broker cluster. In this case, you must start and stop Message Queue brokers separately from Payara Server, and use Message Queue tools to configure and tune the broker or broker cluster. The `REMOTE` type is most suitable for brokers running on different machines from the server instances (to share the load among more machines or for higher availability), or for using a different number of brokers and server instances.

With the `REMOTE` type, you must specify Message Queue broker startup parameters using the Message Queue tools. The **Start Arguments** attribute is ignored.

Managing JMS with the Administration Console

In the Administration Console, you can set JMS properties using the Java Message Service node for a particular configuration. You can set properties such as **Reconnect Interval** and **Reconnect Attempts**. For more information, see "Administering the Java Message Service (JMS)" in the Payara Server General Administration section.

The JMS Hosts node under the Java Message Service node contains a list of JMS hosts. You can add and remove hosts from the list. For each host, you can set the host name, port number, and the administration username and password. By default, the JMS Hosts list contains one Message Queue broker, called `default_JMS_host`, that represents the local Message Queue broker integrated with Payara Server.

In `REMOTE` mode, configure the JMS Hosts list to contain all the Message Queue brokers in the cluster. For example, to set up a cluster containing three Message Queue brokers, add a JMS host within the Java Message Service for each one. Message Queue clients use the configuration information in the Jakarta Messaging system to communicate with the Message Queue broker.

Managing JMS with asadmin

In addition to the Administration Console, you can use the `asadmin` command-line utility to manage the Java Message Service and JMS hosts. Use the following `asadmin` commands:

- Configuring Java Message Service attributes: `asadmin set`
- Managing JMS hosts:
  - `asadmin create-jms-host`
  - `asadmin delete-jms-host`
  - `asadmin list-jms-hosts`
- Managing JMS resources:
  - `asadmin create-jms-resource`
  - `asadmin delete-jms-resource`
  - `asadmin list-jms-resources`

Default JMS Host

You can specify the default JMS Host in the Administration Console Java Message Service page. If the Java Message Service type is `LOCAL`, Payara Server starts the default JMS host when the Payara Server instance starts. If the Java Message Service type is `EMBEDDED`, the default JMS host is started lazily when needed.

In `REMOTE` mode, to use a Message Queue broker cluster, delete the default JMS host, then add all the Message Queue brokers in the cluster as JMS hosts. In this case, the default JMS host becomes the first JMS host in the JMS host list.

You can also explicitly set the default JMS host to one of the JMS hosts. When the Payara Server uses a Message Queue cluster, the default JMS host executes Message Queue-specific commands. For example, when a physical destination is created for a Message Queue broker cluster, the default JMS host executes the command to create the physical destinations, but all brokers in the cluster use the physical destination.

Example Deployment Scenarios

To accommodate your messaging needs, modify the Java Message Service and JMS host list to suit your deployment, performance, and availability needs. The following sections describe some typical scenarios.

For best availability, deploy Message Queue brokers and Payara Servers on different machines, if messaging needs are not just with Payara Server. Another option is to run a Payara Server instance and a Message Queue broker instance on each machine until there is sufficient messaging capacity.

Default Deployment

Installing the Payara Server automatically creates a domain administration server (DAS). By default, the Java Message Service type for the DAS is `EMBEDDED`. So, starting the DAS also starts its default Message Queue broker.

Creating a new domain also creates a new broker. By default, when you add a stand-alone server instance or a cluster to the domain, its Java Message Service is configured as `EMBEDDED` and its default JMS host is the broker started by the DAS.

Using a Message Queue Broker Cluster with a Payara Server Cluster

In `EMBEDDED` or `LOCAL` mode, when a Payara Server is configured, a Message Queue broker cluster is autoconfigured with each Payara Server instance associated with a Message Queue broker instance.

In `REMOTE` mode, to configure a Payara Server cluster to use a Message Queue broker cluster, add all the Message Queue brokers as JMS hosts in the Payara Server's Java Message Service. Any JMS connection factories created and MDBs deployed then uses the JMS configuration specified.

Specifying an Application-Specific Message Queue Broker Cluster

In some cases, an application may need to use a different Message Queue broker cluster than the one used by the Payara Server cluster. To do so, use the `AddressList` property of a JMS connection factory or the `activation-config` element in an MDB deployment descriptor to specify the Message

Queue broker cluster.

For more information about configuring connection factories, see "Administering JMS Connection Factories and Destinations" in the Payara Server Administration section. For more information about MDBs, see "Using Message-Driven Beans" in the Payara Server Application Development section.

Application Clients

When an application client or standalone application accesses a JMS administered object for the first time, the client JVM retrieves the Java Message Service configuration from the server. Furthermore, changes to the JMS service will not be available to the client JVM until it is restarted.

Checklist for Deployment

This appendix provides a checklist to get started on evaluation and production using Payara Server.

Checklist

This table provides a checklist of the steps to be performed before deploying an application to production.

Table 14. Checklist

Component/Feature	Description
Application	Determine the following requirements for the application to be deployed. • Required/acceptable response time. • Peak load characteristics. • Necessary persistence scope and frequency. • Session timeout in `web.xml`. • Fail-over and availability requirements.
Hardware	• Have necessary amounts of hard disk space and memory installed. • Use the sizing exercise to identify the requirements for deployment.
Operating System	• Ensure that the product is installed on a supported platform. • Ensure that the patch levels are up-to-date and accurate.
Network Infrastructure	• Identify single points of failures and address them. • Make sure that the NICs and other network components are correctly configured. • Run `ttcp` benchmark test to determine if the throughput meets the requirements/expected result. • Setup `ssh` based on your preference.

Component/Feature	Description
Back-ends and other external data sources	Check with the domain expert or vendor to ensure that these data sources are configured appropriately.
System Changes/Configuration	• Make sure that changes to `/etc/system` and its equivalent on Windows are completed before running any performance/stress tests. • Make sure the changes to the TCP/IP settings are complete. • By default, the system comes with lots of services pre-configured. Not all of them are required to be running. Turn off services that are not needed to conserve system resources.
Installation	• Ensure that these servers are not installed on NFS mounted volumes. • Check for enough disk space and RAM when installing Payara Server.
Payara Server Configuration	• Logging: Enable access log rotation. • Choose the right logging level. `WARNING` is usually appropriate. • Configure Jakarta EE containers using the Administration Console. • Configure HTTP listeners using the Administration Console. • Configure ORB thread pool using the Administration Console. • Ensure that the appropriate persistence scope and frequency are used, and they are not overridden underneath in the individual Web/EJB modules. • Ensure that only critical methods in the SFSB are checkpointed.
Java Virtual Machine Configuration	• Initially set the minimum and maximum heap sizes to be the same, and at least one GB for each instance. • See Java Hotspot VM Options for more information. • When running multiple instances of Payara Server, consider creating a processor set and bind Payara Server to it. This helps in cases where the CMS collector is used to sweep the old generation.

Component/Feature	Description

Configuring time-outs in Payara Server	`max-wait-time-millis`
	Wait time to get a connection from the pool before throwing an exception. Default is 6s. Consider changing this value for highly loaded systems where the size of the data being persisted is greater than 50 KB.
	
	`cache-idle-timeout-in-seconds`
	Time an EJB is allowed to be idle in the cache before it gets passivated. Applies only to entity beans and stateful session beans.
	
	`removal-timeout-in-seconds`
	Time that an EJB remains passivated (idle in the backup store). Default value is 60 minutes. Adjust this value based on the need for SFSB failover.

Tune VM Garbage Collection (GC)	Garbage collection pauses of four seconds or more can cause intermittent problems in persisting session state. To avoid this problem, tune the VM heap. In cases where even a single failure to persist data is unacceptable or when the system is not fully loaded, use the CMS collector or the throughput collector. These can be enabled by adding: `<jvm-options>-XX:+UseConcMarkSweepGC</jvm-options>` This option may decrease throughput.

Application Deployment

Overview

Payara Server provides an environment for developing and deploying Jakarta applications and web services. Payara Server applications include Jakarta Platform, Enterprise Edition (Jakarta EE platform) standard features as well as features specific to Payara Server. This guide explains the tools and processes used for deploying applications and modules in the Payara Server environment. Only Payara Server features are described in detail in this document.

Information and instructions on deploying from the command line are provided in this document. Information and instructions for accomplishing the deployment tasks by using the Administration Console are contained in the Administration Console online help.

About Application Deployment

Assembly, also known as packaging, is the process of combining discrete components of an application or module into a single unit that can be installed on an application server. The Payara Server assembly process conforms to the customary Jakarta EE specifications. The only difference is that when you assemble applications or modules in Payara Server, you can include optional

Payara Server deployment descriptors that enhance functionality.

Deployment is the process of installing an application or module on Payara Server, optionally specifying location-specific information, such as a list of local users that can access the application, or the name of the local database. Payara Server deployment tools expand the archive file into an open directory structure that is ready for users. Payara Server deployment tools are described in About Deployment Tools.

The following topics are addressed here:

- General Deployment Functionality
- Deployment Descriptors and Annotations
- Modules and Applications
- Access to Shared Framework Classes
- Naming Standards
- Module and Application Versions

General Deployment Functionality

Various Jakarta EE module types, such as connector module, web module, EJB module, application client module, can be deployed in the following ways:

- Archive Deployment. Deploys the application as an archive file. For instructions, see To Deploy an Application or Module.
- Dynamic Reloading. Redeploys the application by creating or modifying a special `.reload` file in the **applications** repository. For instructions, see To Reload Changes to Applications or Modules Dynamically.
- Automatic Deployment. Deploys the application archive that is placed in the `autodeployment` directory. For instructions, see To Deploy an Application or Module Automatically.
- Directory Deployment. Deploys the application in a directory format. For instructions, see To Deploy an Application or Module in a Directory Format.

A deployment plan, which deploys a portable archive along with a deployment plan containing Payara Server deployment descriptors, can apply to any of these deployment techniques. For instructions, see To Deploy an Application or Module by Using a Deployment Plan.

There are two work situations that require different safeguards and processes:

- A development environment provides a loose set of tools and work spaces for a relatively small number of developers who are creating and testing applications and modules.
- A production environment provides a stable, protected environment where applications are tuned to maximum efficiency for business use rather than for development.

Some deployment methods that are used effectively in a development environment should not be used in production. In addition, whenever a reload is done, the sessions that are in transit become invalid, which might not be a concern for development, but can be a serious matter in production. The client must restart the session, another negative in a production environment.

For production environments, any upgrade should be performed as a **rolling upgrade**, which upgrades applications and modules without interruption in service.

Deployment Descriptors and Annotations

A deployment descriptor is an XML file that describes how a Jakarta EE application or module should be deployed. Each deployment descriptor XML file has a corresponding Document Type Definition (DTD) file or schema (XSD) file, which defines the elements, data, and attributes that the deployment descriptor file can contain. The deployment descriptor directs a deployment tool to deploy a module or application with specific container options, and also describes specific configuration requirements that you must resolve.

Because the information in a deployment descriptor is declarative, it can be changed without requiring modifications to source code. During deployment, Payara Server reads the information in the deployment descriptor and deploys the application or module as directed.

The following types of deployment descriptors are associated with Payara Server:

- **Jakarta EE Standard Descriptors**. Jakarta EE standard deployment descriptors are described in the Jakarta EE specification. You can find the specification at `https://jakarta.ee/specifications/`. Information about the XML schemas that define Jakarta EE standard deployment descriptors is available at `https://jakarta.ee/xml/ns/jakartaee/`.

  The Jakarta EE specification permits the use of alternate top-level standard deployment descriptors that reside outside the application archive using the `alt-dd` mechanism (alternate module-level deployment descriptors were permitted prior to Java EE 7). Alternate deployment descriptors are described in the Jakarta EE specification. You can find the specification at `https://jakarta.ee/specifications/`. Alternate deployment descriptors override the top-level deployment descriptors packaged in an application archive.

  For example, for EAR files, an alternate deployment descriptor overrides `application.xml`.

  For standalone modules, an alternate deployment descriptor overrides the top-level module descriptor, such as `web.xml`.

- **Payara Server Descriptors**. Payara Server provides optional deployment descriptors for configuring features that are specific to Payara Server. For example, when you assemble an EJB module, you annotate or create two Payara Server deployment descriptor files with these names: `ejb-jar.xml` and `glassfish-ejb-jar.xml`.

  For complete descriptions of these files and their elements, see Payara Server Deployment Descriptor Files and Elements of the Payara Server Deployment Descriptors.

  Payara Server also permits the use of alternate top-level Payara Server runtime deployment descriptors that reside outside an application archive. Alternate Payara Server deployment descriptors override the top-level deployment descriptors packaged in the archive.

  For example, for EAR files, an alternate Payara Server deployment descriptor overrides `payara-application.xml`. For standalone modules, an alternate Payara Server deployment descriptor overrides the top-level module descriptor, such as `payara-web.xml`. The name of the Payara

Server alternate deployment descriptor file must begin with `payara-`.

Alternate deployment descriptors do not apply to `sun-*.xml` deployment descriptors.

Unless otherwise stated, settings in the Payara Server deployment descriptors override corresponding settings in the Jakarta EE standard descriptors and in the Payara Server configuration.

An annotation, also called metadata, enables a declarative style of programming. You can specify information within a class file by using annotations.

When the application or module is deployed, the information can either be used or overridden by the deployment descriptor. Payara Server supports annotation according to the following specifications:

- Jakarta Annotations
- Jakarta Web Services Metadata
- Jakarta Enterprise Beans

The following annotation and deployment descriptor combinations are supported:

- Jakarta EE applications or modules can be packaged with full Jakarta EE compliant standard and runtime deployment descriptors. If the standard deployment descriptors have specified the `metadata-complete` attribute, annotations in the application or module are ignored.
- Jakarta EE applications or modules can be fully annotated with metadata defined by the listed specifications. Annotation eliminates the need for Jakarta EE standard deployment descriptors. In most cases, the Payara Server deployment descriptors are also not needed.
- Jakarta EE applications or modules can be partially annotated with some deployment information in standard deployment descriptors. In case of conflicts, deployment descriptor values supersede the annotated metadata, and a warning message is logged.

Modules and Applications

An application is a logical collection of one or more modules joined by application annotations or deployment descriptors. You assemble components into JAR, WAR, or RAR files, then combine these files and, optionally, deployment descriptors into an Enterprise archive (EAR) file which is deployed.

A module is a collection of one or more Jakarta EE components that run in the same container type, such as a web container or EJB container. The module uses annotations or deployment descriptors of that container type. You can deploy a module alone or as part of an application.

The following topics are addressed here:

- Types of Modules
- Module-Based Deployment
- Application-Based Deployment

Types of Modules

Payara Server supports the following types of modules:

- **Web Module**. A web module, also known as a web application, is a collection of servlets, EJBs, HTML pages, classes, and other resources that you can bundle and deploy to several Jakarta EE application servers. A web application archive (WAR) file is the standard format for assembling web applications. A WAR file can consist of the following items: servlets, Jakarta Server Pages (JSP) files, JSP tag libraries, utility classes, static pages, client-side applets, beans, bean classes, enterprise bean classes, plus annotations or web deployment descriptors (`web.xml` and `payara-web.xml`).
- **EJB Module**. An EJB module is a deployable software unit that consists of one or more enterprise beans, plus an EJB deployment descriptor. A Java archive (JAR) file is the standard format for assembling enterprise beans. An EJB JAR file contains the bean classes (home, remote, local, and implementation), all of the utility classes, and annotations or deployment descriptors (`ejb-jar.xml` and `glassfish-ejb-jar.xml`).
- **Connector Module**. A connector module, also known as a resource adapter module, is a deployable software unit that provides a portable way for EJB components to access foreign enterprise information system (EIS) data. A connector module consists of all Jakarta interfaces, classes, and native libraries for implementing a resource module, plus a resource deployment descriptor. A resource adapter archive (RAR) is the standard format for assembling connector modules. Each Payara Server connector has annotations or a deployment descriptor file (`ra.xml`).

  After deploying a Jakarta EE connector module, you must configure it as described in Developing Connectors in the Payara Server Application Development section.

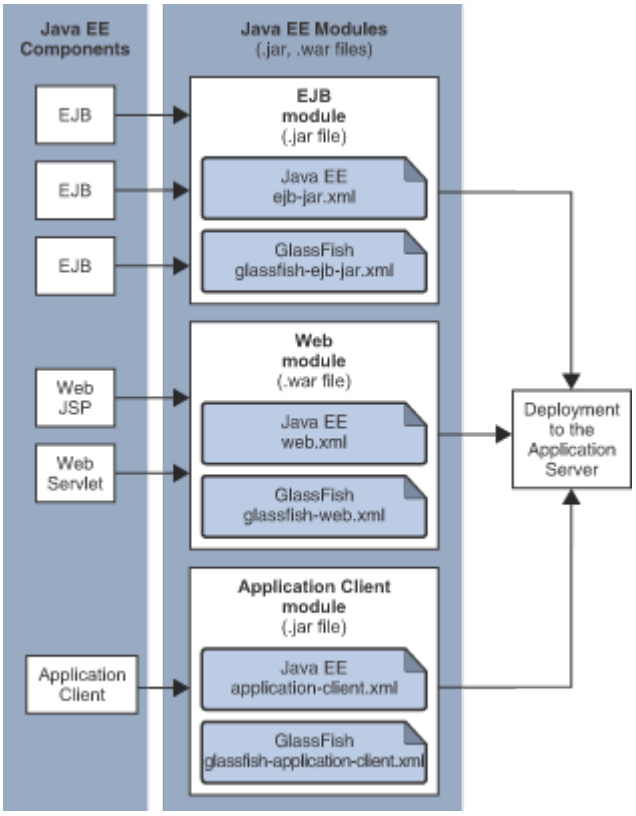
- **Application Client Module**. An application client module is a deployable software unit that consists of one or more classes, and application client deployment descriptors (`application-client.xml` and `payara-application-client.xml`). An application client JAR file applies to a Payara Server type of Jakarta EE client. An application client supports the standard Jakarta EE Application Client specifications.

Module-Based Deployment

You can deploy web, EJB, and application client modules separately, outside any application. Module-based deployment is appropriate when components need to be accessed by other modules, applications, or application clients. Module-based deployment allows shared access to a bean from a web, EJB, or application client component.

The following figure shows separately-deployed EJB, web, and application client modules.

[[Technical Documentation-Payara Server Documentation-Application Deployment-Overview:::figure-1-1-module-based-assembly-and-deployment]#Technical Documentation-Payara Server Documentation-Application Deployment-Overview:::figure-1-1-module-based-assembly-and-deployment] .**Figure 1-1 Module-Based Assembly and Deployment**

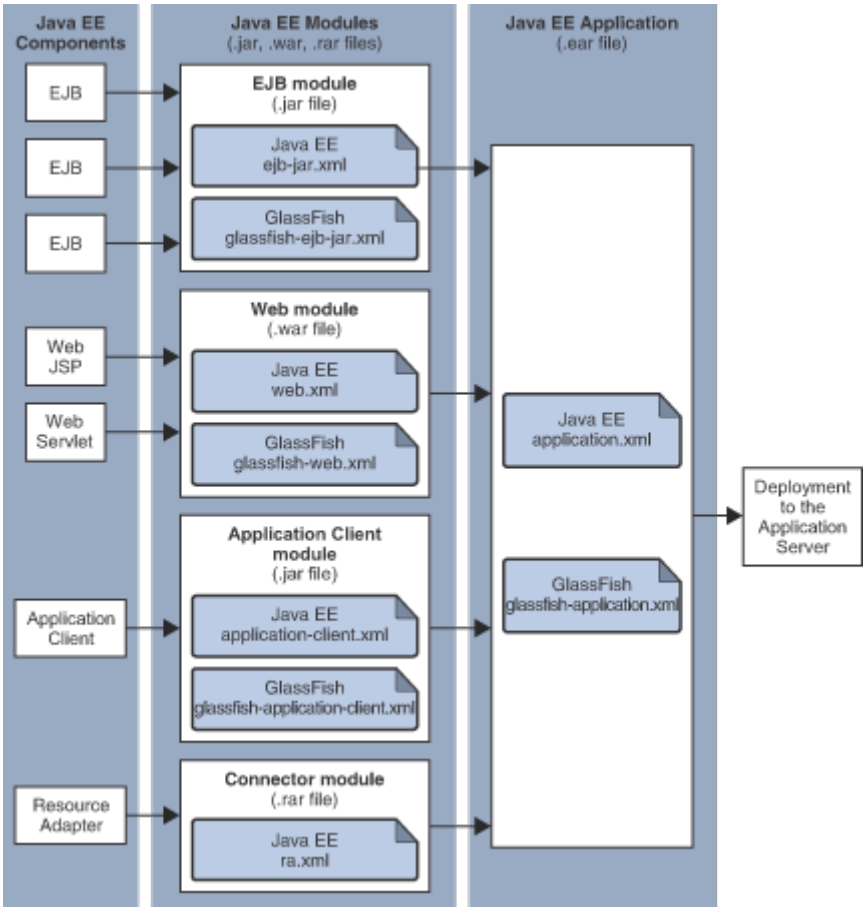


Application-Based Deployment

Application-based deployment is appropriate when components need to work together as one unit.

The following figure shows EJB, web, application client, and connector modules assembled into a Jakarta EE application.

[[Technical Documentation-Payara Server Documentation-Application Deployment-Overview:::figure-1-2-application-based-assembly-and-deployment]#Technical Documentation-Payara Server Documentation-Application Deployment-Overview:::figure-1-2-application-based-assembly-and-deployment] .**Figure 1-2 Application-Based Assembly and Deployment**



Access to Shared Framework Classes

If you assemble a large, shared library into every module that uses it, the result is a huge file that takes too long to register with the server. In addition, several versions of the same class could exist in different class loaders, which is a waste of resources. When Jakarta EE applications and modules use shared framework classes (such as utility classes and libraries), the classes can be put in the path for the common class loader or an application-specific class loader rather than in an application or module.

To specify an application-specific library file during deployment, use the `--libraries` option of the `deploy` or `redeploy` subcommand of the `asadmin` command. To add a library JAR file to the Common class loader directory, the Jakarta optional package directory, or the application-specific class loader directory, use the `add-library` subcommand. You can then list the libraries with `list-libraries` and remove the libraries with `remove-library`. For more information about all these commands, see the Payara Server Reference Manual.

For more information about class loaders, see Class Loaders in the Payara Server Application Development section.

According to the Jakarta EE specification, you cannot package utility classes within an individually-deployed EJB module. Instead, you must package the EJB module and utility JAR within an application using the JAR Extension Mechanism Architecture.

Naming Standards

Names of applications and individually-deployed modules must be unique within a Payara Server domain. Modules within an application must have unique names.

You should use a hierarchical naming scheme for module file names, EAR file names, module names as found in the `module-name` portion of the `ejb-jar.xml` files, and EJB names as found in the `ejb-name` portion of the `ejb-jar.xml` files. This hierarchical naming scheme ensures that name collisions do not occur. The benefits of this naming practice apply not only to Payara Server, but to other Jakarta EE application servers as well.

The following topics are addressed here:

- Portable Naming
- JNDI Naming
- Directory Structure

Portable Naming

The Jakarta EE specification defines the portable `application-name`, which allows you to specify an application name in the `application.xml` file.

For example:

```
<application-name>xyz</application-name>
```

The Jakarta EE specification also defines the portable `module-name` element in the module standard deployment descriptors.

Payara Server determines the application registration name according to the following order of precedence:

1. The name specified at deployment time in the Administration Console or in the `--name` option of the `asadmin deploy` command is used.
2. If no name is specified at deployment time, the portable `application-name` or `module-name` in the Jakarta EE deployment descriptor is used.
3. If no name is specified at deployment time or in the deployment descriptors, the archive name, minus the file type suffix, is used.

Deploying from an IDE

When deploying an application or a module on Payara Server from an IDE (like **Apache NetBeans** or **IntelliJ Idea**), the IDE deploys to Payara Server using the asadmin deploy command, with the `--name` option specified.

This will force the application or module to have the specified name over the name defined in deployment descriptor. This is undesired because the IDE usually infers the application or module name from the name of the project or the package file and doesn't take the correct name of the

application or module into account.

To solve the issue, application or module name defined in the deployment descriptor will **always** take precedence over the `--name` option. But you use the `--name` and `--forcename` options to override this behaviour.

JNDI Naming

Jakarta Naming and Directory Interface (JNDI) lookup names for EJB components must also be unique. Establishing a consistent naming convention can help. For example, appending the application name and the module name to the EJB name is a way to guarantee unique names, such as, `jms/qConnPool`.

Directory Structure

Application and module directory structures must follow the structure outlined in the Jakarta EE specification. During deployment, the application or module is expanded from the archive file to an open directory structure. The directories that hold the individual modules are named with `_jar`, `_rar`, and `_war` suffixes.

If you deploy a directory instead of an EAR file, your directory structure must follow this same convention. For instructions on performing directory deployment, see To Deploy an Application or Module in a Directory Format.

Module and Application Versions

Application and module versioning allows multiple versions of the same application to exist in a Payara Server domain, which simplifies upgrade and rollback tasks. At most one version of an application or module can be enabled on a server any given time. Versioning provides extensions to tools for deploying, viewing, and managing multiple versions of modules and applications, including the Administration Console and deployment-related `asadmin` subcommands. Different versions of the same module or application can have the same context root or JNDI name. Use of versioning is optional.

The following topics are addressed here:

- Version Identifiers and Expressions
- Choosing the Enabled Version
- Versioning Restrictions and Limitations

Version Identifiers and Expressions

The version identifier is a suffix to the module or application name. It is separated from the name by a colon (`:`). It must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. The following examples show valid version identifiers for the `foo` application:

```
foo:1
foo:BETA-2e
```

```
foo:3.8
foo:patch39875
```

A module or application without a version identifier is called the untagged version. This version can coexist with other versions of the same module or application that have version identifiers.

In some deployment-related `asadmin` commands, you can use an asterisk (`*`) as a wildcard character to specify a version expression, which selects multiple version identifiers. Using the asterisk by itself after the colon selects all versions of a module or application, including the untagged version. The following table shows example version expressions and the versions they select.

Version Expression	Selected Versions
`foo:*`	All versions of `foo`, including the untagged version
`foo:BETA*`	All `BETA` versions of `foo`
`foo:3.*`	All `3.`x versions of `foo`
`foo:patch*`	All `patch` versions of `foo`

The following table summarizes which `asadmin` subcommands are identifier-aware or expression-aware. All expression-aware subcommands are also identifier-aware.

Identifier-Aware Subcommands	Expression-Aware Subcommands
`deploy`, `redeploy`	`undeploy`
`enable`	`disable`
`list-sub-components`	`show-component-status`
`get-client-stubs`	`create-application-ref`, `delete-application-ref`

The `create-application-ref` subcommand is expression-aware only if the `--enabled` option is set to `false`. Because the `--enabled` option is set to `true` by default, the create-application-ref` subcommand is identifier-aware by default.

The `list-applications` and `list-application-refs` subcommands display information about all deployed versions of a module or application. To find out which version is enabled, use the `--long` option.

Choosing the Enabled Version

At most one version of a module or application can be enabled on a server instance. All other versions are disabled. Enabling one version automatically disables all others. You can disable all versions of a module or application, leaving none enabled.

The `--enabled` option of the `deploy` and `redeploy` subcommands is set to `true` by default. Therefore, simply deploying or redeploying a module or application with a new version identifier enables the new version and disables all others. To deploy a new version in a disabled state, set the `--enabled` option to `false`.

To enable a version that has been deployed previously, use the `enable` subcommand.

Versioning Restrictions and Limitations

Module and application versioning in Payara Server is subject to the following restrictions and limitations:

- Use of the `--name` option is mandatory for modules and applications that use versioning. There is no automatic version identifier generation.
- Payara Server does not recognize any relationship between versions such as previous or later versions. All version relationships must be tracked manually.
- There is no limit to the number of versions you can deploy except what is imposed by disk space limits.
- A module or application in a directory should not be deployed twice with a different version identifier. To redeploy a module or application from a directory with a new version, you must use the `--force` option of the `deploy` subcommand.
- Database tables created or deleted as part of deployment and un-deployment are global resources and cannot be qualified by an application version. Be very careful when using global resources among versions of the same application.
- Web sessions are preserved during redeployment of a new version. However, preserving sessions among different versions of the same module or application is complex, because the key used for session variables is the same for the old and new versions.
- Resources are created with reference to a resource-adapter's module or application name. This means that an older version's resources do not automatically refer to a newer version of the module or application. Therefore, you must explicitly create resources for a newer version of a module or application. Payara Server ignores duplicate exported global resources and lets deployment succeed.
- OSGi already has its own versioning system. Therefore, when you deploy an OSGi bundle, Payara Server ignores any version information provided with the name but permits the deployment to succeed with warnings.

About Assembly and Deployment Events

The deployment tools that are provided by Payara Server can be used by any user authorized as an administrator to deploy applications and modules into any Payara Server environment. However, effective application deployment requires planning and care. Only the developer knows exactly what is required by an application, so the developer is responsible for initial assembly and deployment.

1. **Deployment Descriptor or Annotation Creation**. The developer creates the deployment descriptors or equivalent annotations using Jakarta standards and tools.

   Details of the Payara Server deployment descriptors are contained in Payara Server Deployment Descriptor Files and Elements of the Payara Server Deployment Descriptors.

   The Payara Server sample applications contain deployment descriptors that can be used as templates for developing deployment descriptors.

2. **Assembly**. The developer assembles the archive file(s) using Jakarta standards and tools, such

as the `jar` command. The application or module is packaged into a JAR, WAR, RAR, or EAR file. For guidelines on naming, see Naming Standards. There are no Payara Server issues to consider.

3. **Test Deployment**. The developer performs a test deployment of the archive. For instructions, see To Deploy an Application or Module.
4. **Archive Submission**. The developer submits the verified archive to the administrator for deployment into a production environment. The developer includes instructions for any additional deployment tasks that the administrator must perform. For an example of such additional instructions, see Access to Shared Framework Classes.
5. **Configuration**. The administrator applies additional deployment specifics. Sometimes the developer has indicated additional deployment needs, such as specifying the production database. In this case, the administrator edits and reassembles the archive.
6. **Production Deployment**. The administrator deploys the archive to production. See To Deploy an Application or Module.
7. **Troubleshooting**. If deployment fails, the administrator returns the archive to the developer.

   The developer fixes the problem and resubmits the archive to the administrator. Sometimes the administrator resolves the problem, depending on what the problem is.

About Deployment Tools

Payara Server provides tools for assembling and deploying a module or application.

Administration Console

The Payara Server Administration Console is a browser-based utility that features a graphical interface that includes extensive online help for the administrative tasks. The format for starting the Administration Console in a web browser is `http://hostname:port`. For example:

```
http://localhost:4848
```

Step-by-step instructions for using the Administration Console for deployment are provided in the Administration Console online help. You can display the help material for a page by clicking the Help button. The initial help page describes the functions and fields of the page itself. To find instructions for performing associated tasks, click a link in the See Also list.

The `asadmin` Utility

The Payara Server `asadmin` utility is a command-line tool that invokes subcommands for identifying the operation or task that you want to perform. You can run `asadmin` commands either from a command prompt or from a script. The format for starting the `asadmin` utility on the command line is **`as-install`**`/bin/asadmin` **`subcommand --option`**. For example:

```
asadmin list-applications --type web
```

Application deployment commands are listed in The `asadmin` Deployment Subcommands.

For the most part, you can perform the same administrative tasks by using either the graphical Administration Console or the `asadmin` command-line utility, however, there are exceptions. Procedures for using the command-line utilities are provided in this guide and in the command-line help pages, which are similar to man pages. You can display the help material for a command by typing help followed by the subcommand. For example:

```
asadmin help list-applications
```

For additional information on the `asadmin` utility, see "Using the `asadmin` Utility" in *Payara Server General Administration section* and the `asadmin`(1M) help page.

Additional Information on Application Deployment

As specified from Jakarta Platform, the following are relevant specifications to this guide:

- Jakarta EE Platform, Enterprise Edition Specification `https://jakarta.ee/specifications/platform/`
- Jakarta Annotations Specification `https://jakarta.ee/specifications/annotations/`
- Jakarta Servlet Specification `https://jakarta.ee/specifications/servlet/`
- Jakarta Enterprise Beans Specification `https://jakarta.ee/specifications/enterprise-beans/`
- Jakarta Connectors Specification `https://jakarta.ee/specifications/connectors/`

Deploying Applications

This chapter provides procedures and guidelines for deploying applications and modules in the Payara Server environment by using the `asadmin `command-line utility.

Deploying Applications and Modules

Application deployment is a dynamic process, which means that deployed applications and modules become available without requiring you to restart the server instance.

Dynamic deployment can be useful in production environments to bring new applications and modules online easily. If you do restart the server, all deployed components are still deployed and available.

The following topics are addressed here:

- To Deploy an Application or Module
- To Change Targets for a Deployed application or Module
- To List Deployed Applications or Modules
- To Redeploy an Application or Module
- To Disable an Application or Module
- To Enable an Application or Module
- To Undeploy an Application or Module

- To Reload Changes to Applications or Modules Dynamically
- To Deploy an Application or Module Automatically
- To Deploy an Application or Module by Using a Deployment Plan
- To Deploy an Application or Module in a Directory Format
- To Deploy an Application on Server start
- To Deploy from a URL
- To Deploy using a Maven Artifact

Instructions for accomplishing these tasks by using the Administration Console are contained in the Administration Console online help.

To Deploy an Application or Module

Use the `deploy` subcommand in remote mode to deploy an assembled application or module to Payara Server. If an error occurs during deployment, the application or module is not deployed. If a module within an application contains an error, the entire application is not deployed.

These failures prevent a partial deployment that could leave the server in an inconsistent state.

By default, the deployment target is the default server instance, `server`. To deploy only to the default server instance, specify no target. If you deploy the application or module only to the domain target, it exists in the domain central repository, but no server instances or clusters can reference the component unless you add references.

You can also deploy a component to a specific stand-alone server instance or cluster. When you deploy to server instances or clusters, the application or module exists in the domain's central repository and is referenced by any clusters or server instances that you deployed to. For a cluster, the preselected deployment target is `server`.

If the component is already deployed or already exists, you can forcefully redeploy if you set the `--force` option of the `deploy` subcommand to true. The `redeploy` subcommand also accomplishes this. See this example.

You can see the enabled or disabled status of an application or module by using the `show-component-status` subcommand.

For information about how the application or module name is derived, see Naming Standards.

Use the `--altdd` or `--runtimealtdd` options of the `deploy` (and `redeploy`) subcommand to deploy an application or module using a top-level alternate deployment descriptor. The `--altdd` option specifies a top-level alternate Jakarta EE standard deployment descriptor.

The `--runtimealtdd` option specifies a top-level alternate Payara Server runtime deployment descriptor. See this example for more information.

For more information about deployment descriptors associated with Payara Server, see Deployment Descriptors and Annotations.

You can also specify the deployment order of an application by using the `--deploymentorder` option of the `deploy` (and `redeploy`) subcommand. This is useful for applications that must be loaded in a certain order at server startup. Applications with lower deployment order numbers are loaded first. See this example for more information.

If a deployment order is not specified at the time an application is deployed, the default deployment order of `100` is assigned. If two applications have the same deployment order, the application that was deployed first is loaded first at server startup.

1. Ensure that the server is running. Remote commands require a running server.
2. List deployed applications by using the `list-applications` subcommand.
3. Deploy the application or module by using the `deploy` subcommand.

   Information about the options and properties of the subcommand is included in this help page.
4. If needed, fix issues and rerun the `deploy` subcommand.

Example - Deploying an Enterprise Application

This example deploys `newApp.ear` to the default server, `server`.

```
asadmin> deploy Cart.ear
Application deployed successfully with name Cart.
Command deploy executed successfully
```

Example - Deploying a Connector Module

This example deploys a connector module that is packaged in an RAR file.

```
asadmin> deploy jdbcra.rar
Application deployed successfully with name jdbcra.
Command deploy executed successfully
```

Example - Using an Alternate Jakarta EE Standard Deployment Descriptor

This example deploys an application using an alternate Jakarta EE standard deployment descriptor file that resides outside an application archive. Specify an absolute path or a relative path to the alternate deployment descriptor file.

```
asadmin> deploy --altdd path_to_alternate_descriptor cart.ear
Application deployed successfully with name cart.
Command deploy executed successfully
```

Example - Specifying the Deployment Order of an Application

This example specifies the deployment order of two applications. The `cart` application is loaded before the `horse` application at server startup.

Some lines of output are omitted from this example for readability.

```
asadmin deploy --deploymentorder 102 --name cart cart.war

asadmin deploy --deploymentorder 110 --name horse horse.war
```

You can also view the full syntax and options of the subcommand by typing `asadmin help deploy` at the command line.

To Change Targets for a Deployed Application or Module

After deployment, the deployed application or module exists in the central repository and can be referenced by the server instances or clusters that you deployed to as targets.

The `asadmin create-application-ref` and `asadmin delete-application-ref` subcommands enable you to add or delete targets for a deployed component.

Because the application or module itself is stored in the central repository, adding or deleting targets adds or deletes the same version of the component on different targets.

1. Ensure that the server is running. Remote commands require a running server.
2. Add and remove targets by using the `create-application-ref` and `delete-application-ref` subcommands.

You can also view the full syntax and options of the subcommand by typing`asadmin help create-application-ref` or `asadmin help delete-application-ref` at the command line.

To List Deployed Applications or Modules

There are a number of commands that can be used to list deployed applications or modules and their subcomponents. Use the commands in this section in remote mode.

1. Ensure that the server is running. Remote commands require a running server.
2. List the desired applications by using the `list-applications` subcommand or the `list-sub-components` subcommand.

   Information about these commands is included in these help pages.

3. Show the status of a deployed component by using the `show-component-status` subcommand.

Example Listing Applications

The `list-applications` subcommand lists all deployed Jakarta EE applications or modules. If the `--type` option is not specified, all components are listed.

This example lists deployed applications.

```
asadmin> list-applications --type web
hellojsp <web>
Command list-applications executed successfully
```

Example - Listing Subcomponents

The `list-sub-components` subcommand lists EJBs or servlets in a deployed module or in a module of the deployed application. If a module is not identified, all modules are listed. The `--appname` option functions only when the given module is standalone.

To display a specific module in an application, you must specify the module name and the `--appname` option.

This example gets the subcomponents of module `mejb.jar` within application `MEjbApp`.

```
asadmin> list-sub-components --appname MEjbApp mejb.jar
MEJBBean <StatelessSessionBean>
Command list-sub-components executed successfully
```

Example - Showing Status of a Deployed Component

The `show-component-status` subcommand gets the status (enabled or disabled) of the deployed component. This example gets the status of the `MEjbApp` component.

```
asadmin show-component-status MEjbApp
Status of MEjbApp is enabled
Command show-component-status executed successfully
```

To Redeploy an Application or Module

Use the `redeploy` subcommand in remote mode to overwrite a previously-deployed application or module. You can also accomplish this task by using the `--force` option of the `deploy` subcommand. Whenever a redeployment is done, the HTTP and SFSB sessions in transit at that time, and the EJB timers, become invalid unless you use the `--keepstate=true` option of the `redeploy` subcommand.

Before You Begin
You must remove a preconfigured resource before it can be updated.

1. Ensure that the server is running.

   Remote commands require a running server.

2. Redeploy an application or module by using the `redeploy` subcommand or the `deploy` subcommand with the `--force` option.

   Information about the options and properties of these commands is included in these help pages.

Example - Retaining HTTP Session State During Redeployment

This example redeploys the `hello` web application. In a production environment, you usually want to retain sessions.

If you use the `--keepstate` option, active sessions of the application are retained and restored when redeployment is complete.

```
asadmin> redeploy --name hello --keepstate=true hello.war
Application deployed successfully with name hello.
Command redeploy executed successfully.
```

Keep State is a checkbox option when you redeploy using the Administration Console. For instructions, see the Administration Console online help.

Example - Redeploying a Web Application That Was Deployed From a Directory

This example redeploys the `hello` web application, which was originally deployed from the `hellodir` directory.

```
asadmin>redeploy --name hellodir
Application deployed successfully with name hellodir.
Command redeploy executed successfully.
```

Example - Redeploying an Application by Using `asadmin deploy --force`

The `--force` option is set to `false` by default. This example redeploys `newApp.ear` even if has been deployed or already exists.

```
asadmin> deploy --force=true newApp.ear
Application deployed successfully with name newApp.
Command deploy executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help redeploy` at the command line.

To Disable an Application or Module

Use the `disable` subcommand in remote mode to immediately deactivate a deployed application or module without removing it from the server.

Disabling a component makes the component inaccessible to clients. However, the component is not overwritten or uninstalled, and can be enabled by using the `asadmin enable` subcommand.

An application or module is enabled by default.

1. Ensure that the server is running. Remote commands require a running server.

2. Obtain the exact name of the application or module that you are disabling.
   To list deployed applications or modules, use the `list-applications` subcommand. If you do not specify a type, all deployed applications and modules are listed. For example, valid types can be `web`, `ejb`, `connector`, `application`, and `webservice`.
   To see the status of deployed components, use the `show-component-status` subcommand.
3. Deactivate the application or module by using the `disable` subcommand.

   Information about the options and properties of the subcommand is included in this help page.

Example - Listing Deployed Web Applications

This example lists all deployed web applications.

```
asadmin> list-applications --type web
hellojsp <web>
Command list-applications executed successfully.
```

Example 2-12 Disabling a Web Application

This example disables the `hellojsp` application.

```
asadmin> disable hellojsp
Command disable executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help disable` at the command line.

To Enable an Application or Module

An enabled application or module is runnable and can be accessed by clients if it has been deployed to an accessible server instance or cluster. An application or module is enabled by default.

Use the `enable` subcommand in remote mode to enable an application or module that has been disabled.

An application or module that is deployed to more than one target can be enabled on one target and disabled on another. If a component is referenced by a target, it is not available to users unless it is enabled on that target.

1. Ensure that the server is running. Remote commands require a running server.
2. Enable the application or module by using the `enable` subcommand.

   If the component has not been deployed, an error message is displayed. If the component is already enabled, it is re-enabled.

   To see the status of deployed components, use the `show-component-status` subcommand.

   Information about the options and properties of the subcommand is included in this help page.

Example - Enabling an Application

This example enables the `sampleApp` application.

```
asadmin> enable sampleApp
Command enable executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help enable` at the command line.

To Undeploy an Application or Module

Use the `undeploy` subcommand in remote mode to uninstall a deployed application or module and remove it from the repository. To reinstate the component, you must deploy the component again using the `deploy` subcommand.

1. Ensure that the server is running. Remote commands require a running server.
2. Obtain the exact name of the application or module you are un-deploying.

   To list deployed applications or modules, use the `list-applications` subcommand.

   If you do not specify a type, all deployed applications and modules are listed. For example, valid types can be `web`, `ejb`, `connector`, `application`, and `webservice`.

   To see the status of deployed components, use the `show-component-status` subcommand.
3. Undeploy the application or module by using the `undeploy` subcommand.

   Information about the options and properties of the subcommand is included in this help page.

Example 2-14 Listing Deployed Applications or Modules

This example lists all applications of type `web`.

```
asadmin> list-applications --type web
hellojsp <web>
Command list-applications executed successfully.
```

Example - Un-deploying an Application

This example uninstalls the `hellojsp` application.

```
asadmin> undeploy hellojsp
hellojsp <web>
Command undeploy executed successfully.
```

You can also view the full syntax and options of the subcommand by typing

`asadmin help undeploy` at the command line.

To Reload Changes to Applications or Modules Dynamically

Dynamic reloading enables you to change the code or deployment descriptors of an application or module without needing to perform an explicit redeployment.

Instead, you can copy the changed class files or descriptors into the deployment directory for the application or module. The server checks for changes periodically and automatically redeploys the changes if the timestamp of the `.reload` file in the root directory for the application or module has changed.

Dynamic reloading is enabled by default, and is available only on the default server instance.

1. Go to the root directory of the deployed application or module.

   For an application:

   ```
   domain-dir/applications/app-name
   ```

   For an individually deployed module:

   ```
   domain-dir/applications/module-name
   ```

   Deployment directories might change between Payara Server releases.

2. Create or update the timestamp of the `.reload` file to load the changes.

   For UNIX: `touch .reload`

   For Windows: `echo> .reload`

   If the `.reload` file doesn't exist, the `touch` or `echo` command creates it.

To Deploy an Application or Module Automatically

This task is best suited for use in a development environment.

Automatic deployment involves copying an archive file into a special auto-deploy directory where the archive is automatically deployed by Payara Server at predefined intervals.

This method is useful in a development environment because it allows new code to be tested quickly. Automatic deployment is enabled by default, and is available only on the default server instance.

1. Use the `set` subcommand to adjust the auto-deployment interval.

This sets the interval at which applications and modules are checked for code changes and dynamically reloaded. The default is `2`.

2. Use the `set` subcommand to enable JSP precompilation.
3. Copy your archive file to the auto-deploy directory.

   The default location is `domain-dir/autodeploy`. The application will be deployed at the next interval.

   To undeploy an automatically deployed application or module, remove its archive file from the auto-deploy directory.

Deployment directories might change between Payara Server releases.

Example - Setting the Auto-deployment Interval

This example sets the auto-deployment interval to 3 seconds (default is 2).

```
asadmin set server.admin-service.das-config.autodeploy-polling-interval-in-seconds=3
Command set executed successfully.
```

Example - Setting JSP Precompilation

This example enables JSP precompilation (default is `false`).

```
asadmin>
set server.admin-service.das-config.autodeploy-jsp-precompilation-enabled=true
Command set executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin set --help` at the command line.

To Deploy an Application or Module by Using a Deployment Plan

In the deployment plan for an EAR file, the `payara-application.xml` file is located at the root. The deployment descriptor for each module is stored according to this syntax: `module-name.gf-dd-name`, where the `gf-dd-name` depends on the module type.

Each `/` (forward slash) is replaced by a `#` (pound sign).

1. Ensure that the server is running. Remote commands require a running server.
2. Deploy the application or module by using the `deploy` subcommand with the `--deploymentplan` option.

Deployment directories might change between Payara Server releases.

Example - Deploying by Using a Deployment Plan

This example deploys the application in the `myrostapp.ear` file according to the plan specified by the `mydeployplan.jar` file.

```
asadmin deploy --deploymentplan mydeployplan.jar myrostapp.ear

Application deployed successfully with name myrostapp.
Command deploy executed successfully.
```

Example - Deployment Plan Structure for an Enterprise Application

This listing shows the structure of the deployment plan JAR file for an EAR file.

```
$ jar -tvf mydeployplan.jar
420 Thu Mar 13 15:37:48 PST 2003 glassfish-application.xml
370 Thu Mar 13 15:37:48 PST 2003 RosterClient.war.payara-web.xml
418 Thu Mar 13 15:37:48 PST 2003 roster-ac.jar.glassfish-application-client.xml
1281 Thu Mar 13 15:37:48 PST 2003 roster-ejb.jar.glassfish-ejb-jar.xml
2317 Thu Mar 13 15:37:48 PST 2003 team-ejb.jar.glassfish-ejb-jar.xml
84805 Thu Mar 13 15:37:48 PST 2003 team-ejb.jar.RosterSchema.dbschema
```

To Deploy an Application or Module in a Directory Format

This task is best suited for use in a development environment.

An expanded directory, also known as an exploded directory, contains an un-assembled (un-packaged) application or module. To deploy a directory format instead of an archive, file, use the `asadmin deploy` subcommand in remote mode and specify a path to a directory instead of to an archive file.

The contents of the directory must be the same as the contents of a corresponding archive file, with one exception.

An application archive file contains archive files for its modules, for example `myUI.war` and `myEJB.jar`.

The expanded application directory contains expanded directories for the modules, for example `myUI_war` and `myEJB_jar`, instead.

You can change deployment descriptor files directly in the expanded directory.

If your environment is configured to use dynamic reloading, you can also dynamically reload applications or modules that are deployed from the directory. For instructions, see To Reload Changes to Applications or Modules Dynamically.

Unlike archive file deployment, directory deployment does not copy the directory contents to the remote hosts.

This means that for deployment to a cluster, the directory path may exist for both the DAS and the remote server instances but may not actually correspond to the same physical location. If any target server instance cannot see the deployed directory, or finds that it contains different files from those detected by the DAS, deployment fails.

Integrated development environments (IDEs) typically use directory deployment, so you do not need to deal directly with the expanded format.

Before You Begin

On each cluster or stand-alone server instance to which the application or module is deployed, the directory must be accessible and must contain the same files as found by the DAS.

On Windows, if you are deploying a directory on a mapped drive, you must be running Payara Server as the same user to which the mapped drive is assigned. This enables Payara Server to access the directory.

1. Ensure that the server is running. Remote commands require a running server.
2. Verify that the expanded directory contents match the archive file.

   For information about the required directory contents, see the appropriate specifications.
3. Deploy the directory by using the `deploy` subcommand and specifying the path to the expanded directory.

Deployment directories might change between Payara Server releases.

Example - Deploying an Application From a Directory

This example deploys the expanded directory `/apps/MyApp` for the `hello` application.

```
asadmin> deploy --name hello /apps/MyApp
Application deployed successfully with name hello.
Command deploy executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help deploy` at the command line.

To Deploy an Application on Server Start

As described in [Technical Documentation-Payara Server Documentation-Application Deployment-Deploying Applications:::to-deploy-an-application-or-module-automatically] Payara Server has the ability to automatically deploy applications on server start using the `autodeploy` directory. While acceptable in development environments, the internal scanner used to deploy files in this directory is a security risk for production environments.

To introduce the capability of deploying an application on server startup without the risk of enabling the deployment scanner, Payara Server has the ability to run asadmin commands at startup via command scripts, either before or after the server's boot sequence has been completed.

To enable this feature, the `start-domain` Asadmin command accepts two extra options: `--prebootcommandfile` and `--postbootcommandfile` which can be used as follows:

Pre-boot command script usage

```
asadmin start-domain --prebootCommandFile=/path/to/file
```

Due to the time during boot when the commands in this file are executed, this only supports `set` commands.

Post-boot command script usage

```
asadmin start-domain --postbootCommandFile=/path/to/file
```

To deploy an application at startup time, simply create a command script that deploys the application like so:

deployment-script.asadmin

```
deploy --name MyApp /path/to/deployment/archive
```

And use this script file with the `--postbootCommandFile` option:

Post-boot command script usage

```
asadmin start-domain --postbootCommandFile=deployment-script.asadmin
```

Post boot command scripts will guarantee that applications will be deployed AFTER the server has completed its boot sequence, guaranteeing that all required resources will be available for the application to use.

Command Script Considerations

There are some considerations to have on how to structure command scripts:

- Script files should be saved in a text format, with each command on its own line.
- Lines where the first non-whitespace character is `#` are treated as comments
- Any blank lines will be ignored
- Any invalid or failing commands will be logged to the server log and the file will continue to be processed.
- Script files ***must*** exist, and be accessible by the server instance.
- Both pre-boot and post-boot script files can be passed at the same time when starting the domain.

To Deploy from a URL

Payara Server also has the ability to deploy applications whose archives are hosted on a remote location. To deploy an application archive that can be reached via its URL, use the `deploy-remote-archive` subcommand, which works similarly to the standard `deploy` command, and can be used in the same way.

The only difference in the command is that it takes a valid URL instead of a file location in the host's filesystem.

Example - Deploying by Using a URL

The following example showcases how to deploy an application's archive for the `clusterjsp` application hosted in the `https://nexus.payara.fish/repository/payara-artifacts` remote repository using the `deploy-remote-archive` subcommand:

```
asadmin deploy-remote-archive https://nexus.payara.fish/repository/payara-
artifacts/fish/payara/testing/clusterjsp/1.1/clusterjsp-1.1.war
```

The command will only accept HTTP and HTTPS URLs.

To Deploy using a Maven artifact

Payara Server also has the ability to deploy applications whose archives are hosted as Maven artifacts on remote repositories. To deploy an application archive in this manner, use the `deploy-remote-archive` subcommand, which works similarly to the standard `deploy` command, and point it to a set of Maven GAV (Group ID/Artifact ID/Version) coordinates where the artifact is located.

By default, the command will search for the artifact in Maven Central, but specific Maven repositories can be added as search locations by using the `additionalRepositories` option, which accepts a comma separated list of repository URLs.

Example - Deploying by Using a Maven Artifact

The following example showcases how to deploy an application's archive for the `clusterjsp-1.1.1.war` application artifact which is located in the `https://nexus.payara.fish/repository/payara-artifacts` Maven repository using the `deploy-remote-archive` subcommand:

If an application matching the GAV coordinates exists on multiple repositories, the first found will be deployed. The order that the repositories are searched is the order that you specify them in.
For example, given an `additionalRepositories` of *repo1,repo2*, the order that the repositories would be searched is: Maven Central → repo1 → repo2.

```
asadmin deploy-remote-archive --additionalRepositories
https://nexus.payara.fish/repository/payara-artifacts
fish.payara.testing,clusterjsp,1.1
```

Modifying the Configuration of a Web Application or Module

You can modify the configuration of a web application or a module by modifying the deployment descriptors and then repackaging and redeploying the application.

The instructions in this section enable you to change the configuration of a deployed application without the need to modify the application's deployment descriptors and repackage and redeploy the application. If the application or module entry is unset, its value reverts to the value, if any, that is set in the application's deployment descriptor.

The following topics are addressed here:

- To Set a Web Context Parameter
- To Unset a Web Context Parameter
- To List Web Context Parameters
- To Set a Web Environment Entry
- To Unset a Web Environment Entry
- To List Web Environment Entries

To Set a Web Context Parameter

Use the `set-web-context-param` subcommand in remote mode to change the configuration of a deployed application without the need to modify the application's deployment descriptors and repackage and redeploy the application. By using this subcommand, you are either adding a new parameter that did not appear in the original web module's descriptor, or overriding the descriptor's setting of the parameter.

If the `--ignoreDescriptorItem` option is set to `true`, then the server ignores any setting for that context parameter in the descriptor, which means you do not need to specify an overriding value on the `set-web-context-param` subcommand.

The server behaves as if the descriptor had never contained a setting for that context parameter.

This subcommand sets a servlet context-initialization parameter of one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

Before You Begin

The application must already be deployed. Otherwise, an error occurs.

1. Ensure that the server is running.

   Remote commands require a running server.

2. Set a servlet context-initialization parameter by using the `set-web-context-param` subcommand.

   Information about the options for the subcommand is included in this help page.

Example - Setting a Servlet Context-Initialization Parameter for a Web Application

This example sets the servlet context-initialization parameter `jakarta.faces.STATE_SAVING_METHOD` of the web application `basic-ezcomp` to client.

```
asadmin> set-web-context-param --name= jakarta.faces.STATE_SAVING_METHOD
--description="The location where the application?s state is preserved" --value=client
basic-ezcomp

Command set-web-context-param executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help set-web-context-param` at the command line.

To Unset a Web Context Parameter

Use the `unset-web-context-param` subcommand in remote mode to unset an environment entry for a deployed web application or module that has been set by using the `set-web-env-entry` subcommand. There is no need to modify the application's deployment descriptors and repackage and redeploy the application.

This subcommand unsets an environment entry for one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

When an entry is unset, its value reverts to the value, if any, that is set in the application's deployment descriptor. This subcommand cannot be used to change the value of an environment entry that is set in an application's deployment descriptor.

Instead, use the `set-web-context-param` subcommand for this purpose.

Before You Begin

The application must already be deployed, and the entry must have previously been set by using the `set-web-env-entry` subcommand. Otherwise, an error occurs.

1. Ensure that the server is running.

   Remote commands require a running server.

2. Unset an environment entry by using the `unset-web-context-param` subcommand.

   Information about the options for the subcommand is included in this help page.

Example - Unsetting a Servlet Context-Initialization Parameter for a Web Application

This example unsets the servlet context-initialization parameter ` jakarta.faces.STATE_SAVING_METHOD ` of the web application `basic-ezcomp`.

```
asadmin unset-web-context-param --name= jakarta.faces.STATE_SAVING_METHOD basic-ezcomp
Command unset-web-context-param executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help unset-web-context-param` at the command line.

To List Web Context Parameters

Use the `list-web-context-param` subcommand in remote mode to list the parameters that have previously been set by using the `set-web-context-param` subcommand.

The subcommand does not list parameters that are set only in the application's deployment descriptor. For each parameter, the following information is displayed:

- The name of the parameter
- The value to which the parameter is set
- The value of the `--ignoreDescriptorItem` option of the `set-web-context-param` subcommand that was specified when the parameter was set
- The description of the parameter or `null` if no description was specified when the parameter was set

1. Ensure that the server is running.

   Remote commands require a running server.

2. List servlet context-initialization parameters by using the `list-web-context-param` subcommand.

Example - Listing Servlet Context-Initialization Parameters for a Web Application

This example lists all servlet context-initialization parameters of the web application `basic-ezcomp` that have been set by using the `set-web-context-param` subcommand. Because no description was specified when the `jakarta.faces.PROJECT_STAGE` parameter was set, null is displayed instead of a description for this parameter.

```
asadmin list-web-context-param basic-ezcomp jakarta.faces.STATE_SAVING_METHOD = client
ignoreDescriptorItem=false

jakarta.faces.PROJECT_STAGE = null ignoreDescriptorItem=true
Command list-web-context-param executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-web-context-param` at the command line.

To Set a Web Environment Entry

An application uses the values of environment entries to customize its behavior or presentation.

Use the `set-web-env-entry` subcommand in remote mode to change the configuration of a deployed application without the need to modify the application's deployment descriptors and repackage and redeploy the application.

By using this subcommand, you are either adding a new parameter that did not appear in the original web module's descriptor, or overriding the descriptor's setting of the parameter.

If you the `--ignoreDescriptorItem` option is set to `true`, then the server ignores any setting for that environment entry in the descriptor, which means you do not need to specify an overriding value on the `set-web-env-entry` subcommand. The server behaves as if the descriptor had never contained a setting for that environment entry.

This subcommand sets an environment entry for one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

Before You Begin

The application must already be deployed. Otherwise, an error occurs.

1. Ensure that the server is running.

   Remote commands require a running server.

2. Set an environment entry for a deployed web application or module by using the `set-web-env-entry` subcommand.

   Information about the options for the subcommand is included in this help page.

Example - Setting an Environment Entry for a Web Application

This example sets the environment entry `Hello User` of the application hello to `techscribe`. The Java type of this entry is `java.lang.String`.

```
asadmin> set-web-env-entry --name="Hello User" --type=java.lang.String
--value=techscribe --description="User authentication for Hello appplication" hello

Command set-web-env-entry executed successfully
```

You can also view the full syntax and options of the subcommand by typing `asadmin help set-web-env-entry` at the command line.

To Unset a Web Environment Entry

Use the `unset-web-env-entry` subcommand in remote mode to unset an environment entry for a deployed web application or module.

1. Ensure that the server is running.

Remote commands require a running server.

2. Unset a web environment entry by using the `unset-web-env-entry` subcommand.

   Information about the options for the subcommand is included in this help page.

Example - Unsetting an Environment Entry for a Web Application

This example unsets the environment entry `Hello User` of the web application `hello`.

```
asadmin unset-web-env-entry --name="Hello User" hello
Command unset-web-env-entry executed successfully.
```

To List Web Environment Entries

Use the `list-web-env-entry` subcommand to list environment entries for a deployed web application or module. For each entry, the following information is displayed:

- The name of the entry
- The Java type of the entry
- The value to which the entry is set
- The description of the entry or null if no description was specified when the entry was set
- The value of the `--ignoreDescriptorItem` option of the `set-web-env-entry` subcommand that was specified when the entry was set

1. Ensure that the server is running.

   Remote commands require a running server.

2. List the environment entries by using the `list-web-env-entry` subcommand.

Example - Listing Environment Entries for a Web Application

This example lists all environment entries that have been set for the web application `hello` by using the `set-web-env-entry` subcommand.

```
asadmin list-web-env-entry hello

Hello User (java.lang.String) = techscribe ignoreDescriptorItem=false
Hello Port (java.lang.Integer) = null ignoreDescriptorItem=true
Command list-web-env-entry executed successfully.
```

You can also view the full syntax and options of the subcommand by typing asadmin help `list-web-env-entry` at the command line.

Web Module Deployment Guidelines

The following guidelines apply to deploying a web module in Payara Server:

- **Context Root**. When you deploy a web module, if you do not specify a context root, the default is the name of the WAR file without the `.war` extension. The web module context root must be unique within the server instance.

  The domain administration server (DAS) in Payara Server supports the deployment of multiple web applications using the same web context root as long as those applications are deployed to different Payara Server stand-alone instances.

  Deploying multiple applications using the same context root within a single instance produces an error.

- **Data Source**. If a web application accesses a `DataSource` that is not specified in a `resource-ref` in `glassfish-web.xml` or `payara-web.xml`, or there is no `glassfish-web.xml` or `payara-web.xml` files, the `resource-ref-name` defined in `web.xml` is used.

  A warning message is logged, recording the JNDI name that was used to look up the resource.

- **Virtual Servers**. If you deploy a web application and do not specify any assigned virtual servers, the web application is assigned to all currently-defined virtual servers except the virtual server with ID `__asadmin`, which is reserved for administrative purposes.

  If you then create additional virtual servers and want to assign existing web applications to them, you must redeploy the web applications.

- **HTTP Sessions**. If a web application is un-deployed, all its HTTP sessions will be invalidated and removed, unless the application is being un-deployed as part of a redeployment and the `--keepstate` deployment option was set to true.

  This option is not supported and ignored in a clustered environment. See this example.

  For information about HTTP session persistence, see the Payara Server High Availability section.

- **JSP Precompilation**. You can precompile JSP files during deployment by checking the appropriate box in the Administration Console, or by using the `--precompilejsp` option of the `deploy` subcommand.

  You can keep the generated source for JSP files by adding the `keepgenerated` flag to the `jsp-config` element in `glassfish-web.xml` or `payara-web.xml`.

  For example:

```
<payara-web-app>
   <jsp-config>
      <property name="keepgenerated" value="true" />
   </jsp-config>
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

+ If you include this property when you deploy the WAR file, the generated source is kept in `domain-dir/generated/jsp/app-name/module-name` for an application, or `domain-dir/generated/jsp/module-name` for an individually-deployed web module.

+ For more information about JSP precompilation, see `jsp-config`.

- **Web Context Parameters**. You can set web context parameters after deployment. See the following sections:
  - To Set a Web Context Parameter
  - To Unset a Web Context Parameter
  - To List Web Context Parameters
- **Web Environment Entries**. You can set web environment entries after deployment. See the following sections:
  - To Set a Web Environment Entry
  - To Unset a Web Environment Entry
  - To List Web Environment Entries

EJB Module Deployment Guidelines

The Payara Server Web Profile supports the Jakarta Enterprise Beans 4.0 Lite specification, which allows enterprise beans within web applications, among other features.
The Payara Server Full Platform Profile supports the entire Jakarta Enterprise Beans 4.0 specification. For details, see Jakarta Enterprise Beans

The following guidelines apply to deploying an EJB module in Payara Server:

- **JNDI Name**. — If no JNDI name for the EJB JAR module is specified in the `jndi-name` element immediately under the `ejb` element in `payara-ejb-jar.xml`, or there is no `glassfish-ejb-jar.xml` file, a default, non-clashing JNDI name is derived.

  A warning message is logged, recording the JNDI name used to look up the EJB JAR module.

  Because the Jakarta Enterprise Beans 4.0 specification defines portable EJB JNDI names, there is less need for Payara Server specific JNDI names. By default, Payara Server specific default JNDI names are applied automatically for backward compatibility.

  To disable Payara Server specific JNDI names for an EJB module, set the value of the `<disable-nonportable-jndi-names>` element in the `glassfish-ejb-jar.xml` file to `true`. The default is `false`.

- **Stateful Session Bean and Timer State**. — Use the `--keepstate` option of the `redeploy` subcommand or the `<keepstate>` element in the `glassfish-ejb-jar.xml` file to retain stateful session bean instances and persistently created EJB timers across re-deployments.

The `--keepstate` option of the `redeploy` subcommand takes precedence. The default for both is `false`. This option is not supported and ignored in a clustered environment.

Some changes to an application between re-deployments can prevent this feature from working properly. For example, do not change the set of instance variables in the SFSB bean class. Other examples would be changes to EJB names, or adding or removing EJBs to or from an application.

- **EJB Singletons**. — EJB Singletons are created for each server instance in a cluster, and not once per cluster or deployment group. Check the Clustered Singleton proprietary feature of the Public API on how to achieve this.
- **Stubs and Ties**. — Use the `get-client-stubs` subcommand in remote mode to retrieve stubs and ties.
- **Compatibility of JAR Visibility Requirements**. — Use the `compatibility` element of the `payara-application.xml` or `payara-ejb-jar.xml` file to specify the Payara Server release with which to be backward compatible in terms of JAR visibility requirements for applications.

  The current allowed value is `v2`, which refers to older runtimes from where Payara Server is based from.

Starting in Java EE 6, the Java EE specification imposes stricter requirements than Java EE 5 did on which JAR files can be visible to various modules within an EAR file. Setting this element to `v2` removes these Java EE 6 and later restrictions.

Deploying a Connector Module

Deploying a stand-alone connector module allows multiple deployed Jakarta EE applications to share the connector module. A resource adapter configuration is automatically created for the connector module.

The following topics are addressed here:

- To Deploy and Configure a Stand-Alone Connector Module
- Redeploying a Stand-Alone Connector Module
- Deploying and Configuring an Embedded Resource Adapter

To Deploy and Configure a Stand-Alone Connector Module

As an alternative to Step 3 through Step 6, you can define application-scoped resources in the `glassfish-resources.xml` or `payara-resources.xml` deployment descriptor.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

For more information, see Application-Scoped Resources.

1. Ensure that the server is running.

Remote commands require a running server.

2. Deploy the connector module by using the `deploy` subcommand.
3. Configure connector connection pools for the deployed connector module.

   Use the `create-connector-connection-pool` subcommand. For procedures, see "To Create a Connector Connection Pool" in the *General Administration section*.

4. Configure connector resources for the connector connection pools.

   Use the `create-resource-adapter-config` subcommand. For procedures, see "To Create Configuration Information for a Resource Adapter" in the *General Administration section*.

   If needed, you can override the default configuration properties of a resource adapter.

   This step associates a connector resource with a JNDI name.

5. Configure a resource adapter.

   Use the `create-resource-adapter-config` subcommand. For procedures, see "To Create Configuration Information for a Resource Adapter" in the *General Administration section*.

   If needed, you can override the default configuration properties of a resource adapter.

6. If needed, create an administered object for an inbound resource adapter.

   Use the `create-admin-object` subcommand. For procedures, see "To Create an Administered Object" in the *General Administration section*.

Redeploying a Stand-Alone Connector Module

Redeployment of a connector module maintains all connector connection pools, connector resources, and administered objects defined for the previously deployed connector module. You do not need to reconfigure any of these resources.

However, you should redeploy any dependent modules. A dependent module uses or refers to a connector resource of the redeployed connector module. Redeployment of a connector module results in the shared class loader reloading the new classes. Other modules that refer to the old resource adapter classes must be redeployed to gain access to the new classes.

For more information about class loaders, see "Class Loaders" in the Application Development section.

During connector module redeployment, the server log provides a warning indicating that all dependent applications should be redeployed.

Client applications or application components using the connector module's resources may throw class cast exceptions if dependent applications are not redeployed after connector module redeployment.

To disable automatic redeployment, set the `--force` option to `false`. In this case, if the connector

module has already been deployed, Payara Server provides an error message.

Deploying and Configuring an Embedded Resource Adapter

A connector module can be deployed as a Jakarta EE component in a Jakarta EE application. Such connectors are only visible to components residing in the same Jakarta EE application. Deploy this application as you would any other Jakarta EE application.

You can create new connector connection pools and connector resources for a connector module embedded within a Jakarta EE application by prefixing the connector name with `app-name#`.

For example, if an application `appX.ear` has `jdbcra.rar` embedded within it, the connector connection pools and connector resources refer to the connector module as `appX#jdbcra`.

An embedded connector module cannot be un-deployed using the name `app-name#connector-name`. To undeploy the connector module, you must undeploy the application in which it is embedded.

The association between the physical JNDI name for the connector module in Payara Server and the logical JNDI name used in the application component is specified in the Payara Server-specific XML descriptor `glassfish-ejb-jar.xml`.

Assembling and Deploying an Application Client Module

Deployment is necessary for application clients that communicate with EJB components.

The Application Client Container is supported only in the Payara Server Full Platform Profile, not in the Web Profile.

The following topics are addressed here:

- To Assemble and Deploy an Application Client
- To Prepare Another Machine for Running an Application Client
- To Undeploy an Application Client

To Assemble and Deploy an Application Client

1. Assemble the necessary client components.

   The client JAR file is created.

2. Assemble the EJB components that are to be accessed by the client.

   The EJB JAR file is created.

3. Assemble the client and EJB JAR files together in an EAR.

   An EAR file contains all the components of the application.

4. Deploy the application.

   Instructions are contained in To Deploy an Application or Module.

5. If you are using the `appclient` script to run the application client, retrieve the client files.

   The client artifacts contain the ties and necessary classes for the application client. Client artifacts include multiple files.

   You can use either the `get-client-stubs` subcommand or the `--retrieve` option of the `deploy` subcommand, but you do not need to use both.

   - Use the `deploy` subcommand with the `--retrieve` option to retrieve the client files as part of deploying the application.
   - Use the `get-client-stubs` subcommand to retrieve client files for a previously-deployed application.

6. Test the client on the Payara Server machine by using the `appclient` script.

   The `appclient` script is located in the `as-install/bin` directory.

   If you are using the default server instance, the only required option is `-client`, which points to the client JAR file. For example:

   ```
   appclient -client converterClient.jar
   ```

   The `-xml` parameter, which specifies the location of the `sun-acc.xml` file, is also required if you are not using the default instance.

   For more detailed information about the `appclient` script, see `appclient`.

For more detailed information about creating application clients, see "Developing Java Clients" in the Application Development section. This chapter includes information on the following topics:

- Accessing EJB components and JMS resources from application clients
- Connecting to a remote EJB module through a firewall
- Using Java Web Start and creating a custom JNLP file
- Using libraries with application clients
- Specifying a splash screen, login retries, and other customizations

To Prepare Another Machine for Running an Application Client

If the *context-root* or *module-id* is not specified during deployment, the name of the EAR or JAR file without the `.ear` or `.jar` extension is used. For an application, the relative path to the application client JAR file is also included. If the application or module is not in EAR or JAR file format, a *context-root* or *module-id* is generated.

For details about naming, see Naming Standards.

Before You Begin

This task applies if you want to use the `appclient` script to run the application client on a system other than where the server runs.

1. Create the application client package JAR file.

   Use the `package-appclient` script in the `as-install/bin` directory. This JAR file is created in the `as-install/lib/appclient` directory.

2. Copy the application client package JAR file to the client machine.
3. Extract the contents of the JAR file.

   For example: `jar xf filename.jar`

4. Configure the `sun-acc.xml` file.

   If you used the `package-appclient` script, this file is located in the `appclient/appserv/lib/appclient` directory by default.

5. Configure the `asenv.conf` (`asenv.bat` on Windows) file.

   This file is located in `appclient/appserv/bin` by default if you used the `package-appclient` script.

6. Copy the client JAR file to the client machine.

   You are now ready to run the client.

For more detailed information about the `package-appclient` script, see `appclient(1M)`.

To Undeploy an Application Client

After application clients are downloaded, they remain on the client until they are manually removed.

If you undeploy an application client, you can no longer download that application client because it might be in an inconsistent state. If you try to launch an application client that was previously downloaded (even though the server side of the application client is no longer present), the results are unpredictable unless the application client has been written to tolerate such situations.

Web Service Deployment Guidelines

If you installed the Web Profile, web services are not supported unless the optional Metro Web Services Stack add-on component is downloaded.
Without the Metro add-on component, a servlet or EJB component cannot be a web service endpoint, and the `glassfish-web.xml`/`payara-web.xml` and `glassfish-ejb-jar.xml` elements related to web services are ignored.

The following guidelines apply when deploying a web service in Payara Server:

- **Web Service Endpoint**. Deploy a web service endpoint to Payara Server as you would any servlet or stateless session bean.

  If the deployed application or module has a web service endpoint, the endpoint is detected

automatically during deployment.

The Payara Server specific deployment descriptor files, `glassfish-web.xml`, `payara-web.xml` and `glassfish-ejb-jar.xml`, provide optional web service enhancements in their `webservice-endpoint` and `webservice-description` elements.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

- **Web Service Management**. Web service management is fully supported in the Administration Console. After the application or module is deployed, click the Web Service component. The table in the right frame lists deployed web service endpoints.

For more information about web services, see "Developing Web Services" in the Application Development section.

OSGi Bundle Deployment Guidelines

To deploy an OSGi bundle using the Administration Console, select Other from the Type drop-down list and check the OSGI Type checkbox.

To deploy an OSGi bundle using the `asadmin deploy` command, set the `--type` option to the value `osgi`. For example:

```
asadmin deploy --type=osgi MyBundle.jar
```

To automatically deploy an OSGi bundle, copy the bundle archive to the `domain-dir/autodeploy/bundles` directory.

For components packaged as OSGi bundles (`--type=osgi`), the `deploy` subcommand accepts properties arguments to wrap a WAR file as a WAB (Web Application Bundle) at the time of deployment. The subcommand looks for a key named `UriScheme` and, if present, uses the key as a URL stream handler to decorate the input stream.

Other properties are used in the decoration process. For example, the Payara Server OSGi web container registers a URL stream handler named `webbundle`, which is used to wrap a plain WAR file as a WAB.

Transparent JDBC Connection Pool Reconfiguration

In this Payara Server release, reconfiguration of a JDBC connection pool due to attribute or property changes can be transparent to the applications or modules that use the pool, even if pool reconfiguration results in pool recreation. You do not need to redeploy the application or module.

To enable transparent pool reconfiguration, set the `dynamic-reconfiguration-wait-timeout-in-seconds` property. This property specifies the timeout for dynamic reconfiguration of the pool.

In-progress connection requests must complete before this timeout expires, or they must be retried.

New connection requests wait for this timeout to expire before acquiring connections to the reconfigured pool. If this property exists and has a positive value, it is enabled.

You can set this property in the `glassfish-resources.xml` or `payara-resources.xml` file. For more information, see the property descriptions under `jdbc-connection-pool`.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

For JDBC connection pools that are not application-scoped, use the `set` subcommand to set this property. For example, to configure `mypool` on `myserver`, type the following all on one line:

```
asadmin set myserver.resources.jdbc-connection-pool.mypool.property.dynamic-
reconfiguration-wait-timeout-in-seconds=30
```

Application-Scoped Resources

You can define an application-scoped JDBC resource or other resource for an enterprise application, web module, EJB module, connector module, or application client module. This allows single-step deployment for resource-dependent modules and applications.

An application-scoped resource has the following characteristics:

- It is available only to the module or application that defines it.
- It cannot be referenced or looked up by other modules or applications.
- It is created during deployment, destroyed during un-deployment, and recreated during redeployment.
- It is free from unexpected resource starvation or delay in acquiring connections because no other application or module competes for accesses to it.

The following resource types can be application-scoped:

- JDBC connection pools
- JDBC resources
- Connector connection pools
- Connector resources
- Resource adapters
- External JNDI resources
- Custom resources
- Admin object resources
- Jakarta resources

Deployment Descriptor: An application-scoped resource is defined in the `glassfish-resources.xml` or `payara-resources.xml` deployment descriptor file. This file is placed in the `META-INF` directory of

the module or application archive.

For web applications or modules, this file is placed in the `WEB-INF` directory. If any submodule archives of an enterprise application archive have their own `glassfish-resources.xml` or `payara-resources.xml` files, the resource definitions are scoped to those modules only.

For more information about the `glassfish-resources.xml` and `payara-resources.xml` file, see Payara Server Deployment Descriptor Files and Elements of the Payara Server Deployment Descriptors.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

Naming: Application-scoped resource JNDI names begin with `java:app` or `java:module`. If one of these prefixes is not specified in the JNDI name, it is added. For example, application-scoped databases have JNDI names in the following format: `java:app/jdbc/DataSourceName` or `java:module/jdbc/DataSourceName`.

Errors: Application-scoped resource definitions with same resource name, resource type, attributes, and properties are duplicates. These generate `WARNING` level log messages and deployment continues.

Definitions with the same resource name and type but different attributes or properties are conflicts and cause deployment failure. When an application or module tries to look up a scoped resource that does not belong to it, a naming exception is thrown.

Redeployment: When an application or module is un-deployed, its scoped resources are deleted. During redeployment, resources are destroyed and recreated based on changes in the `glassfish-resources.xml` or `payara-resources.xml` file.

To preserve old resource definitions during redeployment, use the `preserveAppScopedResources` property of the `redeploy` (or `deploy --force=true`) subcommand. For example:

```
asadmin> redeploy --property preserveAppScopedResources=true MyApp.ear

asadmin> deploy --force=true --property preserveAppScopedResources=true MyApp.ear
```

For more information, see `redeploy` and `deploy`.

Listing: Use the `--resources` option of the `list-applications` subcommand to list application-scoped resources. Use the `--subcomponents` option in addition to list scoped resources for enterprise application modules or for module subcomponents.

To list scoped resources for subcomponents only, use the `--resources` option of the `list-subcomponents` subcommand

For more information, see `list-applications` and `list-sub-components`.

Restrictions. Use of application-scoped resources is subject to the following restrictions:

- `resource-adapter-config` and `connector-work-security-map` — These can only be specified in the `glassfish-resources.xml` or `payara-resources.xml` file of the corresponding connector module.

  In an enterprise application, the `resource-adapter-config` or `connector-work-security-map` for an embedded connector module must be specified in the `glassfish-resources.xml` or `payara-resources.xml` file of the connector module.

  You cannot specify a `resource-adapter-config` or `connector-work-security-map` in an application for a connector module that is not part of the application.

- Resource to connection pool cross references — A module-level `jdbc-resource` cannot reference an application-level `jdbc-connection-pool`. Likewise, a module-level `connector-resource` cannot reference an application-level `connector-connection-pool`.
- Global resources — Defining `java:global` JNDI names is not supported.
- Cross definitions — Defining `java:app` JNDI names at the module level is not supported.

The Deployment Subcommands

This appendix lists the `asadmin` deployment subcommands that are included with this release of the Payara Server software. For information on additional `asadmin` subcommands, see "Subcommands for the `asadmin` Utility" in the *Payara Server General Administration section*.

`add-library`

Adds one or more library JAR files to Payara Server. You can specify whether the libraries are added to the Common class loader directory, the Jakarta optional package directory, or the application-specific class loader directory.

`create-application-ref`

Creates a reference from a cluster or an un-clustered server instance to a previously deployed Jakarta EE application or module. This effectively results in the application element being deployed and made available on the targeted instance or cluster.

`delete-application-ref`

Removes a reference from a cluster or an un-clustered server instance to a previously deployed Jakarta EE application or module. This effectively results in the application element being un-deployed on the targeted instance or cluster.

`deploy`

Deploys an enterprise application, web application, EJB module, connector module, or application client module. If the component is already deployed or already exists, you can forcefully redeploy if you set the `--force` option to `true`. A directory can also be deployed. Supported in remote mode only. For usage instructions, see To Deploy an Application or Module.

`deploy-remote-archive`

Deploys an enterprise application, web application, EJB module, connector module, or application client module from a remote location, either using a URL or a set of Maven GAV coordinates. For usage instructions, see To Deploy from a URL and To Deploy using a Maven Artifact.

`disable`

Immediately deactivates the named application or module. If the component has not been deployed, an error message is returned. Supported in remote mode only. For usage instructions, see To Disable an Application or Module.

`enable`

Enables the specified application or module. If the component has not been deployed, an error message is returned. If the component is already enabled, then it is re-enabled. Supported in remote mode only. For usage instructions, see To Enable an Application or Module.

`get-client-stubs`

Gets the client stubs JAR file for an application client module or an application containing the application client module, from the server machine to the local directory. For usage instructions, see EJB Module Deployment Guidelines.

`list-applications`

Lists deployed Jakarta EE applications and modules. Optionally lists subcomponents and scoped resources. If the `--type` option is not specified, all applications and modules are listed. Supported in remote mode only. For usage instructions, see To List Deployed Applications or Modules.

`list-application-refs`

Lists Jakarta EE applications and modules deployed on the specified target server instance or cluster.

`list-libraries`

Lists library JAR files that have been added to Payara Server. You can specify whether to list libraries in the Common class loader directory, the Jakarta optional package directory, or the application-specific class loader directory.

`list-sub-components`

Lists EJBs or servlets in a deployed module or in a module of the deployed application. If a module is not identified, all modules are listed. To display a specific module in an application, you must specify the module name and the `--appname` option. Supported in remote mode only. For usage instructions, see To List Deployed Applications or Modules.

`list-web-context-param`

Lists servlet context-initialization parameters of a deployed web application or module. Supported in remote mode only. For usage instructions, see To List Web Context Parameters.

`list-web-env-entry`

Lists environment entries for a deployed web application or module. Supported in remote mode only. For usage instructions, see To List Web Environment Entries.

`redeploy`

Overwrites an application or module that is already deployed. Supported in remote mode only. For usage instructions, see To Redeploy an Application or Module.

`remove-library`

Removes one or more library JAR files from Payara Server. You can specify whether the libraries are removed from the Common class loader directory, the Jakarta optional package directory, or the application-specific class loader directory.

`set-web-context-param`

Sets a servlet context-initialization parameter of a deployed web application or module. Supported in remote mode only. For usage instructions, see To Set a Web Context Parameter.

`set-web-env-entry`

Sets an environment entry for a deployed web application or module. Supported in remote mode only. For usage instructions, see To Set a Web Environment Entry.

`show-component-status`

Shows the status of a deployed component. The possible statuses include `enabled` or `disabled`. Supported in remote mode only. For usage instructions, see To List Deployed Applications or Modules.

`undeploy`

Uninstalls the specified deployed application or module. Supported in remote mode only. For usage instructions, see To Undeploy an Application or Module.

`unset-web-context-param`

Unsets a servlet context-initialization parameter of a deployed web application or module. Supported in remote mode only. For usage instructions, see To Unset a Web Context Parameter.

`unset-web-env-entry`

Unsets an environment entry for a deployed web application or module. Supported in remote mode only. For usage instructions, see To Unset a Web Environment Entry.

Deployment Descriptor Files

This appendix describes the element hierarchies in the Payara Platform deployment descriptors that are supported on top of the standard Jakarta EE deployment descriptors.

About the Payara Platform Deployment Descriptors

Each deployment descriptor XML file has a corresponding Document Type Definition (DTD) file, which defines the elements, data, and attributes that the deployment descriptor file can contain.

For example, the `payara-application_11_0-0.dtd` file defines the structure of the `payara-application.xml` file. The DTD files for the Payara Server deployment descriptors are located in the `as-install/lib/dtds` directory.

The Platform Server deployment descriptor files must be readable and writable by the file owners. In each deployment descriptor file, sub-elements must be defined in the order in which they are listed under each Sub-elements heading, unless otherwise noted.

For general information about DTD files and XML, see the XML specification at `http://www.w3.org/`

TR/REC-xml.

Do not edit the DTD files; their contents change only with new versions of Payara Server.

The following table lists the Payara Platform deployment descriptors and their DTD files.

Table 15. Payara Platform Deployment Descriptors and DTDs

Deployment Descriptor	DTD File	Description
glassfish-application.xml (deprecated) payara-application.xml	glassfish-application_6_0-1.dtd payara-application_11_0-0.dtd	Configures an entire Jakarta EE application (EAR file).
glassfish-web.xml (deprecated) payara-web.xml	glassfish-web-app_3_0-1.dtd payara-web-app_4.dtd	Configures a web application (WAR file).
glassfish-ejb-jar.xml (deprecated) payara-ejb-jar.xml	glassfish-ejb-jar_3_1-1.dtd payara-ejb-jar_4_0-0.dtd	Configures an enterprise bean (EJB JAR file).
glassfish-application-client.xml (deprecated) payara-application-client.xml	glassfish-application-client_6_0-1.dtd payara-application-client_11_0-0.dtd	Configures an Application Client Container (ACC) client (JAR file).
glassfish-resources.xml (deprecated) payara-resources.xml	glassfish-resources_1_5.dtd payara-resources_1_8.dtd	Configures application-scoped resources.
sun-acc.xml (deprecated) glassfish-acc.xml (deprecated) payara-acc.xml	sun-application-client-container_1_2.dtd glassfish-application-client-container_1_3.dtd payara-application-client-container_1_4.dtd	Configures the Application Client Container. This is more of a configuration file than a deployment descriptor. Payara Server provides a default file in the domain-dir/config directory. Specifying a different file is optional.

Deployment descriptors whose names start with the glassfish- prefix are referred as "original" deployment descriptor files from Eclipse GlassFish, since these files names and DTDs were created while supporting Eclipse GlassFish and their support has been inherited by the Payara Platform.

The payara-application.xml File

glassfish-application.xml is deprecated and support will be removed in a future release. It is recommended to use payara-application.xml instead.

The `payara-application.xml` file configures an entire Jakarta EE application (EAR file). The element hierarchy is as follows:

```
payara-application
.  web
.  .  web-uri
.  .  context-root
.  pass-by-reference
.  unique-id
.  security-role-mapping
.  .  role-name
.  .  principal-name
.  .  group-name
.  realm
.  ejb-ref
.  .  ejb-ref-name
.  .  jndi-name
.  resource-ref
.  .  res-ref-name
.  .  jndi-name
.  .  default-resource-principal
.  .  .  name
.  .  .  password
.  resource-env-ref
.  .  resource-env-ref-name
.  .  jndi-name
.  service-ref
.  .  service-ref-name
.  .  port-info
.  .  .  service-endpoint-interface
.  .  .  wsdl-port
.  .  .  .  namespaceURI
.  .  .  .  localpart
.  .  .  stub-property
.  .  .  .  name
.  .  .  .  value
.  .  .  call-property
.  .  .  .  name
.  .  .  .  value
.  .  .  message-security-binding
.  .  .  .  message-security
.  .  .  .  .  message

The `glassfish-web.xml` and `payara-web.xml` Files

The `glassfish-web.xml` file configures a web application (WAR file). It is an original Eclipse GlassFish deployment descriptor.

The `payara-web.xml` is a matching Payara Platform variant which is recommended to be used whenever possible.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

Their element hierarchy is as follows:

```
payara-web-app
.  context-root
.  security-role-mapping
.  .  role-name
.  .  principal-name
.  .  group-name
.  servlet
.  .  servlet-name

```

If any configuration information for an enterprise bean is not specified in the `payara-ejb-jar.xml` file, it defaults to a corresponding setting in the EJB container if an equivalency exists.

A sample `payara-ejb-jar.xml` *file:*

```
<!DOCTYPE payara-ejb-jar PUBLIC "-//Payara.fish//
DTD Payara Application Server 7 EJB 4.0//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-ejb-jar_4_0-0.dtd}">
<payara-ejb-jar>
    <enterprise-beans>
        <ejb>
            <ejb-name>CustomerEJB</ejb-name>
            <jndi-name>customer</jndi-name>
            <bean-pool>
                <steady-pool-size>10</steady-pool-size>
                <resize-quantity>10</resize-quantity>
                <max-pool-size>100</max-pool-size>
```

```
                <pool-idle-timeout-in-seconds>600</pool-idle-timeout-in-seconds>
            </bean-pool>
            <bean-cache>
                <max-cache-size>100</max-cache-size>
                <resize-quantity>10</resize-quantity>
                <removal-timeout-in-seconds>3600</removal-timeout-in-seconds>
                <victim-selection-policy>LRU</victim-selection-policy>
            </bean-cache>
        </ejb>
    </enterprise-beans>
    <keep-state>true</keep-state>
</payara-ejb-jar>
```

The `payara-application-client.xml` file

glassfish-application-client.xml is deprecated and support will be removed in a future release. It is recommended to use payara-application-client.xml instead.

The `payara-application-client.xml` file configures an Application Client Container (ACC) client (JAR file). The element hierarchy is as follows:

```
payara-application-client
.  ejb-ref
.  .  ejb-ref-name
.  .  jndi-name
.  resource-ref
.  .  res-ref-name
.  .  jndi-name
.  .  default-resource-principal

.  .  message-destination-name
.  .  jndi-name
.  java-web-start-access
.  .  context-root
.  .  eligible
.  .  vendor
.  .  jnlp-doc
.  version-identifier
```

A sample `payara-application-client.xml` *file:*

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-application-client PUBLIC "-//Payara.fish//DTD Payara Application
Server 7 Jakarta EE Application Client 11//EN" "{payaraApplicationClientDtd}">
<payara-application-client>
  <message-destination-ref>
    <message-destination-ref-name>ClientQueue</message-destination-ref-name>
    <jndi-name>jms/security_mdb_OutQueue</jndi-name>
  </message-destination-ref>
</payara-application-client>
```

The `glassfish-resources.xml` and `payara-resources.xml` Files

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

The `glassfish-resources.xml` file configures application-scoped resources. It is an original Eclipse GlassFish deployment descriptor.

The `payara-resources.xml` is a matching Payara Platform variant that supports additional elements.

Their element hierarchy is as follows:

```
resources
.  custom-resource
.  .  description
.  .  property (with attributes)
.  .  .  description
.  external-jndi-resource
.  .  description
.  .  property (with attributes)
.  .  .  description
.  jdbc-resource
.  .  description
.  .  property (with attributes)
.  .  .  description
.  mail-resource
.  .  description
.  .  property (with attributes)
.  .  .  description
.  admin-object-resource
.  .  description
.  .  property (with attributes)
.  .  .  description
.  connector-resource
.  .  description
.  .  property (with attributes)
.  .  .  description
.  resource-adapter-config
.  .  property (with attributes)
.  .  .  description
.  jdbc-connection-pool
.  .  description
.  .  log-jdbc-calls
.  .  property (with attributes)
.  .  .  description
.  connector-connection-pool
.  .  description
.  .  security-map
.  .  .  principal
.  .  .  user-group
.  .  .  backend-principal
.  .  property (with attributes)
.  .  .  description
.  work-security-map
.  .  description
.  .  principal-map
.  .  group-map
.  managed-executor-service (*)
```

```
.  managed-scheduled-executor-service (*)
.  managed-thread-factory (*)
```

The elements marked as (*) are only supported in the payara-resources.xml deployment descriptor variant.

1. A sample payara-resources.xml

```
<!DOCTYPE resources PUBLIC "-//Payara.fish//DTD Payara Server {page-version} Resource
Definitions//EN" "{payaraResourcesDtd}">
<resources>
    <!-- Connects to MySql database called 'test' on a server called 'database' -->
    <jdbc-connection-pool name="jdbc/testConnPool"
                          res-type="javax.sql.DataSource"
                          datasource-
classname="com.mysql.jdbc.jdbc2.optional.MysqlDataSource"
                          pool-resize-quantity="2"
                          max-pool-size="32"
                          steady-pool-size="8">
        <property name="URL" value="jdbc:mysql://database:3306/test"/>
        <property name="User" value="root"/>
        <property name="Password" value="password"/>
    </jdbc-connection-pool>
    <jdbc-resource enabled="true" jndi-name="jdbc/testDS" object-type="user" pool-
name="jdbc/testConnPool">
        <description>Test DataSource jdbc/testDS for Connection Pool
jdbc/testConnPool</description>
    </jdbc-resource>
</resources>
```

The sun-acc.xml File

The sun-acc.xml file configures the Application Client Container. This is more of a configuration file than a deployment descriptor.

Payara Server provides a default file in the domain-dir/config directory. Specifying a different file is optional. The element hierarchy is as follows:

```
client-container
.  target-server
.  .  description
.  .  security
.  .  .  ssl
.  .  .  cert-db
.  auth-realm
.  .  property (with attributes)
.  client-credential
.  .  property (with attributes)
```

```
.  log-service
.  .  property (with attributes)
.  message-security-config
.  .  provider-config
.  .  .  request-policy
.  .  .  response-policy
.  .  .  property (with attributes)
.  property (with attributes)
```

Deployment Descriptor Precedence Order

When multiple vendor deployment descriptors are present in the same module (including deployment descriptors of the original **Eclipse GlassFish** and of the old **Sun Application Server**), the descriptors are processed with the following precedence order in default mode:

```
Payara Platform > Eclipse GlassFish Server > Sun Application Server
```

Elements of Deployment Descriptors

This appendix describes the elements of the Payara Platform deployment descriptors.

`activation-config`

Specifies an activation configuration, which includes the runtime configuration properties of the message-driven bean in its operational environment. For example, this can include information about the name of a physical JMS destination. Matches and overrides the `activation-config` element in the `ejb-jar.xml` file.

Superelements

`mdb-resource-adapter` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `activation-config` element.

Table 16. `activation-config` subelements

Element	Required	Description
`description`	zero or one	Specifies a text description of the activation configuration.
`activation-config-property`	one or more	Specifies an activation configuration property.

`activation-config-property`

Specifies the name and value of an activation configuration property.

Superelements

`activation-config` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `activation-config-property` element.

Table 17. `activation-config-property` subelements

Element	Required	Description
`activation-config-property-name`	only one	Specifies the name of an activation configuration property.
`activation-config-property-value`	only one	Specifies the value of an activation configuration property.

`activation-config-property-name`

Specifies the name of an activation configuration property.

Superelements

`activation-config-property` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`activation-config-property-value`

Specifies the value of an activation configuration property.

Superelements

`activation-config-property` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`admin-object-resource`

Defines an administered object for an inbound resource adapter.

Superelements

`resources` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `admin-object-resource` element.

Table 18. `admin-object-resource` Subelements

Element	Required	Description
description	zero or one	Contains a text description of this element.
property (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the admin-object-resource element.

Table 19. admin-object-resource Attributes

Attribute	Default	Description
jndi-name	none	Specifies the JNDI name for the resource.
res-type	none	Specifies the fully qualified type of the resource.
res-adapter	none	Specifies the name of the inbound resource adapter.
object-type	user	(optional) Defines the type of the resource. Allowed values are: • system-all - A system resource for all server instances and the domain application server. • system-admin - A system resource only for the domain application server. • system-instance - A system resource for all server instances only. • user - A user resource.
enabled	true	(optional) Determines whether this resource is enabled at runtime.

Properties

Properties of the admin-object-resource element are the names of setter methods of the class referenced by the adminobject-class of the ra.xml file.

Some of the property names can be specified in the adminobjectType element.

as-context

Specifies the authentication mechanism used to authenticate the client.

Superelements

ior-security-config (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

The following table describes subelements for the as-context element.

Table 20. as-context Subelements

Element	Required	Description
auth-method	only one	Specifies the authentication method. The only supported value is USERNAME_PASSWORD.
realm	only one	Specifies the realm in which the user is authenticated.
required	only one	Specifies whether the authentication method specified in the auth-method element must be used for client authentication.

archive-name

Specifies the name of the archive file. The value of the archive-name element is used to derive the default application name when display-name is not present in the application.xml file.

The default application name is the archive-name value minus the file extension. For example, if archive-name is foo.ear, the default application name is foo.

Superelements

payara-application` (glassfish-application.xml (deprecated) and `payara-application.xml)

Subelements

none - contains data

auth-method

Specifies the authentication method.

If the parent element is as-context, the only supported value is USERNAME_PASSWORD.

If the parent element is login-config, specifies the authentication mechanism for the web service endpoint. As a prerequisite to gaining access to any web resources protected by an authorization constraint, a user must be authenticated using the configured mechanism.

Superelements

login-config (glassfish-web.xml (deprecated) and payara-web.xml), as-context (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

auth-realm

JAAS is available on the ACC. Defines the optional configuration for a JAAS authentication realm. Authentication realms require provider-specific properties, which vary depending on what a particular implementation needs. For more information about how to define realms, see "Realm Configuration" in the Payara Server Application Development section.

Superelements

`client-container` (`sun-acc.xml`)

Subelements

The following table describes subelements for the `auth-realm` element.

Table 21. `auth-realm` subelement

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

`Attributes`

The following table describes attributes for the `auth-realm` element.

Table 22. `auth-realm` attributes

Attribute	Default	Description
`name`	none	Defines the name of this realm.
`classname`	none	Defines the Jakarta class which implements this realm.

Example

Here is an example of the default file realm:

```
<auth-realm name="file"
   classname="com.sun.enterprise.security.auth.realm.file.FileRealm">
   <property name="file" value="domain-dir/config/keyfile"/>
   <property name="jaas-context" value="fileRealm"/>
</auth-realm>
```

Which properties an `auth-realm` element uses depends on the value of the `auth-realm` element's `name` attribute. The file realm uses `file` and `jaas-context` properties. Other realms use different properties. See "Realm Configuration" in the Payara Server Application Development section.

`backend-principal`

Specifies the user name and password required by the Enterprise Information System (EIS).

Superelements

`security-map` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

none

Attributes

The following table describes attributes for the `backend-principal` element.

Table 23. `backend-principal` Attributes

Attribute	Default	Description
`user-name`	none	Specifies the user name required by the EIS.
`password`	none	(optional) Specifies the password required by the EIS, if any.

`bean-cache`

Specifies the entity bean cache properties. Used for entity beans and stateful session beans.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `bean-cache` element.

Table 24. `bean-cache` Subelements

Element	Required	Description
`max-cache-size`	zero or one	Specifies the maximum number of beans allowable in cache.
`cache-idle-timeout-in-seconds`	zero or one	Specifies the maximum time that a stateful session bean or entity bean is allowed to be idle in cache before being passivated. Default value is 10 minutes (600 seconds).
`removal-timeout-in-seconds`	zero or one	Specifies the amount of time a bean remains before being removed. If `removal-timeout-in-seconds` is less than `idle-timeout`, the bean is removed without being passivated.
`resize-quantity`	zero or one	Specifies the number of beans to be created if the pool is empty (subject to the `max-pool-size` limit). Values are from 0 to MAX_INTEGER.
`victim-selection-policy`	zero or one	Specifies the algorithm that must be used by the container to pick victims. Applies only to stateful session beans.

Example

```
<bean-cache>
   <max-cache-size>100</max-cache-size>
   <cache-resize-quantity>10</cache-resize-quantity>
```

```
   <removal-timeout-in-seconds>3600</removal-timeout-in-seconds>
   <victim-selection-policy>LRU</victim-selection-policy>
      <cache-idle-timeout-in-seconds>600</cache-idle-timeout-in-seconds>
   <removal-timeout-in-seconds>5400</removal-timeout-in-seconds>
</bean-cache>
```

bean-pool

Specifies the pool properties of stateless session beans, entity beans, and message-driven bean.

Superelements

ejb (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

The following table describes subelements for the bean-pool element.

Table 25. bean-pool Subelements

Element	Required	Description
steady-pool-size	zero or one	Specifies the initial and minimum number of beans maintained in the pool. Default is 32.
resize-quantity	zero or one	Specifies the number of beans to be created if the pool is empty (subject to the max-pool-size limit). Values are from 0 to MAX_INTEGER.
max-pool-size	zero or one	Specifies the maximum number of beans in the pool. Values are from 0 to MAX_INTEGER. Default is to the EJB container value or 60.
pool-idle-timeout-in-seconds	zero or one	Specifies the maximum time that a bean is allowed to be idle in the pool. After this time, the bean is removed. This is a hint to the server. Default time is 600 seconds (10 minutes).

Example

```
<bean-pool>
   <steady-pool-size>10</steady-pool-size>
   <resize-quantity>10</resize-quantity>
   <max-pool-size>100</max-pool-size>
   <pool-idle-timeout-in-seconds>600</pool-idle-timeout-in-seconds>
</bean-pool>
```

cache

Configures caching for web application components.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `cache` element.

Table 26. `cache` Subelements

Element	Required	Description
`cache-helper`	zero or more	Specifies a custom class that implements the CacheHelper interface.
`default-helper`	zero or one	Allows you to change the properties of the default, built-in `cache-helper` class.
`property` (with attributes)	zero or more	Specifies a cache property, which has a name and a value.
`cache-mapping`	zero or more	Maps a URL pattern or a servlet name to its cacheability constraints.

Attributes

The following table describes attributes for the `cache` element.

Table 27. `cache` Attributes

Attribute	Default	Description
`max-entries`	`4096`	(optional) Specifies the maximum number of entries the cache can contain. Must be a positive integer.
`timeout-in-seconds`	`30`	(optional) Specifies the maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed. Can be overridden by a `timeout` element.
`enabled`	`true`	(optional) Determines whether servlet and JSP caching is enabled.

Properties

The following table describes properties for the `cache` element.

Table 28. `cache` Properties

Property	Default	Description
`cacheClassName`	`com.sun.appserv.web.cache.LruCache`	Specifies the fully qualified name of the class that implements the cache functionality. See Cache Class Names for possible values.

Property	Default	Description
MultiLRUSegmentSize	4096	Specifies the number of entries in a segment of the cache table that should have its own LRU (least recently used) list. Applicable only if cacheClassName is set to com.sun.appserv.web.cache.MultiLruCache.
MaxSize	unlimited; Long.MAX_VALUE	Specifies an upper bound on the cache memory size in bytes (KB or MB units). Example values are 32 KB or 2 MB. Applicable only if cacheClassName is set to com.sun.appserv.web.cache.BoundedMultiLruCache.

Cache Class Names

The following table lists possible values of the cacheClassName property.

Table 29. cacheClassName Values

Value	Description
com.sun.appserv.web.cache.LruCache	A bounded cache with an LRU (least recently used) cache replacement policy.
com.sun.appserv.web.cache.BaseCache	An unbounded cache suitable if the maximum number of entries is known.
com.sun.appserv.web.cache.MultiLruCache	A cache suitable for a large number of entries (>4096). Uses the MultiLRUSegmentSize property.
com.sun.appserv.web.cache.BoundedMultiLruCache	A cache suitable for limiting the cache size by memory rather than number of entries. Uses the MaxSize property.

cache-helper

Specifies a class that implements the com.sun.appserv.web.cache.CacheHelper interface.

Superelements

cache (glassfish-web.xml (deprecated) and payara-web.xml)

Subelements

The following table describes subelements for the cache-helper element.

Table 30. cache-helper Subelements

Element	Required	Description
property (with attributes)	zero or more	Specifies a property, which has a name and a value.

Attributes

The following table describes attributes for the cache-helper element.

Table 31. `cache-helper` Attributes

Attribute	Default	Description
`name`	`default`	Specifies a unique name for the helper class, which is referenced in the `cache-mapping` element.
`class-name`	none	Specifies the fully qualified class name of the cache helper, which must implement the com.sun.appserv.web.CacheHelper interface.

`cache-helper-ref`

Specifies the `name` of the `cache-helper` used by the parent `cache-mapping` element.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none - contains data

`cache-idle-timeout-in-seconds`

Specifies the maximum time that a bean can remain idle in the cache. After this amount of time, the container can passivate this bean. A value of `0` specifies that beans never become candidates for passivation. Default is 600.

Applies to stateful session beans and entity beans.

Superelements

`bean-cache` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`cache-mapping`

Maps a URL pattern or a servlet name to its cacheability constraints.

Superelements

`cache` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `cache-mapping` element.

Table 32. `cache-mapping` Subelements

Element	Required	Description
servlet-name	requires one servlet-name or url-pattern	Contains the name of a servlet.
url-pattern	requires one servlet-name or url-pattern	Contains a servlet URL pattern for which caching is enabled.
cache-helper-ref	required if dispatcher, timeout, refresh-field, http-method, key-field, and constraint-field are not used	Contains the name of the cache-helper used by the parent cache-mapping element.
dispatcher	zero or one if cache-helper-ref is not used	Contains a comma-separated list of RequestDispatcher methods for which caching is enabled.
timeout	zero or one if cache-helper-ref is not used	Contains the cache-mapping specific maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed.
refresh-field	zero or one if cache-helper-ref is not used	Specifies a field that gives the application component a programmatic way to refresh a cached entry.
http-method	zero or more if cache-helper-ref is not used	Contains an HTTP method that is eligible for caching.
key-field	zero or more if cache-helper-ref is not used	Specifies a component of the key used to look up and extract cache entries.
constraint-field	zero or more if cache-helper-ref is not used	Specifies a cacheability constraint for the given url-pattern or servlet-name.

call-property

Specifies JAX-RPC property values that can be set on a javax.xml.rpc.Call object before it is returned to the web service client. The property names can be any properties supported by the JAX-RPC Call implementation.

Superelements

port-info, service-ref (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml`)

Subelements

The following table describes subelements for the `call-property` element.

Table 33. `call-property` subelements

Element	Required	Description
`name`	only one	Specifies the name of the entity.
`value`	only one	Specifies the value of the entity.

`caller-propagation`

Specifies whether the target accepts propagated caller identities. The values are `NONE`, `SUPPORTED`, or `REQUIRED`.

Superelements

`sas-context` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`cert-db`

Not implemented. Included for backward compatibility only. Attribute values are ignored.

Superelements

`security` (`sun-acc.xml`)

Subelements

none

Attributes

The following table describes attributes for the `cert-db` element.

Table 34. `cert-db` attributes

Attribute	Default	Description
`path`	none	Specifies the absolute path of the certificate database.
`password`	none	Specifies the password to access the certificate database.

`checkpoint-at-end-of-method`

Specifies that the stateful session bean state is checkpointed, or persisted, after the specified methods are executed. The `availability-enabled` attribute of the parent `ejb` element must be set to `true`.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `checkpoint-at-end-of-method` element.

Table 35. `checkpoint-at-end-of-method` Subelements

Element	Required	Description
`method`	one or more	Specifies a bean method.

`class-loader`

Configures the class loader for the web module.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `class-loader` element.

Table 36. `class-loader` Subelements

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Attributes

The following table describes attributes for the `class-loader` element.

Table 37. `class-loader` Attributes

Attribute	Default	Description
`extra-class-path`	null	(optional) Specifies a colon or semicolon separated list of additional classpaths for this web module. Paths can be absolute or relative to the web module's root, for example: `extra-class-path="WEB-INF/lib/extra/extra.jar"`

Attribute	Default	Description
`delegate`	`true`	(optional) If `true`, the web module follows the standard class loader delegation model and delegates to its parent class loader first before looking in the local class loader. You must set this to `true` for a web module that accesses EJB components or that acts as a web service client or endpoint. If `false`, the web module follows the delegation model specified in the Servlet specification and looks in its class loader before looking in the parent class loader. It's safe to set this to `false` only for a web module that does not interact with any other modules. For a number of packages, including `java.` and `javax.`, symbol resolution is always delegated to the parent class loader regardless of the delegate setting. This prevents applications from overriding core Java runtime classes or changing the API versions of specifications that are part of the Jakarta EE platform.
`dynamic-reload-interval`	+	(optional) Not implemented. Included for backward compatibility with previous Oracle Web Server versions.

If the `delegate` attribute is set to `false`, the class loader delegation behavior complies with the Servlet 6.0 specification, section 10.7.2. If set to its default value of `true`, classes and resources residing in container-wide library JAR files are loaded in preference to classes and resources packaged within the WAR file. Portable programs that use this element should not be packaged with any classes or interfaces that are a part of the Jakarta EE specification. The behavior of a program that includes such classes or interfaces in its WAR file is undefined.

Properties

The following table describes properties for the `class-loader` element.

Table 38. `class-loader` Properties

Property	Default	Description
`ignoreHiddenJarFiles`	`false`	If `true`, specifies that all JAR and ZIP files in the `WEB-INF/lib` directory that start with a period (`.`) are ignored by the class loader.

`classloading-delegate`

With this option its possible to enable/disable **class loading delegation**. This allows deployed

application to use libraries included on them, overriding the versions included on the server.

For more information about how class delegation can be configured on Payara Server, see the Enhanced Class loading section.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`)

Subelements

none

`client-container`

Defines the Payara Server specific configuration for the application client container. This is the root element; there can only be one `client-container` element in a `sun-acc.xml` file. See The sun-acc.xml File.

Superelements

none

Subelements

The following table describes subelements for the `client-container` element.

Table 39. `client-container` Subelements

Element	Required	Description
`target-server`	one or more	Specifies the IIOP listener for the target server. Also specifies IIOP endpoints used for load balancing. If the Payara Server instance on which the application client is deployed participates in a cluster, Payara Server finds all currently active IIOP endpoints in the cluster automatically. However, a client should have at least two endpoints specified for bootstrapping purposes, in case one of the endpoints has failed. A listener or endpoint is in the form `host:port`, where the host is an IP address or host name, and the port specifies the port number.
`auth-realm`	zero or one	Specifies the optional configuration for JAAS authentication realm.
`client-credential`	zero or one	Specifies the default client credential that is sent to the server.
`log-service`	zero or one	Specifies the default log file and the severity level of the message.

Element	Required	Description
`message-security-config`	zero or more	Specifies configurations for message security providers.
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Attributes

The following table describes attributes for the `client-container` element.

Table 40. `client-container` Attributes

Attribute	Default	Description
`send-password`	`true`	If `true`, specifies that client authentication credentials must be sent to the server. Without authentication credentials, all access to protected EJB components results in exceptions.

`client-credential`

Default client credentials that are sent to the server. If this element is present, the credentials are automatically sent to the server, without prompting the user for the user name and password on the client side.

Superelements

`client-container` (`sun-acc.xml`)

Subelements

The following table describes subelements for the `client-credential` element.

Table 41. `client-credential` subelement

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Attributes

The following table describes attributes for the `client-credential` element.

Table 42. `client-credential` attributes

Attribute	Default	Description
`user-name`	none	The user name used to authenticate the Application client container.
`password`	none	The password used to authenticate the Application client container.
`realm`	default realm for the domain	(optional) The realm (specified by name) where credentials are to be resolved.

`clustered-attach-postconstruct`

Describes whether to call a `@PostConstruct` event listener each time the corresponding singleton bean is created on a different node. This setup will result in multiple calls. Valid values are `true` or `false`.

The default value is `true`.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none

`clustered-bean`

Describes whether this bean should be a Clustered Singleton. Can be applied only to singleton EJBs.

Valid values are `true` or `false`. The default value is `false`.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none

`clustered-detach-predestroy`

Whether to call a `@PreDestroy` event listener when a singleton EJB bean is destroyed on an instance while still being available on another. This setup will result in multiple calls.

Valid values are `true` or `false`. The default value is `true`.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none

`clustered-key-name`

The key used for replication of clustered singletons beans. Applies to a singleton EJBs when the `clustered-bean` element is set to `true`.

This element is optional. If not set, the default key is the value of the `ejb-name` element.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none

`clustered-lock-type`

Describes the type of distributed locking to be performed for a clustered singleton bean:

- For EJB beans, only `INHERIT` and `LOCK_NONE` are valid.
- For CDI beans, valid values are `LOCK` and `INHERIT`, which is equivalent to using `LOCK_NONE`.

The default value is `INHERIT`

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none

`cmt-timeout-in-seconds`

Overrides the Transaction Timeout setting of the Transaction Service for an individual bean. The default value, `0`, specifies that the default Transaction Service timeout is used. If positive, this value is used for all methods in the bean that start a new container-managed transaction. This value is not used if the bean joins a client transaction.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`commit-option`

Specifies the commit option used on transaction completion. Valid values for Payara Server are `B` or `C`. Default value is `B`. Applies to entity beans.

Commit option A is not supported for this Payara Server release.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`compatibility`

Specifies the Payara Server release with which to be backward compatible in terms of JAR visibility requirements for applications. The current allowed value is `v2`, which refers to older runtimes from where Payara Server is based from. Starting in Java EE 6, the Java EE specification imposes stricter requirements than Java EE 5 did on which JAR files can be visible to various modules within an EAR file. Setting this element to `v2` removes these Java EE 6 and later restrictions.

Superelements

`payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `payara-ejb-jar` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`confidentiality`

Specifies if the target supports privacy-protected messages. The values are `NONE`, `SUPPORTED`, or `REQUIRED`.

Superelements

`transport-config` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`connector-connection-pool`

Defines a connector connection pool.

Superelements

`resources` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `connector-connection-pool` element.

Table 43. `connector-connection-pool` Subelements

Element	Required	Description
`description`	zero or one	Contains a text description of this element.
`security-map`	zero or more	Maps the principal received during servlet or EJB authentication to the credentials accepted by the EIS.

Element	Required	Description
property (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the connector-connection-pool element. Changing the following attributes requires a server restart or the redeployment or disabling and re-enabling of applications that refer to the resource: resource-adapter-name, connection-definition-name, transaction-support, associate-with-thread, lazy-connection-association, and lazy-connection-enlistment.

Table 44. connector-connection-pool *Attributes*

Attribute	Default	Description
name	none	Specifies the name of the connection pool. A connector-resource element's pool-name attribute refers to this name.
resource-adapter-name	none	Specifies the name of the deployed connector module or application. If no name is specified during deployment, the name of the .rar file is used. If the resource adapter is embedded in an application, then it is app_name#rar_name.
connection-definition-name	none	Specifies a unique name, identifying a resource adapter's connection-definition element in the ra.xml file. This is usually the connectionfactory-interface of the connection-definition element.
steady-pool-size	8	(optional) Specifies the initial and minimum number of connections maintained in the pool.
max-pool-size	32	(optional) Specifies the maximum number of connections that can be created to satisfy client requests.
max-wait-time-in-millis	60000	(optional) Specifies the amount of time, in milliseconds, that the caller is willing to wait for a connection. If 0, the caller is blocked indefinitely until a resource is available or an error occurs.
pool-resize-quantity	2	(optional) Specifies the number of idle connections to be destroyed if the existing number of connections is above the steady-pool-size (subject to the max-pool-size limit). This is enforced periodically at the idle-timeout-in-seconds interval. An idle connection is one that has not been used for a period of idle-timeout-in-seconds. When the pool size reaches steady-pool-size, connection removal stops.

Attribute	Default	Description
idle-timeout-in-seconds	300	(optional) Specifies the maximum time that a connection can remain idle in the pool. After this amount of time, the pool can close this connection.
fail-all-connections	false	(optional) If true, closes all connections in the pool if a single validation check fails.
transaction-support	none	(optional) Specifies the transaction support for this connection pool. Overrides the transaction support defined in the resource adapter in a downward compatible way: supports a transaction level lower than or equal to the resource adapter's, but not higher. Allowed values in descending order are: • XATransaction - Supports distributed transactions. • LocalTransaction - Supports local transactions only. • NoTransaction - No transaction support.
is-connection-validation-required	false	(optional) Specifies whether connections have to be validated before being given to the application. If a resource's validation fails, it is destroyed, and a new resource is created and returned.
validate-atmost-once-period-in-seconds	0	Specifies the time interval within which a connection is validated at most once. Minimizes the number of validation calls. A value of zero allows unlimited validation calls.
connection-leak-timeout-in-seconds	0	Detects potential connection leaks by the application. A connection that is not returned back to the pool by the application within the specified period is assumed to be potentially leaking, and a stack trace of the caller is logged. A zero value disables leak detection. A nonzero value enables leak tracing.
connection-leak-reclaim	false	If true, the pool will reclaim a connection after connection-leak-timeout-in-seconds occurs.
connection-creation-retry-attempts	0	Specifies the number of attempts to create a new connection.
connection-creation-retry-interval-in-seconds	10	Specifies the time interval between attempts to create a connection when connection-creation-retry-attempts is greater than 0.
lazy-connection-enlistment	false	If true, a connection is not enlisted in a transaction until it is used. If false, any connection object available to a transaction is enlisted in the transaction.

Attribute	Default	Description
lazy-connection-association	false	If true, a physical connection is not associated with a logical connection until it is used. If false, a physical connection is associated with a logical connection even before it is used.
associate-with-thread	false	If true, allows connections to be saved as ThreadLocal in the calling thread. Connections get reclaimed only when the calling thread dies or when the calling thread is not in use and the pool has run out of connections. If false, the thread must obtain a connection from the pool each time the thread requires a connection. This attribute associates connections with a thread such that when the same thread is in need of connections, it can reuse the connections already associated with that thread. In this case, the overhead of getting connections from the pool is avoided. However, when this value is set to true, you should verify that the value of the max-pool-size attribute is comparable to the max-thread-pool-size attribute of the associated thread pool. If the max-thread-pool-size value is much higher than the max-pool-size value, a lot of time is spent associating connections with a new thread after dissociating them from an older one. Use this attribute in cases where the thread pool should reuse connections to avoid this overhead.
match-connections	true	If true, enables connection matching. You can set to false if connections are homogeneous.
max-connection-usage-count	0	Specifies the number of times a connections is reused by the pool, after which it is closed. A zero value disables this feature.
ping	false	(optional) Specifies whether to ping the pool during pool creation or reconfiguration to identify and warn of any erroneous attribute values.
pooling	true	(optional) If false, disables connection pooling.

Properties

Most properties of the connector-connection-pool element are the names of setter methods of the managedconnectionfactory-class element in the ra.xml file. Properties of the connector-connection-pool element override the ManagedConnectionFactory JavaBean configuration settings.

All but the last four properties in the following table are connector-connection-pool properties of jmsra, the resource adapter used to communicate with the Open Message Queue software.

Changes to `connector-connection-pool` properties require a server restart.

Table 45. `connector-connection-pool` Properties

Property	Default	Description
`AddressList`	none	Specifies a list of host/port combinations of the Message Queue software. For JMS resources of the Type `jakarta.jms.TopicConnectionFactory` or `jakarta.jms.QueueConnectionFactory`.
`ClientId`	none	Specifies the JMS Client Identifier to be associated with a `Connection` created using the `createTopicConnection` method of the `TopicConnectionFactory` class. For JMS resources of the Type `jakarta.jms.TopicConnectionFactory` . Durable subscription names are unique and only valid within the scope of a client identifier. To create or reactivate a durable subscriber, the connection must have a valid client identifier. The JMS specification ensures that client identifiers are unique and that a given client identifier is allowed to be used by only one active connection at a time.
`UserName`	`guest`	Specifies the user name for connecting to the Message Queue software. For JMS resources of the Type `jakarta.jms.TopicConnectionFactory` or `jakarta.jms.QueueConnectionFactory`.
`Password`	`guest`	Specifies the password for connecting to the Message Queue software. For JMS resources of the Type `jakarta.jms.TopicConnectionFactory` or `jakarta.jms.QueueConnectionFactory`.
`ReconnectAttempts`	`6`	Specifies the number of attempts to connect (or reconnect) for each address in the `imqAddressList` before the client runtime moves on to try the next address in the list. A value of `-1` indicates that the number of reconnect attempts is unlimited (the client runtime attempts to connect to the first address until it succeeds).
`ReconnectInterval`	`30000`	Specifies the interval between reconnect attempts in milliseconds. This applies to attempts on each address in the `imqAddressList` and on successive addresses in the list. If too short, this time interval does not give a broker time to recover. If too long, the reconnect might represent an unacceptable delay.

Property	Default	Description
ReconnectEnabled	false	If true, specifies that the client runtime attempts to reconnect to a message server (or the list of addresses in imqAddressList) when a connection is lost.
AddressListBehavior	priority	Specifies whether connection attempts are in the order of addresses in the imqAddressList attribute (priority) or in a random order (random). If many clients are attempting a connection using the same connection factory, use a random order to prevent them from all being connected to the same address.
AddressListIterations	-1	Specifies the number of times the client runtime iterates through the imqAddressList in an effort to establish (or reestablish) a connection. A value of -1 indicates that the number of attempts is unlimited.

connector-resource

Defines the connection factory object of a specific connection definition in a connector (resource adapter).

Superelements

resources (glassfish-resources.xml (deprecated) and payara-resources.xml)

Subelements

The following table describes subelements for the connector-resource element.

Table 46. connector-resource Subelements

Element	Required	Description
description	zero or one	Contains a text description of this element.
property (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the connector-resource element.

Table 47. connector-resource Attributes

Attribute	Default	Description
jndi-name	none	Specifies the JNDI name for the resource.
pool-name	none	Specifies the name of the associated connector-connection-pool.

Attribute	Default	Description
`object-type`	`user`	(optional) Defines the type of the resource. Allowed values are: • `system-all` - A system resource for all server instances and the domain application server. • `system-admin` - A system resource only for the domain application server. • `system-instance` - A system resource for all server instances only. • `user` - A user resource.
`enabled`	`true`	(optional) Determines whether this resource is enabled at runtime.

`constraint-field`

Specifies a cacheability constraint for the given `url-pattern` or `servlet-name`.

All `constraint-field` constraints must pass for a response to be cached. If there are `value` constraints, at least one of them must pass.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `constraint-field` element.

Table 48. `constraint-field` Subelements

Element	Required	Description
`constraint-field-value`	zero or more	Contains a value to be matched to the input parameter value.

Attributes

The following table describes attributes for the `constraint-field` element.

Table 49. `constraint-field` Attributes

Attribute	Default	Description
`name`	none	Specifies the input parameter name.
`scope`	`request.parameter`	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are `context.attribute`, `request.header`, `request.parameter`, `request.cookie`, `request.attribute`, and `session.attribute`.

Attribute	Default	Description
cache-on-match	true	(optional) If true, caches the response if matching succeeds. Overrides the same attribute in a constraint-field-value subelement.
cache-on-match-failure	false	(optional) If true, caches the response if matching fails. Overrides the same attribute in a constraint-field-value subelement.

constraint-field-value

Specifies a value to be matched to the input parameter value. The matching is case sensitive. For example:

```
<value match-expr="in-range">1-60</value>
```

Superelements

constraint-field (glassfish-web.xml (deprecated) and payara-web.xml)

Subelements

none - contains data

Attributes

The following table describes attributes for the constraint-field-value element.

Table 50. constraint-field-value Attributes

Attribute	Default	Description
match-expr	equals	(optional) Specifies the type of comparison performed with the value. Allowed values are equals, not-equals, greater, lesser, and in-range. If match-expr is greater or lesser, the value must be a number. If match-expr is in-range, the value must be of the form n1-n2, where n1 and n2 are numbers.
cache-on-match	true	(optional) If true, caches the response if matching succeeds.
cache-on-match-failure	false	(optional) If true, caches the response if matching fails.

context-root

Contains the web context root for the application or web application that was packaged as a WAR file. Overrides the corresponding element in the application.xml or web.xml file.

If the parent element is java-web-start-access, this element contains the context root for the Java

Web Start enabled application client module. If none is specified, a default is generated; see `java-web-start-access`.

If you are setting up load balancing, web module context roots must be unique within a server instance.

Superelements

`web` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `java-web-start-access` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`cookie-properties`

Specifies session cookie properties.

If cookie settings are defined declaratively in the `web.xml` file, the cookie properties defined here take precedence. If cookie settings are defined programmatically using `jakarta.servlet.SessionCookieConfig` methods, those cookie settings take precedence over the cookie properties defined here.

Superelements

`session-config` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `cookie-properties` element.

Table 51. `cookie-properties` Subelements

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Properties

The following table describes properties for the `cookie-properties` element.

Table 52. `cookie-properties` Properties

Property	Default	Description
`cookieName`	none	Specifies the cookie name.

Property	Default	Description
`cookiePath`	Context path at which the web module is installed.	Specifies the pathname that is set when the cookie is created. The browser sends the cookie if the pathname for the request contains this pathname. If set to `/` (slash), the browser sends cookies to all URLs served by Payara Server. You can set the path to a narrower mapping to limit the request URLs to which the browser sends cookies.
`cookieMaxAgeSeconds`	none	Specifies the expiration time (in seconds) after which the browser expires the cookie. If this is unset, the cookie doesn't expire.
`cookieDomain`	(unset)	Specifies the domain for which the cookie is valid.
`cookieComment`	none	Specifies the comment that identifies the session tracking cookie in the cookie file.
`cookieSecure`	`dynamic`	Sets the `Secure` attribute of any `JSESSIONID` cookies associated with the web application. Allowed values are as follows: • `true` — Sets `Secure` to `true`. • `false` — Sets `Secure` to `false`. • `dynamic` — The `JSESSIONID` cookie inherits the `Secure` setting of the request that initiated the session. To set the `Secure` attribute of a `JSESSIONIDSSO` cookie, use the `ssoCookieSecure` `virtual-server` property. For details, see `create-virtual-server`.
`cookieHttpOnly`	none	Specifies that the cookie is marked HTTP only. Allowed values are `true` or `false`.
`cookieSameSite`	none	Users can set up the `SameSite` Cookie attribute for the corresponding web application. Can be one of `Strict`, `Lax` or `None`. For example: `<property name="cookieSameSite" value="Strict" />`

`custom-resource`

Defines a custom resource, which specifies a custom server-wide resource object factory. Such object factories implement the `javax.naming.spi.ObjectFactory` interface.

Superelements

`resources` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `custom-resource` element.

Table 53. `custom-resource` Subelements

Element	Required	Description
`description`	zero or one	Contains a text description of this element.
`property` (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the `custom-resource` element.

Table 54. `custom-resource` Attributes

Attribute	Default	Description
`jndi-name`	none	Specifies the JNDI name for the resource.
`res-type`	none	Specifies the fully qualified type of the resource.
`factory-class`	none	Specifies the fully qualified name of the user-written factory class, which implements `javax.naming.spi.ObjectFactory`.
`object-type`	`user`	(optional) Defines the type of the resource. Allowed values are: • `system-all` - A system resource for all server instances and the domain application server. • `system-admin` - A system resource only for the domain application server. • `system-instance` - A system resource for all server instances only. • `user` - A user resource.
`enabled`	`true`	(optional) Determines whether this resource is enabled at runtime.

`debugging-enabled`

Specifies whether the debugging servlet is enabled for this web service endpoint. Allowed values are `true` (the default) and `false`.

Superelements

`webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`default-helper`

Passes property values to the built-in `default` `cache-helper` class.

Superelements

`cache` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `default-helper` element.

Table 55. `default-helper` Subelements

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Properties

The following table describes properties for the `default-helper` element.

Table 56. `default-helper` Properties

Property	Default	Description
`cacheKeyGeneratorAttrName`	Uses the built-in `default` `cache-helper` key generation, which concatenates the servlet path with `key-field` values, if any.	The caching engine looks in the `ServletContext` for an attribute with a name equal to the value specified for this property to determine whether a customized CacheKeyGenerator implementation is used. An application can provide a customized key generator rather than using the `default` helper. See "The CacheKeyGenerator Interface" in the Payara Server Application Development section.

`default-resource-principal`

Specifies the default principal (user) for the resource.

If this element is used in conjunction with a JMS Connection Factory resource, the `name` and `password` subelements must be valid entries in the Open Message Queue broker user repository.

Superelements

`resource-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`); `mdb-connection-factory` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `default-resource-principal` element.

Table 57. `default-resource-principal` Subelements

Element	Required	Description
`name`	only one	Specifies the default resource principal name used to sign on to a resource manager.
`password`	only one	Specifies password of the default resource principal.

`description`

Specifies a text description of the containing element.

Superelements

`property` (with attributes), `valve` (`glassfish-web.xml` (deprecated) and `payara-web.xml`); `activation-config`, `method` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`); `target-server` (`sun-acc.xml`); `admin-object-resource`, `connector-connection-pool`, `connector-resource`, `custom-resource`, `external-jndi-resource`, `jdbc-connection-pool`, `jdbc-resource`, `mail-resource`, `property` (with attributes), `resource-adapter-config` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

none - contains data

`disable-nonportable-jndi-names`

Because the Jakarta Enterprise Beans specification defines portable EJB JNDI names, there is less need for Payara Server specific JNDI names. By default, Payara Server specific default JNDI names are applied automatically for backward compatibility. To disable Payara Server specific JNDI names for an EJB module, set the value of this element to `true`. The default is `false`.

Superelements

`payara-ejb-jar (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`dispatcher`

Specifies a comma-separated list of `RequestDispatcher` methods for which caching is enabled on the target resource. Valid values are `REQUEST`, `FORWARD`, `INCLUDE`, and `ERROR` . If this element is not specified, the default is `REQUEST`. See `6.2.5` of the Servlet 6.0 specification for more information.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none - contains data

`ejb`

Defines runtime properties for a single enterprise bean within the application. The subelements listed below apply to particular enterprise beans as follows:

- All types of beans: `ejb-name`, `ejb-ref`, `resource-ref`, `resource-env-ref`, `ior-security-config`, `gen-classes`, `jndi-name`, `use-thread-pool-id`, `message-destination-ref`, `pass-by-reference`, `service-ref`
- Stateless session beans: `bean-pool`, `webservice-endpoint`
- Stateful session beans: `bean-cache`, `webservice-endpoint`, `checkpoint-at-end-of-method`
- Entity beans: `commit-option`, `bean-cache`, `bean-pool`, `is-read-only-bean`, `refresh-period-in-seconds`, `flush-at-end-of-method`
- Message-driven beans: `mdb-resource-adapter`, `mdb-connection-factory`, `jms-durable-subscription-name`, `jms-max-messages-load`, `bean-pool`

Superelements

`enterprise-beans` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `ejb` element.

Table 58. `ejb` Subelements

Element	Required	Description
`ejb-name`	only one	Matches the `ejb-name` in the corresponding `ejb-jar.xml` file.
`jndi-name`	zero or more	Specifies the absolute `jndi-name`.
`ejb-ref`	zero or more	Maps the absolute JNDI name to the `ejb-ref` element in the corresponding Jakarta EE XML file.
`resource-ref`	zero or more	Maps the absolute JNDI name to the `resource-ref` in the corresponding Jakarta EE XML file.
`resource-env-ref`	zero or more	Maps the absolute JNDI name to the `resource-env-ref` in the corresponding Jakarta EE XML file.
`service-ref`	zero or more	Specifies runtime settings for a web service reference.
`message-destination-ref`	zero or more	Specifies the name of a physical message destination.
`pass-by-reference`	zero or one	Specifies the passing method used by an enterprise bean calling a remote interface method in another bean that is colocated within the same process.
`principal`	zero or one	Specifies the principal (user) name in an enterprise bean that has the `run-as` role specified.

Element	Required	Description
`mdb-connection-factory`	zero or one	Specifies the connection factory associated with a message-driven bean.
`jms-durable-subscription-name`	zero or one	Specifies the durable subscription associated with a message-driven bean.
`jms-max-messages-load`	zero or one	Specifies the maximum number of messages to load into a Jakarta Messaging session at one time for a message-driven bean to serve. The default is 1.
`ior-security-config`	zero or one	Specifies the security information for the IOR.
`is-read-only-bean`	zero or one	Specifies that this entity bean is read-only.
`refresh-period-in-seconds`	zero or one	Specifies the rate at which a read-only-bean must be refreshed from the data source.
`commit-option`	zero or one	Has valid values of B or C. Default value is B.
`cmt-timeout-in-seconds`	zero or one	Overrides the Transaction Timeout setting of the Transaction Service for an individual bean.
`use-thread-pool-id`	zero or one	Specifies the thread pool from which threads are selected for remote invocations of this bean.
`gen-classes`	zero or one	Specifies all the generated class names for a bean.
`bean-pool`	zero or one	Specifies the bean pool properties. Used for stateless session beans, entity beans, and message-driven beans.
`bean-cache`	zero or one	Specifies the bean cache properties. Used only for stateful session beans and entity beans.
`mdb-resource-adapter`	zero or one	Specifies runtime configuration information for a message-driven bean.
`webservice-endpoint`	zero or more	Specifies information about a web service endpoint.
`flush-at-end-of-method`	zero or one	Specifies the methods that force a database flush after execution. Used for entity beans.
`checkpoint-at-end-of-method`	zero or one	Specifies that the stateful session bean state is checkpointed, or persisted, after the specified methods are executed. The `availability-enabled` attribute must be set to `true`.
`per-request-load-balancing`	zero or one	Specifies the per-request load balancing behavior of EJB 2.x and 3.x remote client invocations on a stateless session bean.
`clustered-attach-postconstruct`	zero or one	Used for clustered singletons. Defines whether the bean's `@PostConstruct` event is called each time it is created on different nodes.
`clustered-bean`	zero or one	Defines whether the bean is treated as a clustered singleton.

Element	Required	Description
clustered-detach-predestroy	zero or one	Used for clustered singletons. Defines whether the bean's @PreDestroy event is called when the bean is destroyed on a node while available on another.
clustered-key-name	zero or one	Used for clustered singletons. Defines the name of the key used for the replication mechanism of the bean across the Data Grid.
clustered-lock-type	zero or one	Used for clustered singletons. Defines the type of distributed lock to be performed on the bean.

Attributes

The following table describes attributes for the ejb element.

Table 59. ejb Attributes

Attribute	Default	Description
availability-enabled	false	(optional) If set to true, and if availability is enabled in the EJB container, high-availability features apply to this bean if it is a stateful session bean.

Example

```
<ejb>
   <ejb-name>CustomerEJB</ejb-name>
   <jndi-name>customer</jndi-name>
   <resource-ref>
      <res-ref-name>jdbc/SimpleBank</res-ref-name>
      <jndi-name>jdbc/__default</jndi-name>
   </resource-ref>
   <is-read-only-bean>false</is-read-only-bean>
   <commit-option>B</commit-option>
   <bean-pool>
      <steady-pool-size>10</steady-pool-size>
      <resize-quantity>10</resize-quantity>
      <max-pool-size>100</max-pool-size>
      <pool-idle-timeout-in-seconds>600</pool-idle-timeout-in-seconds>
   </bean-pool>
   <bean-cache>
      <max-cache-size>100</max-cache-size>
      <resize-quantity>10</resize-quantity>
      <removal-timeout-in-seconds>3600</removal-timeout-in-seconds>
      <victim-selection-policy>LRU</victim-selection-policy>
   </bean-cache>
</ejb>
```

`ejb-name`

In the `payara-ejb-jar.xml` file, matches the `ejb-name` in the corresponding `ejb-jar.xml` file. The name must be unique among the names of the enterprise beans in the same EJB JAR file.

There is no architected relationship between the `ejb-name` in the deployment descriptor and the JNDI name that the deployer assigns to the EJB component's home.

Superelements

`ejb`, `method` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`ejb-ref`

Maps the `ejb-ref-name` in the corresponding Jakarta EE deployment descriptor file `ejb-ref` entry to the absolute `jndi-name` of a resource.

The `ejb-ref` element is used for the declaration of a reference to an EJB's home. Applies to session beans or entity beans.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`), `payara-application-client` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `ejb-ref` element.

Table 60. `ejb-ref` Subelements

Element	Required	Description
`ejb-ref-name`	only one	Specifies the `ejb-ref-name` in the corresponding Jakarta EE deployment descriptor file `ejb-ref` entry.
`jndi-name`	only one	Specifies the absolute `jndi-name` of a resource.

`ejb-ref-name`

Specifies the `ejb-ref-name` in the corresponding Jakarta EE deployment descriptor file `ejb-ref` entry.

Superelements

`ejb-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`eligible`

Specifies whether the application client module is eligible to be Java Web Start enabled. Allowed values are `true` (the default) and `false`.

Superelements

`java-web-start-access` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`enable-implicit-cdi`

In a **WAR** file, it is possible to set the property `bean-discovery-mode` equal to `none` to turn off implicit scanning of the archive for bean defining annotations, as defined by the CDI 1.1 specification.

The default value of this setting is defined as `annotated` in the specification, so the archive is scanned for any bean-defining annotations, which can cause unwanted side effects.

In the `payara-application.xml` deployment descriptor for an EAR file, the property `enable-implicit-cdi` can be set to `false` to achieve the same goal for all modules inside the EAR assembly. The default value is `true`, in line with the default value for WAR files.

If implicit CDI scanning causes problems for an EAR assembly, the value `false` will disable implicit CDI scanning for all CDI modules inside the EAR assembly:

```
<payara-application>
  <enable-implicit-cdi>false</enable-implicit-cdi>
</payara-application>
```

The default behavior of the admin console is for the **Implicit CDI** checkbox to be enabled, but this will **not** override the application configuration.

When implicit CDI is configured by using either the `enable-implicit-cdi` property in the `payara-application.xml` or the attribute `bean-discovery-mode="none"` from the `beans.xml` file in a WAR, the admin console checkbox *is always ignored*.

Superelements

`payara-application`

Subelements

none - contains data

`endpoint-address-uri`

Specifies the relative path combined with the web server root to form the fully qualified endpoint address for a web service endpoint. This is a required element for EJB endpoints and an optional element for servlet endpoints.

For servlet endpoints, this value is relative to the web application context root. For EJB endpoints, the URI is relative to root of the web server (the first portion of the URI is a context root). The context root portion must not conflict with the context root of any web application deployed to the same web server.

In all cases, this value must be a fixed pattern (no "*' allowed).

If the web service endpoint is a servlet that implements only a single endpoint and has only one `url-pattern`, it is not necessary to set this value, because the web container derives it from the `web.xml` file.

Superelements

`webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

Example

If the web server is listening at `http://localhost:8080`, the following `endpoint-address-uri`:

```
<endpoint-address-uri>StockQuoteService/StockQuotePort</endpoint-address-uri>
```

results in the following target endpoint address:

```
http://localhost:8080/StockQuoteService/StockQuotePort
```

`enterprise-beans`

Specifies all the runtime properties for an EJB JAR file in the application.

Superelements

`payara-ejb-jar` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `enterprise-beans` element.

Table 61. `enterprise-beans` Subelements

Element	Required	Description
name	zero or one	Specifies the name string.
unique-id	zero or one	Specifies a unique system identifier. This data is automatically generated and updated at deployment/redeployment. Do not specify or edit this value.
ejb	zero or more	Defines runtime properties for a single enterprise bean within the application.
message-destination	zero or more	Specifies the name of a logical message destination.
webservice-description	zero or more	Specifies a name and optional publish location for a web service.
property (with subelements)	zero or more	Specifies a property or a variable.

Example

```
<enterprise-beans>
 <ejb>
     <ejb-name>CustomerEJB</ejb-name>
     <jndi-name>customer</jndi-name>
     <resource-ref>
         <res-ref-name>jdbc/SimpleBank</res-ref-name>
         <jndi-name>jdbc/__default</jndi-name>
     </resource-ref>
     <is-read-only-bean>false</is-read-only-bean>
     <commit-option>B</commit-option>
     <bean-pool>
         <steady-pool-size>10</steady-pool-size>
        <resize-quantity>10</resize-quantity>
         <max-pool-size>100</max-pool-size>
         <pool-idle-timeout-in-seconds>600</pool-idle-timeout-in-seconds>
     </bean-pool>
     <bean-cache>
         <max-cache-size>100</max-cache-size>
         <resize-quantity>10</resize-quantity>
         <removal-timeout-in-seconds>3600</removal-timeout-in-seconds>
         <victim-selection-policy>LRU</victim-selection-policy>
     </bean-cache>
 </ejb>
</enterprise-beans>
```

Properties

The following table describes properties for the enterprise-beans element.

Table 62. enterprise-beans Properties

Property	Default	Description
default-role-mapping	false	With this property, you can set whether to enable the default group to role mappings for your application's security settings. This element is set up as a property element with a Boolean value attribute like this: `<property name="default-role-mapping" value="true"> <description>Default role mapping</description> </property>` Enabling the default group to role mappings will cause all named groups in the module's linked **security realm** to be mapped to a role of the same name. This will save you the time of having to redefine the same roles and map them to the realm groups each time they are modified.

establish-trust-in-client

Specifies if the target is capable of authenticating a client. The values are NONE, SUPPORTED, or REQUIRED.

Superelements

transport-config (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

establish-trust-in-target

Specifies if the target is capable of authenticating to a client. The values are NONE, SUPPORTED, or REQUIRED.

Superelements

transport-config (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

external-jndi-resource

Defines a resource that resides in an external JNDI repository. For example, a generic Java object could be stored in an LDAP server. An external JNDI factory must implement the javax.naming.spi.InitialContextFactory interface.

Superelements

`resources` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `external-jndi-resource` element.

Table 63. `external-jndi-resource` Subelements

Element	Required	Description
`description`	zero or one	Contains a text description of this element.
`property` (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the `external-jndi-resource` element.

Table 64. `external-jndi-resource` Attributes

Attribute	Default	Description
`jndi-name`	none	Specifies the JNDI name for the resource.
`jndi-lookup-name`	none	Specifies the JNDI lookup name for the resource.
`res-type`	none	Specifies the fully qualified type of the resource.
`factory-class`	none	Specifies the fully qualified name of the factory class, which implements javax.naming.spi.InitialContextFactory .
`object-type`	`user`	(optional) Defines the type of the resource. Allowed values are: • `system-all` - A system resource for all server instances and the domain application server. • `system-admin` - A system resource only for the domain application server. • `system-instance` - A system resource for all server instances only. • `user` - A user resource.
`enabled`	`true`	(optional) Determines whether this resource is enabled at runtime.

`flush-at-end-of-method`

Specifies the methods that force a database flush after execution. Applicable to entity beans.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `flush-at-end-of-method` element.

Table 65. `flush-at-end-of-method` Subelements

Element	Required	Description
`method`	one or more	Specifies a bean method.

`gen-classes`

Specifies all the generated class names for a bean.

This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `gen-classes` element.

Table 66. `gen-classes` Subelements

Element	Required	Description
`remote-impl`	zero or one	Specifies the fully-qualified class name of the generated `EJBObject` impl class.
`local-impl`	zero or one	Specifies the fully-qualified class name of the generated `EJBLocalObject` impl class.
`remote-home-impl`	zero or one	Specifies the fully-qualified class name of the generated `EJBHome` impl class.
`local-home-impl`	zero or one	Specifies the fully-qualified class name of the generated `EJBLocalHome` impl class.

`payara-application`

Defines the Payara Server specific configuration for an application. This is the root element; there can only be one `payara-application` element in a `payara-application.xml` file. See The payara-application.xml File.

Superelements

none

Subelements

The following table describes subelements for the `payara-application` element.

Table 67. `payara-application` Subelements

Element	Required	Description
`web`	zero or more	Specifies the application's web tier configuration.
`pass-by-reference`	zero or one	Determines whether EJB modules use pass-by-value or pass-by-reference semantics.
`unique-id`	zero or one	Contains the unique ID for the application.
`security-role-mapping`	zero or more	Maps a role in the corresponding Jakarta EE XML file to a user or group.
`realm`	zero or one	Specifies an authentication realm.
`ejb-ref`	zero or more	Maps the absolute JNDI name to the `ejb-ref` in the corresponding Jakarta EE XML file.
`resource-ref`	zero or more	Maps the absolute JNDI name to the `resource-ref` in the corresponding Jakarta EE XML file.
`resource-env-ref`	zero or more	Maps the absolute JNDI name to the `resource-env-ref` in the corresponding Jakarta EE XML file.
`service-ref`	zero or more	Specifies runtime settings for a web service reference.
`message-destination-ref`	zero or more	Specifies the name of a physical message destination.
`message-destination`	zero or more	Specifies the name of a logical message destination.
`archive-name`	zero or one	Specifies the name of the archive file.
`compatibility`	zero or one	Specifies the Payara Server release with which to be backward compatible in terms of JAR visibility requirements for applications.
`keep-state`	zero or one	Retains web sessions, stateful session bean instances, and persistently created EJB timers across redeployments.
`version-identifier`	zero or one	Contains version information for an application.
`classloading-delegate`	zero or one	Configures classloading delegation for the enterprise application.
`enable-implicit-cdi`	zero or one	Enables implicit CDI bean scanning for the enterprise archive.
`scanning-include`	zero or one	Includes third party JAR files for CDI scanning using pattern matching.
`scanning-exclude`	zero or one	Excludes third party JAR files for CDI scanning using pattern matching.
`whitelist-package`	zero or one	Marks packages to be whitelisted for extreme classloading isolation.

Properties

The following table describes properties for the `payara-application` element.

Table 68. `payara-application` Properties

Property	Default	Description

`default-role-mapping`	`false`	With this property, you can set whether to enable the default group to role mappings for your application's security settings. This element is set up as a `property` element with a `Boolean` value attribute like this:
		
		`<property name="default-role-mapping" value="true"> <description>Enable default group to role mapping</description> </property>`
		
		Enabling the default group to role mappings will cause all named groups in the application's linked **security realm** to be mapped to a role of the same name. This will save you the time of having to redefine the same roles and map them to the realm groups each time they are modified.
		
		This will have the same effect as executing the following `asadmin` command:
		
		`asadmin set configs.config.server-config.security-service.activate-default-principal-to-role-mapping=true`
		
		Except its effect will only limit itself to the application instead of all applications deployed on the server.
		
		When set using this property, this configuration will ALWAYS take effect and if set in the `payara-web.xml` or `payara-ejb-jar.xml` deployment descriptors, it will be ignored.

payara-application-client

Defines the Payara Server specific configuration for an application client. This is the root element; there can only be one `payara-application-client` element in a `payara-application-client.xml` file. See The payara-application-client.xml file.

Superelements

none

Subelements

The following table describes subelements for the `payara-application-client` element.

Table 69. `payara-application-client` subelements

Element	Required	Description
`ejb-ref`	zero or more	Maps the absolute JNDI name to the `ejb-ref` in the corresponding Jakarta EE XML file.
`resource-ref`	zero or more	Maps the absolute JNDI name to the `resource-ref` in the corresponding Jakarta EE XML file.
`resource-env-ref`	zero or more	Maps the absolute JNDI name to the `resource-env-ref` in the corresponding Jakarta EE XML file.
`service-ref`	zero or more	Specifies runtime settings for a web service reference.
`message-destination-ref`	zero or more	Specifies the name of a physical message destination.
`message-destination`	zero or more	Specifies the name of a logical message destination.
`java-web-start-access`	zero or one	Specifies changes to default Java Web Start parameters.
`version-identifier`	zero or one	Contains version information for an application client.

`payara-ejb-jar`

Defines the Payara Server specific configuration for an EJB JAR file. This is the root element; there can only be one `payara-ejb-jar` element in a `payara-ejb-jar.xml` file.

Superelements

none

Subelements

The following table describes subelements for the `payara-ejb-jar` element.

Table 70. `payara-ejb-jar` Subelements

Element	Required	Description
`security-role-mapping`	zero or more	Maps a role in the corresponding Jakarta EE XML file to a user or group.
`enterprise-beans`	only one	Describes all the runtime properties for an EJB JAR file in the application.

Element	Required	Description
`compatibility`	zero or one	Specifies the Payara Server release with which to be backward compatible in terms of JAR visibility requirements for applications.
`disable-nonportable-jndi-names`	zero or one	Disables Payara Server specific JNDI names.
`keep-state`	zero or one	Retains stateful session bean instances and persistently created EJB timers across redeployments.
`version-identifier`	zero or one	Contains version information for an EJB module.
`webservice-default-login-config`	zero or one	Configures the default login module settings that will apply to all EJBs hosted in this archive.

`glassfish-web-app` or `payara-web-app`

Defines Payara Server specific configuration for a web module. This is the root element; there can only be one `glassfish-web-app`/`payara-web-app` element in a `glassfish-web.xml` (deprecated)/`payara-web.xml` file.

See The glassfish-web.xml and payara-web.xml Files.

Superelements

none

Subelements

The following table describes subelements for the `payara-web-app` element.

Table 71. `payara-web-app` Subelements

Element	Required	Description
`context-root`	zero or one	Contains the web context root for the web module.
`security-role-mapping`	zero or more	Maps roles to users or groups in the currently active realm.
`servlet`	zero or more	Specifies a principal name for a servlet, which is used for the `run-as` role defined in `web.xml`.
`idempotent-url-pattern`	zero or more	Specifies a URL pattern for idempotent requests.
`session-config`	zero or one	Specifies session manager, session cookie, and other session-related information.
`ejb-ref`	zero or more	Maps the absolute JNDI name to the `ejb-ref` in the corresponding Jakarta EE XML file.
`resource-ref`	zero or more	Maps the absolute JNDI name to the `resource-ref` in the corresponding Jakarta EE XML file.

Element	Required	Description
`resource-env-ref`	zero or more	Maps the absolute JNDI name to the `resource-env-ref` in the corresponding Jakarta EE XML file.
`service-ref`	zero or more	Specifies runtime settings for a web service reference.
`message-destination-ref`	zero or more	Specifies the name of a physical message destination.
`cache`	zero or one	Configures caching for web application components.
`class-loader`	zero or one	Specifies class loader configuration information.
`jsp-config`	zero or one	Specifies JSP configuration information.
`parameter-encoding`	zero or one	Determines the default request character encoding and how the web container decodes parameters from forms according to a hidden field value.
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.
`valve`	zero or more	Specifies a custom valve.
`message-destination`	zero or more	Specifies the name of a logical message destination.
`webservice-description`	zero or more	Specifies a name and optional publish location for a web service.
`keep-state`	zero or one	Retains web sessions across redeployments.
`version-identifier`	zero or one	Contains version information for a web application.
`classloading-delegate`	zero or one	Configures classloading delegation for the web application.
`jaxrs-roles-allowed-enabled`	zero or one	Configures out of the box support for the `@RolesAllowed` annotation in a web application.
`scanning-include`	zero or one	Includes third party JAR files for CDI scanning using pattern matching.
`scanning-exclude`	zero or one	Excludes third party JAR files for CDI scanning using pattern matching.
`whitelist-package`	zero or one	Marks packages to be whitelisted for extreme classloading isolation.

Attributes

The following table describes attributes for the `payara-web-app` element.

Table 72. `payara-web-app` Attributes

Attribute	Default	Description
`error-url`	(blank)	(optional) Not implemented. Do not use.
`httpservlet-security-provider`	none	(optional) Specifies the `HttpServlet` message layer provider that the web container's servlet `auth-constraint` processing calls.

Properties

The following table describes properties for the `payara-web-app` element.

Table 73. `payara-web-app` Properties

Property	Default	Description
`allowLinking`	`false`	If `true`, resources in this web application that are symbolic links are served. You can also define this property for a virtual server. Web applications on the virtual server that do not define this property use the virtual server's value. For details, see `create-virtual-server`(1). Setting this property to `true` on Windows systems exposes JSP source code.

Property	Default	Description

`alternatedocroot_n`	none	Specifies an alternate document root (docroot), where n is a positive integer that allows specification of more than one. Alternate docroots allow web applications to serve requests for certain resources from outside their own docroot, based on whether those requests match one (or more) of the URI patterns of the web application's alternate docroots.
		
		If a request matches an alternate docroot's URI pattern, it is mapped to the alternate docroot by appending the request URI (minus the web application's context root) to the alternate docroot's physical location (directory). If a request matches multiple URI patterns, the alternate docroot is determined according to the following precedence order:
		
		• Exact match
		• Longest path match
		• Extension match
		
		For example, the following properties specify three alternate docroots. The URI pattern of the first alternate docroot uses an exact match, whereas the URI patterns of the second and third alternate docroots use extension and longest path prefix matches, respectively.
		
		`<payara-web-app>`
		`<property name="alternatedocroot_1"`
		`value="from=/my.jpg dir=/srv/images/jpg"/>`
		`<property name="alternatedocroot_2"`
		`value="from=*.jpg dir=/srv/images/jpg"/>`
		`<property name="alternatedocroot_3"`
		`value="from=/jpg/* dir=/src/images"/>`
		`</payara-web-app>`
		
		The `value` of each alternate docroot has two components: The first component, `from`, specifies the alternate docroot's URI pattern, and the second component, `dir`, specifies the alternate docroot's physical location (directory). Spaces are allowed in the `dir` component.
		
		You can set this property for all the web applications on a specific virtual server. For details, see `create-virtual-server`.

Property	Default	Description

listener_n	none	Specifies a fully qualified class name of a custom Catalina listener, where n is a positive integer that allows specification of more than one. The listener class must implement the org.apache.catalina.ContainerListener, org.apache.catalina.LifecycleListener, or org.apache.catalina.InstanceListener interface. For example:
		
		`<property name="listener_1"`
		
		`value="org.glassfish.extension.MyLifecycleListener"/>`
		
		You can set this property for all the web applications on a specific virtual server. For details, see create-virtual-server.

crossContextAllowed	true	If true, allows this web application to access the contexts of other web applications using the ServletContext.getContext() method.
relativeRedirectAllowed	false	If true, allows this web application to send a relative URL to the client using HttpServletResponse.sendRedirect(), and instructs the web container not to translate any relative URLs to fully qualified ones.
reuseSessionID	false	If true, sessions generated for this web application use the session ID specified in the request.
securePagesWithPragma	true	Set this property to false to ensure that for this web application file downloads using SSL work properly in Internet Explorer. You can set this property for all the web applications on a specific virtual server. For details, see create-virtual-server(1).
singleThreadedServletPoolSize	5	Specifies the maximum number of servlet instances allocated for each SingleThreadModel servlet in the web application.

Property	Default	Description
tempdir	domain-dir/generated/app-name or domain-dir/generated/module-name	Specifies a temporary directory for use by this web module. This value is used to construct the value of the javax.servlet.context.tempdir context attribute. Compiled JSP files are also placed in this directory.
useResponseCTForHeaders	false	If true, response headers are encoded using the response's charset instead of the default (UTF-8).
default-role-mapping	false	With this property, you can set whether to enable the default group to role mappings for your application's security settings. This element is set up as a property element with a Boolean value attribute like this: `<property name="default-role-mapping" value="true"> <description>Enable default group to role mapping</description> </property>` Enabling the default group to role mappings will cause all named groups in the application's linked **security realm** to be mapped to a role of the same name. This will save you the time of having to redefine the same roles and map them to the realm groups each time they are modified.
container-initializer-enabled	true	This property configures whether to enable or disable the calling of ServletContainerInitializer component classes defined in JAR files bundled inside a WAR assembly. For performance considerations, you can explicitly disable the servlet container initializer by setting the container-initializer-enabled element to false. This can help solve the deployment of web applications that can suffer from conflicts with a custom bootstrapping process.

Property	Default	Description
cacheTTL	5000	This property sets the time to live (TTL), in milliseconds, for the virtual server cache used when serving files. It can also be applied to all web applications on a specific virtual server. When set at the application level, this property overrides the virtual server configuration.

group-map

Maps an EIS group to a group defined in the Payara Server domain.

Superelements

work-security-map (glassfish-resources.xml (deprecated) and payara-resources.xml)

Subelements

none

Attributes

The following table describes attributes for the group-map element.

Table 74. group-map Attributes

Attribute	Default	Description
eis-group	none	Specifies an EIS group.
mapped-group	none	Specifies a group defined in the Payara Server domain.

group-name

Specifies a group name in the current realm.

Superelements

security-role-mapping (glassfish-application.xml (deprecated) and payara-application.xml, glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

http-method

Specifies an HTTP method that is eligible for caching. The default is GET.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none - contains data

`idempotent-url-pattern`

Specifies a URL pattern for idempotent requests.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none

Attributes

The following table describes attributes for the `idempotent-url-pattern` element.

Table 75. `idempotent-url-pattern` Attributes

Attribute	Default	Description
`url-pattern`	none	Specifies a URL pattern, which can contain wildcards. The URL pattern must conform to the mappings specified in section 12.2 of the Servlet 6.0 specification.
`no-of-retries`	`-1`	(optional) Specifies the number of times the load balancer retries an idempotent request. A value of `-1` indicates infinite retries.

Example

The following example specifies that all requests for the URI `sun-java/*` are idempotent.

```
<idempotent-url-pattern url-pattern="sun_java/*" no-of-retries="10"/>
```

`integrity`

Specifies if the target supports integrity-protected messages. The values are `NONE`, `SUPPORTED`, or `REQUIRED`.

Superelements

`transport-config` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`ior-security-config`

Specifies the security information for the interoperable object reference (IOR).

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `ior-security-config` element.

Table 76. `ior-security-config` Subelements

Element	Required	Description
`transport-config`	zero or one	Specifies the security information for transport.
`as-context`	zero or one	Specifies the authentication mechanism used to authenticate the client. If specified, it is `USERNAME_PASSWORD`.
`sas-context`	zero or one	Describes the sas-context fields.

Superelements

`bean-cache` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

`is-read-only-bean`

Specifies that this entity bean is a read-only bean if `true`. If this element is absent, the default value of `false` is used.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`java-method`

Specifies a method.

Superelements

`message` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-applcation-client.xml`)

Subelements

The following table describes subelements for the `java-method` element.

Table 77. `java-method` Subelements

Element	Required	Description
`method-name`	only one	Specifies a method name.
`method-params`	zero or one	Specifies fully qualified Java type names of method parameters.

`java-web-start-access`

Specifies changes to default Java Web Start parameters for an embedded or stand-alone application client module.

Superelements

`payara-application-client` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `java-web-start-access` element.

Table 78. `java-web-start-access` subelements

Element	Required	Description

`context-root`	zero or one	Contains the context root for the Java Web Start enabled application client module. If none is specified, a default is generated.
		
		The default for a web module is as follows:
		
		`http://host:port/app-name/relative-URI-to-appclient-jar`
		
		The default for a stand-alone application client module is as follows:
		
		`http://host:port/module-name`
		
		If the `module-name` is not specified during deployment, the name of the EAR or JAR file without the extension is used. If the web module is not in EAR or JAR file format, a name is generated and written to the server log.

Element	Required	Description
`eligible`	zero or one	Specifies whether the application client module is eligible to be Java Web Start enabled. Allowed values are `true` (the default) and `false`.
`vendor`	zero or one	Specifies the name of the vendor as it appears in Java Web Start download and launch screens. The default value is `Application Client`.
`jnlp-doc`	zero or one	Specifies the name of a custom JNLP file. If none is specified, a default JNLP file is generated.

`jaxrs-roles-allowed-enabled`

The Payara Platform both support using the `@RolesAllowed` annotation out of the box to secure JAX-RS resources. In some cases this may clash with existing code that interprets the same annotation using custom code.

The out-of-the-box support of `@RolesAllowed` for JAX-RS resources can be switched off by setting the `<jaxrs-roles-allowed-enabled>` element like this:

```
<jaxrs-roles-allowed-enabled>false</jaxrs-roles-allowed-enabled>
```

Superelements

`glassfish-web-app or payara-web-app` (`glassfish-web-app.xml`)

Subelements

none

`jdbc-connection-pool`

Defines the attributes and properties that are required for creating a JDBC connection pool.

Superelements

`resources` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `jdbc-connection-pool` element.

Table 79. `jdbc-connection-pool` Subelements

Element	Required	Description
`description`	zero or one	Contains a text description of this element.
`property` (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the `jdbc-connection-pool` element. Changing the following attributes requires a server restart or the redeployment or disabling and re-enabling of applications that refer to the resource: `datasource-classname`, `associate-with-thread`, `lazy-connection-association`, and `lazy-connection-enlistment`.

Table 80. `jdbc-connection-pool` Attributes

Attribute	Default	Description
`name`	none	Specifies the name of the connection pool. A `jdbc-resource` element's `pool-name` attribute refers to this `name`.
`datasource-classname`	none	(optional) Specifies the class name of the associated vendor-supplied data source. This class must implement javax.sql.DataSource, javax.sql.XADataSource, javax.sql.ConnectionPoolDatasource , or a combination.
`res-type`	none	(optional) Specifies the interface the data source class implements. The value of this attribute can be javax.sql.DataSource, javax.sql.XADataSource , javax.sql.ConnectionPoolDatasource , or java.sql.Driver. To support configuration of JDBC drivers and applications that use java.sql.Driver implementations, set this attribute to java.sql.Driver. This attribute must be specified to avoid ambiguity when a data source class implements two or more of these interfaces or when a `driver-classname` is specified. An error occurs if this attribute has a legal value and the indicated interface is not implemented by the data source class.
`driver-classname`	none	(optional) Specifies the vendor-supplied JDBC driver class name. This driver must implement the java.sql.Driver interface.
`ping`	`false`	(optional) Specifies whether to ping the pool during pool creation or reconfiguration to identify and warn of any erroneous attribute values.
`steady-pool-size`	`8`	(optional) Specifies the initial and minimum number of connections maintained in the pool.
`max-pool-size`	`32`	(optional) Specifies the maximum number of connections that can be created to satisfy client requests.

Attribute	Default	Description
max-wait-time-in-millis	60000	(optional) Specifies the amount of time, in milliseconds, that the caller is willing to wait for a connection. If 0, the caller is blocked indefinitely until a resource is available or an error occurs.
pool-resize-quantity	2	(optional) Specifies the number of idle connections to be destroyed if the existing number of connections is above the steady-pool-size (subject to the max-pool-size limit). This is enforced periodically at the idle-timeout-in-seconds interval. An idle connection is one that has not been used for a period of idle-timeout-in-seconds. When the pool size reaches steady-pool-size, connection removal stops.
idle-timeout-in-seconds	300	(optional) Specifies the maximum time that a connection can remain idle in the pool. After this amount of time, the pool can close this connection. This timeout value must be kept shorter than the server side (database) timeout value to prevent the accumulation of unusable connections in the application.
transaction-isolation-level	default JDBC driver isolation level	(optional) Specifies the transaction isolation level on the pooled database connections. Allowed values are read-uncommitted, read-committed , repeatable-read, serializable, or snapshot(snapshot isolation level is only supported by Microsoft SQL Server) . Applications that change the isolation level on a pooled connection programmatically risk polluting the pool, which can lead to errors. See is-isolation-level-guaranteed for more details.
is-isolation-level-guaranteed	true	(optional) Applicable only when transaction-isolation-level is explicitly set. If true, every connection obtained from the pool is guaranteed to have the desired isolation level. This might impact performance on some JDBC drivers. Only set this attribute to false if you are certain that the hosted applications do not return connections with altered isolation levels.
is-connection-validation-required	false	(optional) Specifies whether connections have to be validated before being given to the application. If a resource's validation fails, it is destroyed, and a new resource is created and returned.

Attribute	Default	Description
`connection-validation-method`	`table`	(optional) Legal values are as follows: • `auto-commit`, which uses `Connection.setAutoCommit(Connection.getAutoCommit())` • `meta-data`, which uses `Connection.getMetaData()` • `table`, which performs a query on a table specified in the `validation-table-name` attribute • `custom-validation`, which uses a user-defined validation mechanism specified by the custom implementation class in `validation-classname`. Because many JDBC drivers cache the results of `auto-commit` and `meta-data` calls, they do not always provide reliable validations. Check with the driver vendor to determine whether these calls are cached or not. The `table` must exist and be accessible, but it doesn't require any rows. Do not use an existing table that has a large number of rows or a table that is already frequently accessed.
`validation-table-name`	none	(optional) Specifies the table name to be used to perform a query to validate a connection. This parameter is mandatory if and only if `connection-validation-method` is set to `table`.
`validation-classname`	none	(optional) Specifies the custom validation implementation class name. This parameter is mandatory if `connection-validation-method` is set to `custom-validation`. The classname provided must be accessible to the Payara Server. The specified class must implement the org.glassfish.api.jdbc.ConnectionValidation interface. Payara Server provides the following custom validation class templates for MSSQL, DB2, and Sybase databases. All of them implement the org.glassfish.api.jdbc.ConnectionValidation interface. • `org.glassfish.api.jdbc.MSSQLConnectionValidation` • `org.glassfish.api.jdbc.DB2ConnectionValidation` • `org.glassfish.api.jdbc.SybaseConnectionValidation`

Attribute	Default	Description
`init-sql`	none	(optional) Specifies an SQL string to be executed whenever a connection is created (not reused) in the pool. This initializes the state of the connection.
`fail-all-connections`	`false`	(optional) If `true`, closes all connections in the pool if a single validation check fails. This parameter is mandatory if and only if `is-connection-validation-required` is set to `true`.
`non-transactional-connections`	`false`	(optional) If `true`, non-transactional connections can be made to the JDBC connection pool. These connections are not automatically enlisted with the transaction manager.
`allow-non-component-callers`	`false`	(optional) If `true`, non-Java-EE components, such as servlet filters, and third party persistence managers, can use this JDBC connection pool. The returned connection is automatically enlisted with the transaction context obtained from the transaction manager. Standard Jakarta EE components can also use such pools. Connections obtained by non-component callers are not automatically closed at the end of a transaction by the container. They must be explicitly closed by the caller.
`validate-atmost-once-period-in-seconds`	`0`	(optional) Specifies the time interval within which a connection is validated at most once. Minimizes the number of validation calls. A value of zero implies that Payara Server does not attempt to minimize the number of validation requests by a connection. That is, a value of zero disables this attribute. As a result, the same connection is validated every time the application acquires the connection.
`connection-leak-timeout-in-seconds`	`0`	(optional) Detects potential connection leaks by the application. A connection that is not returned back to the pool by the application within the specified period is assumed to be potentially leaking, and a stack trace of the caller is logged. A zero value disables leak detection. A nonzero value enables leak tracing. Use this attribute along with `connection-leak-reclaim` to avoid potential connection leaks from the application.
`connection-leak-reclaim`	`false`	(optional) If `true`, the pool will reclaim a connection after `connection-leak-timeout-in-seconds` occurs.

Attribute	Default	Description
`connection-creation-retry-attempts`	`0`	(optional) Specifies the number of attempts to create a new connection in case of a failure.
`connection-creation-retry-interval-in-seconds`	`10`	(optional) Specifies the time interval between attempts to create a connection when `connection-creation-retry-attempts` is greater than `0`.
`statement-leak-timeout-in-seconds`	`0`	(optional) Detects potential statement leaks by the application. A statement that is not closed by the application within the specified period is assumed to be potentially leaking, and a stack trace of the caller is logged. A zero value disables leak detection. A nonzero value enables leak tracing. Use this attribute along with `statement-leak-reclaim` to avoid potential statement leaks from the application.
`statement-leak-reclaim`	`false`	(optional) If `true`, the reclaim of a statement after `statement-leak-timeout-in-seconds` occurs.
`statement-timeout-in-seconds`	`-1`	(optional) Sets the query timeout property of a statement to enable termination of abnormally long running queries. The default value of `-1` disables this feature. An abnormally long running JDBC query executed by an application may leave it in a hanging state unless a timeout is explicitly set on the statement. This attribute guarantees that all queries automatically time out if not completed within the specified period. When statements are created, the `queryTimeout` is set according to the value specified in this attribute. This works only when the underlying JDBC driver supports `queryTimeout` for `Statement`, `PreparedStatement`, `CallableStatement`, and `ResultSet`.
`lazy-connection-enlistment`	`false`	(optional) If `true`, a connection is not enlisted in a transaction until it is used. If `false`, any connection object available to a transaction is enlisted in the transaction.
`lazy-connection-association`	`false`	(optional) If `true`, a physical connection is not associated with a logical connection until it is used. If `false`, a physical connection is associated with a logical connection even before it is used.

Attribute	Default	Description
associate-with-thread	false	(optional) Specifies whether connections are associated with the thread to enable the thread to reuse the connections. If true, allows connections to be saved as ThreadLocal in the calling thread. Connections get reclaimed only when the calling thread dies or when the calling thread is not in use and the pool has run out of connections. If false, the thread must obtain a connection from the pool each time the thread requires a connection. This attribute associates connections with a thread such that when the same thread is in need of connections, it can reuse the connections already associated with that thread. In this case, the overhead of getting connections from the pool is avoided. However, when this value is set to true, you should verify that the value of the max-pool-size attribute is comparable to the max-thread-pool-size attribute of the associated thread pool. If the max-thread-pool-size value is much higher than the max-pool-size value, a lot of time is spent associating connections with a new thread after dissociating them from an older one. Use this attribute in cases where the thread pool should reuse connections to avoid this overhead.
match-connections	false	(optional) Specifies whether a connection that is selected from the pool should be matched with the connections with certain credentials. If true, enables connection matching. You can set to false if connections are homogeneous. If the connection pool is used by applications that have multiple user credentials, match-connections must be true. The connection pool matches the request's credential with the connections in the pool and returns a matched connection for use. For new requests with different credentials, unmatched free connections are automatically purged to provide new connections to satisfy the new requests. This attribute need not be true if it is known that there is only one credential used by the applications and therefore the pool has homogeneous connections.

Attribute	Default	Description
`max-connection-usage-count`	`0`	(optional) Specifies the number of times a connections is reused by the pool, after which it is closed. A zero value disables this feature. By limiting the maximum number of times a connection can be reused, you can avoid statement leaks if the application does not close statements.
`sql-trace-listeners`	none	(optional) Specifies that SQL statements executed by applications need to be traced. Helps administrators analyze the statements. Expects as a value a comma-separated list of listener implementation class names. Enables easy filtering of log messages for the SQL statements. SQL trace listeners must implement the org.glassfish.api.jdbc.SQLTraceListener interface.
`statement-cache-size`	`0`	(optional) Specifies the number of statements to be cached using the `lru` (Least Recently Used) caching mechanism. The default value of `0` disables statement caching.
`pooling`	`true`	(optional) If `false`, disables connection pooling.
`wrap-jdbc-objects`	`true`	(optional) If `true`, wrapped JDBC objects are returned for `Statement`, `PreparedStatement`, `CallableStatement`, `ResultSet`, and `DatabaseMetaData`. This option ensures that `Statement.getConnection()` is the same as `DataSource.getConnection()`. Therefore, this option should be `true` when both `Statement.getConnection()` and `DataSource.getConnection()` are done. The default is `false` to avoid breaking existing applications.

Payara Server Properties

The following table describes properties for the `jdbc-connection-pool` element that are specific to Payara Server.

Table 81. `jdbc-connection-pool` Database Properties

Property	Default	Description
dynamic-reconfiguration-wait-timeout-in-seconds	none	Specifies the timeout for dynamic reconfiguration of the pool. In-progress connection requests must complete before this timeout expires or they must be retried. New connection requests wait for this timeout to expire before acquiring connections to the reconfigured pool. If this property exists and has a positive value, it is enabled. If this property is not set and pool reconfiguration results in pool recreation, in-progress connection requests must be retried.
number-of-top-queries-to-report	10	Specifies the number of most frequently used queries to display. For example, the default value of 10 displays the top ten queries. This property is disabled when jdbc-connection-pool monitoring is set to LOW or OFF. It is enabled when jdbc-connection-pool monitoring is set to HIGH and the sql-trace-listeners attribute is set.
time-to-keep-queries-in-minutes	5	Specifies the time to retain queries in a cache before they are purged. This property is disabled when jdbc-connection-pool monitoring is set to LOW or OFF. It is enabled when jdbc-connection-pool monitoring is set to HIGH and the sql-trace-listeners attribute is set.

Database Properties

Most JDBC drivers allow use of standard property lists to specify the user, password, and other resource configuration information. Although properties are optional with respect to the Payara Server, some properties might be necessary for most databases. For details, see the JDBC 4.0 Standard Extension API.

When properties are specified, they are passed to the vendor's data source class (specified by the datasource-classname attribute) as is using setName(value) methods.

The user and password properties are used as the default principal if container managed authentication is specified and a default-resource-principal is not found in the application deployment descriptors.

The following table describes some common properties for the jdbc-connection-pool element.

Changing JDBC driver properties requires a server restart.

Table 82. jdbc-connection-pool Database Properties

Property	Description
user	Specifies the user name for connecting to the database.
password	Specifies the password for connecting to the database.
databaseName	Specifies the database for this connection pool.
serverName	Specifies the database server for this connection pool.
port	Specifies the port on which the database server listens for requests.
networkProtocol	Specifies the communication protocol.
roleName	Specifies the initial SQL role name.
datasourceName	Specifies an underlying XADataSource, or a ConnectionPoolDataSource if connection pooling is done.
description	Specifies a text description.
url	Specifies the URL for this connection pool. Although this is not a standard property, it is commonly used.

jdbc-resource

Defines a JDBC (javax.sql.DataSource) resource.

Superelements

resources (glassfish-resources.xml (deprecated) and payara-resources.xml)

Subelements

The following table describes subelements for the jdbc-resource element.

Table 83. jdbc-resource Subelements

Element	Required	Description
description	zero or one	Contains a text description of this element.
property (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the jdbc-resource element.

Table 84. jdbc-resource Attributes

Attribute	Default	Description
jndi-name	none	Specifies the JNDI name for the resource.
description	none	(optional) Specifies a text description of this element.
pool-name	none	Specifies the name of the associated jdbc-connection-pool.

Attribute	Default	Description
object-type	user	(optional) Defines the type of the resource. Allowed values are: • system-all - A system resource for all server instances and the domain application server. • system-admin - A system resource only for the domain application server. • system-instance - A system resource for all server instances only. • user - A user resource.
enabled	true	(optional) Determines whether this resource is enabled at runtime.

jms-durable-subscription-name

Specifies the durable subscription associated with a message-driven bean class. Only applies to the Jakarta Messaging Topic Destination type, and only when the message-driven bean deployment descriptor subscription durability is Durable.

Superelements

ejb (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

jms-max-messages-load

Specifies the maximum number of messages to load into a Jakarta Messaging session at one time for a message-driven bean to serve. The default is 1.

Superelements

ejb (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

jndi-name

Specifies the absolute jndi-name of a URL resource or a resource.

For entity beans and session beans, this value specifies the global JNDI name of the EJBHome object. It is only needed if the entity or session bean exposes a remote view.

For JMS message-driven beans, this is the JNDI name of the JMS resource from which the message-driven bean consumes JMS messages. This information is alternatively specified within the

`activation-config` subelement of the `mdb-resource-adapter` element. For more information about JMS resources, see "Using the Jakarta Messaging" in the Payara Server Application Development section.

Superelements

`ejb-ref`, `message-destination`, `resource-env-ref`, `resource-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`); `ejb`, `mdb-connection-factory` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`jnlp-doc`

Contains the name of a custom JNLP file, which modifies the behavior of a Java Web Start enabled application client module. If none is specified, a default JNLP file is generated.

The value of this element is a relative path with the following format:

```
[path-to-JAR-in-EAR!]path-to-JNLP-in-JAR
```

The default path-to-JAR-in-EAR is the current application client JAR file. For example, if the JNLP file is in the application client JAR file at `custom/myInfo.jnlp`, the element value would look like this:

```
<java-web-start-access>
   <jnlp-doc>custom/myInfo.jnlp</jnlp-doc>
</java-web-start-access>
```

If the application client is inside an EAR file, you can place the custom JNLP file inside another JAR file in the EAR. For example, if the JNLP file is in a JAR file at `other/myLib.jar`, the element value would look like this, with an exclamation point (`!`) separating the path to the JAR from the path in the JAR:

```
<java-web-start-access>
   <jnlp-doc>other/myLib.jar!custom/myInfo.jnlp</jnlp-doc>
</java-web-start-access>
```

For information about the allowed contents of a custom JNLP file, see "Developing Java Clients" in the Payara Server Application Development section.

Superelements

`java-web-start-access` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`jsp-config`

Specifies JSP configuration information.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `jsp-config` element.

Table 85. `jsp-config` Subelements

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Properties

The default property values are tuned for development of JSP files at the cost of performance. To maximize performance, set `jsp-config` properties to these non-default values:

- `development` - `false` (as an alternative, set to `true` and give `modificationTestInterval` a large value)
- `mappedfile` - `false`
- `trimSpaces` - `true`
- `suppressSmap` - `true`
- `fork` - `false` (on Solaris)
- `classdebuginfo` - `false`

The following table describes properties for the `jsp-config` element.

Table 86. `jsp-config` Properties

Property	Default	Description
`checkInterval`	`0`	If `development` is set to `false` and `checkInterval` is greater than zero, background compilations are enabled. The `checkInterval` is the time in seconds between checks to see if a JSP file needs to be recompiled.
`classdebuginfo`	`true`	Specifies whether the generated Java servlets are compiled with the debug option set (`-g` for `javac`).

Property	Default	Description
classpath	created dynamically based on the current web application	Specifies the classpath to use when compiling generated servlets.
compiler	javac	Specifies the compiler Ant uses to compile JSP files. See the Ant documentation for more information: https://ant.apache.org/manual/index.html
compilerSourceVM	Depends on Payara Server's Java runtime	Specifies the JDK release with which source compatibility of the generated servlets is provided. Same as the -source release option of javac.
compilerTargetVM	Depends on Payara Server's Java runtime	Specifies the Virtual Machine for the Java platform (JVM software) version for which the servlet class files are generated. Same as the -target release option of javac.
defaultBufferNone	false	If true, the default for the buffer attribute of the page directive is none.
development	true	If set to true, enables development mode, which allows JSP files to be checked for modification. Specify the frequency at which JSPs are checked using the modificationTestInterval property.
dumpSmap	false	If set to true, dumps SMAP information for JSR 45 debugging to a file. Set to false if suppressSmap is true.
enablePooling	true	If set to true, tag handler pooling is enabled.
enableTldValidation	false	If set to true, all Tag Library Descriptor (TLD) files referenced by the web application are validated against their underlying schema or DTD file.
errorOnUseBeanInvalidClassAttribute	false	If set to true, issues an error when the value of the class attribute in a useBean action is not a valid bean class.
fork	true	Specifies that Ant forks the compiling of JSP files, using a JVM machine separate from the one in which Tomcat is running.
genStrAsByteArray	true	If true, text strings are generated as bytes (encoded with the page encoding), if the page is not buffered.
genStrAsCharArray	false	If set to true, generates text strings as char arrays, which improves performance in some cases.
httpMethods	* for all methods	Specifies a comma separated list of HTTP methods supported by the JspServlet.

Property	Default	Description
ieClassId	clsid:8AD9C840-044E-11D1-B3E9-00805F499D93	Specifies the Java plug-in COM class ID for Internet Explorer. Used by the <jsp:plugin> tags.
ignoreJspFragmentErrors	false	If set to true, instructs the compiler to ignore any JSP precompilation errors pertaining to statically included JSP segments that, despite not being top level JSP files, use the .jsp or .jspx extension (instead of the recommended .jspf).
initialCapacity	32	Specifies the initial capacity of the HashMap that maps JSP files to their corresponding servlets.
javaEncoding	UTF8	Specifies the encoding for the generated Java servlet. This encoding is passed to the Java compiler that is used to compile the servlet as well. By default, the web container tries to use UTF8. If that fails, it tries to use the javaEncoding value. For encodings, see: https://docs.oracle.com/javase/8/docs/technotes/guides/intl/encoding.doc.html
keepgenerated	true with JDK 5 and before and for jspc, otherwise false	If set to true, keeps the generated Java files. If false, deletes the Java files.
mappedfile	true	If set to true, generates static content with one print statement per input line, to ease debugging.
modificationTestInterval	0	Specifies the frequency in seconds at which JSPs are checked for modification. A value of 0 causes the JSP to be checked on every access. Used only if development is set to true.
reload-interval	0	Specifies the frequency in seconds at which JSP files are checked for modifications. Setting this value to 0 checks JSP files for modifications on every request. Setting this value to -1 disables checks for JSP modifications and JSP recompilation.
saveBytecode	true for jspc, otherwise false	If true, generated byte code is saved to .class files. This option is meaningful only when the Java compiler API, JSR 199 (available with and used as the default on Java 6) is used for javac compilations.
scratchdir	The default work directory for the web application	Specifies the working directory created for storing all the generated code.
suppressSmap	false	If set to true, generation of SMAP information for JSR 45 debugging is suppressed.

Property	Default	Description
`trimSpaces`	`false`	If set to `true`, trims white spaces in template text between actions or directives.
`usePrecompiled`	`false`	If set to `true`, an accessed JSP file is not compiled. Its precompiled servlet class is used instead. It is assumed that JSP files have been precompiled, and their corresponding servlet classes have been bundled in the web application's `WEB-INF/lib` or `WEB-INF/classes` directory.

The default value of the compiler property for this element has changed from 1.5 to 1.8, denoting a change from JDK5 to JDK8.

You can change this to another value by editing the jsp-config element in the payara-web.xml file.

`keep-state`

If set to `true`, retains web sessions, stateful session bean instances, and persistently created EJB timers across redeployments. The `--keepstate` option of the `redeploy` subcommand takes precedence. The default for both is `false`.

Some changes to an application between redeployments prevent this feature from working properly. For example, do not change the set of instance variables in the SFSB bean class.

For web applications, this feature is applicable only if in the `payara-web.xml` file the `persistence-type` attribute of the `session-manager` element is `file`.

For stateful session bean instances, the persistence type without high availability is set in the server (the `sfsb-persistence-type` attribute) and must be set to `file`, which is the default and recommended value.

If any active web session, SFSB instance, or EJB timer fails to be preserved or restored, none of these will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.

To preserve active state data, Payara Server serializes the data and saves it in memory. To restore the data, the class loader of the newly redeployed application deserializes the data that was previously saved.

Superelements

`payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `payara-web-app` (`payara-web.xml`), `payara-ejb-jar` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`key-field`

Specifies a component of the key used to look up and extract cache entries. The web container looks for the named parameter, or field, in the specified scope.

If this element is not present, the web container uses the Servlet Path (the path section that corresponds to the servlet mapping that activated the current request). See the Servlet 6.0 specification, section 3.6, for details on the Servlet Path.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none

Attributes

The following table describes attributes for the `key-field` element.

Table 87. `key-field` Attributes

Attribute	Default	Description
`name`	none	Specifies the input parameter name.
`scope`	`request.parameter`	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are `context.attribute`, `request.header`, `request.parameter`, `request.cookie`, `session.id`, and `session.attribute`.

`local-home-impl`

Specifies the fully-qualified class name of the generated `EJBLocalHome impl` class.

This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

Superelements

`gen-classes` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`local-impl`

Specifies the fully-qualified class name of the generated `EJBLocalObject impl` class.

This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

Superelements

`gen-classes` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`localpart`

Specifies the local part of a QNAME.

Superelements

`service-qname`,`wsdl-port` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`log-service`

Specifies configuration settings for the log file.

Superelements

`client-container` (`sun-acc.xml`)

Subelements

The following table describes subelements for the `log-service` element.

Table 88. `log-service` subelement

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Attributes

The following table describes attributes for the `log-service` element.

Table 89. `log-service` attributes

Attribute	Default	Description
`log-file`	`your-ACC-dir/logs/client.log`	(optional) Specifies the file where the application client container logging information is stored.
`level`	`SEVERE`	(optional) Sets the base level of severity. Messages at or above this setting get logged to the log file.

`login-config`

Specifies the authentication configuration for an EJB web service endpoint. Not needed for servlet web service endpoints. A servlet's security configuration is contained in the `web.xml` file.

Superelements

`webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `login-config` element.

Table 90. `login-config` subelements

Element	Required	Description
`auth-method`	only one	Specifies the authentication method.
`realm`	zero or one	Specifies the name of the realm used to process all authentication requests.

`mail-resource`

Defines a Jakarta Mail (`jakarta.mail.Session`) resource.

Superelements

`resources` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `mail-resource` element.

Table 91. `mail-resource` Subelements

Element	Required	Description
`description`	zero or one	Contains a text description of this element.
`property` (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the `mail-resource` element.

Table 92. `mail-resource` Attributes

Attribute	Default	Description
`jndi-name`	none	Specifies the JNDI name for the resource.
`store-protocol`	`imap`	(optional) Specifies the storage protocol service, which connects to a mail server, retrieves messages, and saves messages in folder(s). Allowed values are `imap`, `pop3`, `imaps`, and `pop3s` .

Attribute	Default	Description
store-protocol- class	org.eclipse.angus.mail.imap.IMAPStore	(optional) Specifies the service provider implementation class for storage. Allowed values are: • org.eclipse.angus.mail.imap.IMAPStore • org.eclipse.angus.mail.pop3.POP3Store • org.eclipse.angus.mail.imap.IMAPSSLStore • org.eclipse.angus.mail.pop3.POP3SSLStore
transport-protocol	smtp	(optional) Specifies the transport protocol service, which sends messages. Allowed values are smtp and smtps.
transport-protocol-class	org.eclipse.angus.mail.smtp.SMTPTransport	(optional) Specifies the service provider implementation class for transport. Allowed values are: org.eclipse.angus.mail.smtp.SMTPTransport org.eclipse.angus.mail.smtp.SMTPSSLTransport
host	none	The mail server host name.
user	none	The mail server username.
from	none	The email address the mail server uses to indicate the message sender.
debug	false	(optional) Determines whether debugging for this resource is enabled.
object-type	user	(optional) Defines the type of the resource. Allowed values are: • system-all - A system resource for all server instances and the domain application server. • system-admin - A system resource only for the domain application server. • system-instance - A system resource for all server instances only. • user - A user resource.
enabled	true	(optional) Determines whether this resource is enabled at runtime.

Properties

You can set properties for the mail-resource element and then get these properties in a Jakarta Mail Session object later. Every property name must start with a mail- prefix.

The Payara Server changes the dash (-) character to a period (.) in the name of the property, then

saves the property to the `MailConfiguration` and Jakarta Mail `Session` objects. If the name of the property doesn't start with `mail-`, the property is ignored.

For example, to define the property `mail.password` in a Jakarta Mail Session object, first edit `payara-resources.xml` as follows:

```
<mail-resource jndi-name="mail/Session">
    <property name="mail-password" value="adminadmin"/>
    <property name="mail-password" value="adminadmin"/>
</mail-resource>
```

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

After getting the Jakarta Mail `Session` object, get the `mail.password` property to retrieve the value `adminadmin`, as follows:

```
public class Component{

    public void businessMethod(){
        var password = session.getProperty("mail.password");
    }
}
```

For more information about Jakarta Mail properties, see Jakarta Mail API Documentation (`https://jakarta.ee/specifications/mail`).

`manager-properties`

Specifies session manager properties.

Superelements

`session-manager` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `manager-properties` element.

Table 93. `manager-properties` Subelements

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Properties

The following table describes properties for the `manager-properties` element.

Table 94. `manager-properties` Properties

Property	Default	Description
`reapIntervalSeconds`	`60`	Specifies the number of seconds between checks for expired sessions. This is also the interval at which sessions are passivated if `maxSessions` is exceeded. If `persistenceFrequency` is set to `time-based`, active sessions are stored at this interval. To prevent data inconsistency, set this value lower than the frequency at which session data changes. For example, this value should be as low as possible (`1` second) for a hit counter servlet on a frequently accessed website, or the last few hits might be lost each time the server is restarted. Applicable only if the `persistence-type` attribute of the parent `session-manager` element is `file`.
`maxSessions`	`-1`	Specifies the maximum number of sessions that are permitted in the cache, or `-1` for no limit. After this, an attempt to create a new session causes an `IllegalStateException` to be thrown. If the `persistence-type` attribute of the parent `session-manager` element is `file`, the session manager passivates sessions to the persistent store when this maximum is reached.

`sessionFilename`	empty string	Specifies the absolute or relative path to the directory in which the session state is preserved between application restarts, if preserving the state is possible. A relative path is relative to the temporary directory for this web module, one of the following:
		
		`domain-dir/generated/jsp/module-name`
		
		`domain-dir/generated/jsp/app-name/module-name`
		
		By default, this property's value is set to an empty string, which disables this property and does not preserve the session state.
		
		Applicable only if the `persistence-type` attribute of the parent `session-manager` element is `memory`.

Property	Default	Description
persistenceFrequency	web-method	Specifies how often the session state is stored. Allowed values are as follows: • web-method - The session state is stored at the end of each web request prior to sending a response back to the client. This mode provides the best guarantee that the session state is fully updated in case of failure. • time-based - The session state is stored in the background at the frequency set by reapIntervalSeconds. This mode provides less of a guarantee that the session state is fully updated. However, it can provide a significant performance improvement because the state is not stored after each request. Applicable only if the persistence-type attribute of the parent session-manager element is hazelcast.

`max-cache-size`

Specifies the maximum number of beans allowable in cache. A value of zero indicates an unbounded cache. In reality, there is no hard limit. The max-cache-size limit is just a hint to the cache implementation. Default is 512.

Applies to stateful session beans and entity beans.

Superelements

`bean-cache` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`max-pool-size`

Specifies the maximum number of bean instances in the pool. Values are from 0 (1 for message-driven bean) to MAX_INTEGER. A value of 0 means the pool is unbounded. Default is 64.

Applies to all beans.

Superelements

`bean-pool` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

Subelements

`mdb-connection-factory`

Specifies the connection factory associated with a message-driven bean. Queue or Topic type must be consistent with the Jakarta Messaging Destination type associated with the message-driven bean class.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `mdb-connection-factory` element.

Table 95. `mdb-connection-factory` Subelements

Element	Required	Description
`jndi-name`	only one	Specifies the absolute `jndi-name`.
`default-resource-principal`	zero or one	Specifies the default sign-on (name/password) to the resource manager.

`mdb-resource-adapter`

Specifies runtime configuration information for a message-driven bean.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `mdb-resource-adapter` element.

Table 96. `mdb-resource-adapter` subelements

Element	Required	Description
`resource-adapter-mid`	zero or one	Specifies a resource adapter module ID.
`activation-config`	one or more	Specifies an activation configuration.

`message`

Specifies the methods or operations to which message security requirements apply.

Superelements

`message-security` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-`

application-client.xml)

Subelements

The following table describes subelements for the message element.

Table 97. message Subelements

Element	Required	Description
java-method	zero or one	Specifies the methods or operations to which message security requirements apply.
operation-name	zero or one	Specifies the WSDL name of an operation of a web service.

message-destination

Specifies the name of a logical message-destination defined within an application. The message-destination-name matches the corresponding message-destination-name in the corresponding Jakarta EE deployment descriptor file. Use when the message destination reference in the corresponding Jakarta EE deployment descriptor file specifies a message-destination-link to a logical message-destination.

Superelements

payara-web-app (glassfish-web.xml (deprecated) and payara-web.xml), enterprise-beans (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml), payara-application-client (glassfish-application-client.xml (deprecated) and payara-application-client.xml)

Subelements

The following table describes subelements for the message-destination element.

Table 98. message-destination subelements

Element	Required	Description a
message-destination-name	only one	Specifies the name of a logical message destination defined within the corresponding Jakarta EE deployment descriptor file.
jndi-name	only one	Specifies the jndi-name of the associated entity.

message-destination-name

Specifies the name of a logical message destination defined within the corresponding Jakarta EE deployment descriptor file.

Superelements

message-destination (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml)

Subelements

none - contains data

`message-destination-ref`

Directly binds a message destination reference to the JNDI name of a `Queue`, `Topic`, or other physical destination. Use only when the message destination reference in the corresponding Jakarta EE deployment descriptor file does not specify a `message-destination-link` to a logical `message-destination`.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`), `payara-application-client` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `message-destination-ref` element.

Table 99. `message-destination-ref` subelements

Element	Required	Description
`message-destination-ref-name`	only one	Specifies the name of a physical message destination defined within the corresponding Jakarta EE deployment descriptor file.
`jndi-name`	only one	Specifies the `jndi-name` of the associated entity.

`message-destination-ref-name`

Specifies the name of a physical message destination defined within the corresponding Jakarta EE deployment descriptor file.

Superelements

`message-destination-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`message-security`

Specifies message security requirements.

- If the grandparent element is `webservice-endpoint`, these requirements pertain to request and response messages of the endpoint.
- If the grandparent element is `port-info`, these requirements pertain to the port of the referenced service.

Superelements

`message-security-binding` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `message-security` element.

Table 100. `message-security` Subelements

Element	Required	Description
`message`	one or more	Specifies the methods or operations to which message security requirements apply.
`request-protection`	zero or one	Defines the authentication policy requirements of the application's request processing.
`response-protection`	zero or one	Defines the authentication policy requirements of the application's response processing.

`message-security-binding`

Specifies a custom authentication provider binding for a parent `webservice-endpoint` or `port-info` element in one or both of these ways:

- By binding to a specific provider
- By specifying the message security requirements enforced by the provider

Superelements

`webservice-endpoint`, `port-info` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `message-security-binding` element.

Table 101. `message-security-binding` Subelements

Element	Required	Description
`message-security`	zero or more	Specifies message security requirements.

Attributes

The following table describes attributes for the `message-security-binding` element.

Table 102. `message-security-binding` Attributes

Attribute	Default	Description
auth-layer	none	Specifies the message layer at which authentication is performed. The value must be SOAP.
provider-id	none	(optional) Specifies the authentication provider used to satisfy application-specific message security requirements. If this attribute is not specified, a default provider is used, if it is defined for the message layer. If no default provider is defined, authentication requirements defined in the message-security-binding are not enforced.

message-security-config

Specifies configurations for message security providers.

Superelements

client-container (sun-acc.xml)

Subelements

The following table describes subelements for the message-security-config element.

Table 103. message-security-config Subelements

Element	Required	Description
provider-config	one or more	Specifies a configuration for one message security provider.

Attributes

The following table describes attributes for the message-security-config element.

Table 104. message-security-config Attributes

Attribute	Default	Description
auth-layer	none	Specifies the message layer at which authentication is performed. The value must be SOAP.
default-provider	none	(optional) Specifies the server provider that is invoked for any application not bound to a specific server provider.
default-client-provider	none	(optional) Specifies the client provider that is invoked for any application not bound to a specific client provider.

`method`

Specifies a bean method.

Superelements

`checkpoint-at-end-of-method`, `flush-at-end-of-method` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `method` element.

Table 105. `method` Subelements

Element	Required	Description
`description`	zero or one	Specifies an optional text description.
`ejb-name`	zero or one	Matches the `ejb-name` in the corresponding `ejb-jar.xml` file.
`method-name`	only one	Specifies a method name.
`method-intf`	zero or one	Specifies the method interface to distinguish between methods with the same name in different interfaces.
`method-params`	zero or one	Specifies fully qualified Java type names of method parameters.

`method-intf`

Specifies the method interface to distinguish between methods with the same name in different interfaces. Allowed values are `Home`, `Remote`, `LocalHome`, and `Local`.

Superelements

`method` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`method-name`

Specifies a method name or * (an asterisk) for all methods. If a method is overloaded, specifies all methods with the same name.

Superelements

`java-method` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`); `method` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

Examples

```
<method-name>findTeammates</method-name>
```

```
<method-name>*</method-name>
```

method-param

Specifies the fully qualified Java type name of a method parameter.

Superelements

method-params (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml)

Subelements

none - contains data

method-params

Specifies fully qualified Java type names of method parameters.

Superelements

java-method (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml); method (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

The following table describes subelements for the method-params element.

Table 106. method-params Subelements

Element	Required	Description
method-param	zero or more	Specifies the fully qualified Java type name of a method parameter.

name

Specifies the name of the entity.

Superelements

call-property, default-resource-principal, stub-property (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml); enterprise-beans, principal, property (with subelements) (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

`namespaceURI`

Specifies the namespace URI.

Superelements

`service-qname`, `wsdl-port` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`operation-name`

Specifies the WSDL name of an operation of a web service.

Superelements

`message` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`parameter-encoding`

Specifies the default request character encoding and how the web container decodes parameters from forms according to a hidden field value.

If both the `payara-web-app` and `locale-charset-info` elements have `parameter-encoding` subelements, the subelement of `payara-web-app` takes precedence. For encodings, see https://docs.oracle.com/javase/8/docs/technotes/guides/intl/encoding.doc.html.

Superelements

`locale-charset-info`, `payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none

Attributes

The following table describes attributes for the `parameter-encoding` element.

Table 107. `parameter-encoding` Attributes

Attribute	Default	Description
`form-hint-field`	none	(optional) The name of the hidden field in the form. This field specifies the character encoding the web container uses for `request.getParameter` and `request.getReader` calls when the charset is not set in the request's `content-type` header.
`default-charset`	`ISO-8859-1`	(optional) The default request character encoding.

`pass-by-reference`

Specifies the passing method used by a servlet or enterprise bean calling a remote interface method in another bean that is colocated within the same process.

- If `false` (the default if this element is not present), this application uses pass-by-value semantics.
- If `true`, this application uses pass-by-reference semantics.

The `pass-by-reference` element only applies to remote calls. As defined in the Jakarta Enterprise Beans 4.0 specification, section 3.2.3, calls to local interfaces use pass-by-reference semantics.

If the `pass-by-reference` element is set to its default value of `false`, the passing semantics for calls to remote interfaces comply with the Jakarta Enterprise Beans 4.0 specification, section 3.2.3. If set to `true`, remote calls involve pass-by-reference semantics instead of pass-by-value semantics, contrary to this specification.

Portable programs cannot assume that a copy of the object is made during such a call, and thus that it's safe to modify the original. Nor can they assume that a copy is not made, and thus that changes to the object are visible to both caller and callee. When this element is set to `true`, parameters and return values should be considered read-only. The behavior of a program that modifies such parameters or return values is undefined.

When a servlet or enterprise bean calls a remote interface method in another bean that is colocated within the same process, by default Payara Server makes copies of all the call parameters in order to preserve the pass-by-value semantics. This increases the call overhead and decreases performance.

However, if the calling method does not change the object being passed as a parameter, it is safe to pass the object itself without making a copy of it. To do this, set the pass-by-reference value to `true`.

The setting of this element in the `payara-application.xml` file applies to all EJB modules in the application. For an individually deployed EJB module, you can set the same element in the `payara-ejb-jar.xml` file. If `pass-by-reference` is used at both the bean and application level, the bean level takes precedence.

Superelements

`payara-application` (`payara-application.xml`), `ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`password`

Specifies the password for the principal.

Superelements

`default-resource-principal` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`per-request-load-balancing`

Specifies the per-request load balancing behavior of EJB 2.x and 3.x remote client invocations on a stateless session bean. If set to `true`, per-request load balancing is enabled for the associated stateless session bean. If set to `false` or not set, per-request load balancing is not enabled. The default is `false`.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`pool-idle-timeout-in-seconds`

Specifies the maximum time, in seconds, that a bean instance is allowed to remain idle in the pool. When this timeout expires, the bean instance in a pool becomes a candidate for passivation or deletion. This is a hint to the server. A value of 0 specifies that idle beans remain in the pool indefinitely. Default value is 600.

Applies to stateless session beans, entity beans, and message-driven beans.

For a stateless session bean or a message-driven bean, the bean is removed (garbage collected) when the timeout expires.

Superelements

`bean-pool` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`port-component-name`

Specifies a unique name for a port component within a web or EJB module.

Superelements

`webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`port-info`

Specifies information for a port within a web service reference.

Either a `service-endpoint-interface` or a `wsdl-port` or both must be specified. If both are specified, `wsdl-port` specifies the port that the container chooses for container-managed port selection.

The same `wsdl-port` value must not appear in more than one `port-info` element within the same `service-ref`.

If a `service-endpoint-interface` is using container-managed port selection, its value must not appear in more than one `port-info` element within the same `service-ref`.

Superelements

`service-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `port-info` element.

Table 108. `port-info` subelements

Element	Required	Description
`service-endpoint-interface`	zero or one	Specifies the web service reference name relative to `java:comp/env`.
`wsdl-port`	zero or one	Specifies the WSDL port.
`stub-property`	zero or more	Specifies JAX-RPC property values that are set on a `javax.xml.rpc.Stub` object before it is returned to the web service client.
`call-property`	zero or more	Specifies JAX-RPC property values that are set on a `javax.xml.rpc.Call` object before it is returned to the web service client.
`message-security-binding`	zero or one	Specifies a custom authentication provider binding.

`principal`

Defines a user name on the platform.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`); `security-map` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `principal` element.

Table 109. `principal` Subelements

Element	Required	Description
`name`	only one	Specifies the name of the user.

`principal-map`

Maps an EIS principal to a principal defined in the Payara Server domain.

Superelements

`work-security-map` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

none

Attributes

The following table describes attributes for the `principal-map` element.

Table 110. `principal-map` Attributes

Attribute	Default	Description
`eis-principal`	none	Specifies an EIS principal.
`mapped-principal`	none	Specifies a principal defined in the Payara Server domain.

`principal-name`

Contains the principal username.

In an enterprise bean, specifies the principal username that has the `run-as` role specified.

Superelements

`security-role-mapping` (`glassfish-application.xml` (deprecated) and `payara-application.xml`, `glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`), `servlet` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none - contains data

Attributes

The following table describes attributes for the `principal-name` element.

Table 111. `principal-name` Attributes

Attribute	Default	Description
`class-name`	`com.sun.enterprise.deployment.PrincipalImpl`	(optional) Specifies the custom principal implementation class corresponding to the named principal.

`property` (with attributes)

Specifies the name and value of a property. A property adds configuration information to its parent element that is one or both of the following:

- Optional with respect to Payara Server
- Needed by a system or object that Payara Server doesn't have knowledge of, such as an LDAP server or a Java class

Superelements

`cache`, `cache-helper`, `class-loader`, `cookie-properties`, `default-helper`, `manager-properties`, `session-properties`, `store-properties`, `payara-web-app`, `valve`, `webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`); `auth-realm`, `client-container`, `client-credential`, `log-service`, `provider-config` (`sun-acc.xml`); `admin-object-resource`, `connector-connection-pool`, `connector-resource`, `custom-resource`, `external-jndi-resource`, `jdbc-connection-pool`, `jdbc-resource`, `mail-resource`, `resource-adapter-config` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`), `payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `property` element.

Table 112. `property` Subelements

Element	Required	Description
`description`	zero or one	Specifies an optional text description of a property.

The `property` element in the `sun-acc.xml` file has no subelements.

Attributes

The following table describes attributes for the `property` element.

Table 113. `property` Attributes

Attribute	Default	Description
`name`	none	Specifies the name of the property.
`value`	none	Specifies the value of the property.

Example

```
<property name="reapIntervalSeconds" value="20" />
```

`property` (with subelements)

Specifies the name and value of a property. A property adds configuration information to its parent element that is one or both of the following:

- Optional with respect to Payara Server
- Needed by a system or object that Payara Server doesn't have knowledge of, such as an LDAP server or a Jakarta class

Superelements

`enterprise-beans`, `webservice-endpoint` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `property` element.

Table 114. `property` subelements

Element	Required	Description
`name`	only one	Specifies the name of the property.
`value`	only one	Specifies the value of the property.

Example

```
<property>
   <name>use-unique-table-names</name>
   <value>true</value>
</property>
```

`provider-config`

Specifies a configuration for one message security provider.

Although the `request-policy` and `response-policy` subelements are optional, the `provider-config` element does nothing if they are not specified.

Use property subelements to configure provider-specific properties. Property values are passed to the provider when its `initialize` method is called.

Superelements

`message-security-config` (`sun-acc.xml`)

Subelements

The following table describes subelements for the `provider-config` element.

Table 115. `provider-config` Subelements

Element	Required	Description
`request-policy`	zero or one	Defines the authentication policy requirements of the authentication provider's request processing.
`response-policy`	zero or one	Defines the authentication policy requirements of the authentication provider's response processing.
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Attributes

The following table describes attributes for the `provider-config` element.

Table 116. `provider-config` Attributes

Attribute	Default	Description
`provider-id`	none	Specifies the provider ID.
`provider-type`	none	Specifies whether the provider is a `client`, `server`, or `client-server` authentication provider.
`class-name`	none	Specifies the Jakarta implementation class of the provider. Client authentication providers must implement the com.sun.enterprise.security.jauth.ClientAuthModule interface. Server authentication providers must implement the com.sun.enterprise.security.jauth.ServerAuthModule interface. Client-server providers must implement both interfaces.

`realm`

Specifies the name of the realm used to process all authentication requests associated with this application. If this element is not specified or does not match the name of a configured realm, the default realm is used. For more information about realms, see "Realm Configuration" in the Payara Server Application Development section.

Superelements

`payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `as-context`, `login-config` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`refresh-field`

Specifies a field that gives the application component a programmatic way to refresh a cached entry.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none

Attributes

The following table describes attributes for the `refresh-field` element.

Table 117. `refresh-field` Attributes

Attribute	Default	Description
`name`	none	Specifies the input parameter name.
`scope`	`request.parameter`	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are `context.attribute`, `request.header`, `request.parameter`, `request.cookie`, `session.id`, and `session.attribute`.

`refresh-period-in-seconds`

Specifies the rate at which a read-only-bean must be refreshed from the data source. If the value is less than or equal to zero, the bean is never refreshed; if the value is greater than zero, the bean instances are refreshed at the specified interval. This rate is just a hint to the container. Default is 0 (no refresh).

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`removal-timeout-in-seconds`

Specifies the amount of time a bean instance can remain idle in the container before it is removed (timeout). A value of 0 specifies that the container does not remove inactive beans automatically. The default value is 5400.

If `removal-timeout-in-seconds` is less than or equal to `cache-idle-timeout-in-seconds`, beans are removed immediately without being passivated.

Applies to stateful session beans.

For related information, see `cache-idle-timeout-in-seconds`.

Superelements

`bean-cache` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`remote-home-impl`

Specifies the fully-qualified class name of the generated `EJBHome impl` class.

This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

Superelements

`gen-classes` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`remote-impl`

Specifies the fully-qualified class name of the generated `EJBObject impl` class.

This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

Superelements

`gen-classes` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`request-policy`

Defines the authentication policy requirements of the authentication provider's request processing.

Superelements

`provider-config` (`sun-acc.xml`)

Subelements

none

Attributes

The following table describes attributes for the `request-policy` element.

Table 118. `request-policy` Attributes

Attribute	Default	Description
`auth-source`	none	Specifies the type of required authentication, either `sender` (user name and password) or `content` (digital signature).
`auth-recipient`	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are `before-content` and `after-content`.

`request-protection`

Defines the authentication policy requirements of the application's request processing.

Superelements

`message-security` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none

Attributes

The following table describes attributes for the `request-protection` element.

Table 119. `request-protection` Attributes

Attribute	Default	Description
`auth-source`	none	Specifies the type of required authentication, either `sender` (user name and password) or `content` (digital signature).
`auth-recipient`	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are `before-content` and `after-content`.

`required`

Specifies whether the authentication method specified in the `auth-method` element must be used for client authentication. The value is `true` or `false` (the default).

Superelements

`as-context` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`res-ref-name`

Specifies the `res-ref-name` in the corresponding Jakarta EE deployment descriptor file `resource-ref` entry. The `res-ref-name` element specifies the name of a resource manager connection factory reference. The name must be unique within an enterprise bean.

Superelements

`resource-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`resize-quantity`

Specifies the number of bean instances to be:

- Created, if a request arrives when the pool has less than `steady-pool-size` quantity of beans (applies to pools only for creation). If the pool has more than `steady-pool-size` minus `resize-quantity` of beans, then `resize-quantity` is still created.
- Removed, when the `pool-idle-timeout-in-seconds` timer expires and a cleaner thread removes any unused instances.
    - For caches, when `max-cache-size` is reached, `resize-quantity` beans are selected for passivation using the `victim-selection-policy`. In addition, the `cache-idle-timeout-in-seconds` or `removal-timeout-in-seconds` timers passivate beans from the cache.
    - For pools, when the `max-pool-size` is reached, `resize-quantity` beans are selected for removal. In addition, the `pool-idle-timeout-in-seconds` timer removes beans until `steady-pool-size` is reached.

Values are from 0 to MAX_INTEGER. The pool is not resized below the `steady-pool-size`. Default is 16.

Applies to stateless session beans, entity beans, and message-driven beans.

For EJB pools, the value can be defined in the EJB container. Default is 16.

For EJB caches, the value can be defined in the EJB container. Default is 32.

For message-driven beans, the value can be defined in the EJB container. Default is 2.

Superelements

`bean-cache`, `bean-pool` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`resource-adapter-config`

Defines a connector (resource adapter) configuration. Stores configuration information for the resource adapter JavaBean in `property` subelements.

Superelements

`resources` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `resource-adapter-config` element.

Table 120. `resource-adapter-config` Subelements

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the `resource-adapter-config` element.

Table 121. `resource-adapter-config` Attributes

Attribute	Default	Description
`name`	none	(optional) Not used. See `resource-adapter-name`.
`thread-pool-ids`	none	(optional) Specifies a comma-separated list of the names of thread pools.
`object-type`	`user`	(optional) Defines the type of the resource. Allowed values are: • `system-all` - A system resource for all server instances and the domain application server. • `system-admin` - A system resource only for the domain application server. • `system-instance` - A system resource for all server instances only. • `user` - A user resource.
`resource-adapter-name`	none	Specifies the name of a deployed connector module or application. If the resource adapter is embedded in an application, then it is `app_name#rar_name`.

Properties

Properties of the `resource-adapter-config` element are the names of setter methods of the

`resourceadapter-class` element in the `ra.xml` file, which defines the class name of the resource adapter JavaBean. Any properties defined here override the default values present in `ra.xml`.

`resource-adapter-mid`

Specifies the module ID of the resource adapter that is responsible for delivering messages to the message-driven bean.

Superelements

`mdb-resource-adapter` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`resource-env-ref`

Maps the `res-ref-name` in the corresponding Jakarta EE deployment descriptor file `resource-env-ref` entry to the absolute `jndi-name` of a resource.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`), `payara-application-client` (`glassfish-application-client.xml`)

Subelements

The following table describes subelements for the `resource-env-ref` element.

Table 122. `resource-env-ref` Subelements

Element	Required	Description
`resource-env-ref-name`	only one	Specifies the `res-ref-name` in the corresponding Jakarta EE deployment descriptor file `resource-env-ref` entry.
`jndi-name`	only one	Specifies the absolute `jndi-name` of a resource.

Example

```
<resource-env-ref>
   <resource-env-ref-name>jms/StockQueueName</resource-env-ref-name>
   <jndi-name>jms/StockQueue</jndi-name>
</resource-env-ref>
```

`resource-env-ref-name`

Specifies the `res-ref-name` in the corresponding Jakarta EE deployment descriptor file `resource-env-ref` entry.

Superelements

`resource-env-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml`)

Subelements

none - contains data

`resource-ref`

Maps the `res-ref-name` in the corresponding Jakarta EE deployment descriptor file `resource-ref` entry to the absolute `jndi-name` of a resource.

Connections acquired from JMS connection factories are not shareable in the current release of Payara Server. The `res-sharing-scope` element in the `ejb-jar.xml` file `resource-ref` element is ignored for JMS connection factories.

When `resource-ref` specifies a JMS connection factory for the Open Message Queue, the `default-resource-principal` (name/password) must exist in the Message Queue user repository.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`), `payara-application-client` (`glassfish-application-client.xml`)

Subelements

The following table describes subelements for the `resource-ref` element.

Table 123. `resource-ref` Subelements

Element	Required	Description
`res-ref-name`	only one	Specifies the `res-ref-name` in the corresponding Jakarta EE deployment descriptor file `resource-ref` entry.
`jndi-name`	only one	Specifies the absolute `jndi-name` of a resource.
`default-resource-principal`	zero or one	Specifies the default principal (user) for the resource.

Example

```
<resource-ref>
   <res-ref-name>jdbc/EmployeeDBName</res-ref-name>
   <jndi-name>jdbc/EmployeeDB</jndi-name>
</resource-ref>
```

`resources`

Defines application-scoped resources for an enterprise application, web module, EJB module, connector module, or application client module. This is the root element; there can only be one `resources` element in a `glassfish-resources.xml` or `payara-resources.xml` file.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

See The glassfish-resources.xml and payara-resources Files.

You must specify a Java Naming and Directory Interface (JNDI) name for each resource. To avoid collisions with names of other enterprise resources in JNDI, and to avoid portability problems, all names in a Payara Server application should begin with the string `java:app/`.

Superelements

none

Subelements

The following table describes subelements for the `resources` element.

Table 124. `resources` Subelements

Element	Required	Description
`custom-resource`	zero or more	Defines a custom resource.
`external-jndi-resource`	zero or more	Defines a resource that resides in an external JNDI repository.
`jdbc-resource`	zero or more	Defines a JDBC (Java Database Connectivity) resource.
`mail-resource`	zero or more	Defines a Jakarta Mail resource.
`admin-object-resource`	zero or more	Defines an administered object for an inbound resource adapter.
`connector-resource`	zero or more	Defines a connector (resource adapter) resource.
`resource-adapter-config`	zero or more	Defines a resource adapter configuration.
`jdbc-connection-pool`	zero or more	Defines the properties that are required for creating a JDBC connection pool.
`connector-connection-pool`	zero or more	Defines the properties that are required for creating a connector connection pool.
`work-security-map`	zero or more	Defines a work security map.

Subelements of a `resources` element can occur in any order.

`response-policy`

Defines the authentication policy requirements of the authentication provider's response processing.

Superelements

`provider-config` (`sun-acc.xml`)

Subelements

none

Attributes

The following table describes attributes for the `response-policy` element.

Table 125. `response-policy` Attributes

Attribute	Default	Description
`auth-source`	none	Specifies the type of required authentication, either `sender` (user name and password) or `content` (digital signature).
`auth-recipient`	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are `before-content` and `after-content`.

`response-protection`

Defines the authentication policy requirements of the application's response processing.

Superelements

`message-security` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none

Attributes

The following table describes attributes for the `response-protection` element.

Table 126. `response-protection` Attributes

Attribute	Default	Description
`auth-source`	none	Specifies the type of required authentication, either `sender` (user name and password) or `content` (digital signature).

Attribute	Default	Description
auth-recipient	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are before-content and after-content.

role-name

Contains the role-name in the security-role element of the corresponding Jakarta EE deployment descriptor file.

Superelements

security-role-mapping (glassfish-application.xml (deprecated) and payara-application.xml`, glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

sas-context

Describes the sas-context fields.

Superelements

ior-security-config (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

The following table describes subelements for the sas-context element.

Table 127. sas-context Subelements

Element	Required	Description
caller-propagation	only one	Specifies whether the target accepts propagated caller identities. The values are NONE, SUPPORTED, or REQUIRED.

scanning-exclude and scanning-include

Modern WAR and EAR files very often include a number of 3rd party JARs. In situations where some JARs require CDI scanning and others may break if scanned, these can now be explicitly included or excluded from such component scanning.

Both the payara-application.xml and the payara-web.xml files support the following directives:

```
<webapp>
    <scanning-exclude>*</scanning-exclude>
    <scanning-include>ejb*</scanning-include>
    <scanning-include>conflicting-web-library</scanning-include>
```

```
</webapp>
```

In the above example, all JARs will be excluded by default, then all JARs beginning with `ejb` will be scanned along with the JAR named `conflicting-web-library`.

Superelements

`payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none

`security`

Defines the SSL security configuration for IIOP/SSL communication with the target server.

Superelements

`target-server` (`sun-acc.xml`)

Subelements

The following table describes subelements for the `security` element.

Table 128. `security` Subelements

Element	Required	Description
`ssl`	only one	Specifies the SSL processing parameters.
`cert-db`	only one	Not implemented. Included for backward compatibility only.

`security-map`

Maps the principal received during servlet or EJB authentication to the credentials accepted by the EIS. This mapping is optional. It is possible to map multiple Payara Server principals to the same back-end principal.

This is different from a `work-security-map`, which maps a principal associated with an incoming work instance to a principal in the Payara Server's security domain.

Superelements

`connector-connection-pool` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

The following table describes subelements for the `security-map` element.

Table 129. `security-map` Subelements

Element	Required	Description
`principal`	one or more	Contains the principal of the servlet or EJB client.
`user-group`	one or more	Contains the group to which the principal belongs.
`backend-principal`	only one	Specifies the username and password required by the EIS.

Attributes

The following table describes attributes for the `security-map` element.

Table 130. `security-map` Attributes

Attribute	Default	Description
`name`	none	Specifies a name for the security mapping.

`security-role-mapping`

Maps roles to users or groups in the currently active realm. See "Realm Configuration" in the Payara Server Application Development section.

The role mapping element maps a role, as specified in the EJB JAR `role-name` entries, to a environment-specific user or group. If it maps to a user, it must be a concrete user which exists in the current realm, who can log into the server using the current authentication method. If it maps to a group, the realm must support groups and the group must be a concrete group which exists in the current realm. To be useful, there must be at least one user in that realm who belongs to that group.

Superelements

`payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `payara-ejb-jar` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `security-role-mapping` element.

Table 131. `security-role-mapping` Subelements

Element	Required	Description
`role-name`	only one	Contains the `role-name` in the `security-role` element of the corresponding Jakarta EE deployment descriptor file.
`principal-name`	one or more if no `group-name`, otherwise zero or more	Contains a principal (user) name in the current realm. In an enterprise bean, the principal must have the run-as role specified.

Element	Required	Description
group-name	one or more if no principal-name, otherwise zero or more	Contains a group name in the current realm.

service-endpoint-interface

Specifies the web service reference name relative to java:comp/env.

Superelements

port-info (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml`)

Subelements

none - contains data

service-impl-class

Specifies the name of the generated service implementation class.

Superelements

service-ref (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml`)

Subelements

none - contains data

service-qname

Specifies the WSDL service element that is being referred to.

Superelements

service-ref (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml`); webservice-endpoint (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

The following table describes subelements for the service-qname element.

Table 132. service-qname subelements

Element	Required	Description
`namespaceURI`	only one	Specifies the namespace URI.
`localpart`	only one	Specifies the local part of a QNAME.

`service-ref`

Specifies runtime settings for a web service reference. Runtime information is only needed in the following cases:

- To define the port used to resolve a container-managed port
- To define the default Stub/Call property settings for Stub objects
- To define the URL of a final WSDL document to be used instead of the one associated with the `service-ref` in the standard Jakarta EE deployment descriptor

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`), `payara-application-client` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `service-ref` element.

Table 133. `service-ref` subelements

Element	Required	Description
`service-ref-name`	only one	Specifies the web service reference name relative to `java:comp/env`.
`port-info`	zero or more	Specifies information for a port within a web service reference.
`call-property`	zero or more	Specifies JAX-RPC property values that can be set on a `javax.xml.rpc.Call` object before it is returned to the web service client.
`wsdl-override`	zero or one	Specifies a valid URL pointing to a final WSDL document.
`service-impl-class`	zero or one	Specifies the name of the generated service implementation class.
`service-qname`	zero or one	Specifies the WSDL service element that is being referenced.

`service-ref-name`

Specifies the web service reference name relative to `java:comp/env`.

Superelements

`service-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`servlet`

Specifies a principal name for a servlet. Used for the `run-as` role defined in `web.xml`.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `servlet` element.

Table 134. `servlet` Subelements

Element	Required	Description
`servlet-name`	only one	Contains the name of a servlet, which is matched to a `servlet-name` in `web.xml`.
`principal-name`	zero or one	Contains a principal (user) name in the current realm.
`webservice-endpoint`	zero or more	Specifies information about a web service endpoint.

`servlet-impl-class`

Specifies the automatically generated name of the servlet implementation class.

Superelements

`webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`servlet-name`

Specifies the name of a servlet, which is matched to a `servlet-name` in `web.xml`. This name must be present in `web.xml`.

Superelements

`cache-mapping`, `servlet` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none - contains data

`session-config`

Specifies session configuration information. Overrides the web container settings for an individual web module.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `session-config` element.

Table 135. `session-config` Subelements

Element	Required	Description
`session-manager`	zero or one	Specifies session manager configuration information.
`session-properties`	zero or one	Specifies session properties.
`cookie-properties`	zero or one	Specifies session cookie properties.

`session-manager`

Specifies session manager information.

Superelements

`session-config` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `session-manager` element.

Table 136. `session-manager` Subelements

Element	Required	Description
`manager-properties`	zero or one	Specifies session manager properties.
`store-properties`	zero or one	Specifies session persistence (storage) properties.

Attributes

The following table describes attributes for the `session-manager` element.

Table 137. `session-manager` Attributes

Attribute	Default	Description
persistence-type	memory	(optional) Specifies the session persistence mechanism. Allowed values are memory, file, and hazelcast.

session-properties

Specifies session properties.

Superelements

session-config (glassfish-web.xml (deprecated) and payara-web.xml)

Subelements

The following table describes subelements for the session-properties element.

Table 138. session-properties Subelements

Element	Required	Description
property (with attributes)	zero or more	Specifies a property, which has a name and a value.

Properties

The following table describes properties for the session-properties element.

Table 139. session-properties Properties

Property	Default	Description
timeoutSeconds	1800	Specifies the default maximum inactive interval (in seconds) for all sessions created in this web module. If set to 0 or less, sessions in this web module never expire. If a session-timeout element is specified in the web.xml file, the session-timeout value overrides any timeoutSeconds value. If neither session-timeout nor timeoutSeconds is specified, the timeoutSeconds default is used. Note that the session-timeout element in web.xml is specified in minutes, not seconds.
enableCookies	true	Uses cookies for session tracking if set to true.
enableURLRewriting	true	Enables URL rewriting. This provides session tracking via URL rewriting when the browser does not accept cookies. You must also use an encodeURL or encodeRedirectURL call in the servlet or JSP.

`ssl`

Defines SSL processing parameters.

Superelements

`security` (`sun-acc.xml`)

Subelements

none

Attributes

The following table describes attributes for the `SSL` element.

Table 140. `ssl attributes`

Attribute	Default	Description
`cert-nickname`	`s1as`	(optional) The nickname of the server certificate in the certificate database or the PKCS#11 token. In the certificate, the name format is `tokenname:nickname`. Including the `tokenname:` part of the name in this attribute is optional.
`ssl2-enabled`	`false`	(optional) Determines whether SSL2 is enabled.
`ssl2-ciphers`	none	(optional) A comma-separated list of the SSL2 ciphers to be used. Ciphers not explicitly listed will be disabled for the target, even if those ciphers are available in the particular cipher suite you are using. If this option is not used, all supported ciphers are assumed to be enabled. Allowed values are `rc4`, `rc4export`, `rc2`, `rc2export`, `idea`, `des`, `desede3`.
`ssl3-enabled`	`true`	(optional) Determines whether SSL3 is enabled.
`ssl3-tls-ciphers`	none	(optional) A comma-separated list of the SSL3 and/or TLS ciphers to be used. Ciphers not explicitly listed will be disabled for the target, even if those ciphers are available in the particular cipher suite you are using. If this option is not used, all supported ciphers are assumed to be enabled. Allowed values are `SSL_RSA_WITH_RC4_128_MD5`, `SSL_RSA_WITH_3DES_EDE_CBC_SHA`, `SSL_RSA_WITH_DES_CBC_SHA`, `SSL_RSA_EXPORT_WITH_RC4_40_MD5`, `SSL_RSA_WITH_NULL_MD5`, `SSL_RSA_WITH_RC4_128_SHA`, `SSL_RSA_WITH_NULL_SHA`. Values available in previous releases are supported for backward compatibility.
`tls-enabled`	`true`	(optional) Determines whether TLS is enabled.

Attribute	Default	Description
`tls-rollback-enabled`	`true`	(optional) Determines whether TLS rollback is enabled. Enable TLS rollback for Microsoft Internet Explorer 5.0 and 5.5.

`steady-pool-size`

Specifies the initial and minimum number of bean instances that are maintained in the pool. Default is 32. Applies to stateless session beans and message-driven beans.

Superelements

`bean-pool` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`store-properties`

Specifies session persistence (storage) properties.

Superelements

`session-manager` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

The following table describes subelements for the `store-properties` element.

Table 141. `store-properties` Subelements

Element	Required	Description
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Properties

The following table describes properties for the `store-properties` element.

Table 142. `store-properties` Properties

Property	Default	Description
`directory`	`domain-dir/generated/jsp/app-name/module-name_war`	Specifies the absolute or relative pathname of the directory into which individual session files are written. A relative path is relative to the temporary work directory for this web module. Applicable only if the `persistence-type` attribute of the parent `session-manager` element is `file`.

Property	Default	Description
persistenceScope	session	Specifies how much of the session state is stored. Allowed values are as follows: • session - The entire session state is stored every time. This mode provides the best guarantee that your session data is correctly stored for any distributable web module. • modified-session - The entire session state is stored if it has been modified. A session is considered to have been modified if HttpSession.setAttribute() or HttpSession.removeAttribute() was called. You must guarantee that setAttribute is called every time an attribute is changed. This is not a Jakarta EE specification requirement, but it is required for this mode to work properly. • modified-attribute - Only modified session attributes are stored. For this mode to work properly, you must follow some guidelines, which are explained immediately following this table. Applicable only if the persistence-type attribute of the parent session-manager element is hazelcast.

If the persistenceScope store property is set to modified-attribute, a web module must follow these guidelines:

- Call setAttribute every time the session state is modified.
- Make sure there are no cross-references between attributes. The object graph under each distinct attribute key is serialized and stored separately. If there are any object cross references between the objects under each separate key, they are not serialized and deserialized correctly.
- Distribute the session state across multiple attributes, or at least between a read-only attribute and a modifiable attribute.

stub-property

Specifies JAX-RPC property values that are set on a javax.xml.rpc.Stub object before it is returned to the web service client. The property names can be any properties supported by the JAX-RPC Stub implementation.

Superelements

port-info (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml, glassfish-application-client.xml (deprecated) and payara-application-client.xml`)

Subelements

The following table describes subelements for the `stub-property` element.

Table 143. `stub-property` subelements

Element	Required	Description
`name`	only one	Specifies the name of the entity.
`value`	only one	Specifies the value of the entity.

Properties

The following table describes properties for the `stub-property` element.

Table 144. `stub-property` properties

Property	Default	Description
`jbi-enabled`	`true`	Determines whether the visibility of this endpoint as a Java Business Integration service is enabled or disabled.

Example

```
<service-ref>
<service-ref-name>service/FooProxy</service-ref-name>
  <port-info>
       <service-endpoint-interface>a.FooPort</service-endpoint-interface>
       <wsdl-port>
          <namespaceURI>urn:Foo</namespaceURI>
          <localpart>FooPort</localpart>
       </wsdl-port>
       <stub-property>
          <name>javax.xml.rpc.service.endpoint.address</name>
          <value>http://localhost:8080/a/Foo</value>
       </stub-property>
  </port-info>
</service-ref>
```

`target-server`

Specifies the IIOP listener for the target server. Also specifies IIOP endpoints used for load balancing. If the Payara Server instance on which the application client is deployed participates in a cluster, Payara Server finds all currently active IIOP endpoints in the cluster automatically. However, a client should have at least two endpoints specified for bootstrapping purposes, in case one of the endpoints has failed.

A listener or endpoint is in the form `host:port`, where the host is an IP address or host name, and the port specifies the port number.

Superelements

`client-container` (`sun-acc.xml`)

Subelements

The following table describes subelements for the `target-server` element.

Table 145. `target-server` subelements

Element	Required	Description
`description`	zero or one	Specifies the description of the target server.
`security`	zero or one	Specifies the security configuration for the IIOP/SSL communication with the target server.

Attributes

The following table describes attributes for the `target-server` element.

Table 146. `target-server` attributes

Attribute	Default	Description
`name`	none	Specifies the name of the server instance accessed by the client container.
`address`	none	Specifies the host name or IP address (resolvable by DNS) of the server to which this client attaches.
`port`	none	Specifies the naming service port number of the server to which this client attaches. For a new server instance, assign a port number other than 3700. You can change the port number in the Administration Console. Click the Help button in the Administration Console for more information.

`tie-class`

Specifies the automatically generated name of a tie implementation class for a port component.

Superelements

`webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`timeout`

Specifies the `cache-mapping` specific maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed. If not specified, the default is the value of the `timeout`

attribute of the `cache` element.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none - contains data

Attributes

The following table describes attributes for the `timeout` element.

Table 147. `timeout` Attributes

Attribute	Default	Description
`name`	none	Specifies the timeout input parameter, whose value is interpreted in seconds. The field's type must be `java.lang.Long` or `java.lang.Integer`.
`scope`	`request.attribute`	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are `context.attribute`, `request.header`, `request.parameter`, `request.cookie`, `request.attribute`, and `session.attribute`.

`transport-config`

Specifies the security transport information.

Superelements

`ior-security-config` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `transport-config` element.

Table 148. `transport-config` Subelements

Element	Required	Description
`integrity`	only one	Specifies if the target supports integrity-protected messages. The values are NONE, SUPPORTED, or REQUIRED.
`confidentiality`	only one	Specifies if the target supports privacy-protected messages. The values are NONE, SUPPORTED, or REQUIRED.
`establish-trust-in-target`	only one	Specifies if the target is capable of authenticating to a client. The values are NONE, SUPPORTED, or REQUIRED.

Element	Required	Description
`establish-trust-in-client`	only one	Specifies if the target is capable of authenticating a client. The values are NONE, SUPPORTED, or REQUIRED.

`transport-guarantee`

Specifies that the communication between client and server is `NONE`, `INTEGRAL`, or `CONFIDENTIAL`.

- `NONE` means the application does not require any transport guarantees.
- `INTEGRAL` means the application requires that the data sent between client and server be sent in such a way that it can't be changed in transit.
- `CONFIDENTIAL` means the application requires that the data be transmitted in a fashion that prevents other entities from observing the contents of the transmission.

In most cases, a value of `INTEGRAL` or `CONFIDENTIAL` indicates that the use of SSL is required.

Superelements

`webservice-endpoint` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`unique-id`

Contains the unique ID for the application. This value is automatically updated each time the application is deployed or redeployed. Do not edit this value.

Superelements

`payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `enterprise-beans` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`url-pattern`

Specifies a servlet URL pattern for which caching is enabled. See the Servlet 6.0 specification section 12.2 for applicable patterns.

Superelements

`cache-mapping` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

Subelements

none - contains data

`user-group`

Contains the group to which the principal belongs.

Superelements

`security-map` (`glassfish-resources.xml` (deprecated) and `payara-resources.xml`)

Subelements

none - contains data

`use-thread-pool-id`

Specifies the thread pool from which threads are selected for remote invocations of this bean.

Superelements

`ejb` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`value`

Specifies the value of the entity.

Superelements

`call-property`, `stub-property` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`); `property` (with subelements) (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

`valve`

Specifies a custom valve for this web application. You can define a valve for all the web applications on a specific virtual server. For details, see `create-virtual-server`.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`)

[[Technical Documentation-Payara Server Documentation-Application Deployment-Elements of Deployment Descriptors:::subelements-202]#Technical Documentation-Payara Server

Documentation-Application Deployment-Elements of Deployment Descriptors:::subelements-202] Subelements

The following table describes subelements for the `valve` element.

Table 149. `valve` Subelements

Element	Required	Description
`description`	zero or one	Specifies a text description of this element.
`property` (with attributes)	zero or more	Specifies a property, which has a name and a value.

Attributes

The following table describes attributes for the `valve` element.

Table 150. `valve` Attributes

Attribute	Default	Description
`name`	none	Specifies a unique name for the valve.
`class-name`	none	Specifies the fully qualified class name of the valve. The valve class must implement the `org.apache.catalina.Valve` interface from Tomcat or previous Payara Server releases, or the `org.glassfish.web.valve.GlassFishValve` interface from the current Payara Server release.

Example

```
<valve name="MyValve" classname="org.glassfish.extension.Valve">
   <property name="MyProperty1" value="MyValue1" />
   <property name="MyProperty2" value="MyValue2" />
</valve>
```

`vendor`

Specifies a vendor-specific icon, splash screen, text string, or a combination of these for Java Web Start download and launch screens. The complete format of this element's data is as follows:

```
<vendor>icon-image-URI::splash-screen-image-URI::vendor-text</vendor>
```

The following example vendor element contains an icon, a splash screen, and a text string:

```
<vendor>images/icon.jpg::otherDir/splash.jpg::MyCorp, Inc.</vendor>
```

The following example vendor element contains an icon and a text string:

```
<vendor>images/icon.jpg::MyCorp, Inc.</vendor>
```

The following example vendor element contains a splash screen and a text string; note the initial double colon:

```
<vendor>::otherDir/splash.jpg::MyCorp, Inc.</vendor>
```

The following example vendor element contains only a text string:

```
<vendor>MyCorp, Inc.</vendor>
```

The default value is the text string `Application Client`.

Superelements

`java-web-start-access` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`version-identifier`

Contains version information for an application or module. For more information about application versioning, see Module and Application Versions.

Superelements

`payara-application` (`glassfish-application.xml` (deprecated) and `payara-application.xml`), `payara-web-app` (`payara-web.xml`), `payara-ejb-jar` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`), `payara-application-client` (`glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

`victim-selection-policy`

Specifies how stateful session beans are selected for passivation. Possible values are First In, First Out (`FIFO`), Least Recently Used (`LRU`), Not Recently Used (`NRU`). The default value is `NRU`, which is actually pseudo-LRU.

You cannot plug in your own victim selection algorithm.

The victims are generally passivated into a backup store (typically a file system or database). This store is cleaned during startup, and also by a periodic background process that removes idle entries

as specified by `removal-timeout-in-seconds`. The backup store is monitored by a background thread (or sweeper thread) to remove unwanted entries.

Applies to stateful session beans.

Superelements

`bean-cache` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

Example

```
<victim-selection-policy>LRU</victim-selection-policy>
```

If both SSL2 and SSL3 are enabled, the server tries SSL3 encryption first. If that fails, the server tries SSL2 encryption. If both SSL2 and SSL3 are enabled for a virtual server, the server tries SSL3 encryption first. If that fails, the server tries SSL2 encryption.

`web`

Specifies the application's web tier configuration.

Superelements

`payara-application` (`payara-application.xml`)

Subelements

The following table describes subelements for the `web` element.

Table 151. `web` Subelements

Element	Required	Description
`web-uri`	only one	Contains the web URI for the application.
`context-root`	only one	Contains the web context root for the web module.

`web-uri`

Contains the web URI for the application. Must match the corresponding element in the `application.xml` file.

Superelements

`web` (`glassfish-application.xml` (deprecated) and `payara-application.xml`)

Subelements

none - contains data

webservice-default-login-config

When declaring a secured Web Service based on an EJB using the `payara-ejb-jar.xml` deployment descriptor, it's necessary to define the login configuration (authentication method, security realm name, etc.) for each EJB Web Service that is secured inside the assembly.

For example, if an application contains 2 EJB web services called **EJBWS1** and **EJBWS2**, and they need to be secured using `BASIC` authentication against the *file* security realm, the following configuration would be needed:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-ejb-jar PUBLIC "-//Payara.fish//DTD Payara Application Server 7 EJB
4.0//EN" "https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-ejb-jar_4_0-0.dtd}">
<payara-ejb-jar>
    <enterprise-beans>
        <ejb>
            <ejb-name>EJBWS1</ejb-name>
            <webservice-endpoint>
              <port-component-name>EJBWS1Port</port-component-name>
              <endpoint-address-uri>EJBWS1/EJBWebService</endpoint-address-uri>
              <login-config>
                <auth-method>BASIC</auth-method>
                <realm>file</realm>
              </login-config>
            </webservice-endpoint>
          </ejb>
        <ejb>
            <ejb-name>EJBWS2</ejb-name>
            <webservice-endpoint>
              <port-component-name>EJBWS2Port</port-component-name>
              <endpoint-address-uri>EJBWS2/EJBWebService</endpoint-address-uri>
              <login-config>
                <auth-method>BASIC</auth-method>
                <realm>file</realm>
              </login-config>
            </webservice-endpoint>
          </ejb>
    </enterprise-beans>
</payara-ejb-jar>
```

Notice that the `login-config` element is repeated exactly like it is in the 2 EJB definitions. Not only that, but if these Web services are defined using annotations for each EJB component, then the **JAX-WS** information (Port Component Name, Endpoint Address, etc.) would be duplicated too, which is too cumbersome for cases when there are lots of EJB Web service definitions.

For this scenario, the `webservice-default-login-config` has been introduced to simplify this configuration. When this element is declared, the login configuration inside it will apply to all the EJB defined Web Services by default.

The previous example can be simplified like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-ejb-jar PUBLIC "-//Payara.fish//DTD Payara Application Server 7 EJB
4.0//EN" "https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-ejb-jar_4_0-0.dtd}">
<payara-ejb-jar>
  <webservice-default-login-config>
      <auth-method>BASIC</auth-method>
      <realm>file</realm>
  </webservice-default-login-config>
</payara-ejb-jar>
```

All sub-elements tags of the `login-config` can be used inside this element.

If an EJB Web service definition needs a different login configuration from the default, just redefine it as shown in the example, and it will override the default configuration.

Superelements

`payara-ejb-jar (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `webservice-default-login-config` element.

Table 152. `webservice-default-login-config` subelements

Element	Required	Description
`auth-method`	only one	Specifies the authentication method.
`realm`	zero or one	Specifies the name of the realm used to process all authentication requests.

`webservice-description`

Specifies a name and optional publish location for a web service.

Superelements

`payara-web-app` (`glassfish-web.xml` (deprecated) and `payara-web.xml`), `enterprise-beans` (`glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

The following table describes subelements for the `webservice-description` element.

Table 153. `webservice-description` subelements

Element	Required	Description
webservice-description-name	only one	Specifies a unique name for the web service within a web or EJB module.
wsdl-publish-location	zero or one	Specifies the URL of a directory to which a web service's WSDL is published during deployment.

webservice-description-name

Specifies a unique name for the web service within a web or EJB module.

Superelements

webservice-description (glassfish-web.xml (deprecated) and payara-web.xml, glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

none - contains data

webservice-endpoint

Specifies information about a web service endpoint.

Superelements

servlet (glassfish-web.xml (deprecated) and payara-web.xml), ejb (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)

Subelements

The following table describes subelements for the webservice-endpoint element.

Table 154. webservice-endpoint subelements

Element	Required	Description
port-component-name	only one	Specifies a unique name for a port component within a web or EJB module.
endpoint-address-uri	zero or one	Specifies the automatically generated endpoint address.
login-config	zero or one	Specifies the authentication configuration for an EJB web service endpoint.
message-security-binding	zero or one	Specifies a custom authentication provider binding.
transport-guarantee	zero or one	Specifies that the communication between client and server is NONE, INTEGRAL, or CONFIDENTIAL.
service-qname	zero or one	Specifies the WSDL service element that is being referenced.
tie-class	zero or one	Specifies the automatically generated name of a tie implementation class for a port component.

Element	Required	Description
servlet-impl-class	zero or one	Specifies the automatically generated name of the generated servlet implementation class.
debugging-enabled	zero or one	Specifies whether the debugging servlet is enabled for this web service endpoint. Allowed values are true and false (the default).
property (with attributes) (glassfish-web.xml (deprecated) and payara-web.xml) property (with subelements) (glassfish-ejb-jar.xml (deprecated) and payara-ejb-jar.xml)	zero or more	Specifies a property, which has a name and a value.

whitelist-package

This element can be used to whitelist packages on **extreme class loading isolation**.

Whitelisted packages are taken into account by the server when scanning libraries.

For more information about how extreme class loading isolation works on Payara Server, see the Enhanced Classloading section.

Superelements

payara-application` (glassfish-application.xml (deprecated) and payara-application.xml), `glassfish-web-app or payara-web-app (payara-web.xml)

Subelements

none

work-security-map

Defines a work security map, which maps a principal associated with an incoming work instance to a principal in the Payara Server's security domain. It is possible to map multiple EIS group or user principals to the same Payara Server principal.

This is different from a security-map, which maps the principal received during servlet or EJB authentication to the credentials accepted by the EIS.

Superelements

resources (glassfish-resources.xml (deprecated) and payara-resources.xml)

Subelements

The following table describes subelements for the work-security-map element.

Table 155. work-security-map Subelements

Element	Required	Description
`description`	zero or one	Contains a text description of this element.
`principal-map`	zero or more	Maps an EIS principal to a principal defined in the Payara Server domain.
`group-map`	zero or more	Maps an EIS group to a group defined in the Payara Server domain.

Attributes

The following table describes attributes for the `work-security-map` element.

Table 156. `work-security-map` Attributes

Attribute	Default	Description
`name`	none	Specifies a unique name for the work security map.
`description`	none	Specifies a text description for this element.

`wsdl-override`

Specifies a valid URL pointing to a final WSDL document. If not specified, the WSDL document associated with the `service-ref` in the standard Jakarta EE deployment descriptor is used.

Superelements

`service-ref` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

none - contains data

Example

```
<!-- available via HTTP -->
<wsdl-override>http://localhost:8000/myservice/myport?WSDL</wsdl-override>
```

```
<!-- in a file -->
<wsdl-override>file:/home/user1/myfinalwsdl.wsdl</wsdl-override>
```

`wsdl-port`

Specifies the WSDL port.

Superelements

`port-info` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated)

and `payara-ejb-jar.xml`, `glassfish-application-client.xml` (deprecated) and `payara-application-client.xml`)

Subelements

The following table describes subelements for the `wsdl-port` element.

Table 157. `wsdl-port` subelements

Element	Required	Description
`namespaceURI`	only one	Specifies the namespace URI.
`localpart`	only one	Specifies the local part of a QNAME.

`wsdl-publish-location`

Specifies the URL of a directory to which a web service's WSDL is published during deployment. Any required files are published to this directory, preserving their location relative to the module-specific WSDL directory (`META-INF/wsdl` or `WEB-INF/wsdl`).

Superelements

`webservice-description` (`glassfish-web.xml` (deprecated) and `payara-web.xml`, `glassfish-ejb-jar.xml` (deprecated) and `payara-ejb-jar.xml`)

Subelements

none - contains data

Example

Suppose you have an `ejb.jar` file whose `webservices.xml` file's `wsdl-file` element contains the following reference:

```
META-INF/wsdl/a/Foo.wsdl
```

Suppose your `glassfish-ejb.jar` file contains the following element:

```
<wsdl-publish-location>file:/home/user1/publish</wsdl-publish-location>
```

The final WSDL is stored in `/home/user1/publish/a/Foo.wsdl`.

High Availability

Overview

This chapter describes the high availability features in Payara Server.

The following topics are addressed here:

- Overview of High Availability
- How Payara Server Provides High Availability
- Recovering from Failures

Overview of High Availability

High availability applications and services provide their functionality continuously, regardless of hardware and software failures. To make such reliability possible, Payara Server provides mechanisms for maintaining application state data between clustered Payara Server instances. Application state data, such as HTTP session data, stateful EJB sessions, and dynamic cache information, is replicated in real time across server instances. If any one server instance goes down, the session state is available to the next failover server, resulting in minimum application downtime and enhanced transactional security.

Payara Server provides the following high availability features:

- Load Balancing With the Apache mod_jk or mod_proxy_ajp Module
- High Availability Session Persistence
- High Availability Java Message Service
- RMI-IIOP Load Balancing and Failover

Load Balancing With the Apache `mod_jk` or `mod_proxy_ajp` Module

A common load balancing configuration for Payara Server is to use the Apache HTTP Server as the web server front-end, and the Apache `mod_jk` or `mod_proxy_ajp` module as the connector between the web server and Payara Server. See Configuring Payara Server with Apache HTTP Server and `mod_jk` and Configuring Payara Server with Apache HTTP Server and `mod_proxy_ajp` for more information.

High Availability Session Persistence

Payara Server provides high availability of HTTP requests and session data (both HTTP session data and stateful session bean data).

Jakarta EE applications typically have significant amounts of session state data. A web shopping cart is the classic example of a session state. Also, an application can cache frequently-needed data in the session object. In fact, almost all applications with significant user interactions need to maintain session state. Both HTTP sessions and stateful session beans (SFSBs) have session state data.

Preserving session state across server failures can be important to end users. If the Payara Server instance hosting the user session experiences a failure, the session state can be recovered, and the session can continue without loss of information. High availability is implemented in Payara Server by means of in-memory session replication on Payara Server instances running in a cluster.

For more information about in-memory session replication in Payara Server, see How Payara Server Provides High Availability. For detailed instructions on configuring high availability session persistence, see Configuring High Availability Session Persistence and Failover.

High Availability Java Message Service

Payara Server supports the Java Message Service (JMS) API and JMS messaging through its built-in `jmsra` resource adapter communicating with Open Message Queue as the JMS provider. This combination is often called the **JMS Service**.

The JMS service makes JMS messaging highly available as follows:

Message Queue Broker Clusters

By default, when a Payara Server cluster is created, the JMS service automatically configures a Message Queue broker cluster to provide JMS messaging services, with one clustered broker assigned to each cluster instance. This automatically created broker cluster is configurable to take advantage of the two types of broker clusters, conventional and enhanced, supported by Message Queue.

Additionally, Message Queue broker clusters created and managed using Message Queue itself can be used as external, or remote, JMS hosts. Using external broker clusters provides additional deployment options, such as deploying Message Queue brokers on different hosts from the Payara instances they service, or deploying different numbers of Message Queue brokers and Payara instances.

For more information about Message Queue clustering, see Using Message Queue Broker Clusters With Payara Server.

Connection Failover

The use of Message Queue broker clusters allows connection failover in the event of a broker failure. If the primary JMS host (Message Queue broker) in use by a Payara Server instance fails, connections to the failed JMS host will automatically fail over to another host in the JMS host list, allowing messaging operations to continue and maintaining JMS messaging semantics.

For more information about JMS connection failover, see Connection Failover.

RMI-IIOP Load Balancing and Failover

With RMI-IIOP load balancing, IIOP client requests are distributed to different server instances or name servers, which spreads the load evenly across the cluster, providing scalability. IIOP load balancing combined with EJB clustering and availability also provides EJB failover.

When a client performs a JNDI lookup for an object, the Naming Service essentially binds the request to a particular server instance. From then on, all lookup requests made from that client are sent to the same server instance, and thus all `EJBHome` objects will be hosted on the same target server. Any bean references obtained henceforth are also created on the same target host. This effectively provides load balancing, since all clients randomize the list of target servers when performing JNDI lookups. If the target server instance goes down, the lookup or EJB method invocation will fail over to another server instance.

IIOP Load balancing and failover happens transparently. No special steps are needed during application deployment. If the Payara Server instance on which the application client is deployed participates in a cluster, the Payara Server finds all currently active IIOP endpoints in the cluster automatically. However, a client should have at least two endpoints specified for bootstrapping

purposes, in case one of the endpoints has failed.

For more information on RMI-IIOP load balancing and failover, see RMI-IIOP Load Balancing and Failover.

How Payara Server Provides High Availability

Payara Server provides high availability through the following subcomponents and features:

- Storage for Session State Data
- Highly Available Clusters

Storage for Session State Data

Storing session state data enables the session state to be recovered after the failover of a server instance in a cluster. Recovering the session state enables the session to continue without loss of information. Payara Server supports in-memory session replication on other servers in the cluster for maintaining HTTP session and stateful session bean data.

In-memory session replication is implemented in Payara Server via the use of the Data Grid (implemented using Hazelcast Community Edition). As such, to use this feature the Data Grid has to be enabled in the domain first.

Highly Available Clusters

A highly available cluster integrates a state replication service with clusters and load balancer.

When implementing a highly available cluster solution, use a load balancer that includes session-based stickiness as part of its load-balancing algorithm. Otherwise, session data can be misdirected or lost.

Clusters, Instances, Sessions, and Load Balancing

Clusters, server instances, load balancers, and sessions are related as follows:

- A server instance is not required to be part of a cluster. However, an instance that is not part of a cluster cannot take advantage of high availability through transfer of session state from one instance to other instances.
- The server instances within a cluster can be hosted on one or multiple hosts. You can group server instances across different hosts into a cluster.
- A particular load balancer can forward requests to server instances on multiple clusters. You can use this ability of the load balancer to perform an online upgrade without loss of service.
- A single cluster can receive requests from multiple load balancers. If a cluster is served by more than one load balancer, you must configure the cluster in exactly the same way on each load balancer.
- Each session is tied to a particular cluster. Therefore, although you can deploy an application on multiple clusters, session failover will occur only within a single cluster.

The cluster thus acts as a safe boundary for session failover for the server instances within the cluster. You can use the load balancer and upgrade components within the Payara Server without loss of service.

Protocols for Centralized Cluster Administration

Payara Server uses the secure shell (SSH) to ensure that clusters that span multiple hosts can be administered centrally. To perform administrative operations on Payara Server instances that are remote from the domain administration server (DAS), the DAS must be able to communicate with those instances. If an instance is running, the DAS connects to the running instance directly. For example, when you deploy an application to an instance, the DAS connects to the instance and deploys the application to the instance.

However, the DAS cannot connect to an instance to perform operations on an instance that is not running, such as creating or starting the instance. For these operations, the DAS uses SSH to contact a remote host and administer instances there. SSH provides confidentiality and security for data that is exchanged between the DAS and remote hosts.

The use of SSH to enable centralized administration of remote instances is optional. If the use of SSH is not feasible in your environment, you can administer remote instances locally.

For more information, see Enabling Centralized Administration of Payara Server Instances.

Recovering from Failures

You can use various techniques to manually recover individual subcomponents after hardware failures such as disk crashes.

The following topics are addressed here:

- Recovering the Domain Administration Server
- Recovering Payara Server Instances
- Recovering Message Queue

Recovering the Domain Administration Server

Loss of the Domain Administration Server (DAS) affects only administration. Payara Server clusters and standalone instances, and the applications deployed to them, continue to run as before, even if the DAS is not reachable

Use any of the following methods to recover the DAS:

- Back up the domain periodically, so you have periodic snapshots. After a hardware failure, re-create the DAS on a new host, as described in "Re-Creating the Domain Administration Server (DAS)" in Payara Server General Administration section.
- Put the domain installation and configuration on a shared and robust file system (NFS for example). If the primary DAS host fails, a second host is brought up with the same IP address and will take over with manual intervention or user supplied automation.

- Zip the Payara Server installation and domain root directory. Restore it on the new host, assigning it the same network identity.

Recovering Payara Server Instances

Payara Server provide tools for backing up and restoring Payara Server instances. For more information, see To Resynchronize an Instance and the DAS Offline.

Recovering Message Queue

When a Message Queue broker becomes unavailable, the method you use to restore the broker to operation depends on the nature of the failure that caused the broker to become unavailable:

- Power failure or failure other than disk storage
- Failure of disk storage

Additionally, the urgency of restoring an unavailable broker to operation depends on the type of the broker:

Standalone Broker

When a standalone broker becomes unavailable, both service availability and data availability are interrupted. Restore the broker to operation as soon as possible to restore availability.

Broker in a Conventional Cluster

When a broker in a conventional cluster becomes unavailable, service availability continues to be provided by the other brokers in the cluster. However, data availability of the persistent data stored by the unavailable broker is interrupted. Restore the broker to operation to restore availability of its persistent data.

Broker in an Enhanced Cluster

When a broker in an enhanced cluster becomes unavailable, service availability and data availability continue to be provided by the other brokers in the cluster. Restore the broker to operation to return the cluster to its previous capacity.

Recovering From Power Failure and Failures Other Than Disk Storage

When a host is affected by a power failure or failure of a non-disk component such as memory, processor or network card, restore Message Queue brokers on the affected host by starting the brokers after the failure has been remedied.

To start brokers serving as `EMBEDDED` or `LOCAL` JMS hosts, start the Payara instances the brokers are servicing.

To start brokers serving as `REMOTE` JMS hosts, use the `imqbrokerd` Message Queue utility.

Recovering from Failure of Disk Storage

Message Queue uses disk storage for software, configuration files and persistent data stores. In a default Payara Server installation, all three of these are generally stored on the same disk: the Message Queue software in `as-install-parent/mq`, and broker configuration files and persistent data

stores (except for the persistent data stores of enhanced clusters, which are housed in highly available databases) in `domain-dir/imq`. If this disk fails, restoring brokers to operation is impossible unless you have previously created a backup of these items.

To create such a backup, use a utility such as `zip`, `gzip` or `tar` to create archives of these directories and all their content. When creating the backup, you should first quiesce all brokers and physical destinations, as described in the Open Message Queue Administration Guide, respectively. Then, after the failed disk is replaced and put into service, expand the backup archive into the same location.

Restoring the Persistent Data Store From Backup.

For many messaging applications, restoring a persistent data store from backup does not produce the desired results because the backed up store does not represent the content of the store when the disk failure occurred. In some applications, the persistent data changes rapidly enough to make backups obsolete as soon as they are created.

To avoid issues in restoring a persistent data store, consider using a RAID or SAN data storage solution that is fault-tolerant, especially for data stores in production environments.

See Also

For information about planning a high-availability deployment, including assessing hardware requirements, planning network configuration, and selecting a topology, see the Payara Server Deployment Planning section. This manual also provides a high-level introduction to concepts such as:

- Payara Server components such as node agents, domains, clusters and deployment groups
- IIOP load balancing in a cluster or deployment group
- Message queue fail-over

For more information about developing applications that take advantage of high availability features, see the Payara Server Application Development section.

Enabling Centralized Administration of Server Instances

At the moment of the publication of this documentation, using the natively provided SSH utilities by Windows OS environments doesn't work. The main reason for this is significant issues with file transfers not working correctly across nodes.

We have discovered that when SSH is provided using a Cygwin-based OpenSSH and Bash shell from Cygwin is used to manage Payara Server, remote nodes can be created and operated without issues.

Until the problems with natively provided OpenSSH implementation are addressed, we recommend you configure SSH nodes using the Cygwin-based OpenSSH toolset in production environments.

Payara Server uses the secure shell (SSH) to ensure that instances that span multiple hosts can be administered centrally.

To perform administrative operations on Payara Server instances that are remote from the domain administration server (DAS), the DAS must be able to communicate with those instances.

If an instance is running, the DAS connects to the running instance directly. For example, when you deploy an application to an instance, the DAS connects to the instance and deploys the application to the instance.

However, the DAS cannot connect to an instance to perform operations on an instance that is not running, such as creating or starting the instance.

For these operations, the DAS uses SSH to contact a remote host and administer instances there. SSH provides confidentiality and security for data that is exchanged between the DAS and remote hosts.

About Centralized Administration of Payara Server Instances

The use of SSH to enable centralized administration of remote instances is optional and is required only for specific operations. Instances local to the DAS can be administered without SSH. If SSH is not a possibility in your environment, you can administer remote instances locally instead.

Determining Whether to Enable Centralized Administration

Before setting up a Payara Server cluster or deployment group, use the following considerations to determine whether to enable centralized administration of remote instances:

- If you are planning to set up a large cluster or deployment group of many instances, consider enabling centralized administration of their corresponding instances.

  Centralized administration of instances simplifies the administration of the Deployment Groups by enabling you to perform all administrative operations on the Deployment Groups and its instances from the DAS.

- If you are planning a small Deployment Groups of few instances, consider whether enabling centralized administration requires more effort than logging in to individual hosts to administer remote instances locally.

How you administer instances and the nodes on which they reside varies depending on whether and how centralized administration is enabled. The following table provides cross-references to instructions for administering nodes and instances depending on the protocol that is used for enabling centralized administration, if any.

Protocol	Node Administration Instructions	Instance Administration Instructions
Administering Payara Server Instances Centrally	SSH	Creating, Listing, Testing, and Deleting SSH Nodes

Protocol	Node Administration Instructions	Instance Administration Instructions
Administering Payara Server Instances Centrally	None	Creating, Listing, and Deleting `CONFIG` Nodes

Considerations for Using SSH for Centralized Administration

In a typical Payara Server deployment, the DAS acts as the SSH client, and hosts where instances reside act as SSH servers. The SSH Server Daemon `sshd` must be running on hosts where instances reside, but is not required to be running on the DAS host.

The DAS uses its own SSH client for communicating with hosts where instances reside. However, to generate keys and test SSH setup, a native SSH client must be installed on the DAS host.

The requirements for SSH configuration and user management are different for each operating system on which Payara Server is supported. Therefore, the use of SSH for centralized administration involves using SSH tools to configure SSH on the operating system that you are using.

On UNIX and Linux systems, SSH is typically installed and preconfigured, and requires minimal additional setup. On Windows systems, additional setup is required to install and configure an SSH provider.

Obtaining SSH Software

On UNIX and Linux systems, SSH software is typically installed as part of the base operating system.

However, on Windows systems, you must install one of the following SSH providers:

- Cygwin
- MKS Toolkit for Developers

Determining the SSH User

Before setting up SSH, decide which SSH user Payara Server will use when connecting to remote hosts. For the following reasons, administration is simplest if the SSH user is the user that starts the DAS:

- For public key authentication, the user that starts the DAS must be able to read the SSH user's private key file.
- Remote instances are started as the SSH user.
- By default, the DAS assumes that the SSH user is the user that is running the DAS.

Requirements for the SSH User's Environment

The SSH user's environment on a host is set by the environment set-up files that are run when the user uses SSH to run a command on the host. You must ensure that these files set up the SSH user's

environment correctly.

The files that are run when the user uses SSH to run a command are different from the files that are run when the user logs in to a host. For example, in the bash shell, `.profile` and `.bashrc` are run when the user logs in, but only `.bashrc` is run when the user runs a command.

Therefore, in the bash shell, you must ensure that `.bashrc` contains the required environment settings for the SSH user.

File Access Permissions on UAC-Enabled Windows Systems

The User Account Control (UAC) (`http://technet.microsoft.com/en-us/library/cc709691%28WS.10%29.aspx`) feature is available only on older versions of the Windows operating system(like Windows 7, Windows Vista, and Windows Server 2008).

You might be using a UAC-enabled Windows system and choose to store files for Payara Server instances in a directory other than the SSH user's home directory. In this situation, the SSH user must have native (that is, non-virtual) read and write access to the file system where the instances are to be stored. The OS-level administrator has such access by default.

You can also configure the system to grant such access to other users. For more information, see the documentation for the Windows operating system.

Setting Up Cygwin SSH on Windows

Set up Cygwin SSH on the DAS host and on all hosts where instances in your Deployment Groups or clusters will reside.

Download and Install Cygwin

For centralized Payara Server administration, a basic Cygwin installation that includes the SSH client and the SSH server daemon `sshd` is sufficient. The default installation options are sufficient to create such a basic installation.

1. Log in as a user with Administrator privileges.
2. Create the `C:\cygwin` directory.
3. From the Cygwin home page (`http://www.cygwin.com/`), download and save the `setup.exe` file to your desktop.
4. Run the `setup.exe` file.
5. Select the default for the following options:
    - Install from Internet
    - Install Root Directory: `C:\cygwin`
    - Install for All Users
6. Specify a folder for the local package directory that is not the Cygwin root folder, for example, `C:\cygwin\packages`.

7. Specify the connection method.

   For example, if the host is connected to the Internet through a proxy server, specify the proxy server.

8. Select the mirror site from which to download the software.
9. Select the `openssh` package for installation.
10. Under the *Net* category, search for `openssh`.
11. Locate the `openssh` package and click *Skip*.

    The package is selected.

12. Click Next.

    Any unsatisfied dependencies are listed.

13. Leave the Select Required Packages option selected and click Next

    The packages are installed.

14. Click Finish.

See Also

For detailed information about installing Cygwin, see "Internet Setup" in Cygwin User's Guide (`http://cygwin.com/cygwin-ug-net/setup-net.html#internet-setup`).

To Set the Path for Windows and for the Cygwin Shell

To enable Payara Server tools to find commands for SSH, each user's path for Windows and for the Cygwin shell must contain the following directories:

- The Cygwin `bin` directory, for example `C:\cygwin\bin`
- The `bin` directory of the JDK software

1. Log in as a user with Administrator privileges.

   Logging in as a user with Administrator privileges ensures that the change applies to all users.

2. In the *System Information* control panel, click *Advanced* → *Environment Variables*.
3. Add the following directories to the `PATH` environment variable:

- The Cygwin `bin` directory, for example `C:\cygwin\bin`
- The `bin` directory of the JDK software installation

To Set the Home Directory for the Cygwin SSH User

The SSH Server Daemon `sshd` locates a user's home directory from the configuration in the user database, not from environment variables such as `HOME`. To ensure that all Payara Server commands can run without errors, each SSH user must be configured to have a home directory.

Each user on a Windows host where SSH is set up potentially has two home directories:

Windows home directory

Payara Server commands, which are run in a Windows command window, use the Windows home directory.

SSH home directory

SSH commands, which are run in a shell such as `bash` or `ksh`, use the SSH home directory.

If these home directories are different, Payara Server and SSH each locate a user's `.ssh` directory in different directories. To simplify the setup of SSH, configure each user's home directory for SSH and Windows to be the same directory. A disadvantage of this approach is that the SSH home directory has spaces in its path name. Spaces in path names are cumbersome in the UNIX environment.

1. Log in as a user with Administrator privileges.
2. In the `c:\cygwin\etc\passwd` file, edit the home directory setting for the SSH user to specify the user's home directory for Windows.

To Configure and Start the Cygwin SSH Server Daemon `sshd`

Before You Begin

Ensure that the following prerequisites are met:

- A user account is created for each user that will log in to the host through SSH.
- A password is set for each user account.

The SSH server daemon `sshd` disallows authentication of any user for whose account a password is not set. . Double-click the Cygwin icon.

+ A Cygwin terminal is started.

1. If necessary, set the password for your user account.
   a. Run the `passwd` command as follows:

   ```
   $ passwd user-name
   ```

   user-name

   The username for your account.

   b. Type a password.

   The password for your Windows account is also set.
2. Configure SSH on the host.
   a. Run the `ssh-host-config` command.

```
$ ssh-host-config
```

If you are using Windows XP, specify the `-y` option of `ssh-host-config` to answer `yes` to all prompts. If you run `ssh-host-config` with the `-y` option, omit Step **b**.

b. Ensure that the `StrictModes` and `PubkeyAuthentication` options are set to `yes` in the file `/etc/ssh_config`.

   The file `/etc/ssh_config` can also be accessed as `/cygdrive/c/cygwin/etc/sshd_config`.

3. Start the SSH server daemon `sshd`.

```
$ net start sshd
```

4. Confirm that the SSH server daemon `sshd` is running.

```
$ cygrunsrv --query sshd
 Service             : sshd
 Display name        : CYGWIN sshd
 Current State       : Running
 Controls Accepted   : Stop
 Command             : /usr/sbin/sshd -D
```

Next Steps

After you have completed the setup of SSH on a host, test the setup on the host as explained in Testing the SSH Setup on a Host.

Setting Up the MKS Toolkit on Windows

Set up the MKS Toolkit on the DAS host and on all hosts where instances in your Deployment Groups will reside.

To Install the MKS Toolkit

For centralized Payara Server administration, the default installation of the MKS Toolkit is sufficient.

Follow the instructions in the MKS Toolkit product documentation to install OpenSSH from the MKS Toolkit with default installation options.

See Also

For detailed information about installing MKS Toolkit, see "Installing MKS Toolkit" in the MKS Toolkit v9.4 Release Notes (`http://www.mkssoftware.com/docs/rn/relnotes_tk94.asp#install`).

To Set the Path for Windows and for the MKS Toolkit Shell

To enable Payara Server tools to find commands for SSH, each user's path for Windows and for the MKS Toolkit shell must contain the following directories:

- The MKS Toolkit `bin` directory, for example `C:\Program Files\MKS Toolkit\mksnt`
- The `bin` directory of the JDK software

The MKS Toolkit installer automatically adds the MKS Toolkit `bin` directory to the path. However, you must add the `bin` directory of the JDK software to the path yourself.

1. Log in as a user with Administrator privileges.

   Logging in as a user with Administrator privileges ensures that the change applies to all users.

2. In the System Information control panel, click Advanced>Environment Variables.
3. Add the `bin` directory of the JDK software to the Path environment variable.

To Set the Home Directory for the MKS Toolkit SSH User

The SSH Server Daemon `sshd` locates a user's home directory from the configuration in the user database, not from environment variables such as `HOME`. To ensure that all Payara Server commands can run without errors, each SSH user must be configured to have a home directory.

Each user on a Windows host where SSH is set up potentially has two home directories:

- Windows home directory. Payara Server commands, which are run in a Windows command window, use the Windows home directory.
- SSH home directory. SSH commands, which are run in a shell such as `bash` or `ksh`, use the SSH home directory.

If these home directories are different, Payara Server and SSH each locate a user's `.ssh` directory in different directories. To simplify the setup of SSH, configure each user's home directory for SSH and Windows to be the same directory.

A disadvantage of this approach is that the SSH home directory has spaces in its path name. Spaces in path names are cumbersome in a UNIX environment.

1. Compare the pairs of settings for Windows and the MKS Toolkit that are listed in the following table.

Windows Environment Variable	MKS Toolkit Field
`HOMEPATH`	Home Directory
`HOMEDRIVE`	Home Directory Drive

   a. In a Windows command window, determine the values of the `HOMEPATH` and `HOMEDRIVE` environment variables.

   b. In an MKS Toolkit shell, determine the current settings of the Home Directory and Home Directory Drive fields for the user.

```
$ userinfo user-name
```

user-name

The username for the user whose home directory you are setting, for example `Administrator`.

2. If the settings do not match, update setting of each MKS Toolkit field to match its corresponding Windows environment variable.

   If the settings match, no further action is required.

   To update the settings, run the following command in an MKS Toolkit shell:

   ```
   $ userinfo -u -fHomeDirDrive:"drive" -fHomeDir:"path" user-name
   ```

   drive

   The drive identifier of the disk drive on which the user's Windows home directory resides, for example, `C:`.

   path

   The path to the user's Windows home directory, for example, `\Documents and Settings\Administrator`.

   user-name

   The username for the user whose home directory you are setting, for example `Administrator`.

   Do not set the `HOME` environment variable explicitly. If the Home Directory and Home Directory Drive are set correctly, the `HOME` environment variable specifies the correct path by default.

3. In an MKS Toolkit shell, confirm that the settings were updated.

   ```
   $ userinfo user-name
   ```

   user-name

   The username for the user whose home directory you are setting, for example `Administrator`.

4. Log out of the host and log in to the host again.
5. Confirm that the home directories are the same as explained in Step **1**.

The following example sets the home directory for the MKS Toolkit user `Administrator` to `C:\Documents and Settings\Administrator`.

```
$ userinfo -u -fHomeDirDrive:"C:" -fHomeDir:"\Documents and Settings\Administrator"
```

```
Administrator
```

To Configure and Start the MKS Toolkit SSH Server Daemon `sshd`

Do not set the command shell to `cmd.exe`. The use of SSH for centralized Payara Server administration requires a shell in the style of a UNIX shell.

1. From the Programs menu, choose *MKS Toolkit → Configuration → Configuration Information*.
2. Enable password authentication and strict modes.
   a. Click the *Secure Shell Service* tab.
   b. Select the *Password Authentication* option.
   c. Click *Advanced* settings.
   d. Click the *Login* tab.
   e. Deselect the *Strict Modes* option.
3. If you are using SSH key-file authentication, enable `MKSAUTH` password authentication.
   a. Click the Authentication tab.
   b. Under *Enable/Disable Password* using `MKSAUTH`, type the user's password and click the Enable.
4. Start the SSH server daemon `sshd`.
   a. Confirm that the SSH server daemon `sshd` is running.

```
$ service query MKSSecureSH

Name:           MKS Secure Shell Service
Service Type:   WIN32_OWN_PROCESS
Current State:  RUNNING
Controls Accepted:      ACCEPT_STOP
Check Point:    0
Wait Hint:      0
Start Type:     AUTO_START
Error Control:  IGNORE
Path:           "C:\Program Files\MKS Toolkit\bin\secshd.exe"
Dependency:     NuTCRACKERService
Dependency:     tcpip
Service Start Name:     LocalSystem
```

Next Steps

After you have completed the setup of SSH on a host, test the setup on the host as explained in Testing the SSH Setup on a Host.

Setting Up SSH on UNIX and Linux Systems

Setting up SSH on UNIX and Linux systems involves verifying that the SSH server daemon `sshd` is running and, if necessary, starting this daemon. Set up SSH on the DAS host and on all hosts where

instances in your Deployment Groups will reside.

On UNIX and Linux systems, SSH software is typically installed as part of the base operating system. If SSH is not installed, download and install the appropriate OpenSSH (`http://www.openssh.com/`) SSH package for your operating system.

To Set Up SSH on Oracle Solaris Systems

1. Ensure that the following options in the configuration file `/etc/ssh/sshd_config` are set to `yes`:
   - `StrictModes`
   - `PubkeyAuthentication`
2. Determine if the SSH server daemon `sshd` is running.

   ```
   $ /usr/bin/svcs ssh
   ```

3. If the SSH server daemon `sshd` is not running, start this daemon.

   If the daemon is running, no further action is required.

   ```
   $ /usr/sbin/svcadm enable ssh
   ```

The following example confirms that the SSH server daemon `sshd` is running on an Oracle Solaris system.

```
$ /usr/bin/svcs ssh
STATE          STIME    FMRI
online         Jul_06   svc:/network/ssh:default
```

See Also

`svcs(1)`

Next Steps

After you have completed the setup of SSH on a host, test the setup on the host as explained in Testing the SSH Setup on a Host.

To Set Up SSH on macOS Systems

1. Open *System Preferences* and click *Sharing*.

   The Sharing window opens.

2. Ensure that *Remote Login* is selected in the Service list.
3. Ensure that either of the following is allowed access:
   - All Users

- The user that running the DAS or instance

4. (macOS 10.6 systems only) Ensure that the SSH server daemon `sshd` allows password authentication.

   On macOS 10.5 systems, the SSH server daemon `sshd` allows password authentication by default. However, on macOS 10.6 systems, the SSH server daemon `sshd` disallows password authentication by default. .. Edit the configuration file `/etc/sshd_config` to set the `PasswordAuthentication` option to `yes`. .. Stop the SSH server daemon `sshd`.

   +

   ```
   $ sudo launchctl stop com.openssh.sshd
   ```

5. Start the SSH server daemon `sshd`.

   ```
   $ sudo launchctl start com.openssh.sshd
   ```

Next Steps

After you have completed the setup of SSH on a host, test the setup on the host as explained in Testing the SSH Setup on a Host.

To Set Up SSH on Linux systems

1. Ensure that the following options in the configuration file `/etc/ssh/sshd_config` are set to `yes`:
   - `StrictModes`
   - `PubkeyAuthentication`
2. Determine if the SSH server daemon `sshd` is running.

   ```
   $ /sbin/service sshd status
   ```

3. If the SSH server daemon `sshd` is not running, start this daemon.

   If the daemon is running, no further action is required.

   ```
   $ /sbin/service sshd start
   ```

This example confirms that the SSH server daemon `sshd` is running on a Linux system.

```
$ /sbin/service sshd status
openssh-daemon (pid  2373) is running...
```

Next Steps

After you have completed the setup of SSH on a host, test the setup on the host as explained in Testing the SSH Setup on a Host.

Testing the SSH Setup on a Host

After setting up SSH on a host, test the setup to ensure that you can use SSH to contact the host from another host. Testing the SSH setup on a host verifies that the SSH server daemon `sshd` is running and that the SSH user has a valid user account on the host.

If you cannot use SSH to contact the host, troubleshoot the SSH setup before setting up SSH user authentication.

To Test the SSH Setup on a Host

1. From another host, use SSH to log in into the host that you are testing as the SSH user.

   ```
   $ ssh -l user-name host-name
   ```

   user-name
   The username for the SSH user's account on the host.

   host-name
   The host name of the host that you are logging in to.

2. In response to the prompt, type your password.

   If this step succeeds, your setup of SSH is complete.

   The first time that you connect to a host, you might be warned that the authenticity cannot be established and be asked if you want to continue connection. If you trust the host, answer `yes` to connect to the host.

Troubleshooting

To obtain diagnostic information, use the `-v` option of the command-line SSH client and the `-d` option of the SSH server daemon `sshd`. How to start the SSH server daemon `sshd` manually depends on the operating system and SSH provider that you are using.

If the SSH server daemon `sshd` is set up on a host that has a firewall, ensure that a rule is defined to allow inbound traffic on the SSH port. The default SSH port is port `22`.

If your connection is refused, the SSH server daemon `sshd` is not running, and you must start the daemon.

If your connection is accepted, but you cannot log in, ensure that the SSH user has a valid user account on the host.

Next Steps

After testing the SSH setup, set up SSH user authentication to enable SSH to authenticate users

without prompting for a password. For more information, see Setting Up SSH User Authentication.

Setting Up SSH User Authentication

When a Payara Server subcommand uses SSH to log in to a remote host, Payara Server must be able to authenticate the SSH user. Setting up SSH user authentication ensures that this requirement is met.

Before setting up SSH user authentication, determine the authentication scheme to use. If SSH is already deployed at your site, the authentication scheme to use might already be chosen for you.

The following table lists the authentication schemes that Payara Server supports. The table also lists the advantages and disadvantages of each authentication scheme.

Authentication Scheme	Advantages	Disadvantages
Public key without encryption	Payara Server provides tools to simplify set up.	SSH must be configured to locate users' key files in the correct location. File access permissions for key files and the directory that contains the key files must be set correctly.
Public key with passphrase-protected encryption	This scheme is more secure than public key authentication without encryption.	SSH must be configured to locate users' key files in the correct location. File access permissions for key files and the directory that contains the key files must be set correctly. For each SSH user, Payara Server password aliases are required for the encryption passphrase.
Password	No SSH configuration is required to locate key files or to ensure that file access permissions are correct.	For each SSH user, Payara Server password aliases are required for the SSH password.

To Set Up Public Key Authentication Without Encryption

Use the `setup-ssh` subcommand in local mode to set up public key authentication without encryption. This subcommand enables you to set up public key authentication on multiple hosts in a single operation.

The `setup-ssh` subcommand generates a key pair and distributes the public key file to specified hosts. The private key file and the public key file are protected only by the file system's file access permissions.

If you require additional security, set up public key authentication with passphrase-protected encryption as explained in To Set Up Encrypted Public Key Authentication.

Before You Begin

Ensure that the following prerequisites are met:

- SSH is set up on each host where you are setting up public key authentication. For more information, see the following sections:
  - Setting Up Cygwin SSH on Windows
  - Setting Up the MKS Toolkit on Windows
  - Setting Up SSH on UNIX and Linux Systems
- Only the SSH user has write access to the following files and directories on each host where you are setting up public key authentication:
  - The SSH user's home directory
  - The `~/.ssh` directory
  - The `authorized_key` file

If other users can write to these files and directories, the secure service might not trust the `authorized_key` file and might disallow public key authentication.

1. Generate an SSH key pair and distribute the public key file to the hosts where you are setting up public key authentication.

   Only the options that are required to complete this task are provided in this step. For information about all the options for setting up an SSH key, see the `setup-ssh`(1) help page.

   ```
   asadmin> setup-ssh [--sshuser sshuser] host-list
   ```

   sshuser

   The SSH user for which you are generating the SSH key pair. If you are running the subcommand as the SSH user, you may omit this option.

   host-list

   A space-separated list of the names of the hosts where the SSH public key is to be distributed.

   After generating the SSH key pair, the subcommand uses SSH to log in to each host in host-list as the SSH user to distribute the public key. Each time a password is required to log in to a host, you are prompted for the SSH user's password.

2. In response to each prompt for a password, type the SSH user's password.

The following example generates and sets up an SSH key for the user `gfuser` on the hosts `sua01` and `sua02`. The command is run by the user `gfuser`.

```
asadmin> setup-ssh --generatekey=true sua01 sua02
```

```
Enter SSH password for gfuser@sua01>
Created directory /home/gfuser/.ssh
/usr/bin/ssh-keygen successfully generated the identification /home/gfuser/.ssh/id_rsa
Copied keyfile /home/gfuser/.ssh/id_rsa.pub to gfuser@sua01
Successfully connected to gfuser@sua01 using keyfile /home/gfuser/.ssh/id_rsa
Copied keyfile /home/gfuser/.ssh/id_rsa.pub to gfuser@sua02
Successfully connected to gfuser@sua02 using keyfile /home/gfuser/.ssh/id_rsa
Command setup-ssh executed successfully.
```

Next Steps

After setting up public key authentication, test the setup by using `ssh` to log in as the SSH user to each host where the public key was distributed. For each host, log in first with the unqualified host name and then with the fully qualified name. If SSH does not prompt for password, public key authentication is set up correctly on the host.

If you are prompted for a password, verify that the public key file was copied correctly to the SSH user's `authorized_keys` file.

Troubleshooting

Setup might fail because file access permissions in the SSH user's home directory are too permissive. In this situation, ensure that the file access permissions in the SSH user's home directory meet the requirements for performing this procedure.

If you have set the file access permissions in the SSH user's home directory correctly, setup might still fail if you are using the MKS Toolkit. In this situation, correct the problem in one of the following ways:

- On each remote host, copy the public key file to the SSH user's `~/.ssh` directory and import the file. To import the file, select the Secure Service tab in the MKS configuration GUI and click *Passwordless*.
- Disable strict modes.

See Also

- Setting Up Cygwin SSH on Windows
- Setting Up the MKS Toolkit on Windows
- Setting Up SSH on UNIX and Linux Systems
- `setup-ssh`(1)

You can also view the full syntax and options of the subcommand by typing `asadmin help setup-ssh` at the command line.

To Set Up Encrypted Public Key Authentication

Encrypted key file authentication uses an encrypted private key file that is protected with a passphrase. This passphrase must be provided to use the private key to unlock the public key.

If you require encrypted public key authentication, you must use the SSH utility `ssh-keygen` to generate an SSH key pair with an encrypted private key. You can then use the `setup-ssh` subcommand to distribute the public key file to specified hosts.

To use the encrypted key file, Payara Server requires the passphrase with which the key file was encrypted. To provide this passphrase securely to Payara Server, create a Payara Server password alias to represent the passphrase and store this alias in a password file that is passed to the `asadmin` utility.

Only the options that are required to complete this task are provided in each step. For information about all the options for the commands and subcommands in this task, see their help pages or man pages.

Before You Begin

Ensure that the following prerequisites are met:

- SSH is set up on each host where you are setting up public key authentication. For more information, see the following sections:
  - Setting Up Cygwin SSH on Windows
  - Setting Up the MKS Toolkit on Windows
  - Setting Up SSH on UNIX and Linux Systems
- Only the SSH user has write access to the following files and directories on each host where you are setting up public key authentication:
  - The SSH user's home directory
  - The `~/.ssh` directory
  - The `authorized_key` file

  If other users can write to these files and directories, the secure service might not trust the `authorized_key` file and might disallow public key authentication.

  1. Generate an SSH key pair with an encrypted private key file.

     Use the SSH utility `ssh-keygen` for this purpose.

     ```
     $ ssh-keygen -t type
     ```

     type
     The algorithm that is to be used for the key and which must be `rsa`, `dsa`, or `rsa1`.

     The `ssh-keygen` utility prompts you for a file in which to save the key.

  2. To simplify the distribution of the key file, accept the default file.

     The `ssh-keygen` utility prompts you for a passphrase.

3. In response to the prompt, type your choice of passphrase for encrypting the private key file. The `ssh-keygen` utility prompts you to type the passphrase again.
4. In response to the prompt, type the passphrase that you set in Step **3**.
5. Distribute the public key file to the hosts where you are setting up public key authentication.

   Use the `setup-ssh` `asadmin` subcommand for this purpose.

```
$ asadmin setup-ssh --generatekey=false host-list
```

host-list

A space-separated list of the names of the hosts where the SSH public key is to be distributed.

The subcommand uses SSH to log in to each host in host-list as the SSH user to distribute the public key. Each time a passphrase or a password is required to log in to a host, you are prompted for the passphrase or the SSH user's password.

1. In response to each prompt, type the requested information.
   - In response to each prompt for a passphrase, type the passphrase that you set in Step **3**.
   - In response to each prompt for a password, type the SSH user's password.
2. Create a Payara Server password alias for the passphrase that you set in Step **3**.
   a. Ensure that the DAS is running.

      Remote subcommands require a running server.

   b. Run the `create-password-alias` `asadmin` subcommand.

```
$ asadmin create-password-alias alias-name
```

alias-name

Your choice of name for the alias that you are creating.

The `create-password-alias` subcommand prompts you to type the passphrase for which you are creating an alias. .. In response to the prompt, type the passphrase that you set in Step **3**.

+ The `create-password-alias` subcommand prompts you to type the passphrase again.

a. In response to the prompt, type the passphrase that you set in Step **3** again.

1. Create a plain text file that contains the following entry for the passphrase alias:

```
AS_ADMIN_SSHKEYPASSPHRASE=${ALIAS=alias-name}
```

When you create an `SSH` node, pass this file as the `--passwordfile` option of the

> `asadmin` utility. For more information, see To Create an SSH Node.

The following example generates an SSH key pair with an encrypted private key for the user `gfadmin` and distributes the public key to the hosts `sj01` and `ja02`. The example also creates an alias that is named `ssh-key-passphrase` for the private key's passphrase.

```
$ ssh-keygen -t rsa

Generating public/private rsa key pair.
Enter file in which to save the key (/home/gfadmin/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/gfadmin/.ssh/id_rsa.
Your public key has been saved in /home/gfadmin/.ssh/id_rsa.pub.
The key fingerprint is:
db:b5:f6:0d:fe:16:33:91:20:64:90:1a:84:66:f5:d0 gfadmin@dashost
$ asadmin setup-ssh --generatekey=false sj01 sj02
Key /home/gfadmin/.ssh/id_rsa is encrypted
Enter key passphrase>
Enter SSH password for gfadmin@sj01>
Copied keyfile /home/gfadmin/.ssh/id_rsa.pub to gfadmin@sj01
Successfully connected to gfadmin@sj01 using keyfile /home/gfadmin/.ssh/id_rsa
Successfully connected to gfadmin@sj02 using keyfile /home/gfadmin/.ssh/id_rsa
SSH public key authentication is already configured for gfadmin@sj02
Command setup-ssh executed successfully.
$ asadmin create-password-alias ssh-key-passphrase
Enter the alias password>
Enter the alias password again>
Command create-password-alias executed successfully.
```

The entry in the password file for the `ssh-key-passphrase` alias is as follows:

```
AS_ADMIN_SSHKEYPASSPHRASE=${ALIAS=ssh-key-passphrase}
```

Troubleshooting

Setup might fail because file access permissions in the SSH user's home directory are too permissive. In this situation, ensure that the file access permissions in the SSH user's home directory meet the requirements for performing this procedure.

If you have set the file access permissions in the SSH user's home directory correctly, setup might still fail if you are using the MKS Toolkit. In this situation, correct the problem in one of the following ways:

- On each remote host, copy the public key file to the SSH user's `~/.ssh` directory and import the file. To import the file, select the Secure Service tab in the MKS configuration GUI and click *Passwordless*.
- Disable strict modes.

- Setting Up Cygwin SSH on Windows
- Setting Up the MKS Toolkit on Windows
- Setting Up SSH on UNIX and Linux Systems
- `asadmin`(1M)
- `create-password-alias`(1)
- `setup-ssh`(1)
- `ssh-keygen`(1)

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help create-password-alias`
- `asadmin help setup-ssh`

To Set Up Password Authentication

To use SSH to log in to a remote host, Payara Server requires the SSH user's password. To provide this password securely to Payara Server, create a Payara Server password alias to represent the password and store this alias in a password file that is passed to the `asadmin` utility.

Before You Begin

Ensure that SSH is set up on each host where you are setting up password authentication.

1. Ensure that the DAS is running.

   Remote subcommands require a running server.

2. Create an alias for the SSH user's password.

   Only the options that are required to complete this task are provided in this step. For information about all the options for creating a password alias, see the `create-password-alias`(1) help page.

   ```
   asadmin> create-password-alias alias-name
   ```

   alias-name

   Your choice of name for the alias that you are creating.

   The `create-password-alias` subcommand prompts you to type the password for which you are creating an alias.

3. In response to the prompt, type the SSH user's password.

   The `create-password-alias` subcommand prompts you to type the password again.

4. In response to the prompt, type the SSH user's password again.

5. Create a plain text file that contains the following entry for the password alias:

```
AS_ADMIN_SSHPASSWORD=${ALIAS=alias-name}
```

alias-name

The alias name that you specified in Step **2**.

When you create an `SSH` node, pass this file as the `--passwordfile` option of the `asadmin` utility. For more information, see To Create an SSH Node.

The following example creates an alias that is named `ssh-password` for the SSH user's password.

```
$ asadmin create-password-alias ssh-password
Enter the alias password>
Enter the alias password again>
Command create-password-alias executed successfully.
```

The entry in the password file for the `ssh-password` alias is as follows:

```
AS_ADMIN_SSHPASSWORD=${ALIAS=ssh-password}
```

You can also view the full syntax and options of the subcommand by typing `asadmin help create-password-alias` at the command line.

Installing and Removing Payara Server Software on Multiple Hosts

Payara Server software must be installed on all hosts where Payara Server will run. How to install Payara Server software on multiple hosts depends on the degree of control that you require over the installation on each host.

- If you require complete control over the installation on each host, install the software from a Payara Server distribution on each host individually.
- If the same setup on each host is acceptable, copy an existing Payara Server installation to the hosts. For more information, see To Copy a Payara Server Installation to Multiple Hosts.

Payara Server also enables you to remove Payara Server software from multiple hosts in a single operation. For more information, see To Remove Payara Server Software From Multiple Hosts.

To Copy a Payara Server Installation to Multiple Hosts

Use the `install-node-ssh` subcommand in local mode to copy an installation of Payara Server software to multiple hosts.

Before You Begin

Ensure that SSH is set up on the host where you are running the subcommand and on each host where you are copying the Payara Server software.

Run the appropriate subcommand for the protocol that is set up for communication between the hosts.

- If SSH is set up for communication between the hosts, run the `install-node-ssh` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for copying an installation of Payara Server software, see the link `install-node-ssh(1)` help page.

```
asadmin> install-node-ssh host-list
```

host-list

A space-separated list of the names of the hosts where you are copying the installation of Payara Server software.

The following example copies the Payara Server software on the host where the subcommand is run to the default location on the SSH-enabled hosts `sj03.example.com` and `sj04.example.com`.

```
asadmin> install-node-ssh sj03.example.com sj04.example.com

Created installation zip /home/gfuser/glassfish2339538623689073993.zip
Successfully connected to gfuser@sj03.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Copying /home/gfuser/payara2339538623689073993.zip (81395008 bytes) to
sj03.example.com:/export/payara
Installing payara2339538623689073993.zip into sj03.example.com:/export/payara
Removing sj03.example.com:/export/payara/payara2339538623689073993.zip
Fixing file permissions of all files under sj03.example.com:/export/payara/bin
Successfully connected to gfuser@sj04.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Copying /home/gfuser/payara2339538623689073993.zip (81395008 bytes) to
sj04.example.com:/export/payara
Installing payara2339538623689073993.zip into sj04.example.com:/export/payara
Removing sj04.example.com:/export/payara/payara2339538623689073993.zip
Fixing file permissions of all files under sj04.example.com:/export/payara/bin
Command install-node-ssh executed successfully
```

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help install-node-ssh`

To Remove Payara Server Software From Multiple Hosts

Use the `uninstall-node-ssh` subcommand in local mode to remove Payara Server software from multiple hosts.

Before You Begin

Ensure that the following prerequisites are met:

- SSH is set up on the host where you are running the subcommand and on each host from which you are removing the Payara Server software.
- No process is accessing the parent of the base installation directory for the Payara Server software or any subdirectory of this directory.
- The parent of the base installation directory for the Payara Server software is the same on each host from which you are removing the Payara Server software.
- For hosts that use SSH for remote communication, the configuration of the following items is the same on each host:
  - SSH port
  - SSH user
  - SSH key file

Run the appropriate subcommand for the protocol that is set up for communication between the hosts.

- If SSH is set up for communication between the hosts, run the `uninstall-node-ssh` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for removing Payara Server software, see the `uninstall-node-ssh(1)` help page.

```
asadmin> uninstall-node-ssh host-list
```

host-list

A space-separated list of the names of the hosts from which you are removing Payara Server software.

The following example removes Payara Server software on the SSH-enabled hosts `sj03.example.com` and `sj04.example.com` from the default location.

```
asadmin> uninstall-node-ssh sj03 sj04
Successfully connected to gfuser@sj03.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Successfully connected to gfuser@sj04.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Command uninstall-node-ssh executed successfully.
```

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help uninstall-node-ssh`

Administering Payara Server Nodes

A node represents a host on which the Payara Server software is installed. A node must exist for every host on which Payara Server instances reside.

A node's configuration contains information about the host such as the name of the host and the location where the Payara Server is installed on the host.

The following topics are addressed here:

- Types of Payara Server Nodes
- Creating, Listing, Testing, and Deleting SSH Nodes
- Creating, Listing, and Deleting CONFIG Nodes
- Creating, Listing, and Deleting DOCKER Nodes
- Updating and Changing the Type of a Node

Types of payara Server Nodes

Each Payara Server node is one of the following types of node:

`SSH`

An `SSH` node supports communication over secure shell (SSH). If SSH is set up, and you plan to administer your Payara Server instances centrally, the instances must reside on `SSH` nodes.

An `SSH` node's configuration contains the information that is required to connect to the host through SSH. This information includes, for example, the username of the SSH user and the port number for SSH connections to the host.

`CONFIG`

A `CONFIG` node does not support remote communication. If SSH is set up, and you plan to administer your instances locally, the instances can reside on `CONFIG` nodes. You cannot use `CONFIG` nodes for instances that you plan to administer centrally.

Each domain contains a predefined `CONFIG` node that is named `localhost-`domain, where domain is the name of the domain. On the host where the domain administration server (DAS) is running, this node represents the local host.

`DOCKER`

A Docker node is similar to the existing SSH and CONFIG nodes in that it is a virtual representation of a Payara Server installation, providing connection details that the Domain Administration Server (DAS) uses to communicate with the installation to create, stop, start, and delete instances.

Where it differs from these existing node types is that instances created against it are actually housed in Docker containers, and so also contains details on how to communicate with the Docker engine of the remote machine.

To Create an `SSH` Node

Use the `create-node-ssh` subcommand in remote mode to create an `SSH` node.

Before You Begin

Ensure that the SSH user can use SSH to log in to the host that the node will represent. By default, the `create-node-ssh` subcommand validates the node's parameters and the SSH connection to the host.

If the SSH user cannot use SSH to log in to the host, the validation fails.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `create-node-ssh` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for configuring the node, see the `create-node-ssh` help page.

If you are using password authentication for the SSH user, you must specify a password file through the `--passwordfile` option of the `asadmin` utility. For more information about SSH user authentication, see link:Technical Documentation/Payara Server Documentation/High Availability/ssh-setup.adoc#setting-up-ssh-user-authentication[Setting Up SSH User Authentication].

```
asadmin> create-node-ssh --nodehost node-host [--installdir install-dir ] node-name
```

node-host

The name of the host that the node represents. The name of the host must be specified. Otherwise, an error occurs.

install-dir

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara/`. If the Payara Server software is installed in the same

directory on the node's host and the DAS host, you can omit this option.

node-name

Your choice of name for the node that you are creating.

The following example creates the SSH node `sj01` to represent the host `sj01.example.com`. The Payara Server software is installed in the same directory on the DAS host and on the host `sj01.example.com`.

```
asadmin> create-node-ssh --nodehost sj01.example.com sj01

Command create-node-ssh executed successfully.
```

Troubleshooting

The `create-node-ssh` subcommand might fail to create the node and report the error `Illegal sftp packet len`. If this error occurs, ensure that no the startup file on the remote host displays text for noninteractive shells. Examples of startup files are `.bashrc`, `.cshrc`, `.login`, and `.profile`.

The SSH session interprets any text message that is displayed during login as a file-transfer protocol packet. Therefore, any statement in a startup file that displays text messages corrupts the SSH session, causing this error.

See also

`create-node-ssh`

You can also view the full syntax and options of the subcommand by typing `asadmin help create-node-ssh` at the command line.

Next Steps

After creating a node, you can create instances on the node as explained in the following sections:

- To Create an Instance Centrally
- To Create an Instance Locally

To List SSH Nodes in a Domain

Use the `list-nodes-ssh` subcommand in remote mode to obtain information about existing SSH nodes in a domain.

To obtain information about all existing nodes in a domain, use the `list-nodes` subcommand.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `list-nodes-ssh` subcommand.

```
asadmin> list-nodes-ssh
```

This example lists the name, type, and host of all SSH nodes in the current domain.

```
asadmin> list-nodes-ssh
sj01  SSH  sj01.example.com
sj02  SSH  sj02.example.com
Command list-nodes-ssh executed successfully.
```

The following example lists detailed information about all SSH nodes in the current domain.

```
asadmin> list-nodes-ssh --long=true

NODE NAME   TYPE   NODE HOST          INSTALL DIRECTORY    REFERENCED BY
sj01        SSH    sj01.example.com   /export/payara   pmd-i1
sj02        SSH    sj02.example.com   /export/payara   pmd-i2
Command list-nodes-ssh executed successfully.
```

See also

- list-nodes
- list-nodes-ssh

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- asadmin help list-nodes
- asadmin help list-nodes-ssh

To Test if an SSH Node is Reachable

Use the ping-node-ssh subcommand in remote mode to test if an SSH node is reachable.

Before You Begin

Ensure that SSH is configured on the host where the DAS is running and on the host that the node represents.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the ping-node-ssh subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for testing the node, see the ping-node-ssh help page.

```
asadmin> ping-node-ssh node-name
```

node-name

The name of the node to test.

The following example tests if the SSH node sj01 is reachable.

```
asadmin> ping-node-ssh sj01
Successfully made SSH connection to node sj01 (sj01.example.com)
Command ping-node-ssh executed successfully.
```

See also

ping-node-ssh

You can also view the full syntax and options of the subcommand by typing asadmin help ping-node-ssh at the command line.

To Delete an SSH Node

Use the delete-node-ssh subcommand in remote mode to delete an SSH node.

Deleting a node removes the node from the configuration of the DAS. The node's directories and files are deleted when the last Payara Server instance that resides on the node is deleted.

Before You Begin

Ensure that no Payara Server instances reside on the node that you are deleting. For information about how to delete an instance, see the following sections.

- To Delete an Instance Centrally
- To Delete an Instance Locally

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Confirm that no instances reside on the node that you are deleting.

   ```
   asadmin> list-nodes-ssh --long=true
   ```

3. Run the delete-node-ssh subcommand.

   ```
   asadmin> delete-node-ssh node-name
   ```

   node-name

   The name of the node that you are deleting.

The following example confirms that no instances reside on the SSH node sj01 and deletes the node sj01.

```
asadmin> list-nodes-ssh --long=true
```

```
NODE NAME   TYPE   NODE HOST          INSTALL DIRECTORY    REFERENCED BY
sj01        SSH    sj01.example.com   /export/payara
sj02        SSH    sj02.example.com   /export/payara   pmd-i2

Command list-nodes-ssh executed successfully.
asadmin> delete-node-ssh sj01
Command delete-node-ssh executed successfully.
```

See also

- To Delete an Instance Centrally
- To Delete an Instance Locally
- `delete-node-ssh`
- `list-nodes-ssh`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help delete-node-ssh`
- `asadmin help list-nodes-ssh`

Creating, Listing, and Deleting `CONFIG` Nodes

A `CONFIG` node does not support remote communication. If SSH is set, up and you plan to administer your instances locally, the instances can reside on `CONFIG` nodes. You cannot use `CONFIG` nodes for instances that you plan to administer centrally.

Payara Server enables you to create `CONFIG` nodes for use by instances, obtain information about `CONFIG` nodes, and delete `CONFIG` nodes that are no longer required.

The following topics are addressed here:

- To Create a CONFIG Node
- To List CONFIG Nodes in a Domain
- To Delete a CONFIG Node

To Create a `CONFIG` Node

Use the `create-node-config` command in remote mode to create a `CONFIG` node.

If you create an instance locally on a host for which no nodes are defined, you can create the instance without creating a node beforehand.
In this situation, Payara Server creates a `CONFIG` node for you. The name of the node is the unqualified name of the host.
For more information, see To Create an Instance Locally.

1. Ensure that the DAS is running. Remote subcommands require a running server.

2. Run the `create-node-config` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for configuring the node, see the `create-node-config` help page.

```
asadmin> create-node-config [--nodehost node-host] [--installdir install-dir ]
node-name
```

node-host

The name of the host that the node represents. You may omit this option. The name of the host can be determined when instances that reside on the node are created.

install-dir

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara/`. You may omit this option. The installation directory can be determined when instances that reside on the node are created.

node-name

Your choice of name for the node that you are creating.

The following example creates the `CONFIG` node `cfg01`. The host that the node represents and the installation directory of the Payara Server software on the host are to be determined when instances are added to the node.

```
asadmin> create-node-config cfg01
Command create-node-config executed successfully.
```

See also

`create-node-config`

You can also view the full syntax and options of the subcommand by typing `asadmin help create-node-config` at the command line.

Next Steps

After creating a node, you can create instances on the node as explained in To Create an Instance Locally.

To List `CONFIG` Nodes in a Domain

Use the `list-nodes-config` subcommand in remote mode to obtain information about existing `CONFIG` nodes in a domain.

To obtain information about all existing nodes in a domain, use the `list-nodes` subcommand.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `list-nodes-config` subcommand.

```
asadmin> list-nodes-config
```

The following example lists the name, type, and host of all `CONFIG` nodes in the current domain.

```
asadmin> list-nodes-config
localhost-domain1  CONFIG  localhost
cfg01  CONFIG  cfg01.example.com
cfg02  CONFIG  cfg02.example.com
Command list-nodes-config executed successfully.
```

The following example lists detailed information about all `CONFIG` nodes in the current domain.

```
asadmin> list-nodes-config --long=true

NODE NAME           TYPE     NODE HOST            INSTALL DIRECTORY    REFERENCED BY
localhost-domain1   CONFIG   localhost            /export/payara
cfg01               CONFIG   cfg01.example.com    /export/payara   yml-i1
cfg02               CONFIG   cfg02.example.com    /export/payara   yml-i2
Command list-nodes-config executed successfully.
```

See also

- `list-nodes`
- `list-nodes-config`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help list-nodes`
- `asadmin help list-nodes-config`

To Delete a `CONFIG` Node

Use the `delete-node-config` subcommand in remote mode to delete a `CONFIG` node.

Deleting a node removes the node from the configuration of the DAS. The node's directories and files are deleted when the last Payara Server instance that resides on the node is deleted.

Before You Begin

Ensure that no Payara Server instances reside on the node that you are deleting. For information about how to delete an instance that resides on a `CONFIG` node, see To Delete an Instance Locally.

1. Ensure that the DAS is running. Remote subcommands require a running server.

2. Confirm that no instances reside on the node that you are deleting.

```
asadmin> list-nodes-config --long=true
```

3. Run the `delete-node-config` subcommand.

```
asadmin> delete-node-config node-name
```

node-name

The name of the node that you are deleting.

The following example confirms that no instances reside on the `CONFIG` node `cfg01` and deletes the node `cfg01`.

```
asadmin> list-nodes-config --long=true

NODE NAME           TYPE     NODE HOST           INSTALL DIRECTORY    REFERENCED BY
localhost-domain1   CONFIG   localhost           /export/payara
cfg01               CONFIG   cfg01.example.com   /export/payara
cfg02               CONFIG   cfg02.example.com   /export/payara   yml-i2
Command list-nodes-config executed successfully.
asadmin> delete-node-config cfg01
Command delete-node-config executed successfully.
```

See also

- To Delete an Instance Locally
- `delete-node-config`
- `list-nodes-config`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help delete-node-config`
- `asadmin help list-nodes-config`

Creating, Listing and Deleting Docker Nodes

As previously explained, a Docker node shares similarities with existing SSH and CONFIG nodes as it serves as a virtual representation of a Payara Server installation.

The Docker engine must expose its REST admin service on an HTTP port that is reacheable by the DAS to configure a DOCKER node.

Exposing the Docker REST Admin Service

To expose the REST admin service of the Docker engine, you need to specify the `-H` option in your `DOCKER_OPTS` environment variable, or otherwise specify it in the command that starts the docker service.

For example:

```
DOCKER_OPTS="-H=0.0.0.0:2376"
```

You can test that it is exposed by navigating to it with your browser (assuming you're exposing the port in the example above): `http://localhost:2376/info`

Creating a Docker Node

Creating a Docker node is done in a similar manner to creating an SSH or CONFIG node, either by asadmin command, or by the Nodes page of the admin console.

Docker nodes do have some unique configuration properties however:

- **Docker Password File** - This is the fully-qualified path of the password file that the Docker instance will use for authentication against the DAS.

  Please note, that this path should be the path to the file on the **remote** machine. This file should be a standard Payara Server password file as you would use with asadmin. This must be specified, as Docker instances require secure admin to be enabled to start.

- TLS - Whether or not to use HTTPS to communicate with the Docker engine or not.
- Docker Port - The port that the Docker engine is listening on. Defaults to `2376`.
- Docker Image - The Docker image to use. Payara Server will default to using the `payara/server-node:main-7` image.

The configuration options of CONFIG nodes are also available, namely `nodehost`, `nodedir`, and `installdir`. Specifying the `nodehost` option remains mandatory, but for docker nodes the `installdir` and `nodedir` options can safely be left as their defaults unless you're specifying your own Docker image.

Please take particular note of the *Docker Password File* option: this is mandatory and **must be present on the remote machine**. Payara Server does not currently support propagating password files from the DAS to your remote machines. Secure admin must also be enabled for Docker Nodes to function correctly, which entails setting an admin password. See below for an example of enabling secure admin for the default *admin* user:

```
asadmin change-admin-password --user admin
Enter the admin password>
Enter the new admin password>
Enter the new admin password again>
Command change-admin-password executed successfully.
```

```
asadmin enable-secure-admin
Authentication failed with password from login store
Enter admin password for user "admin">
You must restart all running servers for the change in secure admin to take effect.
Command enable-secure-admin executed successfully.

asadmin restart-domain
```

As an example of an extremely simple password file, here is the contents of a sample, `passwordfile.txt`:

```
AS_ADMIN_PASSWORD=changeit
```

Where `changeit` is the password of the default *admin* user.

Once you have ensured that you have secure admin enabled, and that a password file granting access to the DAS is present on the remote machine, you can run the asadmin command for creating a Docker node:

```
asadmin create-node-docker --nodehost localhost --dockerPasswordFile
/opt/passwordfile.txt --dockerport 2376 docker-node-1
```

The admin console page for creating Docker nodes is the same as creating the other node types: simply select `DOCKER` as the node type from the dropdown.

Configuring TLS

As Docker must expose an HTTP port, it is recommended that it be protected using TLS outside of development environments.

A full guide for how to do so can be found here In short, create self-signed TLS certificates (or use your own signed ones), and add them to your `DOCKER_OPTS` variable to secure the Docker REST admin service:

```
DOCKER_OPTS="--tlsverify --tlscacert=/home/anon/tls/ca.pem
--tlscert=/home/anon/tls/server-cert.pem --tlskey=/home/anon/tls/server-key.pem
-H=0.0.0.0:2376"
```

Assuming you followed this guide, you will need to perform the following steps to allow Payara Server to communicate with the Docker engine correctly:

1. Import the CA certificate into the Domain truststore (defaults to `domain-dir/config/cacerts.p12`)
2. Create a PKCS12 bundle from the client certificate and key
3. Import the generated PKCS12 bundle into the Domain's keystore (defaults to `domain-dir/config/keystore.p12`)

Once you've enabled TLS for the Docker REST admin service and added the necessary certificates & keys to Payara Server, you can create a Docker Node with TLS enabled like so:

```
asadmin create-node-docker --nodehost localhost --useTls true --dockerPasswordFile
/opt/passwordfile.txt --dockerport 2376 docker-node-1
```

Please ensure that the `useTLS` option of the node matches whether or not you have configured TLS for the Docker engine, as otherwise any communication with the Docker engine will fail.

To Delete a DOCKER Node

Use the `delete-node-docker` subcommand in remote mode to delete a DOCKER node.

Deleting a node removes the node from the configuration of the DAS and the Docker container that corresponds to the node's system is stopped and removed. Follow these steps to remove a Docker node:

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Confirm that no instances reside on the node that you are deleting.

   ```
   asadmin list-nodes-config --long=true
   ```

3. Run the `delete-node-docker` subcommand.

   ```
   asadmin> delete-node-docker node-name
   ```

   node-name

   The name of the node that you are deleting.

Updating and Changing the Type of a Node

Payara Server enables you to update the configuration data of any node and to change the type of a node.

To Update an `SSH` Node

Use the `update-node-ssh` subcommand in remote mode to update an `SSH` node.

Options of this subcommand specify the new values of the node's configuration data. If you omit an option, the existing value is unchanged.

Before You Begin

Ensure that the following prerequisites are met:

- SSH is configured on the host where the DAS is running and on the host that the node

represents.

- The node that you are updating exists.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `update-node-ssh` subcommand.

```
asadmin> update-node-ssh options node-name
```

options

Options of the `update-node-ssh` subcommand for changing the node's configuration data. For information about these options, see the `update-node-ssh` help page.

node-name

The name of the `SSH` node to update.

The following example updates the host that the node `sj01` represents to `adc01.example.com`.

```
asadmin> update-node-ssh --nodehost adc01.example.com sj01
Command update-node-ssh executed successfully.
```

See also

`update-node-ssh`

You can also view the full syntax and options of the subcommand by typing `asadmin help update-node-ssh` at the command line.

To Update a `CONFIG` Node

Use the `update-node-config` subcommand in remote mode to update a `CONFIG` node.

Options of this subcommand specify the new values of the node's configuration data. If you omit an option, the existing value is unchanged.

Before You Begin

Ensure that the node that you are updating exists.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `update-node-config` subcommand.

```
asadmin> update-node-config options node-name
```

options

Options of the `update-node-config` subcommand for changing the node's configuration data. For information about these options, see the `update-node-config` help page.

node-name

The name of the `CONFIG` node to update.

The following example updates the host that the node `cfg02` represents to `adc02.example.com`.

```
asadmin> update-node-config --nodehost adc02.example.com cfg02
Command update-node-config executed successfully.
```

See also

`update-node-config`

You can also view the full syntax and options of the subcommand by typing `asadmin help update-node-config` at the command line.

To Change the Type of a Node

The subcommands for updating a node can also be used to change the type of a node.

Due to the structure and mechanisms used to configure `DOCKER` nodes, it is not possible to switch the type of a `DOCKER` node to either `CONFIG`/`SSH` nodes or viceversa.

Changing the type of a `CONFIG` node to a `SSH` node enables remote communication for the node. It is also possible to change an `SSH` node to a `CONFIG` node too.

As part of the process of changing the type of a node, you can also change other configuration data for the node.

Options of the subcommands for updating a node specify the new values of the node's configuration data. For most options, if you omit the option, the existing value is unchanged. However, default values are applied in the following situations:

- Any of the following options of the `update-node-ssh` subcommand is omitted:
  - `--sshport`
  - `--sshuser`
  - `--sshkeyfile`

Changing an `SSH` node to a `CONFIG` node disables remote communication for the node.

Before You Begin

Ensure that the following prerequisites are met:

- SSH is configured on the host where the DAS is running and on the host that the node represents.
- The node the type of which you are changing exists.

Execute the following steps:

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the appropriate subcommand for updating a node, depending on the type of the node after the change.

   config-or-ssh-node-name

   The name of the `CONFIG` node or the `SSH` node to change.

   - To change the type of a node to `SSH`, run the `update-node-ssh` subcommand on the node.

   options

   Options of the `update-node-ssh` subcommand for changing the node's configuration data. For information about these options, see the `update-node-ssh` help page.

   - To change the type of a node to `CONFIG`, run the `update-node-config` subcommand on the node.

     ```
     asadmin> update-node-config [options] ssh-node-name
     ```

   options

   Options of the `update-node-config` subcommand for changing the node's configuration data. For information about these options, see the `update-node-config` help page.

   ssh-node-name

   The name of the `SSH` node to change.

The following example changes the `CONFIG` node `cfg02` to an `SSH` node.

```
asadmin> update-node-ssh cfg02
Command update-node-ssh executed successfully.
```

See also

- `update-node-config`
- `update-node-ssh`

You can also view the full syntax and options of the subcommand by typing the following commands at the command line.

- `asadmin help update-node-config`
- `asadmin help update-node-ssh`

Administering Payara Server Clusters

Clusters have been deprecated and officially replaced with Deployment Groups. We do not recommend setting up highly-available architectures using traditional

clusters.

A cluster is a collection of Payara Server instances that work together as one logical entity. A cluster provides a runtime environment for one or more Jakarta Platform, Enterprise Edition (Jakarta EE) applications. A cluster provides high availability through failure protection, scalability, and load balancing.

About Payara Server Clusters

A cluster is a named collection of Payara Server instances that share the same applications, resources, and configuration information.

For information about Payara Server instances, see Administering Payara Server Instances.

Payara Server enables you to administer all the instances in a cluster as a single unit from a single host, regardless of whether the instances reside on the same host or different hosts. You can perform the same operations on a cluster that you can perform on an un-clustered instance, for example, deploying applications and creating resources.

A cluster provides high availability through failure protection, scalability, and load balancing.

- Failure protection. If an instance or a host in a cluster fails, Payara Server detects the failure and recovers the user session state.

  If a load balancer is configured for the cluster, the load balancer redirects requests from the failed instance to other instances in the cluster.

  Because the same applications and resources are on all instances in the cluster, an instance can fail over to any other instance in the cluster.

  To enable the user session state to be recovered, each instance in a cluster sends in-memory state data to another instance. As state data is updated in any instance, the data is replicated.

- Scalability. If increased capacity is required, you can add instances to a cluster with no disruption in service. When an instance is added or removed, the changes are handled automatically.
- Load balancing. If instances in a cluster are distributed among different hosts, the workload can be distributed among the hosts to increase overall system throughput.

Group Management Service

The Group Management Service (GMS) is an infrastructure component that is enabled for the instances in a cluster. When GMS is enabled, if a clustered instance fails, the cluster and the Domain Administration Server (DAS) are aware of the failure and can take action when failure occurs.

GMS is a core service of the Shoal framework.

About GMS in Payara Server

In previous versions of Payara Server, specifically Payara Server 4.x, clusters were implemented using the Group Management Service (GMS) and the Shoal framework to allow server instances to communicate between each other and coordinate high-availability features. GMS enables instances to participate in a cluster by detecting changes in cluster membership and notifying instances of the changes.

Starting in Payara Server 5, GMS has been replaced internally with the use of Hazelcast, the technology used to provision the server's Data Grid functionality. This replacement has been implemented in an encapsulated manner: Users will still interact with GMS settings via the Admin Console and Asadmin CLI, but under the covers the communication is managed through a set of adapters that use Hazelcast. This was done to keep a certain degree of backward compatibility between Payara Server 4 and 5.

To this effect, most of the configuration settings listed in the next section may not properly work as clusters have been effectively replaced by deployment groups.

GMS Configuration Settings

Payara Server has the following types of GMS settings:

- GMS cluster settings — These are determined during cluster creation. For more information about these settings, see To Create a Cluster.
- GMS configuration settings — These are determined during configuration creation and are explained here.

The following GMS configuration settings are used in GMS for group discovery and failure detection:

`group-discovery-timeout-in-millis`

Indicates the amount of time (in milliseconds) an instance's GMS module will wait during instance startup for discovering other members of the group.

The `group-discovery-timeout-in-millis` timeout value should be set to the default or higher. The default is 5000.

`max-missed-heartbeats`

Indicates the maximum number of missed heartbeats that the health monitor counts before the instance can be marked as a suspected failure. GMS also tries to make a peer-to-peer connection with the suspected member. If the maximum number of missed heartbeats is exceeded and peer-to-peer connection fails, the member is marked as a suspected failure. The default value is `3`.

`heartbeat-frequency-in-millis`

Indicates the frequency (in milliseconds) at which a heartbeat is sent by each server instance to the cluster.

The failure detection interval is the `max-missed-heartbeats` multiplied by the `heartbeat-frequency-in-millis`. Therefore, the combination of defaults, 3 multiplied by 2000 milliseconds,

results in a failure detection interval of 6 seconds.

Lowering the value of `heartbeat-frequency-in-millis` below the default would result in more frequent heartbeat messages being sent out from each member. This could potentially result in more heartbeat messages in the network than a system needs for triggering failure detection protocols. The effect of this varies depending on how quickly the deployment environment needs to have failure detection performed. That is, the (lower) number of retries with a lower heartbeat interval would make it quicker to detect failures.

However, lowering this value could result in false positives because you could potentially detect a member as failed when, in fact, the member's heartbeat is reflecting the network load from other parts of the server. Conversely, a higher timeout interval results in fewer heartbeats in the system because the time interval between heartbeats is longer. As a result, failure detection would take a longer. In addition, a startup by a failed member during this time results in a new join notification but no failure notification, because failure detection and verification were not completed.

The default value is `2000`.

`verify-failure-waittime-in-millis`

Indicates the verify suspect protocol's timeout used by the health monitor. After a member is marked as suspect based on missed heartbeats and a failed peer-to-peer connection check, the verify suspect protocol is activated and waits for the specified timeout to check for any further health state messages received in that time, and to see if a peer-to-peer connection can be made with the suspect member. If not, then the member is marked as failed and a failure notification is sent.

The default value is `1500`.

`verify-failure-connect-timeout-in-millis`

Indicates the time it takes for the GMS to detect a hardware or network failure of a server instance. Be careful not to set this value too low. The smaller this timeout value is, the greater the chance of detecting false failures. That is, the instance has not failed but doesn't respond within the short window of time.

The default value is `10000`.

The heartbeat frequency, maximum missed heartbeats, peer-to-peer connection-based failure detection, and the verify timeouts are all needed to ensure that failure detection is robust and reliable in Payara Server.

For the dotted names for each of these GMS configuration settings, see Dotted Names for GMS Settings. For the steps to specify these settings, see To Preconfigure Nondefault GMS Configuration Settings.

Dotted Names for GMS Settings

Below are sample `get` subcommands to get all the GMS configuration settings (attributes associated with the referenced `mycfg` configuration) and GMS cluster settings (attributes and properties associated with a cluster named `mycluster`).

```
asadmin> get "configs.config.mycfg.group-management-service.*"

configs.config.mycfg.group-management-service.failure-detection.heartbeat-frequency-
in-millis=2000
configs.config.mycfg.group-management-service.failure-detection.max-missed-
heartbeats=3
configs.config.mycfg.group-management-service.failure-detection.verify-failure-
connect-timeout-in-millis=10000
configs.config.mycfg.group-management-service.failure-detection.verify-failure-
waittime-in-millis=1500
configs.config.mycfg.group-management-service.group-discovery-timeout-in-millis=5000

asadmin> get clusters.cluster.mycluster

clusters.cluster.mycluster.config-ref=mycfg
clusters.cluster.mycluster.gms-bind-interface-address=${GMS-BIND-INTERFACE-ADDRESS-
mycluster}
clusters.cluster.mycluster.gms-enabled=true
clusters.cluster.mycluster.gms-multicast-address=228.9.245.47
clusters.cluster.mycluster.gms-multicast-port=9833
clusters.cluster.mycluster.name=mycluster

asadmin> get "clusters.cluster.mycluster.property.*"
clusters.cluster.mycluster.property.GMS_LISTENER_PORT=${GMS_LISTENER_PORT-mycluster}
clusters.cluster.mycluster.property.GMS_MULTICAST_TIME_TO_LIVE=4
clusters.cluster.mycluster.property.GMS_LOOPBACK=false
clusters.cluster.mycluster.property.GMS_TCPSTARTPORT=9090
clusters.cluster.mycluster.property.GMS_TCPENDPORT=9200
```

The last `get` subcommand displays only the properties that have been explicitly set.

For the steps to specify these settings, see To Preconfigure Nondefault GMS Configuration Settings and To Change GMS Settings After Cluster Creation.

To Preconfigure Nondefault GMS Configuration Settings

You can preconfigure GMS with values different than the defaults without requiring a restart of the DAS and the cluster.

1. Create a configuration using the `copy-config` subcommand. For example:

   ```
   asadmin> copy-config default-config mycfg
   ```

   For more information, see To Create a Named Configuration.

2. Set the values for the new configuration's GMS configuration settings. For example:

   ```
   asadmin> set configs.config.mycfg.group-management-service.group-discovery-timeout-
   ```

```
in-millis=8000
asadmin> set configs.config.mycfg.group-management-service.failure-detection.max-
missed-heartbeats=5
```

For a complete list of the dotted names for these settings, see Dotted Names for GMS Settings.

3. Create the cluster so it uses the previously created configuration. For example:

```
asadmin> create-cluster --config mycfg mycluster
```

You can also set GMS cluster settings during this step. For more information, see To Create a Cluster.

4. Create server instances for the cluster. For example:

```
asadmin> create-instance --node localhost-domain1 --cluster mycluster instance01
asadmin> create-instance --node localhost-domain1 --cluster mycluster instance02
```

5. Start the cluster. For example:

```
asadmin> start-cluster mycluster
```

You can also view the full syntax and options of a subcommand by typing `asadmin help` subcommand at the command line.

To Change GMS Settings After Cluster Creation

To avoid the need to restart the DAS and the cluster, configure GMS configuration settings before cluster creation as explained in To Preconfigure Nondefault GMS Configuration Settings.

To avoid the need to restart the DAS and the cluster, configure the GMS cluster settings during cluster creation as explained in To Create a Cluster.

Changing any GMS settings using the `set` subcommand after cluster creation requires a domain administration server (DAS) and cluster restart as explained here.

1. Ensure that the DAS and cluster are running. Remote subcommands require a running server.
2. Use the `get` subcommand to determine the settings to change. For example:

```
asadmin> get "configs.config.mycfg.group-management-service.*"

configs.config.mycfg.group-management-service.failure-detection.heartbeat-
frequency-in-millis=2000
configs.config.mycfg.group-management-service.failure-detection.max-missed-
heartbeats=3
configs.config.mycfg.group-management-service.failure-detection.verify-failure-
```

```
connect-timeout-in-millis=10000
configs.config.mycfg.group-management-service.failure-detection.verify-failure-
waittime-in-millis=1500
configs.config.mycfg.group-management-service.group-discovery-timeout-in-
millis=5000
```

For a complete list of the dotted names for these settings, see Dotted Names for GMS Settings.

3. Use the `set` subcommand to change the settings. For example:

```
asadmin> set configs.config.mycfg.group-management-service.group-discovery-timeout-
in-millis=6000
```

4. Use the `get` subcommand again to confirm that the changes were made. For example:

```
asadmin> get configs.config.mycfg.group-management-service.group-discovery-timeout-
in-millis
```

5. Restart the DAS. For example:

```
asadmin> stop-domain domain1
asadmin> start-domain domain1
```

6. Restart the cluster. For example:

```
asadmin> stop-cluster mycluster
asadmin> start-cluster mycluster
```

You can also view the full syntax and options of a subcommand by typing `asadmin help` subcommand at the command line.

To Check the Health of Instances in a Cluster

The `list-instances` is the quickest way to evaluate the health of a cluster and to detect if cluster is properly operating; that is, all members of the cluster are running and visible to DAS.

1. Ensure that the DAS and cluster are running. Remote subcommands require a running server.
2. Check whether server instances in a cluster are running by using the `list-instances` subcommand.

This example checks the health of a cluster named `mycluster`.

```
asadmin> list-instances mycluster
instance01   running
instance02   running
```

```
Command list-instances executed successfully.
```

You can also view the full syntax and options of the subcommand by typing `asadmin help list-instances` at the command line.

Using the Multi-Homing Feature With GMS

Multi-homing enables Payara Server clusters to be used in an environment that uses multiple Network Interface Cards (NICs). A multi-homed host has multiple network connections, of which the connections may or may not be the on same network. Multi-homing provides the following benefits:

- Provides redundant network connections within the same subnet. Having multiple NICs ensures that one or more network connections are available for communication.
- Supports communication across two or more different subnets. The DAS and all server instances in the same cluster must be on the same subnet for GMS communication, however.
- Binds to a specific IPv4 address and receives GMS messages in a system that has multiple IP addresses configured. The responses for GMS messages received on a particular interface will also go out through that interface.
- Supports separation of external and internal traffic.

Traffic Separation Using Multi-Homing

You can separate the internal traffic resulting from GMS from the external traffic. Traffic separation enables you plan a network better and augment certain parts of the network, as required.

Consider a simple cluster, `c1`, with three instances, `i101`, `i102`, and `i103`. Each instance runs on a different machine.

In order to separate the traffic, the multi-homed machine should have at least two IP addresses belonging to different networks. The first IP as the external IP and the second one as internal IP. The objective is to expose the external IP to user requests, so that all the traffic from the user requests would be through them. The internal IP is used only by the cluster instances for internal communication through GMS.

The following procedure describes how to set up traffic separation.

To configure multi-homed machines for GMS without traffic separation, skip the steps or commands that configure the `EXTERNAL-ADDR` system property, but perform the others.

To avoid having to restart the DAS or cluster, perform the following steps in the specified order.

To set up traffic separation, follow these steps:

1. Create the system properties `EXTERNAL-ADDR` and `GMS-BIND-INTERFACE-ADDRESS-c1` for the DAS.
    - `asadmin create-system-properties target server EXTERNAL-ADDR=192.155.35.4`
    - `asadmin create-system-properties target server GMS-BIND-INTERFACE-ADDRESS-c1=10.12.152.20`

2. Create the cluster with the default settings. Use the following command:

```
asadmin create-cluster c1
```

   A reference to a system property for GMS traffic is already set up by default in the `gms-bind-interface-address` cluster setting. The default value of this setting is `${GMS-BIND-INTERFACE-ADDRESS-`cluster-name`}`.

3. When creating the clustered instances, configure the external and GMS IP addresses.
   Use the following commands:
   - `asadmin create-instance node localhost cluster c1 systemproperties EXTERNAL-ADDR=192.155.35.5:GMS-BIND-INTERFACE-ADDRESS-c1=10.12.152.30 i101`
   - `asadmin create-instance node localhost cluster c1 systemproperties EXTERNAL-ADDR=192.155.35.6:GMS-BIND-INTERFACE-ADDRESS-c1=10.12.152.40 i102`
   - `asadmin create-instance node localhost cluster c1 systemproperties EXTERNAL-ADDR=192.155.35.7:GMS-BIND-INTERFACE-ADDRESS-c1=10.12.152.50 i103`
4. Set the address attribute of HTTP listeners to refer to the `EXTERNAL-ADDR` system properties. Use the following commands:

```
asadmin set c1-config.network-config.network-listeners.network-listener.http-1.address=\${EXTERNAL-ADDR}
asadmin set c1-config.network-config.network-listeners.network-listener.http-2.address=\${EXTERNAL-ADDR}
```

Creating, Listing, and Deleting Clusters

Payara Server enables you to create clusters, obtain information about clusters, and delete clusters that are no longer required.

To Create a Cluster

Use the `create-cluster` subcommand in remote mode to create a cluster.

To ensure that the GMS can detect changes in cluster membership, a cluster's GMS settings must be configured correctly. To avoid the need to restart the DAS and the cluster, configure a cluster's GMS settings when you create the cluster. If you change GMS settings for an existing cluster, the DAS and the cluster must be restarted to apply the changes.

When you create a cluster, Payara Server automatically creates a Message Queue cluster for the Payara Server cluster.

For more information about Message Queue clusters, see Using Message Queue Broker Clusters With Payara Server.

Before You Begin

If the cluster is to reference an existing named configuration, ensure that the configuration exists.

For more information, see To Create a Named Configuration.

If you are using a named configuration to preconfigure GMS settings, ensure that these settings have the required values in the named configuration.

For more information, see To Preconfigure Nondefault GMS Configuration Settings.

If you are configuring the cluster's GMS settings when you create the cluster, ensure that you have the following information:

- The address on which GMS listens for group events
- The port number of the communication port on which GMS listens for group events
- The maximum number of iterations or transmissions that a multicast message for GMS events can experience before the message is discarded
- The lowest port number in the range of ports from which GMS selects a TCP port on which to listen
- The highest port number in the range of ports from which GMS selects a TCP port on which to listen

If the DAS is running on a multihome host, ensure that you have the Internet Protocol (IP) address of the network interface on the DAS host to which GMS binds.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `create-cluster` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for configuring the cluster, see the `create-cluster` help page.

- If multicast transport is available, run the `create-cluster` subcommand as follows:

```
asadmin> create-cluster --config configuration
--multicastaddress multicast-address --multicastport multicast-port
--properties GMS_MULTICAST_TIME_TO_LIVE=max-iterations:
GMS_TCPSTARTPORT=start-port:GMS_TCPENDPORT=end-port cluster-name
```

- If multicast transport is not available, run the `create-cluster` subcommand as follows:

```
asadmin> create-cluster --config configuration --properties
GMS_DISCOVERY_URI_LIST=discovery-instances:GMS_LISTENER_PORT=gms-port cluster-name
```

configuration

An existing named configuration that the cluster is to reference.

multicast-address

The address on which GMS listens for group events.

multicast-port

The port number of the communication port on which GMS listens for group events.

max-iterations

The maximum number of iterations or transmissions that a multicast message for GMS events can experience before the message is discarded.

discovery-instances

Instances to use for discovering the cluster.

gms-port

The port number of the port on which the cluster listens for messages from GMS.

start-port

The lowest port number in the range of ports from which GMS selects a TCP port on which to listen. The default is 9090.

end-port

The highest port number in the range of ports from which GMS selects a TCP port on which to listen. The default value is 9200.

cluster-name

Your choice of name for the cluster that you are creating.

1. If necessary, create a system property to represent the IP address of the network interface on the DAS host to which GMS binds. This step is necessary only if the DAS is running on a multihome host.

   ```
   asadmin> create-system-properties
   GMS-BIND-INTERFACE-ADDRESS-cluster-name=das-bind-address
   ```

cluster-name

The name that you assigned to the cluster in Step 2.

das-bind-address

The IP address of the network interface on the DAS host to which GMS binds.

This example creates a cluster that is named `ltscluster` for which port 1169 is to be used for secure IIOP connections. Because the `--config` option is not specified, the cluster references a copy of the named configuration `default-config` that is named `ltscluster-config`.

```
asadmin> create-cluster --systemproperties IIOP_SSL_LISTENER_PORT=1169 ltscluster
Command create-cluster executed successfully.
```

Next Steps

After creating a cluster, you can add Payara Server instances to the cluster as explained in the following sections:

- To Create an Instance Centrally
- To Create an Instance Locally

See Also

- To Create a Named Configuration
- To Preconfigure Nondefault GMS Configuration Settings
- Using Message Queue Broker Clusters With Payara Server
- `create-cluster`
- `create-system-properties`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help create-cluster`
- `asadmin help create-system-properties`

To List All Clusters in a Domain

Use the `list-clusters` subcommand in remote mode to obtain information about existing clusters in a domain.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `list-clusters` subcommand.

```
asadmin> list-clusters
```

This example lists all clusters in the current domain.

```
asadmin> list-clusters
pmdclust not running
ymlclust not running
Command list-clusters executed successfully.
```

This example lists the clusters that contain an instance that resides on the node `sj01`.

```
asadmin> list-clusters sj01
ymlclust not running
Command list-clusters executed successfully.
```

See Also

`list-clusters`

You can also view the full syntax and options of the subcommand by typing `asadmin help list-clusters` at the command line.

To Delete a Cluster

Use the `delete-cluster` subcommand in remote mode to remove a cluster from the DAS configuration.

If the cluster's named configuration was created automatically for the cluster and no other clusters or unclustered instances refer to the configuration, the configuration is deleted when the cluster is deleted.

Before You Begin

Ensure that following prerequisites are met:

- The cluster that you are deleting is stopped. For information about how to stop a cluster, see To Stop a Cluster.
- The cluster that you are deleting contains no Payara Server instances. For information about how to remove instances from a cluster, see the following sections:
  - To Delete an Instance Centrally
  - To Delete an Instance Locally

Follow these steps:

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Confirm that the cluster is stopped.

   ```
   asadmin> list-clusters cluster-name
   ```

   cluster-name

   The name of the cluster that you are deleting.

3. Confirm that the cluster contains no instances.

   ```
   asadmin> list-instances cluster-name
   ```

   cluster-name

   The name of the cluster that you are deleting.

4. Run the `delete-cluster` subcommand.

```
asadmin> delete-cluster cluster-name
```

cluster-name

The name of the cluster that you are deleting.

This example confirms that the cluster `adccluster` is stopped and contains no instances and deletes the cluster `adccluster`.

```
asadmin> list-clusters adccluster
adccluster not running
Command list-clusters executed successfully.
asadmin> list-instances adccluster
Nothing to list.
Command list-instances executed successfully.
asadmin> delete-cluster adccluster
Command delete-cluster executed successfully.
```

See Also

- To Stop a Cluster
- To Delete an Instance Centrally
- To Delete an Instance Locally
- `delete-cluster`
- `list-clusters`
- `list-instances`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help delete-cluster`
- `asadmin help list-clusters`
- `asadmin help list-instances`

Administering Deployment Groups

Deployment Groups were introduced in Payara Platform 5 as an effective replacement for clusters. Deployment groups are a complement to the Data Grid whereas the grid is responsible to managing distributed application data across multiple instances, deployment groups manage how application deployment is targeted in general.

A Deployment Group is a loose grouping of Payara Server instances that can be used as a target for **deployments**. Deployment Groups consist of one or more Payara Server standalone instances and each instance can belong to one or more deployment groups.

Deployment Groups can then be used to manage the lifecycle of the standalone instances in the

group. All instances can be started, re-started and stopped via their corresponding deployment group.

Deployment Group Benefits

With the introduction of Deployment Groups and the Domain Data Grid, Payara Server instances are the primary resource for management: First, you create the managed servers you need running on various nodes in your environment. You can then add these instances to various deployment groups depending on your business requirements.

For example, imagine you are in a cloud environment, and you have a couple of deployment groups:

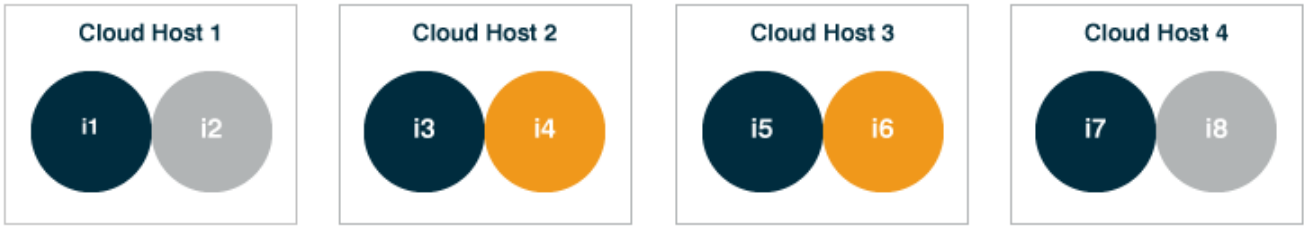
- `core-web` running your core e-commerce system
- `reporting` running applications for management reporting.

With deployment groups in response to peak load it is very simple to re-purpose a reporting instance to the core-web deployment group with a single asadmin command like this:

```
asadmin add-instance-to-deployment-group --instance reporting-1 --deploymentgroup
core-web
```

For another example in a cloud environment (shown below), you could have each IAAS virtual server configured to have a couple of generic Payara Server instances running on them (colored grey). Then, when you come to deploy applications, you could select a number of these instances to be in deployment group 1 (colored blue), a number in deployment group 2 (colored orange) and so on.

With the flexibility to change the distribution as time goes on. As data sharing of sessions is spread throughout the whole Payara Server domain, moving instances between deployment groups does not impact accessibility of web session data.



Managing Deployment Groups

Deployment groups can be created, modified, listed and deleted from both the Admin Console and the Asadmin CLI.

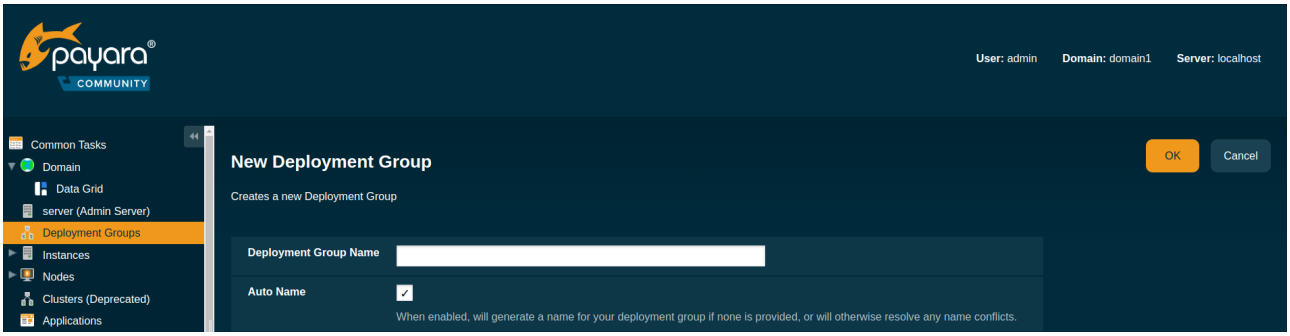
Creating a Deployment Group

Once a new deployment group is created, it will be created in an empty state, as standalone instances will have to be added later.

Using the Administration Console

To create a new deployment group using the Admin Console, follow these steps:

1. Navigate to the *Deployment Groups* node in the navigation tree.
2. Click on the *New* button and give the deployment group a unique name.
3. Alternatively, check the *Auto Name* box to give the deployment group a random name.
4. From this screen it is also possible to add a number of new server instances if desired:



Instances created in this screen will be created alongside a corresponding configuration object that is a copy of the `default-config` object.
If you want these instances to reference an existing configuration object, it is better to create them from the *Instances* screen and add them to the deployment group later.

Using Asadmin commands

To create a new deployment group run the `create-deployment-group` command:

```
asadmin create-deployment-group test
```

Deleting a Deployment Group

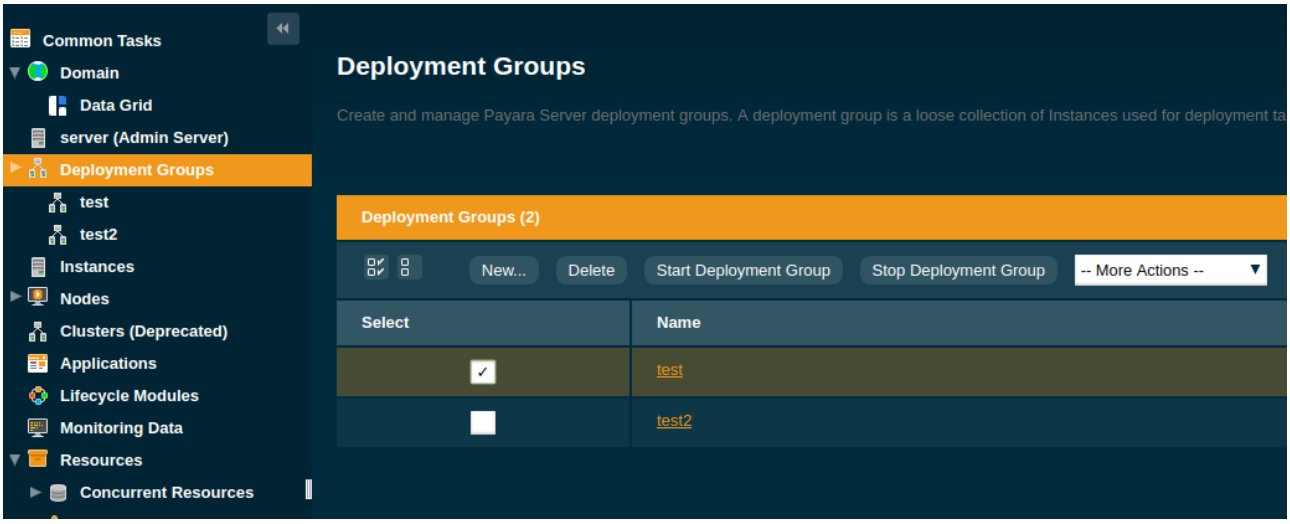
A deployment group can be deleted using both the Administration console and from the command line.

Instances that belong to a deployment group won't be deleted when the group is deleted.

Using the Administration Console

To delete a deployment group using the Admin Console, follow these steps:

1. Navigate to the *Deployment Groups* section in the side panel.
2. Select the group from corresponding table.
3. Click the *Delete* button.



Using asadmin commands

To delete a deployment group use the `delete-deployment-group` command:

```
asadmin> delete-deployment-group test
```

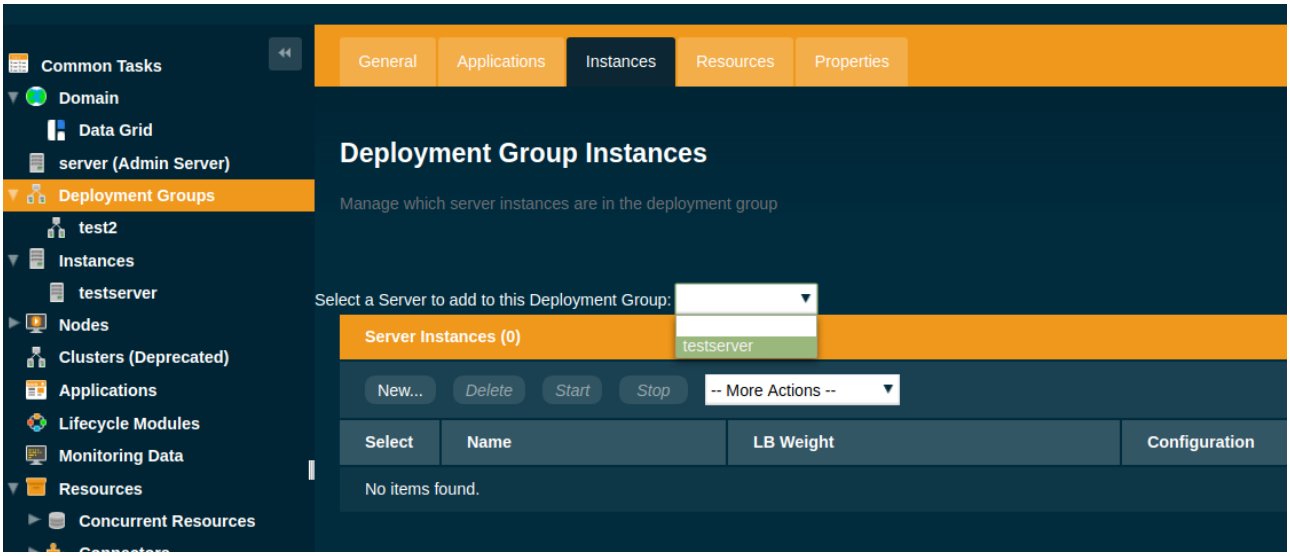
Managing Deployment Group Membership

Deployment group membership can also be managed by either using the Admin console or the Asadmin CLI.

Adding an Instance

Existing standalone instances be assigned to an existing deployment group via the Admin console by following these steps:

1. Navigate to the *Deployment Groups* node in the navigation tree.
2. Navigate to the deployment group you want to modify.
3. Select the instance to add from the dropdown in the *Instances* tab.



The same result can be achieved from the command line by using the `add-instance-to-deployment-group` command:

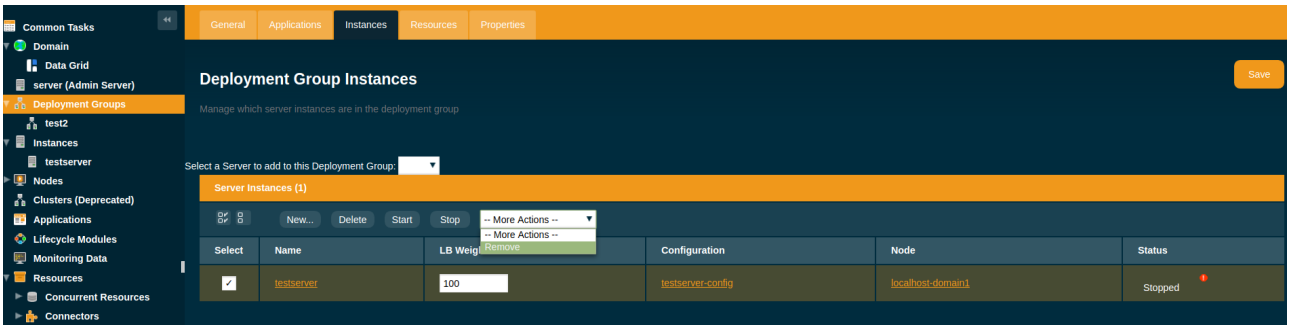
```
asadmin add-instance-to-deployment-group --instance testserver --deploymentgroup test2
```

Remember that an instance can belong to multiple deployment groups.

Removing an Instance

If you want to remove an instance from a deployment group by using the Admin console follow these steps:

1. Navigate to the *Deployment Groups* node in the navigation tree.
2. Navigate to the deployment group you want to modify.
3. Select the instance and choose the *Remove* from the *More actions* drop down.



The same can be achieved using the Asadmin CLI by using the `remove-instance-from-deployment-group` command:

```
asadmin remove-instance-from-deployment-group --instance testserver --deploymentgroup
test2
```

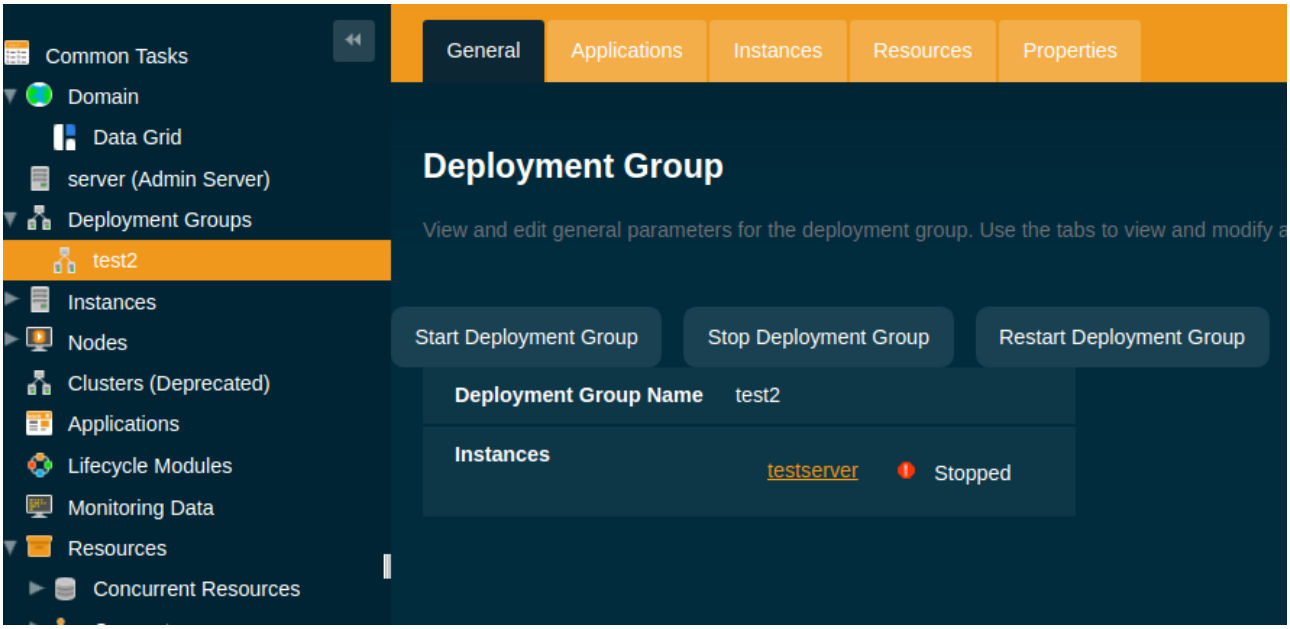
Server Lifecycle Management

Deployment Groups also provide lifecycle management capabilities. You can start a deployment group and all instances currently in the group will be started. Similarly, you can stop a deployment group. In addition, Deployment Groups support a **"rolling restart"** which is Data Grid aware.

In a rolling restart, all instances in the group are stopped and then started again in turn, ensuring that the Data Grid has enough time to adapt and ensure no loss of data during the restart.

To do this from the Admin console, follow these steps:

1. Navigate to the *Deployment Groups* node in the navigation tree.
2. Navigate to the deployment group you want to manage.
3. Choose either the *Start Deployment Group*, *Stop Deployment Group* or *Restart Deployment Group* action.



These commands are Data Grid safe and operated in a way as to minimize the danger of data disruption.

The same can be achieved from the command line by using the following Asadmin commands:

- `start-deployment-group`
- `stop-deployment-group`
- `restart-deployment-group`

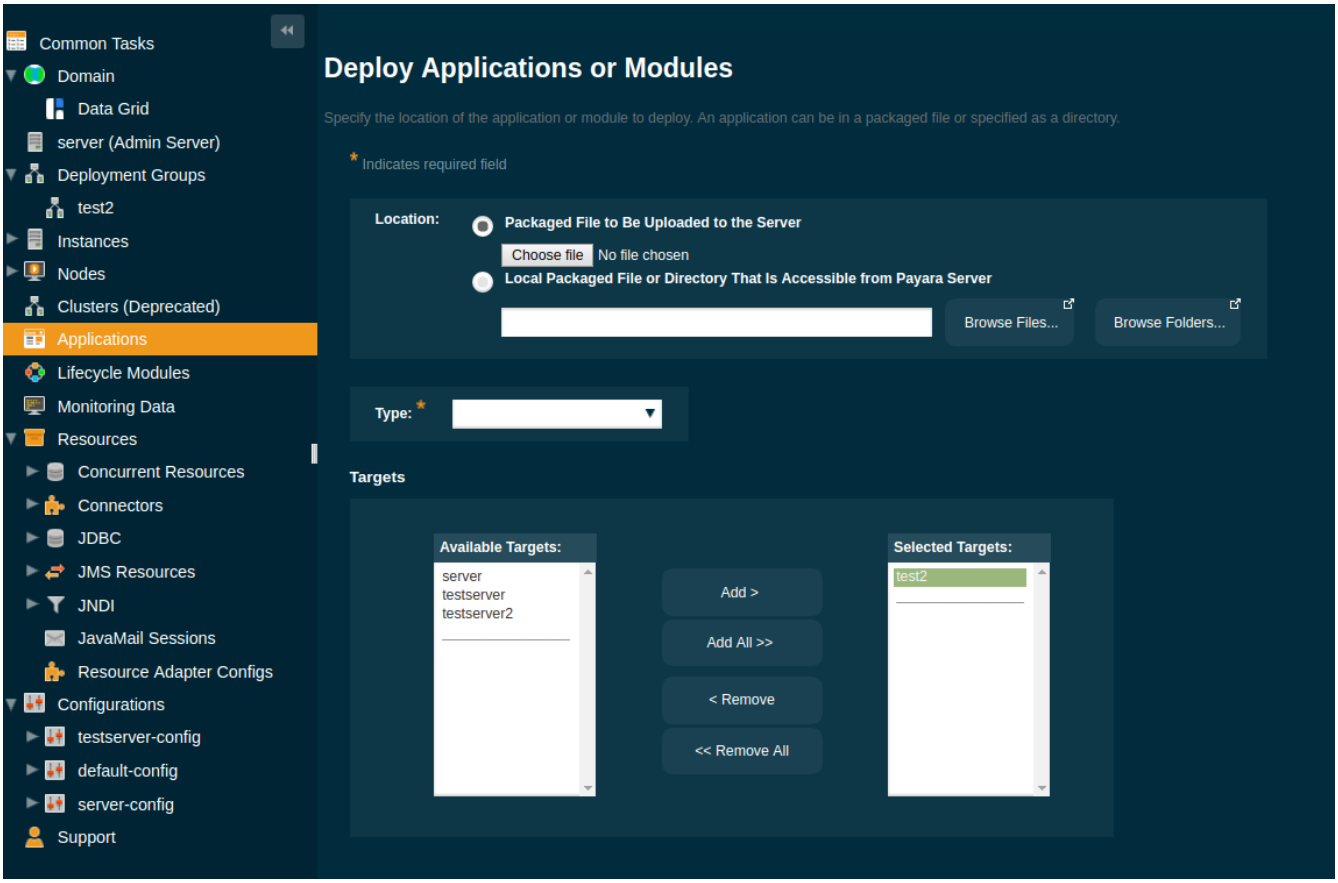
Like this:

```
asadmin start-deployment-group test2
asadmin restart-deployment-group test2
asadmin stop-Deployment Group.adoc test2
```

Deploying Applications to a Deployment Group

To deploy an application to a deployment group when using the Admin console you select the deployment group name in the list of targets in the usual way.

This can be done both on the *Applications* tab of the corresponding deployment group or on the *Applications* section of the administration console:



To deploy an application from the command line by using the `deploy` command, just specify the deployment group as a **target** like this:

```
asadmin deploy --target test2 test.war
```

The same targeting also works for server resources (connection pools, mail resources, JMS resources, etc.)

Administering the Domain Data Grid

The Domain Data Grid uses Hazelcast as its clustering technology to provide an in-memory data structure that is distributed amongst all the Payara Server instances within a Payara Domain.

The Data Grid is highly available and highly scalable and enables in-memory data storage and sharing between all Payara Server instances in a domain. The Domain Data Grid is used as the backing store for web session data, Stateful Session Bean state, JCache caches, Clustered Singletons, and Single Sign On state as well as internal Payara domain data like performance metrics and traces. In addition, Persistent EJB Timers can also be configured to be stored in the grid. The Domain Data Grid also enables light-weight messaging between server instances and is the foundation of the CDI Clustered Event Bus.

The Domain Data Grid greatly simplifies traditional clustering as by default it is always on, always available and usually requires no special configuration.

The Domain Data Grid has been designed to work out of the box in a variety of network topologies and usually requires zero configuration in LAN, Amazon AWS, Google Cloud Platform and Microsoft Azure.

The following topics are addressed here:

- Domain Data Grid Benefits
- Domain Data Grid Discovery Modes
- Enabling and Disabling the Data Grid
- Domain Data Grid's Hazelcast settings
- Viewing Data Grid Members
- Data Grid Encryption

Domain Data Grid Benefits

High Availability

The Domain Data Grid achieves high availability for data storage by maintaining a replica on another Payara Server Instance of any data placed into the Domain Data Grid. This replica will be placed, as a preference, on an instance that is not running on the same host as the primary data item. If the instance holding the primary copy of a piece of data fails then the backup copy will become the primary and another instance will be selected to hold a back up of the data.

Scalability

The Domain Data Grid provides high scalability for data placed into the Data Grid. As a primary and a secondary copy of any data item placed into the grid the more instances that are added to the Payara Domain the more JVM heap is available for storage of data in the grid. The Domain Data Grid can scale to 10s and 100s of instances allowing large data sets to be stored in memory. Read and Write performance for data in the grid is not dependent on the number of Payara Server instances in the domain providing scalability to grids containing large numbers of Payara Server instances.

Elasticity

The Domain Data Grid does require configuring with a specific number of Payara Server instances. Payara Server and Payara Micro instances can be added and removed and the Data Grid will shrink

and grow as required. This meets the needs of cloud and container based architectures which can scale up or scale down the number of Payara instances handling requests.

Payara Micro Interoperability

The Domain Data Grid is designed to be interoperable with Payara Micro and Payara Micro instances can join the Data Grid and store data. Payara Micro has a specific cluster mode which can be enabled to join a Domain Data Grid.

Data Sharing and Encryption

The Domain Data Grid allows multiple Payara Server or Payara Micro instances to join and form a robust cluster of interchangeable nodes that can share and transfer data between applications. Enable encryption and data stored in-memory via the Domain Data Grid will have end-to-end encryption of the data across all instances in the domain. End-to-end encryption is encryption of data both at rest (in storage) and in transit (during communication).

Light-Weight Domain Messaging

Typically, you normally need a 'system' between the sender and receiver to transport data from one domain to another and possibly hold that data until receiver is able to process it. The Domain Data Grid is a lightweight messaging transport system, so you don't need any additional resources and installation of components to send messages within the domain.

Little to No Configuration Needed

The Domain Data Grid simplifies clustering and works out-of-the-box – it's enabled by default and little to no configuration is needed for Amazon AWS, Google Cloud, Microsoft Azure, Kubernetes, and LAN environments.

Domain Data Grid Discovery Modes

The Domain Data Grid has the concept of auto-discovery. When a Payara Server or Payara Micro instance starts it must discover other Data Grid nodes so that it can join the grid. Once an instance has connected to a Payara Instance that is already a member of the grid then it can become a member of the grid. The below are the discovery mechanisms or modes that are included by default in Payara Server.

Domain Discovery Mode

The Domain discovery mode is the default discovery mode in Payara Server. In this mode when a Payara Server instance starts it uses information encoded into the `domain.xml` describing the node IP Address and ports of the other servers in the domain and the DAS to connect to an existing member of the Data Grid. For a Payara Server instance the first server it will try to connect to is the DAS if that fails it will then try each of the other instances in turn. When the DAS starts it tries to connect to each instance in turn.

As the `domain.xml` is used to discover other members of the Data Grid no further user configuration is usually necessary.

TCP-IP Discovery Mode

The TCP-IP discovery mode is an alternative discovery mode. In this mode the user specifies a comma separated list of IP addresses and ports that a Payara Server instance should try to find members of the data grid at upon boot.

This discovery mode can be used to build a topology based on single instances of the DAS joining together to create the Data Grid. This is common in container based topologies with no central domain administration server.

Multicast Discovery Mode

The Multicast discovery mode is an alternative discovery mode. In this mode the user specifies the multicast group and multicast port used to find other members of the Data Grid. When a Payara Server instance configured with multicast discovery starts it broadcasts a message on the multicast group and port to discover other members of the data grid.

This discovery mode can be used to also build a topology based on single instances of the DAS joining together to create the data grid. In this mode multicast must be supported on the network.

This mode is the default mode for Payara Micro

Also change the Data Grid group name and password to prevent other instances on the same LAN inadvertently joining your data grid.

DNS Discovery Mode

The DNS discovery mode is an alternative discovery mode, closely related to the TCP-IP discovery mode. In this mode the user specifies a comma separated list of DNS names and ports that a Payara Server should try to find members of the data grid at upon boot.

Kubernetes Discovery Mode

The Kubernetes discovery mode is an alternative discovery mode intended for use when running in a Kubernetes environment. In this mode, the user specifies the Kubernetes service name and namespace that Payara Server should look to find other data grid members in - Payara Server will then contact the Kubernetes master upon boot to obtain the list of IP addresses of any other running instances under the specified namespace and service name.

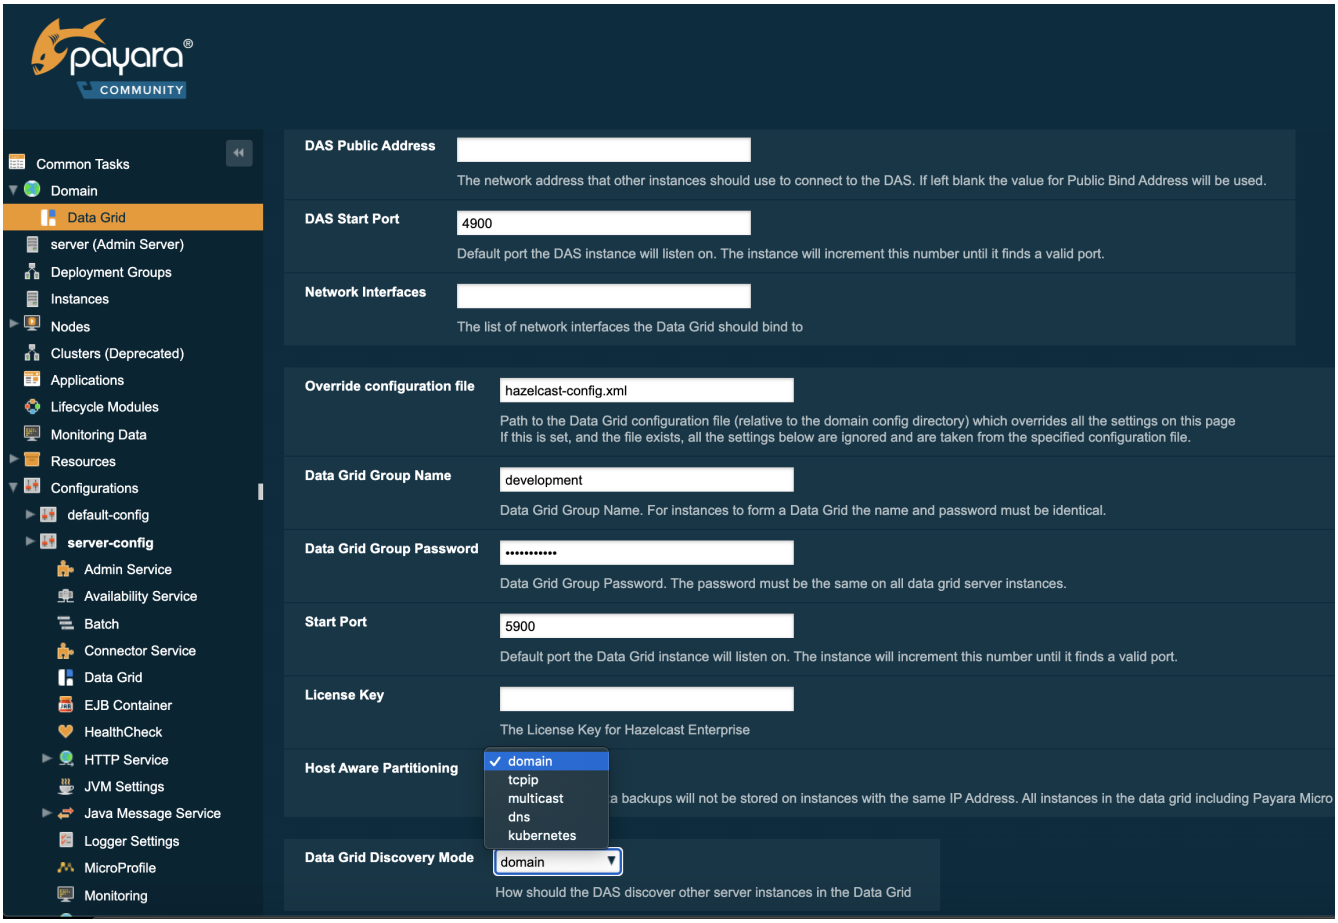
This clustering is done using the Hazelcast Kubernetes plugin, and so you will need to grant Hazelcast permission to query the Kubernetes master node. As per the plugin documentation, you will need to apply the permissions outlined below using `kubectl apply`.
The original documentation on configuring these permissions can be found here, as well as extra documentation on how to restrict these permissions further here.

```
apiVersion: rbac.authorization.k8s.io/v1
```

```
kind: ClusterRoleBinding
metadata:
  name: default-cluster
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: view
subjects:
- kind: ServiceAccount
  name: default
  namespace: default
```

Configuration Discovery Mode in Administration Console

The domain discovery mode can be configured in the administration console under the **Data Grid** menu option. The discovery mode that is set gets to be applied in a domain-wide manner.



Configuration Discovery Mode via Asadmin CLI

The discovery mode can be set via the asadmin CLI, depending on the specific mode to be selected, by running the `set-hazelcast-configuration` commands.

Set TCP-IP Mode

When setting TCP-IP mode the list of IP addresses and ports of all Data Grid members must be specified:

```
asadmin> set-hazelcast-configuration --clustermode tcpip --tcpipmembers
192.168.0.104:4900,192.168.0.105:5900
```

Set Domain Mode

```
asadmin> set-hazelcast-configuration --clustermode domain
```

Set Multicast Mode

When setting multicast mode the multicast group and multicast port must be also specified.

If these settings are not specified they will default to `224.2.2.3` and `54327`

```
asadmin> set-hazelcast-configuration --clustermode multicast --multicastgroup
224.2.2.4 --multicastport 55000
```

Set DNS Mode

When setting DNS mode the list of DNS names and ports of all Data Grid members must be specified.

```
asadmin> set-hazelcast-configuration --clustermode dns --dnsmembers
localhost:4900,www.example.com:5900
```

Set Kubernetes Mode

When setting Kubernetes mode the service name and namespace must be specified using the `--kubernetesservicename` and `--kubernetesnamespace` options respectively.

If a namespace is not specified, Payara Server will use the "default" namespace.

```
asadmin> set-hazelcast-configuration --clustermode kubernetes --kubernetesServiceName
payara --kubernetesNamespace default
```

Enabling and Disabling the Data Grid

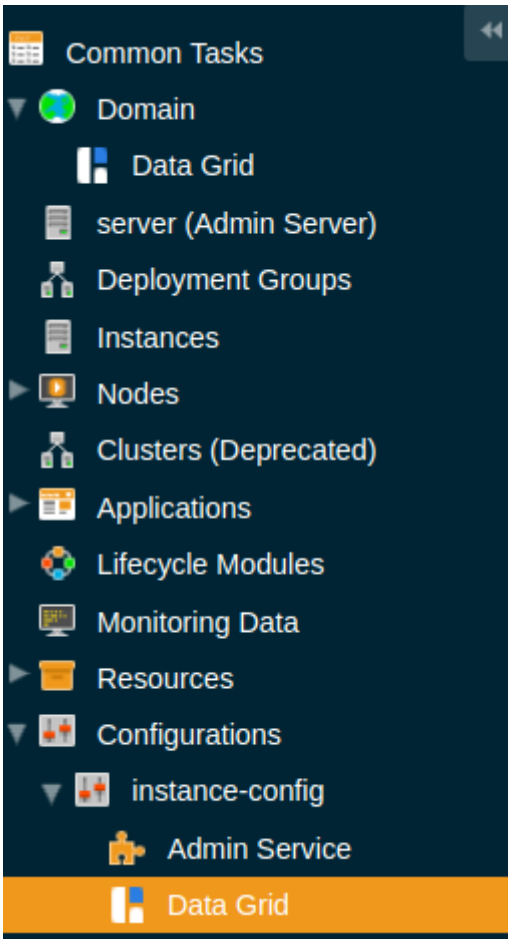
The data grid is enabled by default in Payara Server. It can be disabled and re-enabled either through the Admin Console, or by using a command line asadmin command.

If you are using macOS and have screen sharing enabled, Payara Server will fail to start due to screen sharing using port `5900`, the same as the default Hazelcast port. You can disable macOS screen sharing in Preferences → Sharing, Disable "Screen Sharing"`, or change the Hazelcast start port.

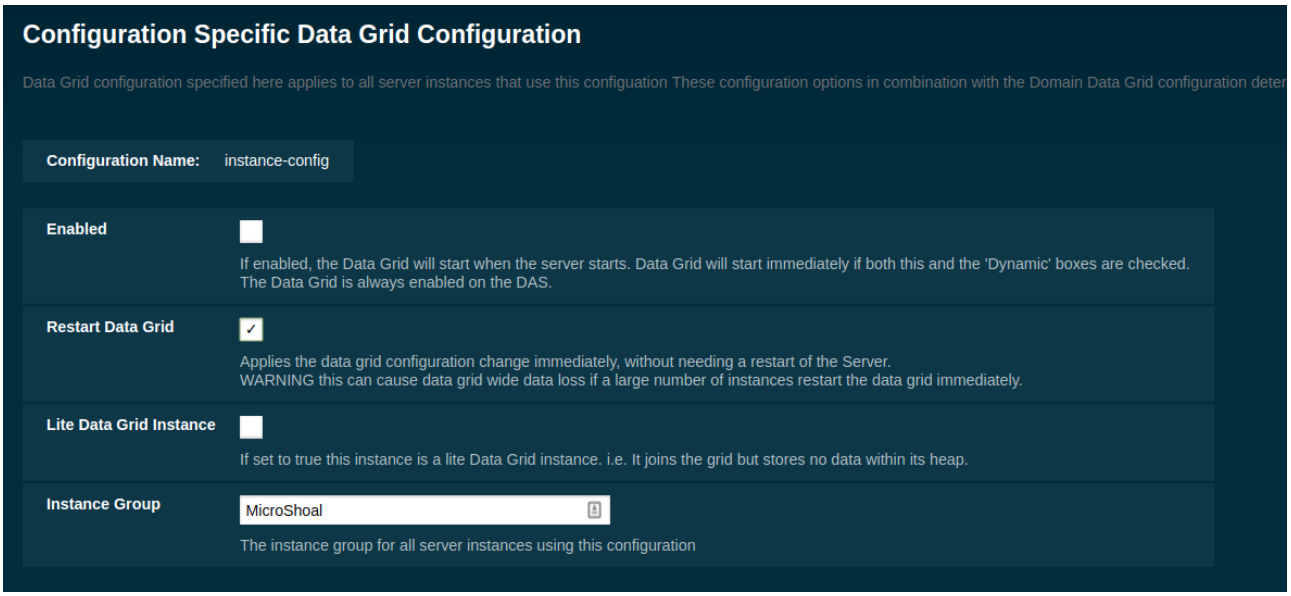
Disabling the Data Grid via the Admin Console

From the Admin Console homepage:

1. Select Data Grid under the instance's configuration from the page tree:



2. Un-check the **Enabled** option (and optionally check the **Dynamic** option to apply the configuration without the need for a restart) and save.



Disabling the Data Grid in a configuration object will disable the Data Grid for all instances using that same configuration. If this change is applied dynamically and

multiple instances are restarted, there is big risk in incurring on data loss.
If this is a problem, ensure not to select the dynamic option and restart each affected instance manually in turn.

Disabling DataGrid using Asadmin CLI

The `set-hazelcast-configuration` asadmin command can be used to enable or disable Hazelcast and therefore the Data Grid.

This command is also used to configure other aspects of Hazelcast, which is covered in this same section. The command requires the Admin Server to be running, and will expect it to be listening on port **4848** unless specified differently with the asadmin utility `--port` option.

```
asadmin> set-hazelcast-configuration --enabled=false
```

If no target is specified, the command will disable Hazelcast on the domain configuration `(server-config)` which equates to the DAS. To disable Hazelcast on another instance, configuration or cluster, use the `--target` option like so:

```
asadmin> set-hazelcast-configuration --enabled=false --target=${Target}
```

The `dynamic` option of the asadmin command defaults to true, so to enable Hazelcast and require a restart of the target instance/cluster, use `--dynamic=false`:

Same as above, dynamic restarting of multiple instances can incur in data loss, so keep this in mind.

```
asadmin> set-hazelcast-configuration --enabled=false --dynamic=false
```

Domain Data Grid's Hazelcast settings

Payara Server supports configuring Hazelcast through the Admin Console and asadmin commands. The Hazelcast configuration file can also be directly edited, but will not be covered in depth in this section.

Configuration of Hazelcast is divided into four sections. The first section applies to the whole domain, the second section applies to specific configurations and therefore to Payara Server instances that use that configuration, the third section covers how certain settings can be specified when a domain is created and the final section covers how to configure config specific Data Grid Start Port during or after the creation of an instance.

Using a Hazelcast configuration file will cause the settings set via the Admin Console and *asadmin* commands to be ignored. Any parameters not specified in the configuration file reverting to the Hazelcast defaults, even if they are specified in the Admin Console or *domain.xml*

The Hazelcast defaults settings are not necessarily the same as the Payara Server's

Hazelcast default settings).

The Payara Platform uses its own serializer instead of the default Hazelcast one. Setting a global serializer will not override it.
This is by design, implemented to avoid a bug that causes `ClassNotFoundException` issues.

The following topics are addressed here:

- Setting a custom Hazelcast Configuration File
- Configuring Server Config Specific Hazelcast Settings with the Admin Console
- Configuring Hazelcast on Domain Creation
- Configuring Config Specific Data Grid Start Port for an Instance
- Configuring the Hazelcast CP Subsystem

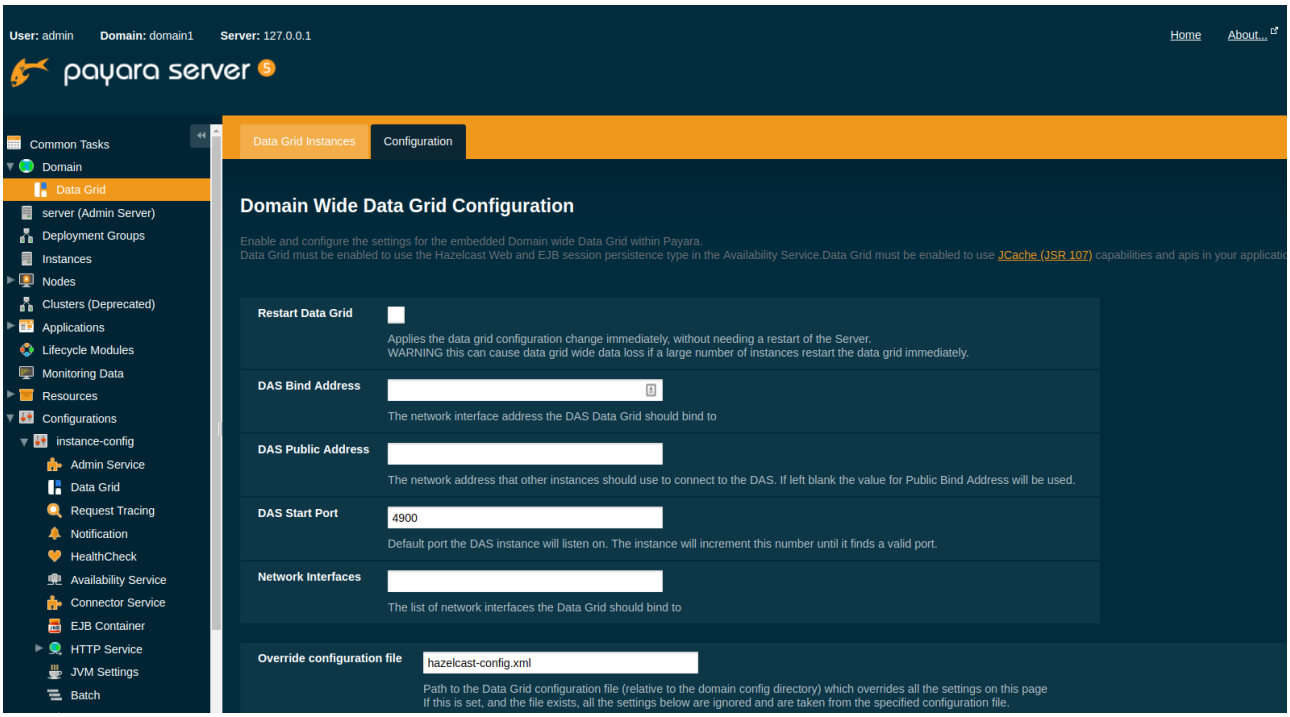
Setting a custom Hazelcast Configuration File

A custom Hazelcast configuration file can be either set using Admin Console or asadmin CLI.

Setting a Hazelcast Configuration File with the Admin Console

To set the Hazelcast configuration from a Hazelcast Configuration file:

1. Select the domain Data Grid configuration from the page tree and click the **Configuration** tab to view the *"Hazelcast Configuration"* page:
2. On the *Hazelcast Configuration* page, add the path to your Hazelcast configuration file and click "Save". This path is relative to your domain configuration directory:



Setting a Hazelcast Configuration File using asadmin

The `set-hazelcast-configuration` command can be used to set the configuration file:

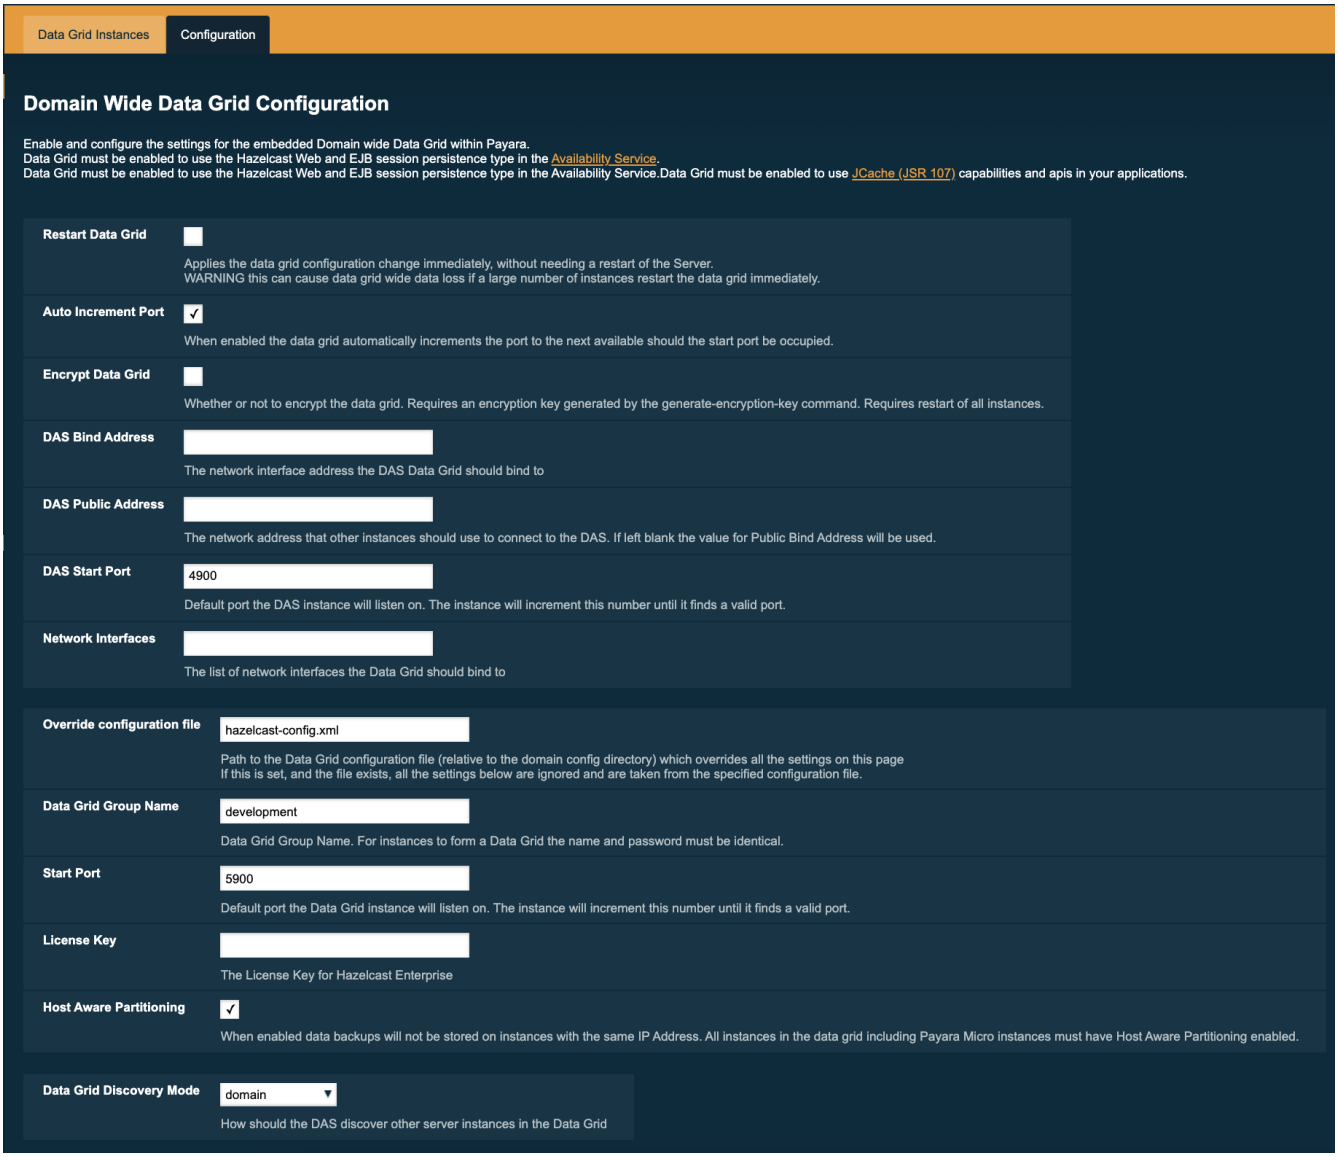
```
asadmin> set-hazelcast-configuration --hazelcastconfigurationfile /path/to/file
```

Payara Server currently supports a custom configuration file in either XML or YAML format.

As with the admin console, this path is relative to your domain configuration directory.

Configuring Domain Wide Hazelcast Settings with the Admin Console

Some Hazelcast configuration settings apply to the whole domain. Navigate to the *Data Grid* page for the domain wide settings:



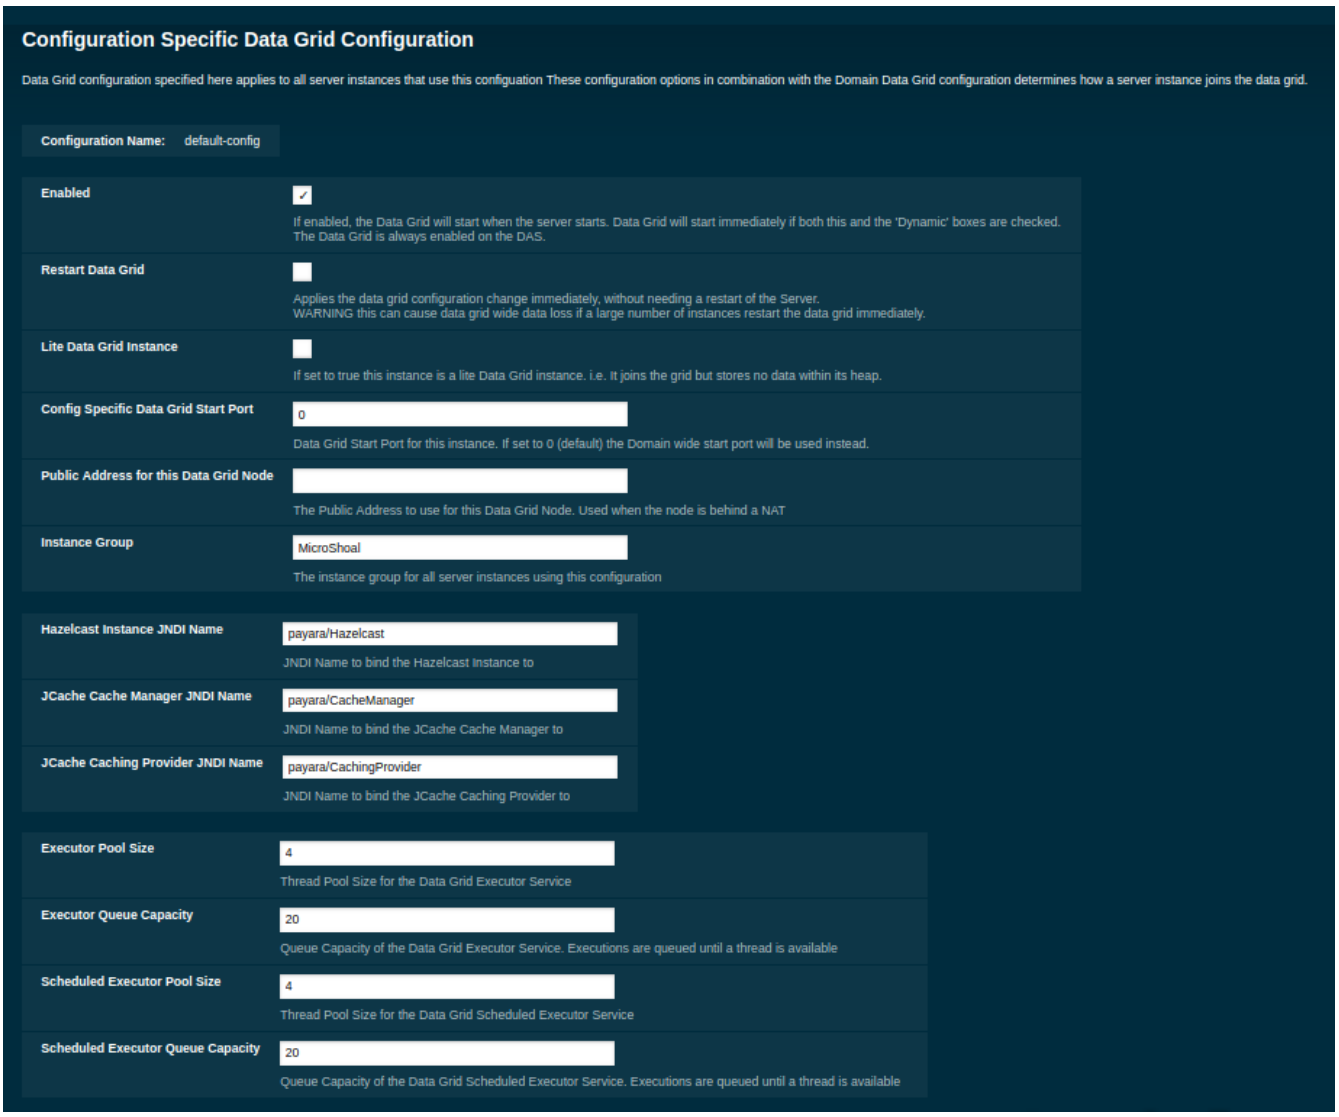
The following configuration options are available here:

Property	Description
Restart Data Grid	Determines if the Hazelcast member embedded in Payara will be restarted to apply any changes made
DAS Bind Address	Explicitly specifies the IP Address the DAS should bind the Hazelcast instance to. By default, Hazelcast will try to choose the correct bind address from the IP addresses available on the host. If you find the DAS is binding to an incorrect IP Address the correct address can be specified here.
DAS Public Address	This is the public IP Address that the DAS should use if the DAS is behind a NAT firewall and other Payara Server Instances need to connect via the public NAT address rather than the internal IP Address
Auto Increment Port	By default, the cluster uses the next unoccupied port that is available starting with the start port. When auto-increment is turned off an occupied start port results in a startup failure instead.
DAS Start Port	The port the DAS uses to run Hazelcast on. If this port is busy, the port specified will be incremented until a valid port is found.
Network Interfaces	Similar to DAS Bind address by default Hazelcast will choose the correct IP Address to bind to. If you find Hazelcast is binding to the incorrect address a comma separated list of IP Addresses can be specified here.
Override Configuration File	Specifies the Hazelcast configuration file to use. The path specified is relative to the domain *config* directory. If you are using a custom configuration for a cluster or standalone instance (e.g. *cluster-config*), then the Hazelcast configuration file should be placed in the directory with the same name (e.g. `<domain-root>/config/cluster-config`). This will ensure it is replicated to the node during startup. Using this option to point to a valid Hazelcast configuration file will cause all other options set to be ignored. Any options unset within the Hazelcast configuration file will be set to the Hazelcast defaults.
Data Grid Group Name	Specifies the Hazelcast group name, to be optionally used to help divide clusters into logical, segregated groups (i.e. *dev-group*, *prod-group*).
Start Port	The port the other Payara Server instances use to run Hazelcast on. If this port is busy, the port specified will be incremented until a valid port is found.
License Key	Enables Hazelcast Enterprise features.

Property	Description
Host Aware Partitioning	Whether to enable host-aware partitioning for the cluster. Host aware partitioning **must be** enabled on all members of the cluster (including Payara Micro instances) for this feature to work correctly. This is default in Payara Server 5.181 onwards for both Payara Server domains and Payara Micro instances.
Data Grid Discovery Mode	See Discovery Modes

Configuring Server Config Specific Hazelcast Settings with the Admin Console

Navigate to the *Data Grid* page for the specific configuration.



The following configuration options are available here:

Property	Description
Enabled	See Disabling Data Grid for detailed information

Property	Description
Restart Data Grid	Determines if the Hazelcast member embedded in Payara will be restarted to apply any changes made
Lite Data Grid Instance	If set to true, cluster members with this configuration will be Hazelcast "lite" nodes, meaning they will not store any cache data locally and rely on other cluster members to store data.
Config Specific Data Grid Start Port	Sets Data Grid Start Port to the instance. If set to 0 (default) the Domain wide start port will be used instead.
Public Address for this Data Grid Node	The Public Address to use for this Data Grid Node. Used when the node is behind a NAT
Instance Group	Instance group name for all Server Instances using the configuration. Future functionality may use this name.
Hazelcast Instance JNDI Name	The JNDI name to bind the Hazelcast instance to.
JCache Manager JNDI Name	The JNDI name to bind the JCache Cache Manager to.
JCache Caching Provider JNDI Name	The JNDI name to bind the JCache Caching Provider to.
Executor Pool Size	The thread pool's size for the Hazelcast Executor service
Executor Queue Capacity	Queue Capacity of the Data Grid Executor Service. Executions are queued until a thread is available
Scheduled Executor Pool Size	The thread pool's size for the Hazelcast Scheduled Executor service
Scheduled Executor Queue Capacity	Queue Capacity of the Data Grid Scheduled Executor Service. Executions are queued until a thread is available

Enter your required values, and click *Save*. Restarting the domain or instance/cluster is not necessary for any changes made to take effect, provided that *"Dynamic"* remains set to `true`

Configuring Hazelcast on Domain Creation

The following options can be used with the `create-domain` command to specify certain Hazelcast settings when a domain is created. An example of create-domain command with Hazelcast specific options:

```
asadmin> create-domain --hazelcastdasport 7900 --hazelcaststartport 8900
```

```
--hazelcastautoincrement true testDomain
```

Configuring Config Specific Data Grid Start Port for an Instance

It is possible to configure the port used by Hazelcast to bind the corresponding instance to the Data Grid by letting users set its value during or after the creation of an instance.

Configuring Config Specific Data Grid Start Port on Instance Creation

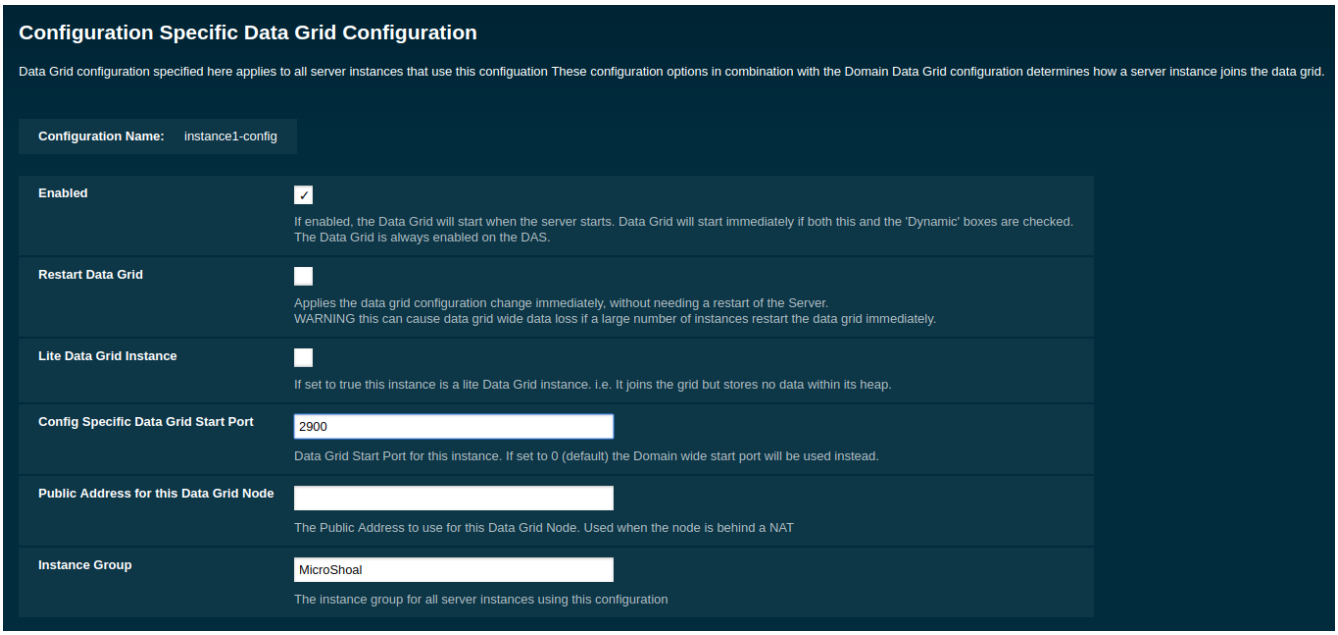
The `--dataGridStartPort` option can be used with the `create-instance` or the `create-local-instance` commands to specify config Specific Data Grid Start Port when an instance is created.

Configuring Data Grid Start Port After Instance Creation

You can configure the start port used by an instance after its creation by either using the Admin Console or the asadmin CLI.

Setting Data Grid Start Port with the Admin Console

1. Select the Configuration from the page tree, click on the relevant instance and finally click on the Data Grid.
2. On the Configuration Specific Data Grid Configuration, set the **Data Grid Start Port** and click **Save**.



Setting Data Grid Start Port using asadmin CLI

The `set-hazelcast-configuration` command can be used to set the Data Grid start port:

```
asadmin> set-hazelcast-configuration --dynamic=true
--configSpecificDataGridStartPort=2900 --target=instance1-config
```

Configuring the Hazelcast CP Subsystem

The CP Subsystem is a component of a Hazelcast cluster that builds a strongly consistent layer for a set of distributed data structures. The CP Subsystem withstands server and client failures and offer special features to Payara Server applications.

You can read more about the CP subsystem in the official Hazelcast Platform documentation.

To enable the CP subsystem, you will have to configure the `hazelcast.cp-subsystem.cp-member-count` system property to a value greater than zero (read the recommendations in the Hazelcast Platform documentation to pick a suitable member count). Hazelcast recommends that a minimum of `3` members need to be configured for the CP subsystem to work as intended.

Additionally, the `hazelcast.cp-subsystem.auto-promote` Payara Platform system property can be used to configure an auto-promote behaviour that will allow other server instances to join the CP subsystem when detected by the DAS.

The CP subsystem is not actively tested as a recommended feature of Payara Server and should be used with extreme caution on highly dynamic environments.

Viewing Data Grid Members

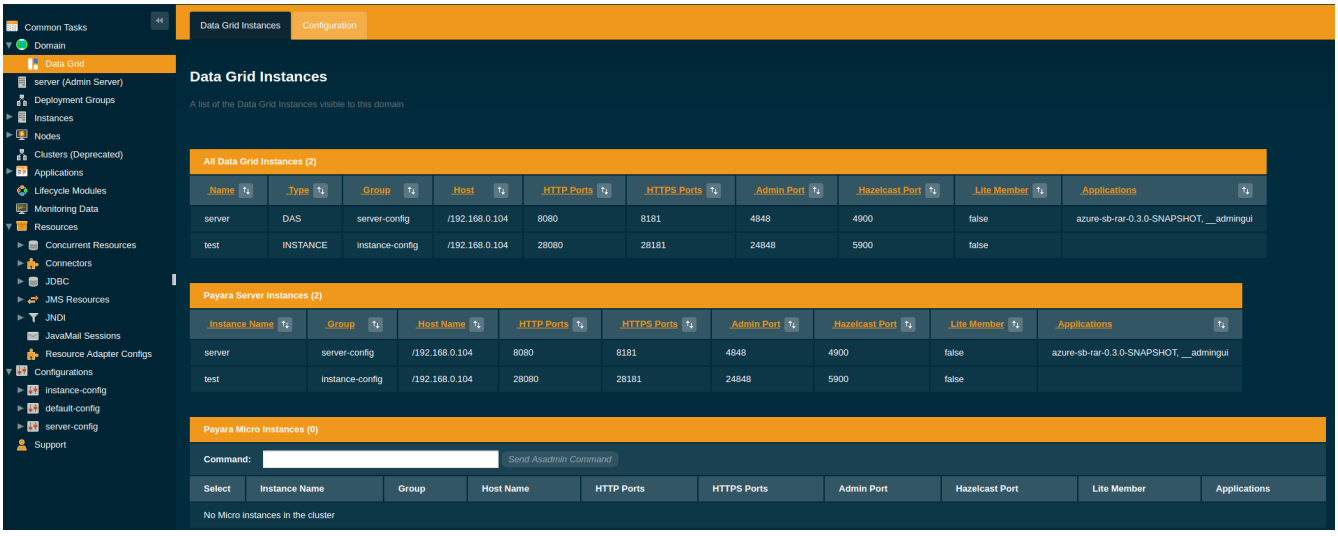
This section details how to visualize the members of the Domain Data Grid in Payara Server.

Viewing Data Grid Members from the Admin Console

To view data grid members from the admin console:

Viewing from the DAS

Selected the **Data Grid** menu option from the domain menu in the sidebar and select the *Data Grid Instances* tab:



Viewing Cluster Members via asadmin

To view the current cluster members from the command line, run either the `list-hazelcast-members` or the `list-hazelcast-cluster-members` asadmin commands:

```
asadmin> list-hazelcast-members
\{ server-MicroShoal-/192.168.1.148:4900-this \}
```

```
asadmin> list-hazelcast-cluster-members

Instance Name  Instance Group  Instance Type  Host Name  HTTP Ports  HTTPS Ports
Admin Port  Hazelcast Port  Lite Member  Deployed Applications  Last Hearbeat
server         server-config   DAS            127.0.1.1  8080        8181         4848
5900            false        __admingui             2019-03-05 09:25:42
```

The **Last Heartbeat** attribute will display the date and time that the DAS last received a heartbeat pulse from a Payara Server or Payara Micro instance. This heartbeat should refresh every 5 seconds.

Data Grid Encryption

Encryption of the data stored within the data grid of Hazelcast has previously required a **Hazelcast Enterprise** subscription. While this remains an option for those who would like the additional features it provides (such as WAN replication), Payara Server now includes its own encryption implementation that provides this feature to you without an additional subscription.

The following topics are addressed here:

- Encryption Mechanism
- Encryption Targets
- Setup
- Generating an Encryption Key
- Enabling Encryption in Hazelcast
- Web Session Availability Configuration
- Stateful Session Bean Configuration
- Request Tracing Configuration
- HealthCheck Configuration

Encryption Mechanism

This feature provides encryption of the data that's being stored in-memory via the Hazelcast data grid, providing end-to-end encryption of the data across all instances in the domain. End-to-end encryption is encryption of data both at rest (in storage) and in transit (during communication).

Payara Server uses a symmetric key to perform the encryption of the data within the data grid store. This means that the same key is used by each member of the data grid to encrypt and decrypt the data.

This key is generated and protected using the master password and a key derivation function. The

key itself is a 256-bit AES key, utilising an initialisation vector and a salt for each call of encryption to help prevent any statistical pattern recognition.

Encryption Targets

The following data stores are encrypted:

- Web Session Persistence
- Stateful Session Bean Persistence
- Request Traces
- Historic Health Checks

Setup

This section details the necessary steps to set up and enable encryption of the data grid and the various data stores.

Documentation around configuration of the data sources for encryption assumes that you've already generated the encryption key and enabled encryption of the data grid.

Generating an Encryption Key

The key to be used by Payara Server to perform the actual encryption and decryption of data can be generated using the generate-encryption-key asadmin command:

```
asadmin> generate-encryption-key
```

This command generates a key using the master password – the same one used to access the key store used by Payara Server. Similar to the `change-master-password` command, this command requires you to shut down the DAS first.

This command should only be run on the DAS since this is the *master* instance, and will be the instance propagating the key out to other instances in the domain.

The default value for the master password is `changeit`. You can also provide the master password via a password file like so:

```
asadmin> -W /path/to/passwordfile.txt generate-encryption-key
```

That will generate a new file with the following contents:

```
AS_ADMIN_MASTERPASSWORD=changeit
```

If you change the master password after generating your key, you'll need to regenerate and propagate the new key to each of your instances since the original

key was created using the old (and now incorrect) password. This should occur under the default `--sync normal`, but `--sync full` can be used to delete the local copy and resynchronize it.

Enabling Encryption in Hazelcast

Enabling encryption of the data grid itself is controlled by the `set-hazelcast-configuration` asadmin command, with the `--encryptdatagrid` parameter:

```
asadmin> set-hazelcast-configuration --encryptdatagrid true
```

This is a domain-wide setting, and thus means that hybrid setups where encryption is enabled only on specific clusters within a domain is not supported.

Once you've generated your key and enabled encryption, you must restart all instances in the domain if they were still running; changes in encryption settings do not take effect until a server is restarted.
It is **highly** recommended that you restart all of your running instances as quickly as possible, since those that haven't been restarted will be unable to decrypt the encrypted data placed in the data grid store by those that have been.

Web Session Availability Configuration

Encrypting web session availability data requires no extra actions on top of configuring the Web Container Availability Persistence Type to *hazelcast* (which it is by default).

```
asadmin> set configs.config.server-config.availability-service.web-container-
availability.persistence-type=hazelcast
```

Stateful Session Bean Configuration

Encrypting Stateful Session Beans (SFSB) availability data requires no extra actions on top of configuring the EJB Container Availability HA and/or SFSB Persistence Type to `hazelcast`:

```
asadmin> set configs.config.server-config.availability-service.ejb-container-
availability.sfsb-ha-persistence-type=hazelcast
asadmin> set configs.config.server-config.availability-service.ejb-container-
availability.sfsb-persistence-type=hazelcast
```

Request Tracing Configuration

No additional actions necessary.

HealthCheck Configuration

No additional actions necessary.

The Hazelcast PhoneHome Service

In a similar manner to the server's Phone Home service, Hazelcast Community Edition also comes with an internal service that makes all instances that belong to the DataGrid send phone data regularly.

As with the Platform's phone home service, if you want to disable Hazelcast Phone Home service, it can be done via either the `HZ_PHONE_HOME_ENABLED` environment variable (set it to `false`) or by using the `hazelcast.phone.home.enabled` system property:

```
asadmin create-jvm-options --target server-config "-
Dhazelcast.phone.home.enabled=false"
```

Administering Payara Server Instances

A Payara Server instance is a single Virtual Machine for the Java platform (Java Virtual Machine or JVM machine) on a single node in which Payara Server is running. A node defines the host where the Payara Server instance resides.

The JVM machine must be compatible with the server's matching Jakarta Platform, Enterprise Edition (Jakarta EE) version.

Payara Server instances form the basis of an application deployment. An instance is a building block in the clustering, load balancing, and session persistence features of Payara Server. Each instance belongs to a single domain and has its own directory structure, configuration, and deployed applications. Every instance contains a reference to a node that defines the host where

the instance resides.

Types of Payara Server Instances

Each Payara Server instance is one of the following types of instance:

Standalone Instance

A standalone instance does not share its configuration with any other instances or clusters. A standalone instance is created if either of the following conditions is met:

- No configuration or cluster is specified in the command to create the instance.
- A configuration that is not referenced by any other instances or clusters is specified in the command to create the instance.

  When no configuration or cluster is specified, a copy of the `default-config` configuration is created for the instance.

  The name of this configuration is `instance-name-config`, where instance-name represents the name of an un-clustered server instance.

Shared instance

A shared instance shares its configuration with other instances or clusters. A shared instance is created if a configuration that is referenced by other instances or clusters is specified in the command to create the instance.

Clustered instance

A clustered instance inherits its configuration from the cluster to which the instance belongs and shares its configuration with other instances in the cluster.

A clustered instance is created if a cluster is specified in the command to create the instance.

Any instance that is not part of a cluster is considered an un-clustered server instance. Therefore, standalone instances and shared instances are un-clustered server instances.

Docker instance

A Docker instance denotes an instance that is running within a Docker container and offers flexibility, portability, and scalability for deploying Payara Server applications in containerized environments.

Administering Payara Server Instances Centrally

Centralized administration requires a secure shell (SSH) to be set up. If SSH is set up, you can administer clustered instances without the need to log in to hosts where remote instances reside.

For information about setting up SSH, see Enabling Centralized Administration of Payara Server Instances.

Administering Payara Server instances centrally involves the following tasks:

To Create an Instance Centrally

Use the `create-instance` subcommand in remote mode to create a Payara Server instance centrally. Creating an instance adds the instance to the DAS configuration and creates the instance's files on the host where the instance resides.

- If the instance is a clustered instance that is managed by GMS, system properties for the instance that relate to GMS must be configured correctly.
- To avoid the need to restart the DAS and the instance, configure an instance's system properties that relate to GMS when you create the instance.
- If you change GMS-related system properties for an existing instance, the DAS and the instance must be restarted to apply the changes.

Before you begin, ensure that following prerequisites are met:

- The node where the instance is to reside exists.
- The node where the instance is to reside is either enabled for remote communication or represents the host on which the DAS is running.

For information about how to create a node that is enabled for remote communication, see the following sections:

- To Create an SSH Node
  - The user of the DAS can use SSH to log in to the host for the node where the instance is to reside.

If any of these prerequisites is not met, create the instance locally as explained in To Create an Instance Locally.

If you are adding the instance to a cluster, ensure that the cluster to which you are adding the instance exists. For information about how to create a cluster, see To Create a Cluster.

If the instance is to reference an existing named configuration, ensure that the configuration exists. For more information, see To Create a Named Configuration.

The instance might be a clustered instance that is managed by GMS and resides on a node that represents a multi-home host.

In this situation, ensure that you have the Internet Protocol (IP) address of the network interface to which GMS binds.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `create-instance` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for configuring the instance, see the `create-instance` help page.

- If you are creating a standalone instance, do not specify a cluster.

If the instance is to reference an existing configuration, specify a configuration that no other cluster or instance references.

```
asadmin> create-instance --node node-name [--config configuration-name] instance-
name
```

node-name

The node on which the instance is to reside.

configuration-name

The name of the existing named configuration that the instance will reference.

If you do not require the instance to reference an existing configuration, omit this option. A copy of the `default-config` configuration is created for the instance. The name of this configuration is instance-name`-config`, where instance-name is the name of the server instance.

instance-name

Your choice of name for the instance that you are creating.

- If you are creating a shared instance, specify the configuration that the instance will share with other clusters or instances.

```
asadmin> create-instance --node node-name --config configuration-name instance-name
```

node-name

The node on which the instance is to reside.

configuration-name

The name of the existing named configuration that the instance will reference.

instance-name

Your choice of name for the instance that you are creating.

- If you are creating a clustered instance, specify the cluster to which the instance will belong.

If the instance is managed by GMS and resides on a node that represents a multi-home host, specify the `GMS-BIND-INTERFACE-ADDRESS-`cluster-name system property.

```
asadmin> create-instance --cluster cluster-name --node node-name [--
systemproperties GMS-BIND-INTERFACE-ADDRESS-cluster-name=bind-address]instance-name
```

cluster-name

The name of the cluster to which you are adding the instance.

node-name

The node on which the instance is to reside.

bind-address

The IP address of the network interface to which GMS binds. Specify this option only if the instance is managed by GMS and resides on a node that represents a multi-home host.

instance-name

Your choice of name for the instance that you are creating.

The following example adds the instance `pmd-i1` to the cluster `pmdclust` in the domain `domain1`. The instance resides on the node `sj01`, which represents the host `sj01.example.com`.

```
asadmin> create-instance --cluster pmdclust --node sj01 pmd-i1
Port Assignments for server instance pmd-i1:
JMX_SYSTEM_CONNECTOR_PORT=28686
JMS_PROVIDER_PORT=27676
HTTP_LISTENER_PORT=28080
ASADMIN_LISTENER_PORT=24848
IIOP_SSL_LISTENER_PORT=23820
IIOP_LISTENER_PORT=23700
HTTP_SSL_LISTENER_PORT=28181
IIOP_SSL_MUTUALAUTH_PORT=23920
The instance, pmd-i1, was created on host sj01.example.com
Command create-instance executed successfully.
```

See Also

- To Create an SSH Node
- To Create an Instance Locally
- `create-instance`

You can also view the full syntax and options of the subcommand by typing `asadmin help create-instance` at the command line.

To List All Instances in a Domain

Use the `list-instances` subcommand in remote mode to obtain information about existing instances in a domain.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `list-instances` subcommand.

```
asadmin> list-instances
```

The following example lists the name and status of all Payara Server instances in the current domain.

```
asadmin> list-instances
pmd-i2 running
yml-i2 running
pmd-i1 running
yml-i1 running
pmdsa1 not running
Command list-instances executed successfully.
```

The following example lists detailed information about all Payara Server instances in the current domain:

```
asadmin> list-instances --long=true
NAME    HOST              PORT   PID    CLUSTER     STATE
pmd-i1  sj01.example.com  24848  31310  pmdcluster   running
yml-i1  sj01.example.com  24849  25355  ymlcluster   running
pmdsa1  localhost         24848  -1     ---          not running
pmd-i2  sj02.example.com  24848  22498  pmdcluster   running
yml-i2  sj02.example.com  24849  20476  ymlcluster   running
ymlsa1  localhost         24849  -1     ---          not running
Command list-instances executed successfully.
```

See Also

`list-instances`

You can also view the full syntax and options of the subcommand by typing `asadmin help list-instances` at the command line.

To Delete an Instance Centrally

Use the `delete-instance` subcommand in remote mode to delete a Payara Server instance centrally.

If you are using a Java Message Service (JMS) cluster with a master broker, do not delete the instance that is associated with the master broker.
If this instance must be deleted, use the `change-master-broker` subcommand first to assign the master broker to a different instance.

Deleting an instance involves the following:

- Removing the instance from the configuration of the DAS
- Deleting the instance's files from file system

Ensure that the instance that you are deleting is not running. For information about how to stop an instance, see the following sections:

- To Stop an Individual Instance Centrally
- To Stop an Individual Instance Locally

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Confirm that the instance is not running.

   ```
   asadmin> list-instances instance-name
   ```

   instance-name

   The name of the instance that you are deleting.

3. Run the `delete-instance` subcommand.

   ```
   asadmin> delete-instance instance-name
   ```

   instance-name

   The name of the instance that you are deleting.

The following example confirms that the instance `pmd-i1` is not running and deletes the instance.

```
asadmin> list-instances pmd-i1
pmd-i1   not running
Command list-instances executed successfully.
asadmin> delete-instance pmd-i1
Command _delete-instance-filesystem executed successfully.
The instance, pmd-i1, was deleted from host sj01.example.com
Command delete-instance executed successfully.
```

See Also

- To Stop an Individual Instance Centrally
- To Stop an Individual Instance Locally
- `change-master-broker`(1)
- `delete-instance`
- `list-instances`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help delete-instance`
- `asadmin help list-instances`

To Start a Cluster

Use the `start-cluster` subcommand in remote mode to start a cluster. Starting a cluster starts all instances in the cluster that are not already running.

Ensure that following prerequisites are met:

- Each node where an instance in the cluster resides is either enabled for remote communication or represents the host on which the DAS is running.
- The operating system user that runs the DAS can use SSH to log in to the host for any node where instances in the cluster reside.

If any of these prerequisites is not met, start the cluster by starting each instance locally as explained in To Start an Individual Instance Locally.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `start-cluster` subcommand.

```
asadmin> start-cluster cluster-name
```

cluster-name

The name of the cluster that you are starting.

The following example starts the cluster `pmdcluster`.

```
asadmin> start-cluster pmdcluster
Command start-cluster executed successfully.
```

See Also

- To Start an Individual Instance Locally
- `start-cluster`

You can also view the full syntax and options of the subcommand by typing `asadmin help start-cluster` at the command line.

To Stop a Cluster

Use the `stop-cluster` subcommand in remote mode to stop a cluster.

Stopping a cluster stops all running instances in the cluster.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `stop-cluster` subcommand.

```
asadmin> stop-cluster cluster-name
```

cluster-name

The name of the cluster that you are stopping.

The following example stops the cluster `pmdcluster`.

```
asadmin> stop-cluster pmdcluster
Command stop-cluster executed successfully.
```

See Also

`stop-cluster`

You can also view the full syntax and options of the subcommand by typing `asadmin help stop-cluster` at the command line.

Troubleshooting

If instances in the cluster have become unresponsive and fail to stop, run the subcommand again with the `--kill` option set to `true`. When this option is `true`, the subcommand uses functionality of the operating system to kill the process for each running instance in the cluster.

To Start an Individual Instance Centrally

Use the `start-instance` subcommand in remote mode to start an individual instance centrally.

Ensure that following prerequisites are met:

- The node where the instance resides is either enabled for remote communication or represents the host on which the DAS is running.
- The operating system user that runs the DAS can use SSH to log in to the host for any node where the instance resides.

If any of these prerequisites is not met, start the instance locally as explained in To Start an Individual Instance Locally.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `start-instance` subcommand.

   ```
   asadmin> start-instance instance-name
   ```

Only the options that are required to complete this task are provided in this step. For information about all the options for controlling the behavior of the instance, see the `start-instance` help page.

instance-name

The name of the instance that you are starting.

The following example starts the instance `pmd-i2`, which resides on the node `sj02`. This node represents the host `sj02.example.com`.

The configuration of the instance on this node already matched the configuration of the instance in the DAS when the instance was started.

```
asadmin> start-instance pmd-i2
CLI801 Instance is already synchronized
Waiting for pmd-i2 to start .............
Successfully started the instance: pmd-i2
instance Location: /export/payara7/glassfish/nodes/sj02/pmd-i2
Log File: /export/payara7/glassfish/nodes/sj02/pmd-i2/logs/server.log
Admin Port: 24851
Command start-local-instance executed successfully.
The instance, pmd-i2, was started on host sj02.example.com
Command start-instance executed successfully.
```

See Also

`start-instance`

You can also view the full syntax and options of the subcommand by typing `asadmin help start-instance` at the command line.

To Stop an Individual Instance Centrally

Use the `stop-instance` subcommand in remote mode to stop an individual instance centrally.

When an instance is stopped, the instance stops accepting new requests and waits for all outstanding requests to be completed.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `stop-instance` subcommand.

The following example stops the instance `pmd-i2`.

```
asadmin> stop-instance pmd-i2
The instance, pmd-i2, is stopped.
Command stop-instance executed successfully.
```

See Also

`stop-instance`

You can also view the full syntax and options of the subcommand by typing `asadmin help stop-instance` at the command line.

Troubleshooting

If the instance has become unresponsive and fails to stop, run the subcommand again with the `--kill` option set to `true`. When this option is `true`, the subcommand uses functionality of the operating system to kill the instance process.

To Restart an Individual Instance Centrally

Use the `restart-instance` subcommand in remote mode to start an individual instance centrally.

When this subcommand restarts an instance, the DAS synchronizes the instance with changes since the last synchronization as described in Default Synchronization for Files and Directories.

If you require different synchronization behavior, stop and start the instance as explained in To Resynchronize an Instance and the DAS Online.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `restart-instance` subcommand.

```
asadmin> restart-instance instance-name
```

instance-name

The name of the instance that you are restarting.

The following example restarts the instance `pmd-i2`.

```
asadmin> restart-instance pmd-i2
pmd-i2 was restarted.
Command restart-instance executed successfully.
```

See Also

- To Stop an Individual Instance Centrally
- To Start an Individual Instance Centrally
- `restart-instance`(1)

You can also view the full syntax and options of the subcommand by typing `asadmin help restart-instance` at the command line.

Troubleshooting

If the instance has become unresponsive and fails to stop, run the subcommand again with the `--kill` option set to `true`. When this option is `true`, the subcommand uses functionality of the operating system to kill the instance process before restarting the instance.

Administering Payara Server Instances Locally

Local administration does not require SSH to be set up. If SSH is set up, you must log in to each host where remote instances reside and administer the instances individually.

Even SSH is set up, you can obtain information about instances in a domain without logging in to each host where remote instances reside. For instructions, see To List All Instances in a Domain.

To Create an Instance Locally

Use the `create-local-instance` subcommand in remote mode to create a Payara Server instance locally. Creating an instance adds the instance to the DAS configuration and creates the instance's files on the host where the instance resides.

If the instance is a clustered instance, system properties for the instance that relate to GMS must be configured correctly.
If you change GMS-related system properties for an existing instance, the DAS and the instance must be restarted to apply the changes. For information about GMS, see Group Management Service.

Before You Begin

If you plan to specify the node on which the instance is to reside, ensure that the node exists.

If you create the instance on a host for which no nodes are defined, you can create the instance without creating a node beforehand. In this situation, Payara Server creates a `CONFIG` node for you. The name of the node is the unqualified name of the host.

For information about how to create a node, see the following sections:

- To Create an `SSH` Node
- To Create a `CONFIG` Node
- To Create a `DOCKER` Node

If the instance is to reference an existing named configuration, ensure that the configuration exists. For more information, see To Create a Named Configuration.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Log in to the host that is represented by the node where the instance is to reside.
3. Run the `create-local-instance` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for configuring the instance, see the `create-local-instance` help page.

   - If you are creating a standalone instance, do not specify a cluster name.

     If the instance is to reference an existing configuration, specify a configuration that no other cluster or instance references.

```
asadmin --host das-host [--port admin-port] create-local-instance [--node node-
name] [--config configuration-name] instance-name
```

das-host

The name of the host where the DAS is running.

admin-port

The HTTP or HTTPS port on which the DAS listens for administration requests. If the DAS listens on the default port for administration requests, you may omit this option.

node-name

The node on which the instance is to reside.

If you are creating the instance on a host for which fewer than two nodes are defined, you may omit this option.

If no nodes are defined for the host, Payara Server creates a CONFIG node for you. The name of the node is the unqualified name of the host.

If one node is defined for the host, the instance is created on that node.

configuration-name

The name of the existing named configuration that the instance will reference.

If you do not require the instance to reference an existing configuration, omit this option.

A copy of the `default-config` configuration is created for the instance. The name of this configuration is `<instance-name>-config`, where instance-name is the name of the server instance.

instance-name

Your choice of name for the instance that you are creating.

- If you are creating a shared instance, specify the configuration that the instance will share with other clusters or instances.

```
asadmin --host das-host [--port admin-port] create-local-instance [--node node-
name] --config configuration-name instance-name
```

das-host

The name of the host where the DAS is running.

admin-port

The HTTP or HTTPS port on which the DAS listens for administration requests. If the DAS listens on the default port for administration requests, you may omit this option.

node-name

The node on which the instance is to reside.

If you are creating the instance on a host for which fewer than two nodes are defined, you may omit this option.

If no nodes are defined for the host, Payara Server creates a `CONFIG` node for you. The name of the node is the unqualified name of the host.

If one node is defined for the host, the instance is created on that node.

configuration-name

The name of the existing named configuration that the instance will reference.

instance-name

Your choice of name for the instance that you are creating.

- If you are creating a clustered instance, specify the cluster to which the instance will belong.

If the instance is managed by GMS and resides on a node that represents a multi-home host, specify the `GMS-BIND-INTERFACE-ADDRESS-`cluster-name system property.

```
$ asadmin --host das-host [--port admin-port] create-local-instance --cluster
cluster-name [--node node-name] [--systemproperties GMS-BIND-INTERFACE-ADDRESS-
cluster-name=bind-address] instance-name
```

das-host

The name of the host where the DAS is running.

admin-port

The HTTP or HTTPS port on which the DAS listens for administration requests.

If the DAS listens on the default port for administration requests, you may omit this option.

cluster-name

The name of the cluster to which you are adding the instance.

node-name

The node on which the instance is to reside.

If you are creating the instance on a host for which fewer than two nodes are defined, you may omit this option.

If no nodes are defined for the host, Payara Server creates a `CONFIG` node for you. The name of the node is the unqualified name of the host.

If one node is defined for the host, the instance is created on that node.

bind-address

The IP address of the network interface to which GMS binds. Specify this option only if the instance is managed by GMS and resides on a node that represents a multi-home host.

instance-name

Your choice of name for the instance that you are creating.

This example adds the instance `kui-i1` to the cluster `kuicluster` locally. The `CONFIG` node `xk01` is created automatically to represent the host `xk01.example.com`, on which this example is run.

The DAS is running on the host `dashost.example.com` and listens for administration requests on the default port.

The commands to list the nodes in the domain are included in this example only to demonstrate the creation of the node `xk01`. These commands are not required to create the instance:

```
> asadmin --host dashost.example.com list-nodes --long

NODE NAME          TYPE    NODE HOST         INSTALL DIRECTORY   REFERENCED BY
localhost-domain1  CONFIG  localhost         /export/payara7
Command list-nodes executed successfully.

> asadmin --host dashost.example.com
create-local-instance --cluster kuicluster kui-i1
Rendezvoused with DAS on dashost.example.com:4848.
Port Assignments for server instance kui-i1:
JMX_SYSTEM_CONNECTOR_PORT=28687
JMS_PROVIDER_PORT=27677
HTTP_LISTENER_PORT=28081
ASADMIN_LISTENER_PORT=24849
JAVA_DEBUGGER_PORT=29009
IIOP_SSL_LISTENER_PORT=23820
IIOP_LISTENER_PORT=23700
OSGI_SHELL_TELNET_PORT=26666
HTTP_SSL_LISTENER_PORT=28182
IIOP_SSL_MUTUALAUTH_PORT=23920
Command create-local-instance executed successfully.

> asadmin --host dashost.example.com list-nodes --long
NODE NAME          TYPE    NODE HOST         INSTALL DIRECTORY   REFERENCED BY
localhost-domain1  CONFIG  localhost         /export/payara7
xk01               CONFIG  xk01.example.com  /export/payara7  kui-i1
Command list-nodes executed successfully.
```

This example adds the instance `yml-i1` to the cluster `ymlcluster` locally. The instance resides on the node `sj01`. The DAS is running on the host `das1.example.com` and listens for administration requests on the default port.

```
> asadmin --host das1.example.com

create-local-instance --cluster ymlcluster --node sj01 yml-i1
Rendezvoused with DAS on das1.example.com:4848.
Port Assignments for server instance yml-i1:
```

```
JMX_SYSTEM_CONNECTOR_PORT=28687
JMS_PROVIDER_PORT=27677
HTTP_LISTENER_PORT=28081
ASADMIN_LISTENER_PORT=24849
JAVA_DEBUGGER_PORT=29009
IIOP_SSL_LISTENER_PORT=23820
IIOP_LISTENER_PORT=23700
OSGI_SHELL_TELNET_PORT=26666
HTTP_SSL_LISTENER_PORT=28182
IIOP_SSL_MUTUALAUTH_PORT=23920
Command create-local-instance executed successfully.
```

See Also

- To Create an `SSH` Node
- To Create a `CONFIG` Node
- `create-local-instance`

You can also view the full syntax and options of the subcommand by typing `asadmin help create-local-instance` at the command line.

Next Steps

After creating an instance, you can start the instance as explained in the following sections:

- To Start an Individual Instance Centrally
- To Stop an Individual Instance Locally

To Delete an Instance Locally

Use the `delete-local-instance` subcommand in remote mode to delete a Payara Server instance locally.

If you are using a Java Message Service (JMS) cluster with a master broker, do not delete the instance that is associated with the master broker.
If this instance must be deleted, use the `change-master-broker` subcommand to assign the master broker to a different instance first.

Deleting an instance involves the following:

- Removing the instance from the configuration of the DAS
- Deleting the instance's files from file system

Before You Begin

Ensure that the instance that you are deleting is not running. For information about how to stop an instance, see the following sections:

- To Stop an Individual Instance Centrally

- To Stop an Individual Instance Locally

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Log in to the host that is represented by the node where the instance resides.
3. Confirm that the instance is not running.

```
> asadmin --host das-host [--port admin-port] list-instances instance-name
```

das-host

The name of the host where the DAS is running.

admin-port

The HTTP or HTTPS port on which the DAS listens for administration requests. If the DAS listens on the default port for administration requests, you may omit this option.

instance-name

The name of the instance that you are deleting.

4. Run the `delete-local-instance` subcommand.

```
> asadmin --host das-host [--port admin-port] delete-local-instance [--node
node-name]instance-name
```

das-host

The name of the host where the DAS is running.

admin-port

The HTTP or HTTPS port on which the DAS listens for administration requests. If the DAS listens on the default port for administration requests, you may omit this option.

node-name

The node on which the instance resides. If only one node is defined for the Payara Server installation that you are running on the node's host, you may omit this option.

instance-name

The name of the instance that you are deleting.

This example confirms that the instance `yml-i1` is not running and deletes the instance.

```
$ asadmin --host das1.example.com list-instances yml-i1
yml-i1   not running
Command list-instances executed successfully.
$ asadmin --host das1.example.com delete-local-instance --node sj01 yml-i1
Command delete-local-instance executed successfully.
```

See Also

- To Stop an Individual Instance Centrally
- To Stop an Individual Instance Locally
- `change-master-broker`
- `delete-local-instance`
- `list-instances`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help delete-local-instance`
- `asadmin help list-instances`

To Start an Individual Instance Locally

Use the `start-local-instance` subcommand in local mode to start an individual instance locally.

1. Log in to the host that is represented by the node where the instance resides.
2. Run the `start-local-instance` subcommand.

```
$ asadmin start-local-instance [--node node-name] instance-name
```

Only the options that are required to complete this task are provided in this step. For information about all the options for controlling the behavior of the instance, see the `start-local-instance` help page.

node-name

The node on which the instance resides. If only one node is defined for the Payara Server installation that you are running on the node's host, you may omit this option.

instance-name

The name of the instance that you are starting.

This example starts the instance `yml-i1` locally. The instance resides on the node `sj01`.

```
$ asadmin start-local-instance --node sj01 yml-i1
Waiting for yml-i1 to start ..............
Successfully started the instance: yml-i1
instance Location: /export/payara7/glassfish/nodes/sj01/yml-i1
Log File: /export/payara7/glassfish/nodes/sj01/yml-i1/logs/server.log
Admin Port: 24849
Command start-local-instance executed successfully.
```

See Also

`start-local-instance`

You can also view the full syntax and options of the subcommand by typing `asadmin help start-local-instance` at the command line.

Next Steps

After starting an instance, you can deploy applications to the instance. For more information, see the Payara Server Application Deployment section.

To Stop an Individual Instance Locally

Use the `stop-local-instance` subcommand in local mode to stop an individual instance locally.

When an instance is stopped, the instance stops accepting new requests and waits for all outstanding requests to be completed.

1. Log in to the host that is represented by the node where the instance resides.
2. Run the `stop-local-instance` subcommand.

```
$ asadmin stop-local-instance [--node node-name]instance-name
```

node-name

The node on which the instance resides. If only one node is defined for the Payara Server installation that you are running on the node's host, you may omit this option.

instance-name

The name of the instance that you are stopping.

This example stops the instance `yml-i1` locally. The instance resides on the node `sj01`.

```
$ asadmin stop-local-instance --node sj01 yml-i1
Waiting for the instance to stop ....
Command stop-local-instance executed successfully.
```

See Also

`stop-local-instance`

You can also view the full syntax and options of the subcommand by typing `asadmin help stop-local-instance` at the command line.

Troubleshooting

If the instance has become unresponsive and fails to stop, run the subcommand again with the `--kill` option set to `true`. When this option is `true`, the subcommand uses functionality of the operating system to kill the instance process.

To Restart an Individual Instance Locally

Use the `restart-local-instance` subcommand in local mode to restart an individual instance locally.

When this subcommand restarts an instance, the DAS synchronizes the instance with changes since the last synchronization as described in Default Synchronization for Files and Directories.

If you require different synchronization behavior, stop and start the instance as explained in To Resynchronize an Instance and the DAS Online.

1. Log in to the host that is represented by the node where the instance resides.
2. Run the `restart-local-instance` subcommand.

```
$ asadmin restart-local-instance [--node node-name]instance-name
```

node-name

The node on which the instance resides. If only one node is defined for the Payara Server installation that you are running on the node's host, you may omit this option.

instance-name

The name of the instance that you are restarting.

This example restarts the instance `yml-i1` locally. The instance resides on the node `sj01`.

```
> asadmin restart-local-instance --node sj01 yml-i1
Command restart-local-instance executed successfully.
```

See Also

`restart-local-instance`

You can also view the full syntax and options of the subcommand by typing `asadmin help restart-local-instance` at the command line.

Troubleshooting

If the instance has become unresponsive and fails to stop, run the subcommand again with the `--kill` option set to `true`.

When this option is `true`, the subcommand uses functionality of the operating system to kill the instance process before restarting the instance.

Administering Docker instances

A Docker instance is the term used to refer to an instance created on a Docker node. These instances exist within their own Docker containers, with the lifecycle of Docker containers being tied to the instance it was created for.

This section will illustrate how to effectively administer these instances and correctly troubleshoot any issues that may arise on the Docker environment where they reside. Here are some considerations about the examples used below:

- `payaraDas` and `dockerHost1` are hostnames known to the local naming service (you can use an IP

addresses when setting this up)

- The DAS is listening on port `4848` on `payaraDas`
- The Docker process is listening on port 2376 on `dockerHost1`
- The DAS is able to reach this location: `http://dockerHost1:2376`
- Docker containers can access this location: `https://payaraDas:4848`
- There are no Docker containers created yet, no Docker nodes and no instances registered in the DAS.
- We'll use the `/app/passwordfile.txt` file which is located on `payaraDas` to set up the DAS' admin password, with the following contents:

```
AS_ADMIN_PASSWORD=admin123
```

- The `/app/passwordfile-docker.txt` file stored on `dockerHost1` has the same contents as the previous file.

Avoid using the `payara/server-node:latest` Docker image tag, because it changes without warning. If you have the intention to use it, you can re-tag the image and use your own stable Docker image tag like this:

```
>> docker tag payara/server-node:latest payara/server-node:mytag
```

Managing Docker Instances

Docker instances are manageable in much the same way as any other instance. Deployment of applications, assignation to Deployment Groups, editing of their configuration, should all be done just as if the instance was hosted on a standard SSH or CONFIG node.

Please note that it is required that secure-admin be enabled for Docker instances to start (which is why a password file is mandatory when creating a Docker node).

Creating a Docker Instance

There are two ways how to create a Payara Docker instance belonging to a Domain Administration Server (DAS). You can create a Docker container node and instances on it using the DAS, but you can also create a Docker container with a temporary node and instance directly from Docker. These two use cases differ a bit in their lifecycles.

From the DAS

Creating a Docker instance from the DAS is done in exactly the same way as when creating a regular instance. First, create a Docker node, and then you can create one or more Payara Server instances that are hosted on it:

```
asadmin --passwordfile /app/passwordfile.txt create-node-docker --nodehost dockerHost1
```

```
--dockerpasswordfile /app/passwordfile-docker.txt --dockerport 2376 DockerNode1
Command create-node-docker executed successfully.

asadmin --passwordfile /app/passwordfile.txt create-instance --node DockerNode1
DockerInstance1
Port Assignments for server instance DockerInstance1:
OSGI_SHELL_TELNET_PORT=26666
JAVA_DEBUGGER_PORT=29009
JMS_PROVIDER_PORT=27676
HTTP_LISTENER_PORT=28080
IIOP_SSL_LISTENER_PORT=23820
ASADMIN_LISTENER_PORT=24848
IIOP_SSL_MUTUALAUTH_PORT=23920
JMX_SYSTEM_CONNECTOR_PORT=28686
HTTP_SSL_LISTENER_PORT=28181
IIOP_LISTENER_PORT=23700

Successfully registered instance with DAS, now attempting to create Docker
container...
Command create-instance executed successfully.
```

When you invoke these commands, a Docker container of the name `DockerInstance1` will be created. If a Docker container of the same name already exists, the `create-instance` command will fail, and Payara Server will attempt to unregister the instance from the DAS.

When auto-naming is enabled, Payara Server will only attempt to resolve conflicts with instance names - it will not attempt to resolve conflicts in container name.

This type of instance is completely managed by the DAS - when you delete it, it will be deleted along with the Docker container including its logs (unless they are re-mapped to an external volume location)

From Docker

Payara Server supports creating instances by using Docker directly, making use of the auto-naming feature to resolve any conflicts.

The `docker container create` command creates a Payara Server Docker container without the need to contact the DAS. This is also the reason why the Docker container has a different name than the server instance - they have different contexts, and it is not possible to avoid naming conflicts, only to minimize them.

You can also specify an existing Docker node name in `PAYARA_NODE_NAME` system property (and ideally also `DOCKER_CONTAINER_IP`) and/or any relevant deployment groups by using the `PAYARA_DEPLOYMENT_GROUP` property. In this case, the Docker instance will be created as if it would be created from the DAS, except the fact that the DAS will be informed about that later when the container is properly started.

If the property was not specified or the node does not exist, a temporary Docker node and instance

will be created on the DAS. The temporary Docker node is bound to the instance, so when you delete the instance, the temporary Docker node will be deleted too. This type of node is also not listed in the DAS or offered in inputs and cannot be edited.

Using a temporary Docker node and instance arrangement is not recommended for production scenarios.

If the instance running on a temporary Docker node is stopped from the DAS, it is immediately unregistered from the DAS. The next start of the same Docker container creates new a Payara Server Instance and a new temporary Docker node again despite the fact that it uses the same Docker container.

If the Docker containers are stopped externally (i.e. by the `docker` command), the node and instance will be marked for deletion and cleaned up on shutdown of the DAS.

Here is an example of how to create a Docker instance using this method:

```
docker container create --network host --mount type=bind,source="/app/passwordfile-
docker.txt",target="/pathInDocker/passwordfile.txt",readonly -e
PAYARA_DAS_HOST=payaraDas -e PAYARA_DAS_PORT=4848 -e
PAYARA_PASSWORD_FILE=/pathInDocker/passwordfile.txt payara/server-node:main-7

Command _set-docker-container-id executed successfully.
Starting instance Cooperative-Spookfish
```

```
...
```

Don’t forget that you are configuring a connection to DAS from the viewpoint of the instance container, so ensure that the container can reach the DAS in the same network.

Starting and Stopping a Docker Instance

Instances on temporary Docker nodes have their lifecycle bound to a started container. So from the DAS point of view, either they are running or do not exist.

Starting a Docker instance on standard Docker node should be done just as if it were an instance on an SSH node. When the `asadmin start-instance` command is invoked, the DAS will contact the Docker Rest API as configured in the node config, and start the Docker container and the instance within it.

If the command remains unresponsive, the Docker instance probably failed to start. Use the `docker logs` command to see what happened.

```
asadmin --passwordfile /app/passwordfile.txt start-instance DockerInstance1
Command start-instance executed successfully.

asadmin --passwordfile /app/passwordfile.txt stop-instance DockerInstance1
The instance, DockerInstance1, is stopped.
Command stop-instance executed successfully.
```

Deleting a Docker Instance

Much as with when creating a standard Docker instance, deleting a Docker instance is done in the same way as other instances: with the `asadmin delete-instance` command. This will unregister the instance from the DAS, and delete the Docker container.

Containers on temporary Docker nodes are not deleted by the DAS, they will be only stopped and removed from the DAS management including the temporary Docker node. The container management is controlled by the Docker.

```
asadmin --passwordfile /app/passwordfile.txt delete-instance DockerInstance1

Successfully removed instance DockerInstance1 from the DAS configuration, and removed
the container from node DockerNode1 (dockerHost1).
Command delete-instance executed successfully.
```

if you would delete the container directly with the `docker` command, the DAS would not be aware of it. Such inconsistency can be resolved only by deletion of the instance from the DAS. This is automatically done on DAS restart, to guarantee an eventual consistency of the instances state on the system.

Configuring the Docker Container

Configuration of the Docker containers where server instances are hosted is done via system properties in the corresponding instance's configuration object (so can be shared across multiple instances that may belong to a deployment group).

A complete list of the available configuration options can be found in the Docker Engine REST API here: link:https://docs.docker.com/engine/api/v1.39/#operation/ContainerCreate

The image name is not configurable. Payara Server expects the image name to match the value from the node configuration.

The configuration within Payara Server of the settings denoted in the above link takes the form of dotted names. These names adhere to the following syntax:

- Each property is prefixed with `Docker`
- Each child object is specified individually, with all of its parents prepended to it
- Arrays must be surrounded with square braces (`[]`)
- Array values are separated using the vertical bar symbol (`|`)
- The colon character (`;`) is used to denote the value of an object within an array
- Objects within an array are separated using a comma (`,`)

Properties that are denoted by arrays of objects containing further objects or arrays are not currently supported. The `Env` property is unique in that the colon character is used to denote the equals sign, as Payara Server does not currently support properties that contain an equals in their value.

See below for some examples:

Example	Original JSON	Payara System Properties
Arrays must be surrounded with square braces & array values separated using the vertical bar symbol `|`	`{ENV: [arg1=foo,arg2=bar]}`	`Docker.Env=[arg1:foo|arg2:bar]`

Each child object of a parent object is specified individually	`{HostConfig: {Memory: 2048, CpuShares: 3}`	`Docker.HostConfig.Memory=2048`
		
		`Docker.HostConfig.CpuShares=3`

The colon character is used to denote the value of an object within an array & objects within an array are separated using a comma `,`	`{HostConfig: {BlkioDeviceReadBps: [{Path: /opt/foo, Rate: 24},{Path: /opt/bar, Rate: 48}]}`	`Docker.HostConfig.BlkioDeviceReadBps=[Path:/opt/foo,Rate:24|Path:/opt/bar,Rate:48]`

Reserved Environment Properties

The following Docker Environment properties are used by the default Docker image, `payara/server-node:main-7`, which you may wish to override to match your configuration (particularly if creating containers directly from Docker):

Environment Property	Use	Default Value
`PAYARA_DAS_HOST`	The IP address or hostname of the Domain Administration Server that the instance will register itself to.	`localhost`
`PAYARA_DAS_PORT`	The port that the Domain Administration Server is running on	`4848`
`PAYARA_NODE_NAME`	The name of the node that the instance should be created on.	""
`PAYARA_INSTANCE_NAME`	The name of the instance to be created.	""
`PAYARA_CONFIG_NAME`	The name of the config that the created instance should use.	""
`DOCKER_CONTAINER_IP`	The IP address or hostname that the Docker Container should use. This is used for verifying that a given node's network config maps to this container, or for when creating new nodes and instances.	First result of `hostname -I` (all IP addresses, excluding loopback)
`PAYARA_DEPLOYMENT_GROUP`	The name of the Deployment Group that the instance should join. Once the instance joins the Deployment Group, all the application targeted at the Deployment Group will automatically deploy to it.	""

The DAS expects to be able to reach each instance using the port listed in its configuration. Don't forget to ensure that the DAS and containers reside on the same network.

Other examples for Docker Instances

Creating a container using the Docker REST API

You can alternatively create a JSON file and then use curl syntax for sending files (i.e. `@create.json`).

```
curl -H 'Accept: application/json' -H 'Content-Type: application/json' -i
'http://dockerHost1:2376/containers/create?name=ManagedContainer2' --data '{
  "Image": "payara/server-node:mytag",
  "HostConfig": {
    "Mounts": [
      {
        "Type": "bind",
        "Source": "/app/passwordfile-docker.txt",
        "Target": "/opt/payara/passwords/passwordfile.txt",
        "ReadOnly": true
      }
    ],
    "NetworkMode": "host"
  },
  "Env": [
    "PAYARA_DAS_HOST=payaraDas",
    "PAYARA_DAS_PORT=4848",
    "PAYARA_NODE_NAME=DockerNode1",
    "PAYARA_INSTANCE_NAME=ManagedContainer2",
    "DOCKER_CONTAINER_IP=dockerHost1"
  ]
}'

Resynchronizing Payara Server Instances and the DAS

Configuration data for a Payara Server instance is stored as follows:

- In the repository of the domain administration server (DAS)
- In a cache on the host that is local to the instance

The configuration data in these locations must be synchronized. The cache is synchronized in the following circumstances:

- Whenever an `asadmin` subcommand is run. For more information, see Impact of Configuration Changes" in Payara Server General Administration section.
- When a user uses the administration tools to start or restart an instance.

Default Synchronization for Files and Directories

The `--sync` option of the subcommands for starting an instance controls the type of synchronization between the DAS and the instance's files when the instance is started. You can use this option to override the default synchronization behavior for the files and directories of an instance. For more information, see To Resynchronize an Instance and the DAS Online.

On the DAS, the files and directories of an instance are stored in the `domain-dir` directory, where `domain-dir` is the directory in which a domain's configuration is stored.

The default synchronization behavior for the files and directories of an instance is as follows:

`applications`

This directory contains a subdirectory for each application that is deployed to the instance.

By default, only a change to an application's top-level directory within the application directory causes the DAS to synchronize that application's directory.

When the DAS resynchronizes the`applications` directory, all the application's files and all generated content that is related to the application are copied to the instance.

If a file below a top-level subdirectory is changed without a change to a file in the top-level subdirectory, full synchronization is required. In `normal` operation, files below the top-level subdirectories of these directories are not changed and such files should not be changed by users.

If an application is deployed and un-deployed, full synchronization is not necessary to update the instance with the change.

`config`

This directory contains configuration files for the entire domain.

By default, the DAS resynchronizes files that have been modified since the last resynchronization only if the `domain.xml` file in this directory has been modified.

If you add a file to the `config` directory of an instance, the file is deleted when the instance is resynchronized with the DAS. However, any file that you add to the `config` directory of the DAS is not deleted when instances and the DAS are resynchronized. By default, any file that you add to the `config` directory of the DAS is not resynchronized.

If you require any additional configuration files to be resynchronized, you must specify the files explicitly.

For more information, see To Resynchronize Additional Configuration Files.

`config/config-name`

This directory contains files that are to be shared by all instances that reference the named configuration config-name. A config-name directory exists for each named configuration in the configuration of the DAS.

Because the `config-name` directory contains the subdirectories `lib` and `docroot`, this directory might be very large. Therefore, by default, only a change to a file or a top-level subdirectory of config-name causes the DAS to resynchronize the config-name directory.

`config/domain.xml`

This file contains the DAS configuration for the domain to which the instance belongs.

By default, the DAS resynchronizes this file if it has been modified since the last resynchronization.

A change to the `config/domain.xml` file is required to cause the DAS to resynchronize an instance's files.

> If the `config/domain.xml` file has not changed since the last resynchronization, none of the instance's files is resynchronized, even if some of these files are out of date in the cache.

`docroot`

This directory is the HTTP document root directory. By default, all instances in a domain use the same document root directory.

To enable instances to use a different document root directory, a virtual server must be created in which the `docroot` property is set.

For more information, see the `create-virtual-server` help page.

The `docroot` directory might be very large. Therefore, by default, only a change to a file or a subdirectory in the top level of the `docroot` directory causes the DAS to resynchronize the `docroot` directory. The DAS checks files in the top level of the `docroot` directory to ensure that changes to the `index.html` file are detected.

When the DAS resynchronizes the `docroot` directory, all modified files and subdirectories at any level are copied to the instance.

If a file below a top-level subdirectory is changed without a change to a file in the top-level subdirectory, full synchronization is required.

`generated`

This directory contains generated files for Jakarta EE applications and modules, for example, EJB stubs, compiled JSP classes, and security policy files.

Do not modify the contents of this directory.

This directory is resynchronized when the `applications` directory is resynchronized. Therefore, only directories for applications that are deployed to the instance are resynchronized.

`lib`

`lib/classes`

These directories contain common Jakarta EE class files or JAR archives and ZIP archives for use by applications that are deployed to the entire domain. Typically, these directories contain common JDBC drivers and other utility libraries that are shared by all applications in the domain.

The contents of these directories are loaded by the common class loader. For more information, see "Using the Common Class Loader" in the Payara Server Application Development section.

The class loader loads the contents of these directories in the following order:

1. `lib/classes`
2. `lib/*.jar`
3. `lib/*.zip`

`lib/applibs`

This directory contains application-specific Jakarta class files or JAR archives and ZIP archives for use by applications that are deployed to the entire domain.

`lib/ext`

This directory contains optional packages in JAR archives and ZIP archives for use by applications that are deployed to the entire domain.

In past versions, these archive files are loaded by using Jakarta extension mechanism. Since Java 11+, as extension library support has been removed, these libraries will be automatically added as classpath elements.

The `lib` directory and its subdirectories typically contain only a small number of files. Therefore, by default, a change to any file in these directories causes the DAS to resynchronize the file that changed.

To Resynchronize an Instance and the DAS Online

Resynchronizing an instance and the DAS updates the instance with changes to the instance's configuration files on the DAS. An instance is resynchronized with the DAS when the instance is started or restarted.

Resynchronization of an instance is only required if the instance is stopped. A running instance does not require resynchronization.

1. Ensure that the DAS is running.
2. Determine whether the instance is stopped.

   ```
   > asadmin list-instances instance-name
   ```

   instance-name

   The name of the instance that you are resynchronizing with the DAS.

   If the instance is stopped, the `list-instances` subcommand indicates that the instance is not running.

3. If the instance is stopped, start the instance.

   If the instance is running, no further action is required.

   If you require full synchronization, set the `--sync` option of the `start-instance` subcommand to `full`. If default synchronization is sufficient, omit this option.

   ```
   > asadmin start-instance [--sync full] instance-name
   ```

   If SSH is set up, start the instance locally from the host where the instance resides.

If you require full synchronization, set the `--sync` option of the `start-local-instance` subcommand to `full`. If default synchronization is sufficient, omit this option.

```
> asadmin start-local-instance [--node node-name] [--sync full] instance-name
```

This example determines that the instance `yml-i1` is stopped and fully resynchronizes the instance with the DAS. Because SSH is set up, the instance is started locally on the host where the instance resides.

In this example, multiple nodes are defined for the Payara Server installation that is running on the node's host.

To determine whether the instance is stopped, the following command is run in multimode on the DAS host:

```
asadmin> list-instances yml-i1
yml-i1   not running
Command list-instances executed successfully.
```

To start the instance, the following command is run in single mode on the host where the instance resides:

```
> asadmin start-local-instance --node sj01 --sync full yml-i1
Removing all cached state for instance yml-i1.
Waiting for yml-i1 to start ..............
Successfully started the instance: yml-i1
instance Location: /export/payara7/glassfish/nodes/sj01/yml-i1
Log File: /export/payara7/glassfish/nodes/sj01/yml-i1/logs/server.log
Admin Port: 24849
Command start-local-instance executed successfully.
```

- `list-instances`
- `start-instance`
- `start-local-instance`

To Resynchronize Library Files

To ensure that library files are resynchronized correctly, you must ensure that each library file is placed in the correct directory for the type of file.

1. Place each library file in the correct location for the type of library file as shown in the following table.

Type of Library Files	Location
Common JAR archives and ZIP archives for all applications in a domain.	`domain-dir/lib`
Common Jakarta EE class files for a domain for all applications in a domain.	`domain-dir/lib/classes`
Application-specific libraries.	`domain-dir/lib/applibs`
Optional packages for all applications in a domain.	`domain-dir/lib/ext`
Library files for all applications that are deployed to a specific cluster or standalone instance.	`domain-dir/config/<config-name>/lib`
Optional packages for all applications that are deployed to a specific cluster or standalone instance.	`domain-dir/config/<config-name>/lib/ext`

domain-dir

The directory in which the domain's configuration is stored.

config-name

For a standalone instance: the named configuration that the instance references.
For a clustered instance: the named configuration that the cluster to which the instance belongs references.

2. When you deploy an application that depends on these library files, use the `--libraries` option of the `deploy` subcommand to specify these dependencies.

   For library files in the `domain-dir/lib/applib` directory, only the JAR file name is required, for example:

   ```
   asadmin> deploy --libraries commons-coll.jar,X1.jar app.ear
   ```

   For other types of library file, the full path is required.

See Also

`deploy`

You can also view the full syntax and options of the subcommands by typing the command `asadmin help deploy` at the command line.

To Resynchronize Custom Configuration Files for an Instance

Configuration files in the `domain-dir/config` directory that are resynchronized for the entire domain.

If you create a custom configuration file for an instance or a cluster, the custom file is resynchronized only for the instance or cluster. You'll have to update any JVM options that

reference this configuration file in the domain configuration settings.

1. Place the custom configuration file in the `domain-dir/config/config-name` directory.

   config-name
   The named configuration that the instance references.

2. If the instance locates the file through an option of the Jakarta EE application launcher, update the option.
3. Delete the JVM option in case of a customized config file location.

   ```
   asadmin> delete-jvm-options --target instance-name option-name=current-value
   ```

   instance-name
   The name of the instance for which the custom configuration file is created.

   option-name
   The name of the option for locating the file.

   current-value
   The current value of the option for locating the file.

4. Re-create the JVM option that you deleted in the previous step.

   ```
   asadmin> create-jvm-options --target instance-name option-name=new-value
   ```

   instance-name
   The name of the instance for which the custom configuration file is created.

   option-name
   The name of the option for locating the file.

   new-value
   The new value of the option for locating the file.

This example updates the option for locating the `server.policy` file to specify a custom file location for the instance `pmd`.

```
asadmin> delete-jvm-options --target pmd
-Djava.security.policy=${com.sun.aas.instanceRoot}/config/server.policy
Deleted 1 option(s)
Command delete-jvm-options executed successfully.

asadmin create-jvm-options --target pmd
-Djava.security.policy=${com.sun.aas.instanceRoot}/config/pmd-config/server.policy
Created 1 option(s)
```

```
Command create-jvm-options executed successfully.
```

See Also

- `create-jvm-options`
- `delete-jvm-options`

To Resynchronize Users' Changes to Files

A change to the `config/domain.xml` file is required to cause the DAS to resynchronize instances' files. If other files in the domain directory are changed without a change to the `config/domain.xml` file, instances are not resynchronized with these changes.

The following changes are examples of changes to the domain directory without a change to the `config/domain.xml` file:

- Adding files to the `lib` directory
- Adding certificates to the key store by using the `keytool` command

1. Change the last modified time of the `config/domain.xml` file.

   Exactly how to change the last modified time depends on the operating system. For example, on UNIX and Linux systems, you can use `touch` command.

2. Resynchronize each instance in the domain with the DAS.

   For instructions, see To Resynchronize an Instance and the DAS Online.

See Also

- To Resynchronize an Instance and the DAS Online
- `touch`(1)

To Resynchronize Additional Configuration Files

By default, Payara Server synchronizes only the following configuration files:

- `admin-keyfile`
- `cacerts.jks`
- `default-web.xml`
- `domain.xml`
- `domain-passwords`
- `keyfile`
- `keystore.jks`
- `server.policy`
- `sun-acc.xml`

- `wss-server-config-1.0`
- `xml wss-server-config-2.0.xml`

If you require instances in a domain to be resynchronized with additional configuration files for the domain, you can specify a list of files to resynchronize.

If you specify a list of files to resynchronize, you must specify all the files that the instances require, including the files that Payara Server resynchronizes by default. Any file in the instance's cache that is not in the list is deleted when the instance is resynchronized with the DAS.

In the `config` directory of the domain, create a plain text file that is named `config-files` that lists the files to resynchronize.

In the `config-files` file, list each file name on a separate line.

This example shows the content of a `config-files` file. This file specifies that the `some-other-info` file is to be resynchronized in addition to the files that Payara Server resynchronizes by default:

```
admin-keyfile
cacerts.jks
default-web.xml
domain.xml
domain-passwords
keyfile
keystore.jks
server.policy
sun-acc.xml
wss-server-config-1.0.xml
wss-server-config-2.0.xml
some-other-info
```

To Prevent Deletion of Application-Generated Files

When the DAS resynchronizes an instance's files, the DAS deletes from the instance's cache any files that are not listed for resynchronization.

If an application creates files in a directory that the DAS resynchronizes, these files are deleted when the DAS resynchronizes an instance with the DAS.

Put the files in a subdirectory under the domain directory that is not a pre-defined directory, for example, `/payara7/glassfish/domains/domain1/myapp/myfile`.

To Resynchronize an Instance and the DAS Offline

Resynchronizing an instance and the DAS offline updates the instance's cache without the need for the instance to be able to communicate with the DAS. Offline resynchronization is typically required for the following reasons:

- To reestablish the instance after an upgrade
- To synchronize the instance manually with the DAS when the instance cannot contact the DAS

Follow these steps:

1. Ensure that the DAS is running.
2. Export the configuration data that you are resynchronizing to an archive file.

   Only the options that are required to complete this task are provided in this step. For information about all the options for exporting the configuration data, see the `export-sync-bundle` help page.

   How to export the data depends on the host from where you run the `export-sync-bundle` subcommand.

   - From the DAS host, run the `export-sync-bundle` subcommand as follows:

     ```
     asadmin> export-sync-bundle --target target
     ```

     target

     The cluster or standalone instance for which to export configuration data.

     Do not specify a clustered instance. If you specify a clustered instance, an error occurs. To export configuration data for a clustered instance, specify the name of the cluster of which the instance is a member, not the instance.

     The file is created on the DAS host.

   - From the host where the instance resides, run the `export-sync-bundle` subcommand as follows:

     ```
     > asadmin --host das-host [--port admin-port] export-sync-bundle [--
     retrieve=true] --target target
     ```

     das-host

     The name of the host where the DAS is running.

     admin-port

     The HTTP or HTTPS port on which the DAS listens for administration requests. If the DAS listens on the default port for administration requests, you may omit this option.

     target

     The cluster or standalone instance for which to export configuration data.

     Do not specify a clustered instance. If you specify a clustered instance, an error occurs. To export configuration data for a clustered instance, specify the name of the cluster of which the instance is a member, not the instance.

To create the archive file on the host where the instance resides, set the `--retrieve` option to `true`. If you omit this option, the archive file is created on the DAS host.

3. If necessary, copy the archive file that you created in **Step 2** from the DAS host to the host where the instance resides.
4. From the host where the instance resides, import the instance's configuration data from the archive file that you created in **Step 2**.

Only the options that are required to complete this task are provided in this step. For information about all the options for importing the configuration data, see the `import-sync-bundle` help page.

```
> asadmin import-sync-bundle [--node node-name] --instance instance-name archive-
file
```

node-name

The node on which the instance resides. If you omit this option, the subcommand determines the node from the DAS configuration in the archive file.

instance-name

The name of the instance that you are resynchronizing.

archive-file

The name of the file, including the path, that contains the archive file to import.

This example resynchronizes the clustered instance `yml-i1` and the DAS offline. The instance is a member of the cluster `ymlcluster`. The archive file that contains the instance's configuration data is created on the host where the instance resides.

```
asadmin --host dashost.example.com export-sync-bundle --retrieve=true --target
ymlcluster
Command export-sync-bundle executed successfully.

asadmin import-sync-bundle --node sj01 --instance yml-i1 ymlcluster-sync-bundle.zip
Command import-sync-bundle executed successfully.
```

See Also

- `export-sync-bundle`
- `import-sync-bundle`

The Extra Terse Option

The `extraterse` option is intended for use with scripts, adding an extra level of terseness to the command output to the CLI.

Currently, this feature only works with the `create-instance` and `create-local-instance` commands.

When enabled, the `create-instance` and `create-local-instance` commands should only return the name of the instance created.

The intention behind this feature being that you should be able to set variables from this output for use with scripts, since you can't know beforehand what the name of an instance is if a name conflict is resolved or a name is generated from scratch.

This option can be enabled either by specifying `--extraterse` or simply `-T` on the command line (in comparison, the normal terse option is enabled with `--terse` or `-t`) before or after the command name. Being a CLI option rather than a command parameter, it is recommended that you specify it before the command name, as the ability to specify asadmin options (like `--host`) after the command name is technically deprecated syntax and will be ignored in certain circumstances.

The `extraterse` option implicitly enables the terse option - this is true for **all** commands (not just `create-instance` and `create-local-instance`).

ExtraTerse Examples

```
$INSTANCE_NAME = asadmin create-local-instance --node localhost-domain1 --autoname
--extraterse
asadmin start-instance $INSTANCE_NAME

$SECOND_INSTANCE_NAME = asadmin -a -T create-local-instance --node localhost-domain1
```

Migrating EJB Timers

If a Payara Server instance stops or fails abnormally, it may be desirable to migrate the EJB timers defined for that stopped server instance to another running server instance.

Automatic timer migration is enabled by default for clustered server instances that are stopped normally. Automatic timer migration can also be enabled to handle clustered server instance crashes.

In addition, timers can be migrated manually for stopped or crashed server instances.

- To Enable Automatic EJB Timer Migration for Failed Clustered Instances
- To Migrate EJB Timers Manually

To Enable Automatic EJB Timer Migration for Failed Clustered Instances

Automatic migration of EJB timers is enabled by default for clustered server instances that are stopped normally. The procedure in this section is only necessary if you want to enable automatic timer migration for clustered server instances that have stopped abnormally.

If the GMS is enabled, the default automatic timer migration cannot be disabled.

> To disable automatic timer migration, you must first disable the GMS. For information about the GMS, see Group Management Service.

Before You Begin

Automatic EJB timer migration can only be configured for clustered server instances. Automatic timer migration is not possible for standalone server instances.

Enable delegated transaction recovery for the cluster.

This enables automatic timer migration for failed server instances in the cluster.

For instructions on enabling delegated transaction recovery, see "Administering Transactions" in Payara Server General Administration section.

To Migrate EJB Timers Manually

EJB timers can be migrated manually from a stopped source instance to a specified target instance in the same cluster if GMS notification is not enabled.

If no target instance is specified, the DAS will attempt to find a suitable server instance. A migration notification will then be sent to the selected target server instance.

Note the following restrictions:

- If the source instance is part of a cluster, then the target instance must also be part of that same cluster.
- It is not possible to migrate timers from a standalone instance to a clustered instance, or from one cluster to another cluster.
- It is not possible to migrate timers from one standalone instance to another standalone instance.
- All EJB timers defined for a given instance are migrated with this procedure. It is not possible to migrate individual timers.

Before You Begin

The server instance from which the EJB timers are to be migrated should not be active during the migration process.

1. Verify that the source clustered server instance from which the EJB timers are to be migrated is not currently running.

   ```
   > asadmin list-instances source-instance
   ```

2. Stop the instance from which the timers are to be migrated, if that instance is still running.

   ```
   > asadmin stop-instance source-instance
   ```

The target instance to which the timers will be migrated should be running.

3. List the currently defined EJB timers on the source instance, if desired.

```
> asadmin list-timers source-cluster
```

4. Migrate the timers from the stopped source instance to the target instance.

```
> asadmin migrate-timers --target target-instance source-instance
```

The following example show how to migrate timers from a clustered source instance named `football` to a clustered target instance named `soccer`.

```
asadmin> migrate-timers --target soccer football
```

See Also

`list-timers`, `migrate-timers`, `list-instances`, `stop-instance`

Administering Named Configurations

A named configuration is a set of configuration information for Payara Server instances and clusters. A configuration sets port numbers for listeners that an instance or a cluster uses and defines settings for items such as the EJB container, security, logging, and monitoring. Applications and resources are not defined in named configurations.

Payara Server enables you to create configurations for use by clusters and instances. Payara Server creates configurations automatically for clusters and instances that do not reference an existing configuration. You can modify any existing named configuration regardless of how the configuration was created.

About Named Configurations

Configurations exist in a domain. Multiple Payara Server instances or clusters in the domain can reference the same configuration, or they can have separate configurations. To ensure that the environment in a cluster's instances is homogenous, all instances in the cluster inherit the cluster's configuration.

Types of Named Configurations

Each named configuration is one of the following types of configuration:

Standalone configuration

A standalone configuration is referenced by only one instance or cluster and is not shared with any other instances or clusters.

A configuration that is referenced by only one cluster is a standalone

configuration, even if the cluster contains multiple instances.

Shared configuration

A shared configuration is referenced by multiple instances (even if they live on a deployment group) or clusters.

The type of un-clustered instances is determined by the type of the configuration that the instance references.

For more information, see Types of Payara Server Instances.

The `default-config` Configuration

The `default-config` configuration is a special configuration that acts as a template for creating new named configurations. Clusters and instances cannot refer to the `default-config` configuration. The `default-config` configuration can only be copied to create configurations.

Automatically Created Configurations

When you create a cluster or an instance, you can choose whether to specify an existing configuration that the new cluster or instance will reference. If you choose to create a cluster or an instance without specifying an existing configuration, Payara Server automatically creates a configuration for the cluster or instance.

For more information, see the following sections:

- To Create a Cluster
- To Create an Instance Centrally
- To Create an Instance Locally

Payara Server automatically creates a configuration by copying the `default-config` configuration. If you require an instance or cluster to reference a copy of a different configuration, copy the configuration and specify the copy when you create the instance or cluster.

For information about how to copy a configuration, see To Create a Named Configuration.

Payara Server assigns the name `<cluster-or-instance>-config` to an automatically created configuration. `<cluster-or-instance>` is the name of the cluster or instance for which the configuration is created.

The `server-config` configuration is automatically created for the domain administration server (DAS) when the domain is created.

Directory for Configuration Synchronization

When a named configuration is created, Payara Server creates a configuration directory on the domain administration server (DAS) at `domain-dir/config/config-name`.

domain-dir

The directory in which the domain's configuration is stored.

config-name

The name that was assigned to the configuration when the configuration was created.

This contents of this directory are synchronized to all instances that inherit or reference the configuration.

Creating, Listing, and Deleting Named Configurations

Payara Server enables you to create configurations for use by clusters and instances, obtain information about configurations, and delete configurations that are no longer required.

To Create a Named Configuration

Use the `copy-config` subcommand in remote mode to create a named configuration by copying an existing configuration. Payara Server requires you to create a configuration by copying a configuration because a configuration contains many required settings.

The newly created configuration is identical to the configuration that you copy until you change its configuration settings.

Create a named configuration only if you plan to share the configuration among multiple un-clustered instances or clusters.

Otherwise, create clusters and instances without specifying an existing configuration. If no configuration is specified, Payara Server creates a copy of the default configuration for the cluster or instance.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `copy-config` subcommand.

Only the options that are required to complete this task are provided in this step. For information about all the options for configuring the named configuration, see the `copy-config` help page.

```
asadmin> copy-config source-config-name destination-config-name
```

source-config-name

The name of the configuration that you are copying. You must specify a configuration to copy even if you are copying the default configuration. The configuration must already exist.

destination-config-name

Your choice of name for the configuration that you are creating by copying the source configuration.

The following example creates the named configuration `cluster-presets-config` by copying the default configuration.

```
asadmin> copy-config default-config cluster-presets-config
Command copy-config executed successfully.
```

See Also

- To Create a Cluster
- To Create an Instance Centrally
- To Create an Instance Locally
- `copy-config`

You can also view the full syntax and options of the subcommand by typing `asadmin help copy-config` at the command line.

To List the Named Configurations in a Domain

Use the `list-configs` subcommand in remote mode to list existing named configurations in a domain.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Run the `list-configs` subcommand.

   ```
   asadmin> list-configs
   ```

The following example lists all named configurations in the current domain.

```
asadmin> list-configs
server-config
default-config
cluster-presets-config
Command list-configs executed successfully.
```

See Also

`list-configs`

You can also view the full syntax and options of the subcommand by typing `asadmin help list-configs` at the command line.

To List the Targets of a Named Configuration

Use the `list-clusters` subcommand and the `list-instances` subcommand in remote mode to list the targets of a named configuration.

The targets of a named configuration are the clusters and Payara Server instances that reference the configuration.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. List the clusters that refer to the configuration.

   ```
   asadmin> list-clusters config-name
   ```

   config-name
   The name of the configuration whose targets you are listing.

3. List the instances that refer to the configuration.

   ```
   asadmin> list-instances config-name
   ```

   config-name
   The name of the configuration whose targets you are listing.

The following example shows that the cluster `ymlcluster` and the instances `yml-i1` and `yml-i2` reference the named configuration `ymlcluster-config`.

```
asadmin> list-clusters ymlcluster-config

ymlcluster partially running
Command list-clusters executed successfully.
asadmin> list-instances ymlcluster-config
yml-i1   running
yml-i2   not running
Command list-instances executed successfully.
```

See Also

- `list-clusters`
- `list-instances`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help list-clusters`
- `asadmin help list-instances`

To Delete a Named Configuration

Use the `delete-config` subcommand in remote mode to delete an existing named configuration from the configuration of the DAS.

You cannot delete the `default-config` configuration.

A standalone configuration that was created automatically for a cluster or a

> Payara Server instance is deleted when the cluster or instance is deleted.

Before You Begin

Ensure that no clusters or instances refer to the configuration. If a cluster or instance refers to the configuration and is no longer required, delete the cluster or instance.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. Confirm that no clusters refer to the configuration that you are deleting.

   ```
   asadmin> list-clusters config-name
   ```

   config-name
   The name of the configuration that you are deleting.

3. Confirm that no instances refer to the configuration that you are deleting.

   ```
   asadmin> list-instances config-name
   ```

   config-name
   The name of the configuration that you are deleting.

4. Run the `delete-config` subcommand.

   ```
   asadmin> delete-config config-name
   ```

   config-name
   The name of the configuration that you are deleting.

The following example confirms that no clusters or instances refer to the configuration `cluster-presets-config` and then deletes the configuration.

```
asadmin> list-clusters cluster-presets-config
Nothing to list
Command list-clusters executed successfully.

asadmin> list-instances cluster-presets-config
Nothing to list.
Command list-instances executed successfully.

asadmin> delete-config cluster-presets-config
Command delete-config executed successfully.
```

See Also

- To Delete an Instance Centrally
- To Delete an Instance Locally
- To Delete a Cluster
- `delete-config`
- `list-clusters`
- `list-instances`

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help delete-config`
- `asadmin help list-clusters`
- `asadmin help list-instances`

Modifying Properties for Named Configurations and Instances

The properties in a named configuration define port numbers for un-clustered instances that reference the configuration or clustered instances that inherit the configuration. An instance initially obtains port numbers from the configuration that the instance references or inherits.

To avoid port conflicts, edit the properties of named configurations and instances.

Properties for Port Numbers in a Named Configuration

The default configuration `default-config` contains properties that define the initial values of port numbers in a configuration that is copied from `default-config`. When an instance or a cluster that references the configuration is created, these properties are set for the instance.

You can create additional system properties for a configuration either by specifying the `--systemproperties` option of the `copy-config` subcommand or by using the `create-system-properties` subcommand.

To reference a system property from the configuration, use the `${property-name}` notation, where prop-name is the name of the system property.

For example, if a configuration defines additional HTTP listeners, use system properties to define the ports for those listeners. However, these properties are not set automatically when an instance or a cluster that references the configuration is created.

You must set these properties explicitly when you create the instance or cluster.

The properties in a named configuration that define port numbers are as follows:

`ASADMIN_LISTENER_PORT`

: This property specifies the port number of the HTTP port or HTTPS port through which the DAS connects to the instance to manage the instance.

`HTTP_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTP requests.

`HTTP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTPS requests.

`IIOP_LISTENER_PORT`

This property specifies the port number of the port that is used for IIOP connections.

`IIOP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used for secure IIOP connections.

`IIOP_SSL_MUTUALAUTH_PORT`

This property specifies the port number of the port that is used for secure IIOP connections with client authentication.

`JAVA_DEBUGGER_PORT`

This property specifies the port number of the port that is used for connections to the Java Platform Debugger Architecture (JPDA) debugger.

`JMS_PROVIDER_PORT`

This property specifies the port number for the Jakarta Message Service provider.

`JMX_SYSTEM_CONNECTOR_PORT`

This property specifies the port number on which the JMX connector listens.

`OSGI_SHELL_TELNET_PORT`

This property specifies the port number of the port that is used for connections to the Apache Felix Remote Shell.

This shell uses the Felix shell service to interact with the OSGi module management subsystem.

Valid port values are `1-65535`.

On UNIX operating systems, creating sockets that listen on ports `1-1024` requires superuser privileges.

To Modify a Named Configuration's Properties

Use the `get` subcommand and the `set` subcommand in remote mode to modify a named configuration's properties.

You might copy a configuration for use by instances that reside on the same host as instances that refer to the original configuration. In this situation, edit the properties of one of the configurations to ensure that instances that will refer to the configuration have the correct initial settings.

If you change the port number in a configuration, the port number is changed for any instance that references or inherits the configuration.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. For each property that you are modifying, determine the current value and set the new value.
3. Determine the current value of the property.

```
asadmin> get configs.config.config-name.system-property.property-name.value
```

config-name

The name of the configuration whose properties you are modifying.

property-name

The name of the property that you are modifying. For a list of available properties, see Properties for Port Numbers in a Named Configuration.

4. Set the property to its new value.

```
asadmin> set configs.config.config-name.system-property.property-name.value=new-
value
```

config-name

The name of the configuration whose properties you are modifying.

property-name

The name of the property that you are modifying. For a list of available properties, see Properties for Port Numbers in a Named Configuration.

new-value

The value to which you are setting the property.

The following example changes the value of the `JMS_PROVIDER_PORT` property in the `cluster-presets-config` configuration from `27676` to `27678`.

```
asadmin> get configs.config.cluster-presets-config.system-
property.JMS_PROVIDER_PORT.value

configs.config.cluster-presets-config.system-property.JMS_PROVIDER_PORT.value=27676
Command get executed successfully.

asadmin> set configs.config.cluster-presets-config.system-
property.JMS_PROVIDER_PORT.value=27678

Command set executed successfully.
```

See Also

You can also view the full syntax and options of the subcommands by typing the following commands at the command line:

- `asadmin help get`
- `asadmin help set`

To Modify Port Numbers of an Instance

Use the `get` subcommand and the `set` subcommand in remote mode to modify the port numbers of an instance.

The port numbers of an instance are initially set in the configuration that the instance references or inherits from its parent cluster. Multiple instances that reside on the same host must each listen on a unique port number.

Therefore, if multiple instances that reference or inherit the same configuration reside on the same host, a port conflict prevents all except one of the instances from starting. To avoid port conflicts, modify the port numbers on which individual instances listen.

If you modify an instance's port number and later modify the port number in the instance's configuration, the instance's port number remains unchanged.

The port numbers of an instance are stored as Java system properties. When Payara Server is started, it treats these properties in the same way as properties that are passed through the `-D` option of the Java application launcher.

1. Ensure that the DAS is running. Remote subcommands require a running server.
2. For each port number that you are modifying, determine the current value and set the new value.
3. Determine the current value of the port number.

   ```
   asadmin> get
   servers.server.instance-name.system-property.port-property.value
   ```

   instance-name

   The name of the instance whose port numbers you are modifying.

   port-property

   The name of the property that corresponds to the port number that you are modifying. For a list of available properties, see Properties for Port Numbers in a Named Configuration.

4. Set the port number to its new value.

   ```
   asadmin> get
   servers.server.instance-name.system-property.port-property.value=new-value
   ```

instance-name

The name of the instance whose port numbers you are modifying.

port-property

The name of the property that corresponds to the port number that you are modifying. For a list of available properties, see Properties for Port Numbers in a Named Configuration.

new-value

The value to which you are setting the port number.

The following example changes the port number of the HTTP port or the HTTPS port for administration of the `pmdsainst` instance from `24849` to `24859`.

```
asadmin> get servers.server.pmdsainst.system-property.ASADMIN_LISTENER_PORT.value

servers.server.pmdsainst.system-property.ASADMIN_LISTENER_PORT.value=24849

Command get executed successfully.
asadmin> set servers.server.pmdsainst.system-
property.ASADMIN_LISTENER_PORT.value=24859

Command set executed successfully.
```

Configuring HTTP Load Balancing

This chapter describes how to configure HTTP load balancing on Payara Server.

Setting Up HTTP Load Balancing

This section describes how to set up load balancing for Payara Server.

Prerequisites for Setting Up HTTP Load Balancing

Before configuring your load balancer, you must:

- Install a supported web server (or web proxy) and configure it. If using the `mod_jk` or `mod_proxy_ajp` modules, the only supported web server is Apache HTTP Server 2.x.
- Configure the `mod_jk` connector module, as described in Configuring Payara Server with Apache

HTTP Server and `mod_jk`, or configure the `mod_proxy_ajp` connector module, as described in Configuring Payara Server with Apache HTTP Server and `mod_proxy_ajp`.

- Create Payara Server clusters or server instances (in a deployment group) to participate in load balancing.
- Deploy applications to these clusters or instances.

Configuring Payara Server with Apache HTTP Server and `mod_jk`

Payara Server can be configured for load balancing with Apache HTTP Server as a front end by enabling the Apache `mod_jk` connector module. To enable the `mod_jk` module in Payara Server, set the Payara Server `jk-enabled network-listener` attribute.

You can also create `jk-connectors` under different virtual-servers using the `jk-enabled network-listener` attribute.

To Configure the `mod_jk` Connector Module

1. Install Apache HTTP Server and mod_jk.
2. Configure `workers.properties` and `httpd.conf`. For example:
   - `apache2/config/workers.properties`

     ```
     # Define 1 real worker using ajp13
     worker.list=worker1
     # Set properties for worker1 (ajp13)
     worker.worker1.type=ajp13
     worker.worker1.host=localhost
     worker.worker1.port=8009
     ```

   - `apache2/conf/httpd.conf`

     ```
     LoadModule jk_module /Users/Amy/apache2/modules/mod_jk-1.2.25-httpd-2.2.4.so
     JkWorkersFile /Users/Amy/apache2/conf/worker.properties
     # Where to put jk logs
     JkLogFile /Users/Amy/apache2/logs/mod_jk.log
     # Set the jk log level [debug/error/info]
     JkLogLevel debug
     # Select the log format
     JkLogStampFormat "[%a %b %d %H:%M:%S %Y] "
     # JkOptions indicate to send SSL KEY SIZE,
     JkOptions +ForwardKeySize +ForwardURICompat -ForwardDirectories
     # JkRequestLogFormat set the request format
     JkRequestLogFormat "%w %V %T"
     # Send everything for context /examples to worker named worker1 (ajp13)
     JkMount /examples/* worker1
     ```

3. Start the Apache HTTP Server.

4. Create a `jk-enabled` network listener by using the `create-network-listener` subcommand.

```
asadmin> create-network-listener --protocol http-listener-1 --listenerport 8009
--jkenabled true jk-connector
```

5. If you are using an external file (like `payara-jk.properties`), set the `jk-configuration-file` property of the network listener to its absolute path's location.

```
asadmin> set server-config.network-config.network-listeners.network-listener.jk-
connector.jk-configuration-file=domain-dir/config/payara-jk.properties
```

6. If you expect to need more than five threads for the listener, increase the maximum threads in the `http-thread-pool` pool:

```
asadmin> set configs.config.server-config.thread-pools.thread-pool.http-thread-
pool.max-thread-pool-size=value
```

7. Restart the Payara Server instances.

This example shows an `httpd.conf` file that is set for load balancing.

```
LoadModule jk_module /usr/lib/httpd/modules/mod_jk.so
JkWorkersFile /etc/httpd/conf/worker.properties
# Where to put jk logs
JkLogFile /var/log/httpd/mod_jk.log
# Set the jk log level [debug/error/info]
JkLogLevel debug
# Select the log format
JkLogStampFormat "[%a %b %d %H:%M:%S %Y] "
# JkOptions indicate to send SSL KEY SIZE,
JkOptions +ForwardKeySize +ForwardURICompat -ForwardDirectories
# JkRequestLogFormat set the request format
JkRequestLogFormat "%w %V %T"
# Send all jsp requests to Payara Server
JkMount /*.jsp worker1
# Send all glassfish-test requests to Payara Server
JkMount /payara-test/* loadbalancer
```

The following example shows a `workers.properties` or `payara-server-jk.properties` file that is set for load balancing. The `worker.worker*.port` should match with the JK ports you configured:

```
worker.list=worker1,worker2,loadbalancer
worker.worker1.type=ajp13
worker.worker1.host=localhost
worker.worker1.port=8009
worker.worker1.lbfactor=1
```

```
worker.worker1.socket_keepalive=1
worker.worker1.socket_timeout=300
worker.worker2.type=ajp13
worker.worker2.host=localhost
worker.worker2.port=8010
worker.worker2.lbfactor=1
worker.worker2.socket_keepalive=1
worker.worker2.socket_timeout=300
worker.loadbalancer.type=lb
worker.loadbalancer.balance_workers=worker1,worker2
```

Configuring Payara Server with Apache HTTP Server and `mod_proxy_ajp`

Payara Server can be configured for load balancing with Apache HTTP Server as a front end by enabling the Apache `mod_proxy_ajp` connector module.

To enable the `mod_proxy_ajp` module in Payara Server, set the Payara Server `jk-enabled network-listener` attribute. You can also create `jk-connectors` under different virtual-servers using the `jk-enabled network-listener` attribute.

To Configure the `mod_proxy_ajp` Connector Module

1. Install Apache HTTP Server.
2. Configure the `httpd.conf` configuration file. For example:

```
LoadModule proxy_module /usr/lib/httpd/modules/mod_proxy.so
LoadModule proxy_ajp_module /usr/lib/httpd/modules/mod_proxy_ajp.so

Listen 1979
NameVirtualHost *:1979
<VirtualHost *:1979>
   ServerName localhost
   ErrorLog /var/log/apache2/ajp.error.log
   CustomLog /var/log/apache2/ajp.log combined

   <Proxy *>
     AddDefaultCharset Off
     Order deny,allow
     Allow from all
   </Proxy>

   ProxyPass / ajp://localhost:8009/
   ProxyPassReverse / ajp://localhost:8009/
</VirtualHost>
```

3. Start the Apache HTTP Server.
4. Create a `jk-enabled` network listener by using the `create-network-listener` subcommand.

```
asadmin> create-network-listener --protocol http-listener-1 --listenerport 8009
--jkenabled true jk-connector
```

5. If you expect to need more than five threads for the listener, increase the maximum threads in the `http-thread-pool` pool:

```
asadmin> set configs.config.server-config.thread-pools.thread-pool.http-thread-
pool.max-thread-pool-size=value
```

6. Restart the Payara Server instances.

HTTP Load Balancer Deployments

You can configure your load balancer in different ways, depending on your goals and environment, as described in the following sections:

Using Clustered Server Instances

The most common way to deploy the load balancer is with a cluster or clusters of server instances. By default, all the instances in a cluster have the same configuration and the same applications deployed to them. The load balancer distributes the workload between the server instances and requests fail over from an unhealthy instance to a healthy one. If you've configured HTTP session persistence, session information persists when the request is failed over.

If you have multiple clusters, requests can be load balanced across clusters but are only failed over between the instances in a single cluster. Use multiple clusters in a load balancer to easily enable **rolling upgrades** of applications.

Using Multiple Standalone Instances

It is also possible to configure your load balancer to use multiple standalone instances, and load balance and failover requests between them. However, in this configuration, you must manually ensure that the standalone instances have homogenous environments and the same applications deployed to them.

Because clusters automatically maintain a homogenous environment, for most situations it is better and easier to use clusters.

Load balancing across multiple standalone instances only provides failover for requests, and any associated HTTP session data will not be failed over.
This is another reason why using a cluster, which can provide session failover, is a more desirable load balancing configuration.

Configuring HA Session Persistence and Failover

This chapter explains how to enable and configure high availability session persistence.

Overview of Session Persistence and Failover

Payara Server provides high availability session persistence through failover of HTTP session data and stateful session bean (SFSB) session data. Failover means that in the event of a server instance or hardware failure, another server instance in a Cluster takes over a distributed session.

For example, Jakarta EE applications typically have significant amounts of session state data. A web shopping cart is the classic example of session state. Also, an application can cache frequently-needed data in the session object. In fact, almost all applications with significant user interactions need to maintain session state.

When using high availability session persistence together with a load balancer, use a load balancer that includes session-based stickiness as part of its load-balancing algorithm. Otherwise, session data can be misdirected or lost.

Requirements

A distributed session can run in multiple Payara Server instances, if:

- Each server instance has access to the same session state data.

  Payara Server supports in-memory session replication on standalone server instances (and as part of a deployment group) through the use of the Data Grid.

  In-memory session replication is enabled by default for Payara Server traditional clusters if the **Group Management Service** is enabled. For more information about GMS, see Group Management Service.

  If server instances in a cluster are located on different hosts, ensure that the following prerequisites are met:

  - To ensure that GMS and in-memory replication function correctly, the hosts must be on the same subnet.
  - To ensure that in-memory replication functions correctly, the system clocks on all hosts in the cluster must be synchronized as closely as possible.
- Each server instance has the same distributable web application deployed to it. The `web-app` element of the `web.xml` deployment descriptor file must contain the `distributable` element.
- The web application uses high-availability session persistence. If a non-distributable web application is configured to use high-availability session persistence, the server writes an error to the log file.
- The web application must be deployed using the `deploy` subcommand with the `--availabilityenabled` option set to `true`. For more information on these subcommands, see `deploy`.

Restrictions

When configuring session persistence and failover, note the following restrictions:

- When a session fails over, any references to open files or network connections are lost.

Applications must be coded with this restriction in mind.

- EJB Singletons are created for each server instance in a cluster, and not once per cluster.
- The high availability session persistence service is not compatible with dynamic deployment, dynamic reloading, and auto-deployment features.

  These features are for development, not production environments, so you must disable them before enabling the session persistence service.

  For information about how to disable these features, see the Payara Server Application Deployment section.

- Payara Server does not support High Availability Database (HA-DB) configurations. Instead, use in-memory replication, as described in High Availability Session Persistence.
- You can only bind certain objects to distributed sessions that support failover. Contrary to the Jakarta Servlet specification, Payara Server does not throw an `IllegalArgumentException` if an object type not supported for failover is bound into a distributed session.

  You can bind the following objects into a distributed session that supports failover:

  - Local home and object references for all EJB components.
  - Co-located stateless session, stateful session, or entity bean reference .
  - Distributed stateless session, stateful session, or entity bean reference.
  - JNDI Context for `InitialContext` and `java:comp/env`.
  - `UserTransaction` objects.

    However, if the instance that fails is never restarted, any prepared global transactions are lost and might not be correctly rolled back or committed.

  - Serializable Jakarta EE object types.
- You cannot bind the following object types into sessions that support failover:
  - JDBC DataSource
  - Jakarta Messaging `ConnectionFactory` and `Destination` objects
  - Jakarta Mail Session
  - Connection Factory
  - Administered Objects
  - Web service reference

    In general, for these objects, failover will not work. However, failover might work in some cases, if for example the object is serializable.

Scope

The availability service can be enabled for the following scopes, ranging from highest to lowest:

- Cluster

- Standalone server instance (may be part of a deployment group)
- Web, EJB, or JMS container in a cluster
- Application
- Standalone Web, EJB, or JMS module
- Individual Stateful Session Bean (SFSB)

In general, enabling or disabling availability session persistence for a cluster or container involves setting the boolean `availability-service` property to `true` or `false` by means of the `asadmin set` subcommand.

The availability service is enabled by default for Payara Server clusters and all Web, EJB, and JMS containers running in a cluster.

The value set for the `availability-service` property is inherited by all child objects running in a given cluster or container unless the value is explicitly overridden at the individual module or application level.

For example, if the `availability-service` property is set to `true` for an EJB container, the availability service will be enabled by default for all EJB modules running in that container.

Conversely, to enable availability at a given scope, you must enable it at all higher levels as well. For example, to enable availability at the application level, you must also enable it at the cluster or server instance and container levels.

Enabling the High Availability Session Persistence Service

This section explains how to configure and enable the high availability session persistence service.

To Enable Availability for a Cluster, Standalone Instance or Container

This procedure explains how to enable high availability for a cluster as a whole, or for Web, EJB, or JMS containers that run in a cluster, or for a standalone instance that may belong to a deployment group.

1. Create a Payara Server cluster or a new deployment group.
2. Set up load balancing for the cluster/deployment group.

   For instructions, see Setting Up HTTP Load Balancing.
3. Verify that all instances within the cluster/deployment group for which you want to enable availability are running.

   These steps are also necessary when enabling availability for a Web, EJB, or JMS container.

   a. Verify that all instances in the cluster/deployment group are running.

   ```
   asadmin> list-instances
   ```

A list of instances and their status is displayed. If the instances for which you want to enable availability are not running, you can start them by using the following command for each instance:

```
asadmin> start-instance instance-name
```

4. Use one of the following `asadmin set` subcommands to enable availability for a specific cluster or deployment group configuration, or for a specific Web, EJB, or JMS container.
   - For a cluster/deployment group as a whole

     ```
     asadmin> set <config>-name.availability-service.availability-enabled=true
     ```

     For example, for a cluster named `c1`:

     ```
     asadmin> set c1-config.availability-service.availability-enabled=true
     ```

   - For the Web container in a cluster/deployment group

     ```
     asadmin> set cluster-config.availability-service.web-container-
     availability.availability-enabled=true
     ```

   - For the EJB container in a cluster/deployment group

     ```
     asadmin> set cluster-config.availability-service.ejb-container-
     availability.availability-enabled=true
     ```

   - For the JMS container in a cluster/deployment group

     ```
     asadmin> set cluster-config.availability-service.jms-availability.availability-
     enabled=true
     ```

   - For a standalone server instance:

     ```
     asadmin> set <instance-name>-config.availability-service.availability-
     enabled=true
     ```

5. Restart the standalone server instance or each server instance in the cluster/deployment group.
6. Enable availability for any SFSB that requires it.

   Select methods for which checkpointing the session state is necessary.

   For more information, see Configuring Availability for an Individual Bean.

7. Make each web module distributable if you want it to be highly available.

   For more information, see "Web Module Deployment Guidelines" in the Payara Server Application Deployment section.

8. Enable availability for individual applications, web modules, or EJB modules during deployment.

   See the links below for instructions.

See Also

- Configuring Availability for Individual Web Applications
- Using Single Sign-on with Session Failover

Configuring Availability for Individual Web Applications

To enable and configure availability for an individual web application, edit the application deployment descriptor file (`glassfish-web.xml` or `payara-web.xml`). The settings in an application's deployment descriptor override the web container's availability settings.

The `session-manager` element's `persistence-type` attribute determines the type of session persistence an application uses.

It must be set to `hazelcast` (as this is the default persistence mode) to enable high availability session persistence.

Example

```
<payara-web-app>
  <session-config>
    <session-manager persistence-type="hazelcast">
      <manager-properties>
        <property name="persistenceFrequency" value="web-method" />
      </manager-properties>
      <store-properties>
        <property name="persistenceScope" value="session" />
      </store-properties>
    </session-manager>
  </session-config>
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

Configuring DataGrid Replication and Multi-Threaded Concurrent Access to `HttpSessions`

If you are using data replication via the Data Grid (`hazelcast`) and your web application involves multiple client threads concurrently accessing the same session ID, then you may experience

session loss even without any instance failure.

The problem is that the Payara Server Data Grid's replication framework makes use of session versioning.

This feature was designed with the more traditional HTTP request/response communication model in mind. However, for some types of applications, the traditional request/response model does not work. Examples include many Ajax-related frameworks and the use of **Frames**.

Another example is when a page includes many static resources, such as `JPG` files. In these situations, most browsers will optimize the loading of these resources by using multiple parallel connections, each of which is handled by a separate request processing thread. If the application has already established a session, then this will also involve more than one thread at a time accessing a single `HttpSession`.

The solution in such cases is to use the `relaxVersionSemantics` property in the `glassfish-web.xml` or `payara-web.xml` deployment descriptor file for the application.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

This enables the web container to return for each requesting thread whatever version of the session that is in the active cache regardless of the version number.

This is critical when multiple threads are interacting in an essentially non-deterministic fashion with the container.

Example

The following is an example snippet from a `payara-web.xml` file that illustrates where to add the `relaxVersionSemantics` property.

```
<payara-web-app>
  <session-config>
    <session-manager persistence-type="hazelcast">
      <manager-properties>
        <property name="relaxCacheVersionSemantics" value="true"/>
      </manager-properties>
    </session-manager>
  </session-config>
</payara-web-app>
```

Using Single Sign-on with Session Failover

In a single application server instance, once a user is authenticated by an application, the user is not required to re-authenticate individually to other applications running on the same instance. This is called single sign-on (SSO).

For this feature to continue to work even when an HTTP session fails over to another instance in a

cluster or deployment group, single sign-on information must be persisted using in-memory replication via the Data Grid

To persist single sign-on information, first, enable availability for the server instance and the web container, and then enable single-sign-on state failover.

You can enable single sign-on state failover by using the `asadmin set` command to set the configuration's `availability-service.web-container-availability.sso-failover-enabled` property to true.

For example, use the `set` command as follows, where `config1` is the configuration name:

```
asadmin> set config-1.availability-service.web-container-availability.sso-failover-
enabled="true"
```

Single Sign-On Groups

Applications that can be accessed through a single name and password combination constitute a **single sign-on group**.

For HTTP sessions corresponding to applications that are part of a single sign-on group, if one of the sessions times out, other sessions are not invalidated and continue to be available. This is because time out of one session should not affect the availability of other sessions.

As a corollary of this behavior, if a session times out and you try to access the corresponding application from the same browser window that was running the session, you are not required to authenticate again. However, a new session is created.

Take the example of a shopping cart application that is a part of a single sign-on group with two other applications. Assume that the session time out value for the other two applications is higher than the session time out value for the shopping cart application.

If your session for the shopping cart application times out and you try to run the shopping cart application from the same browser window that was running the session, you are not required to authenticate again. However, the previous shopping cart is lost, and you have to create a new shopping cart.

The other two applications continue to run as usual even though the session running the shopping cart application has timed out.

Similarly, suppose a session corresponding to any of the other two applications times out. You are not required to authenticate again while connecting to the application from the same browser window in which you were running the session.

This behavior applies only to cases where the session times out.
If single sign-on is enabled and you invalidate one of the sessions using `HttpSession.invalidate()`, the sessions for all applications belonging to the single sign-on group are invalidated

If you try to access any application belonging to the single sign-on group, you are required to authenticate again, and a new session is created for the client accessing the application.

Stateful Session Bean Failover

Stateful session beans (SFSBs) contain client-specific state. There is a one-to-one relationship between clients and the stateful session beans. At creation, the EJB container gives each SFSB a unique session ID that binds it to a client.

An SFSB state can be saved in a persistent store in case a server instance fails. The state of an SFSB is saved to the persistent store at predefined points in its life cycle. This is called *checkpointing*. If enabled, checkpointing generally occurs after the bean completes any transaction, even if the transaction rolls back.

However, if an SFSB participates in a bean-managed transaction, the transaction might be committed in the middle of the execution of a bean method. Since the bean's state might be undergoing transition as a result of the method invocation, this is not an appropriate time to checkpoint the bean's state.

In this case, the EJB container checkpoints the bean's state at the end of the corresponding method, provided the bean is not in the scope of another transaction when that method ends. If a bean-managed transaction spans across multiple methods, checkpointing is delayed until there is no active transaction at the end of a subsequent method.

The state of an SFSB is not necessarily transactional and might be significantly modified as a result of non-transactional business methods. If this is the case for an SFSB, you can specify a list of checkpointed methods, as described in Specifying Methods to Be Checkpointed

If a distributable web application references an SFSB, and the web application's session fails over, the EJB reference is also failed over.

If an SFSB that uses session persistence is un-deployed while the Payara Server instance is stopped, the session data in the persistence store might not be cleared.

To prevent this, undeploy the SFSB while the Payara Server instance is running.

Configuring Availability for the EJB Container

To enable availability for the EJB container use the `asadmin set` command to set the following three properties for the configuration:

- `availability-service.ejb-container-availability.availability-enabled`
- `availability-service.ejb-container-availability.sfsb-persistence-type`
- `availability-service.ejb-container-availability.sfsb-ha-persistence-type`

For example, if `config1` is the configuration name, use the following commands:

```
asadmin> set config1.availability-service.ejb-container-availability.availability-
enabled="true"
```

```
asadmin> set config1.availability-service.ejb-container-availability.sfsb-persistence-
type="file"

asadmin> set config1.availability-service.ejb-container-availability.sfsb-ha-
persistence-type="hazelcast"
```

Configuring the SFSB Session Store When Availability Is Disabled

If availability is disabled, the local file system is used for SFSB state passivation, but not persistence. To change where the SFSB state is stored, change the **Session Store Location** setting in the EJB container.

Configuring Availability for an Individual Application or EJB Module

You can enable SFSB availability for an individual application or EJB module during deployment:

- If you are deploying with the Administration Console, check the *Availability Enabled* checkbox.
- If you are deploying using use the `asadmin deploy` commands, set the `--availabilityenabled` option to `true`.

  For more information, see `deploy`.

Configuring Availability for an Individual Bean

To enable availability and select methods to be checkpointed for an individual SFSB, use the `glassfish-ejb-jar.xml` deployment descriptor file. To enable high availability session persistence, set `availability-enabled=true` in the `ejb` element, like this:

```
<glassfish-ejb-jar>
    <enterprise-beans>
        <ejb availability-enabled="true">
            <ejb-name>MySFSB</ejb-name>
        </ejb>
    </enterprise-beans>
</glassfish-ejb-jar>
```

Specifying Methods to Be Checkpointed

If enabled, checkpointing generally occurs after the bean completes any transaction, even if the transaction rolls back.

To specify additional optional checkpointing of SFSBs at the end of non-transactional business methods that cause important modifications to the bean's state, use the `checkpoint-at-end-of-method` element in the `ejb` element of the `glassfish-ejb-jar.xml` deployment descriptor file.

The non-transactional methods in the `checkpoint-at-end-of-method` element can be:

- `create()` methods defined in the home interface of the SFSB, if you want to checkpoint the initial state of the SFSB immediately after creation

- For SFSBs using container managed transactions only, methods in the remote interface of the bean marked with the transaction attribute `TX_NOT_SUPPORTED` or `TX_NEVER`
- For SFSBs using bean managed transactions only, methods in which a bean managed transaction is neither started nor committed

  Any other methods mentioned in this list are ignored.

At the end of invocation of each of these methods, the EJB container saves the state of the SFSB to persistent store.

If an SFSB does not participate in any transaction, and if none of its methods are explicitly specified in the `checkpoint-at-end-of-method`element, the bean's state is not checkpointed at all even if `availability-enabled="true"` for this bean. For better performance, specify a small subset of methods. The methods should accomplish a significant amount of work or result in important modification to the bean's state.

Example of EJB Deployment Descriptor Specifying Method Checkpoints

```
<glassfish-ejb-jar>
    <enterprise-beans>
        <ejb availability-enabled="true">
            <ejb-name>ShoppingCartEJB</ejb-name>
            <checkpoint-at-end-of-method>
                <method>
                    <method-name>addToCart</method-name>
                </method>
            </checkpoint-at-end-of-method>
        </ejb>
    </enterprise-beans>
</glassfish-ejb-jar>
```

Configuring JMS High Availability

This chapter describes how to configure the high availability features of the Java Message Service (JMS). It covers how to configure Message Queue broker clusters and how to use them to provide connection failover and load balancing.

It is important to be aware of the distinction between a message broker cluster (a group of broker instances) and a Payara Server cluster (a traditional group of server instances) to fully understand the concepts and instructions described in this chapter.

Documentation for the *Open Message Queue* software can be found in the following online resources:

- OpenMQ Technical Overview
- OpenMQ Administration Guide

Using Message Queue Broker Clusters With Payara Server

This section describes how the JMS service uses Message Queue broker clusters to support **high-availability** JMS messaging in Payara Server clusters and deployment groups. It describes the different cluster and broker types that are supported and how to configure them.

About Message Queue Broker Clusters

The following discussion provides a brief overview of Message Queue broker clusters.

Message Queue supports two clustering models both of which provide a scalable message service, but with each providing a different level of message service availability:

Conventional broker clusters

A conventional broker cluster provides for service availability. When a broker fails, clients connected to the failed broker reconnect to another broker in the cluster.

However, messages and state information stored in the failed broker cannot be recovered until the failed broker is brought back online.

The broker failure can therefore result in a significant delay and in JMS message order semantics not being preserved.

Message Queue supports two types of conventional cluster, based on where the cluster configuration change record is stored:

- **Conventional cluster with master broker**: In a conventional cluster with a master broker, one of the brokers, designated as the **master broker**, stores and maintains the cluster configuration change record. The other brokers in the cluster must communicate with the master broker to keep abreast of changes to the cluster configuration.

  This is the simplest broker cluster to configure, and is the type of broker cluster that Payara Server uses by default.

- **Conventional cluster of peer brokers**: In a conventional cluster of peer brokers, the cluster configuration change record is stored in a **JDBC data store** accessible to all the brokers.

  Thus, brokers can access cluster configuration information whether any other brokers in the cluster are running or not.

Enhanced broker clusters

An enhanced broker cluster provides for data availability in addition to service availability. When a broker fails, another broker takes over the pending work of the failed broker.

The failover broker has access to the failed broker's messages and state information. Clients connected to the failed broker reconnect to the failover broker.

In an enhanced cluster, as compared to a conventional cluster, messages owned by the failed broker are delivered by the failover broker **as soon as it takes over**, and JMS message order semantics are preserved.

By its very nature, an enhanced broker cluster is always cluster of peer brokers.

Despite the message service availability offered by both conventional and enhanced broker clusters, they do not provide a guarantee against failure and the possibility that certain failures, for example in the middle of a transaction, could require that some operations be repeated.
It is the responsibility of the messaging application (both producers and consumers) to respond to JMS exceptions appropriately.

Configuring Payara Server Clusters to Use Message Queue Broker Clusters

When a Payara Server cluster is created, the JMS service automatically configures a Message Queue **conventional broker cluster with master broker** for the cluster, provided that the JMS host type in the Payara Server cluster's configuration is either `Embedded` or `Local`.

The JMS service configures one Message Queue broker for each instance in the Payara Server cluster, and designates as master broker the broker associated with the **first instance** created in the cluster.

- In the case of `Embedded` JMS hosts, each broker inherently runs on the same host as the instance with which it is associated because it runs in the same JVM as the instance.
- In the case of `Local` JMS hosts, the JMS service configures each broker to run on the same host as the instance with which it is associated.

The JMS service manages the lifecycle of `Embedded` and `Local` JMS hosts, and this management extends to the management of Message Queue broker clusters as `Embedded` and `Local` JMS hosts. For a Payara Server cluster whose configuration specifies `Embedded` or `Local` JMS host type, the JMS service:

1. Creates and manages ONE Message Queue broker for each instance in the Payara Server cluster, using this broker instance as the primary JMS host for the instance, keeping a one-to-one relationship between both.
2. Maintains the JMS host list for each instance in the Payara cluster such that its primary JMS host appears first in its JMS host list.

The JMS service supports the following types of Message Queue broker clusters with Payara Server clusters, based on the JMS host type:

`Embedded`

- Conventional broker cluster with master broker (default)
- Conventional broker cluster of peer brokers

`Local`

- Conventional broker cluster with master broker (default)
- Conventional broker cluster of peer brokers
- Enhanced broker cluster

`Remote`

- Conventional broker cluster with master broker.

  Brokers can differ in number from Payara Server instances and can be located on other hosts

- Conventional broker cluster of peer brokers.

  Brokers can differ in number from Payara Server instances and can be located on other hosts

- Enhanced broker cluster.

  Brokers can differ in number from Payara Server instances and can be located on other hosts.

It is recommended that in a robust production environment configuration, the JMS service must be configured in either `Local` or `Remote` mode.
The `Embedded` mode is not recommended for the usual reliability and scalability that a production system may require.

The following topics provide instructions for configuring broker clusters in all these contexts.

Deployment Groups Considerations

The instructions provided will also apply to **deployment groups** as well, however, it is mandatory that all Payara Server instances reference the same named configuration object. If multiple instances in the same deployment group reference multiple, separate configuration objects, high availability for the JMS service won't be guaranteed.

When running the commands listed in the respective instructions, instead of targeting a server cluster, you can target a deployment group instead.

To Configure a Payara Cluster to Use an Embedded or Local Conventional Broker Cluster With Master Broker

Use the `configure-jms-cluster` subcommand in remote `asadmin` mode to configure a conventional broker cluster with master broker to service a Payara Server cluster that uses either `Embedded` or `Local` JMS hosts.

Note that the `Embedded` mode brokers configuration is the default for Payara Server clusters.

Before You Begin: Perform the following steps after you have created the Payara Server cluster, but before you have added instances to the cluster or started the cluster.

Before using this procedure to reconfigure an existing cluster, you must follow the special procedures to migrate to another type of broker cluster, as described in To Migrate Between Types of Embedded or Local Conventional Broker Clusters.
Failing to perform these special procedures could lead to data loss or corruption and even render your setup unusable, depending on the JMS operations performed on the existing cluster.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Configure the Payara Server cluster to use a Message Queue conventional broker cluster with master broker by using the `configure-jms-cluster` subcommand:

```
asadmin configure-jms-cluster --clustertype=conventional
--configstoretype=masterbroker payara-cluster-name
```

See Also

You can also view the full syntax and options of the subcommand by typing `asadmin help configure-jms-cluster` at the command line.

To Configure a Payara Server Cluster to Use an Embedded or Local Conventional Broker Cluster of Peer Brokers

Use the `configure-jms-cluster` subcommand in remote `asadmin` mode to configure a conventional broker cluster of peer brokers to service a Payara Server cluster that uses `Embedded` or `Local` JMS hosts.

Before You Begin: Perform the following steps after you have created the Payara Server cluster, but before you have added instances to the cluster or started it.

Before using this procedure to reconfigure an existing cluster, you must follow the special procedures to migrate to another type of broker cluster, as described in To Migrate Between Types of Embedded or Local Conventional Broker Clusters.
Failing to perform these special procedures could lead to data loss or corruption and even render your setup unusable, depending on the JMS operations performed on the existing cluster.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Create a password file with the entry `AS_ADMIN_JMSDBPASSWORD` specifying the password of the database user.

   For information about password file entries, see the `asadmin` help page.

3. Place a copy of, or a link to, the database's JDBC driver `.jar` file in the appropriate directory, depending on the JMS host type, on each host where a Payara Server cluster instance is to run:
   - Embedded: `as-install-parent/payara/lib/install/applications/jmsra`
   - Local: `as-install-parent/mq/lib/ext`
4. Configure the Payara Server cluster to use a Message Queue conventional broker cluster with master broker by using the `configure-jms-cluster` subcommand:

```
asadmin --passwordfile password-file configure-jms-cluster
--clustertype=conventional --configstoretype=shareddb --dbvendor database-vendor-
name --dbuser database-user-name --dburl database-url --property list-of-database-
specific-properties <server-cluster-name>
```

See Also

You can also view the full syntax and options of the subcommand by typing `asadmin help configure-jms-cluster` at the command line.

To Change the Master Broker in an Embedded or Local Broker Cluster

Use the `change-master-broker` subcommand in remote `asadmin` mode to change the master broker to a different broker in a conventional broker cluster with master broker serving a Payara Server cluster that uses `Embedded` or `Local` JMS hosts.

Follow this procedure, for example, before you remove from a Payara Server cluster the instance associated with the current master broker.

Before You Begin: Although not an absolute requirement, you should make sure all Payara Server instances and Message Queue brokers in the cluster are running before using the `change-master-broker` command in order to avoid later internal configuration synchronization of any unavailable instance or broker.

1. Ensure that the server is running.

   Remote `asadmin` subcommands require a running server.

2. Change the master broker by using the `change-master-broker` subcommand:

   ```
   asadmin change-master-broker payara-clustered-instance-name
   ```

See Also

You can also view the full syntax and options of the subcommand by typing `asadmin help change-master-broker` at the command line.

To Migrate Between Types of Embedded or Local Conventional Broker Clusters

If the need arises to convert from a conventional broker cluster with master broker to a conventional broker cluster of peer brokers, or the reverse, follow the instructions in the **Managing Conventional Clusters** section of the OpenMQ Administration Guide.

To Configure a Payara Server Cluster to Use a Local Enhanced Broker Cluster

Use the `configure-jms-cluster` subcommand in remote `asadmin` mode to configure an enhanced broker cluster to service a Payara Server cluster that uses `Local` JMS hosts.

Before You Begin: Perform the following steps after you have created the Payara Server cluster, but before you have added instances to the cluster or started it.

Before using this procedure to reconfigure an existing cluster, you must follow the special procedures to migrate from a conventional broker cluster to an enhanced broker cluster, as described in the **Converting a Conventional Cluster to an Enhanced Cluster** section in the OpenMQ Administration Guide.

> Failing to perform these special procedures could lead to data loss or corruption and even render your setup unusable, depending on the JMS operations performed on the existing cluster.

1. Ensure that the server is running. Remote `asadmin` subcommands require a running server.
2. Create a password file with the entry `AS_ADMIN_JMSDBPASSWORD` specifying the password of the database user.

   For information about password file entries, see the `asadmin` help page.
3. Place a copy of, or a link to, the database's JDBC driver `.jar` file in the `as-install-parent/mq/lib/ext` directory on each host where a Payara Server cluster instance is running.
4. Configure the Payara Server cluster to use a Message Queue enhanced broker cluster by using the `configure-jms-cluster` subcommand:

   ```
   asadmin --passwordfile password-file configure-jms-cluster --clustertype=enhanced
   --configstoretype=shareddb --messagestoretype=jdbc --dbvendor database-vendor-name
   --dbuser database-user-name --dburl database-url --property list-of-database-
   specific-properties payara-cluster-name
   ```

See Also

You can also view the full syntax and options of the subcommand by typing `asadmin help configure-jms-cluster` at the command line.

To Configure a Payara Server Cluster to Use a Remote Broker Cluster

Before You Begin

Perform the following steps after you have:

- Used Message Queue to create a broker cluster.
- Created the Payara Server cluster, but not yet created instances for the cluster.

1. Ensure that the server is running. The remote subcommands used in this procedure require a running server.
2. Delete the `default_JMS_host` JMS host by using the `delete-jms-host` subcommand:

   ```
   asadmin delete-jms-host --target payara-cluster-name default_JMS_host
   ```
3. Create a JMS host for each broker in the broker cluster by using the `create-jms-host` subcommand.

   For each broker, use an `asadmin create-jms-host` command instruction like this:

   ```
   asadmin create-jms-host --target payara-cluster-name --mqhost broker-host
   --mqport broker-port --mquser mq-user --mqpassword mq-user-password <jms-host-
   ```

```
name-for-broker>
```

4. Start the brokers in the cluster by using the Message Queue `imqbrokerd` command, as described in the **Managing Broker Clusters** section the in OpenMQ Administration Guide.
5. Create instances in the Payara Server cluster, as described in To Create an Instance Centrally and To Create an Instance Locally.

Connection Failover

The use of Message Queue broker clusters provides JMS connection failover, including several options that control how connection failures are handled.

Use the Administration Console's Java Message Service page to configure these options. To display this page, click the configuration for the Payara server cluster or instance's configuration in the navigation pane, and then click the **Java Message Service** link on the Configuration page.

The way in which connection failover operates depends on whether the broker cluster is configured to be conventional or enhanced:

- In a **conventional cluster**, when a broker fails, clients may reconnect to any other broker in the cluster.

  The *Reconnect* field specifies whether reconnection should take place, and the *Address List Behavior* and *Address List Iterations* fields specify how the client chooses what broker to fail over to.

- In an **enhanced cluster**, when a broker fails, another broker automatically takes over its messages and clients.

  Clients automatically fail over to the appropriate broker. The *Reconnect*, *Address List Behavior* and *Address List Iterations* fields are ignored.

For more information on connection failover, including how failover on conventional clusters differs from failover on enhanced clusters, see the **Automatic Reconnection** in the OpenMQ Administration Guide.

Reconnect

Applies only to conventional clusters. Enables reconnection and connection failover.

When **disabled**, the Java Message Service does not attempt to reconnect if a connection fails.

Reconnect Interval

Specifies the number of seconds between reconnection attempts.

If it is too short, this time interval does not give a broker time to recover.

If it is too long, the wait time might represent an unacceptable delay.

The default value is `5` seconds.

Reconnect Attempts

Specifies the number of attempts to connect (or reconnect) to a particular JMS host before trying another host in the JMS host list. The host list is also known as the *Address List*.

Hosts are chosen from the address list either in order or randomly, depending on the setting of Address List Behavior.

Address List Behavior

For conventional clusters, this field specifies how the Java Message Service selects which JMS host in the JMS hosts list to initially connect to, and if the broker fails, how the Java Message Service selects which JMS host in the JMS hosts list to fail over to.

For enhanced clusters, this field specifies how the Java Message Service selects which JMS host in the JMS hosts list to initially connect to.

When performing initial connection or, for conventional clusters only, when performing failover, then if this attribute is set to `Priority`, the Java Message Service tries to connect to the first JMS host specified in the JMS hosts list and uses another one only if the first one is not available. If this attribute is set to `Random`, the Java Message Service selects the JMS host randomly from the JMS hosts list. If that host is not available, another one is chosen randomly.

The default value for `Embedded` and `Local` JMS host types is `Priority`, and the default for the Remote JMS host type is `Random`.

For `Embedded` and `Local` JMS host types, the Java Message Service ensures that the Message Queue broker servicing a clustered instance appears first in that instance's JMS host list.

Thus, having `Priority` as the default *Address List Behavior* ensures that an application deployed to a clustered instance will always try to create its initial connection to that instance's co-located broker.

If there are many clients attempting a connection using the same connection factory, use the `Random` setting to prevent them from all attempting to create their initial connection to the same JMS host.

Address List Iterations

For conventional clusters, this field specifies the number of times the Java Message Service iterates through the JMS hosts list in an effort to establish its initial connection.

If the broker fails, this field specifies the number of times the Java Message Service iterates through the JMS hosts list in an effort to fail over to another broker.

For enhanced clusters, this field specifies the number of times the Java Message Service iterates through the JMS hosts list in an effort to establish its initial connection. If the broker fails, this field is not used when performing reconnection.

You can override these settings using JMS connection factory settings. For details, see "Administering JMS Connection Factories and Destinations" in the Payara Server General Administration section.

Load-Balanced Delivery to MDBs

When a message-driven bean (MDB) application is deployed to a Payara Server cluster, incoming messages are delivered randomly to MDBs without regard to the server cluster instances in which they are running.

If the MDB is configured to receive messages from a durable or non-durable subscription on a topic, then only one MDB instance across the whole Payara Server cluster will receive each message.

For more information about these features, see the **About Shared Topic Subscriptions for Clustered Containers** section in the OpenMQ Administration Guide.

RMI IIOP Load Balancing and Failover

This chapter describes using high-availability features for remote EJB references and JNDI objects over RMI-IIOP in Payara Server.

- Overview
- InitialContext Load Balancing
- Per-Request Load Balancing (PRLB)

Overview

With RMI-IIOP load balancing, IIOP client requests are distributed to different server instances or name servers. The goal is to spread the load evenly across the cluster, thus providing scalability. IIOP load balancing combined with EJB clustering and availability also provides EJB failover.

General Requirements for Configuring Load Balancing

Payara Server provides high availability of remote EJB references and `NameService` objects over RMI-IIOP, provided all the following apply:

- Your deployment has a cluster (or deployment group) of at least two instances.
- Jakarta EE applications are deployed to all instances and clusters that participate in load balancing.
- RMI-IIOP client applications are enabled for load balancing.

Payara Server supports load balancing for Jakarta applications executing in the Application Client Container (ACC).

See Enabling RMI-IIOP Hardware Load Balancing and Failover.

Payara Server does not support RMI-IIOP load balancing and failover over secure sockets layer (SSL).

Load Balancing Models

Payara Server supports two general models for load balancing:

`InitialContext` Load Balancing

When a client performs a JNDI lookup for an object, the Naming Service creates a `InitialContext` (IC) object associated with a particular server instance.

From then on, all lookup requests made using that IC object are sent to the same server instance. `InitialContext` load balancing can be configured automatically across an entire cluster.

Per-Request Load Balancing (PRLB)

Per Request Load Balancing (PRLB) is a method for load balancing stateless EJBs that enables load-balancing for each request to an EJB instance.

PRLB chooses the first node in a cluster to use on each request. PRLB is configured on a per-EJB basis.

`InitialContext` Load Balancing

`InitialContext` Summary

When `InitialContext` load balancing is used, the client calls the `InitialContext()` method to create a new `InitialContext` (IC) object that is associated with a particular server instance. JNDI lookups are then performed on that IC object, and all lookup requests made using that IC object are sent to the same server instance.

All `EJBHome` objects looked up with that `InitialContext` are hosted on the same target server. Any bean references obtained henceforth are also created on the same target host. This effectively provides load balancing, since all clients randomize the list of live target servers when creating `InitialContext` objects.

If the target server instance goes down, the lookup or EJB method invocation will fail over to another server instance. All objects derived from same `InitialContext` will fail over to the same server instance.

IIOP load balancing and failover happens transparently. No special steps are needed during application deployment. IIOP load balancing and failover for the Payara Server supports dynamically reconfigured clusters.

If the Payara Server instance on which the application client is deployed participates in a cluster, the Payara Server finds all currently active IIOP endpoints in the cluster automatically. Therefore, you are not required to manually update the list of endpoints if a new instance is added to the cluster or deleted from the cluster.

However, a client should have at least two endpoints specified for bootstrapping purposes, in case one of the endpoints has failed.

`InitialContext` Algorithm

Payara Server uses a randomization and round-robin algorithm for RMI-IIOP load balancing and failover.

When an RMI-IIOP client first creates a new `InitialContext` object, the list of available Payara

Server IIOP endpoints is randomized for that client.

For that `InitialContext` object, the load balancer directs lookup requests and other `InitialContext` operations to an endpoint on the randomized list. If that endpoint is not available then a different random endpoint in the list is used.

Each time the client subsequently creates a new `InitialContext` object, the endpoint list is rotated so that a different IIOP endpoint is used for `InitialContext` operations. The rotation is randomized, so the rotation is not to the next endpoint in the list, but instead to a random endpoint in the list.

When you obtain or create beans from references obtained by an `InitialContext` object, those beans are created on the Payara Server instance serving the IIOP endpoint assigned to the `InitialContext` object. The references to those beans contain the IIOP endpoint addresses of all Payara Server instances in the cluster.

The primary endpoint is the bean endpoint corresponding to the `InitialContext` endpoint used to look up or create the bean.

The other IIOP endpoints in the cluster are designated as alternate endpoints. If the bean's primary endpoint becomes unavailable, further requests on that bean fail over to one of the alternate endpoints.

You can configure RMI-IIOP load balancing and failover to work with applications running in the ACC.

Enabling RMI-IIOP Hardware Load Balancing and Failover

You can enable RMI-IIOP load balancing and failover for applications running in the application client container (ACC). Weighted round-robin load balancing is also supported.

To Enable RMI-IIOP Hardware Load Balancing for the Application Client Container

This procedure provides an overview of the steps necessary to enable RMI-IIOP load balancing and failover with the application client container (ACC). For additional information on the ACC, see "Developing Clients Using the ACC" in Payara Server Application Development section.

Before You Begin

The first five steps in this procedure are only necessary if you are enabling RMI-IIOP load balancing on a system other than the DAS.

This is common in production environment, but less common in a development environment.

For example, a developer who wants to experiment with a cluster and load balancing might create two instances on the same system on which the DAS is running. In such cases, these steps are unnecessary.

1. Go to the `install_dir/bin` directory.
2. Run the `package-appclient` utility.

   This utility produces an `appclient.jar` file. For more information on `package-appclient`, see

`package-appclient`.

3. Copy the `appclient.jar` file to the machine where you want your client and extract it.
4. Edit the `asenv.conf` or `asenv.bat` path variables to refer to the correct directory values on that machine.

   The file is at `appclient-install-dir/config/`.

   For a list of the path variables to update, see `package-appclient`.

5. If required, make the `appclient` script executable.

   For example, on UNIX use `chmod 700`.

6. [[Technical Documentation-Payara Server Documentation-High Availability-RMI IIOP Load Balancing and Failover:::find-the-iiop-listener-port-number-for-at-least-two-instances-in-the-cluster]]Find the IIOP listener port number for at least two instances in the cluster.

   You specify the IIOP listeners as endpoints in Add at least two `target-server` elements in the `sun-acc.xml` file..

   For each instance, obtain the IIOP listener ports as follows:

   a. Verify that the instances for which you want to determine the IIOP listener port numbers are running.

      ```
      asadmin> list-instances
      ```

      A list of instances and their status (running, not running) is displayed. The instances for which you want to display the IIOP listener ports must be running.

   b. For each instance, enter the following command to list the various port numbers used by the instance.

      ```
      asadmin> get servers.server.instance-name.system-property.*.value
      ```

      For example, for an instance name `in1`, you would enter the following command:

      ```
      asadmin> get servers.server.in1.system-property.*.value
      ```

7. [[Technical Documentation-Payara Server Documentation-High Availability-RMI IIOP Load Balancing and Failover:::add-at-least-two-target-server-elements-in-the-sun-acc.xml-file]] Add at least two `target-server` elements in the `sun-acc.xml` file.

   Use the endpoints that you obtained in Find the IIOP listener port number for at least two instances in the cluster.

   If the Payara Server instance on which the application client is deployed participates in a

cluster, the ACC finds all currently active IIOP endpoints in the cluster automatically. However, a client should have at least two endpoints specified for bootstrapping purposes, in case one of the endpoints has failed.

The `target-server` element specifies one or more IIOP endpoints used for load balancing. The `address` attribute is an IPv4 address or hostname, and the `port` attribute specifies the port number. See "client-container" in the Payara Server Application Deployment section.

As an alternative to using `target-server` elements, you can use the `endpoints` property as follows:

```
jvmarg value = "-Dcom.sun.appserv.iiop.endpoints=host1:port1,host2:port2,..."
```

8. If you require weighted round-robin load balancing, perform the following steps:
   a. Set the load-balancing weight of each server instance.

      ```
      asadmin set instance-name.lb-weight=weight
      ```

   b. In the `sun-acc.xml`, set the `com.sun.appserv.iiop.loadbalancingpolicy` property of the ACC to `ic-based-weighted`.

      ```
      <client-container send-password="true">
        <property name="com.sun.appserv.iiop.loadbalancingpolicy" value="ic-based-
      weighed"/>
      </client-container>
      ```

9. Deploy your client application with the `--retrieve` option to get the client jar file. Keep the client jar file on the client machine. For example:

   ```
   asadmin  --user admin --passwordfile pw.txt deploy --target cluster1 --retrieve
   my_dir myapp.ear
   ```

10. Run the application client as follows:

    ```
    appclient --client my_dir/myapp.jar
    ```

In the following example, the load-balancing weights in a cluster of three instances are to be set as shown in the following table.

Instance Name	Load-Balancing Weight
i1	100
i2	200

Instance Name	Load-Balancing Weight
i3	300

The sequence of commands to set these load balancing weights is as follows:

```
asadmin set i1.lb-weight=100
asadmin set i2.lb-weight=200
asadmin set i3.lb-weight=300
```

Next Steps

To test failover, stop one instance in the cluster and see that the application functions normally. You can also have breakpoints (or thread sleep calls) in your client application.

To test load balancing, use multiple clients and see how the load gets distributed among all endpoints.

See Also

See Enabling the High Availability Session Persistence Service for instructions on enabling the session availability service for a cluster or for a Web, EJB, or JMS container running in a cluster.

Per-Request Load Balancing (PRLB)

Per Request Load Balancing (PRLB) is a method for load balancing stateless EJBs that enables load-balancing for each request to an EJB instance. **PRLB** chooses the first node in a cluster to use on each request. By contrast, `InitialContext` (hardware) load balancing chooses the first node to use when the `InitialContext` is created, and each request thereafter uses the same node unless a failure occurred.

PRLB is enabled by means of the boolean `per-request-load-balancing` property in the `glassfish-ejb-jar.xml` deployment descriptor file for the EJB. If this property is not set, the original load balancing behavior is preserved.

PRLB is only supported for stateless session beans. Using PRLB with any other bean types will result in a deployment error.

Enabling Per-Request Load Balancing

You can enable Per-Request Load Balancing (PRLB) by setting the boolean `per-request-load-balancing` property to `true` in the `glassfish-ejb-jar.xml` deployment descriptor file for the EJB. On the client side, the `initContext.lookup` method is used to access the stateless EJB.

To Enable RMI-IIOP Per-Request Load Balancing for a Stateless EJB

This procedure describes how to enable PRLB for a stateless EJB that is deployed to clustered Payara Server instances. This procedure also provides a client-side example for accessing a stateless EJB that uses PRLB.

1. Choose or assemble the EJB that you want to deploy. In this example, an EJB named `TheGreeter` is used.

   For instructions on developing and assembling an EJB for deployment to Payara Server, refer to the following documentation:

   - "Using Jakarta Enterprise Beans Technology" in the Payara Server Application Development section
   - "EJB Module Deployment Guidelines" in the Payara Server Application Deployment section
   - "Assembling and Deploying an Application Client Module" in the Payara Server Application Deployment section

2. Set the `per-request-load-balancing` property to `true` in the `glassfish-ejb-jar.xml` deployment descriptor file for the EJB.

   For more information about the `glassfish-ejb-jar.xml` deployment descriptor file, refer to "The glassfish-ejb-jar.xml File" in the Payara Server Application Deployment section.

   For example, the `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` file for a sample EJB named `TheGreeter` is listed below.

   ```
   <payara-ejb-jar>
     <enterprise-beans>
       <unique-id>1</unique-id>
       <ejb>
           <ejb-name>TheGreeter</ejb-name>
           <jndi-name>greeter</jndi-name>
           <per-request-load-balancing>true</per-request-load-balancing>
       </ejb>
     </enterprise-beans>
   </payara-ejb-jar>
   ```

3. Deploy the EJB.

   If the EJB was previously deployed, it must be re-deployed.

   For instructions on deploying EJBs, refer to the following documentation: * "To Deploy an Application or Module" in the Payara Server Application Deployment section * "To Redeploy an Application or Module" in the Payara Server Application Deployment section

4. Verify the PRLB configuration by looking for the following `FINE` message in the CORBA log file:

   ```
   Setting per-request-load-balancing policyfor EJB EJB-name
   ```

5. Configure a client application to access the PRLB-enabled EJB. For example:

   ```
   public class EJBClient {
   ```

```
    public static void main(String[] args) {
        try {
            // only one lookup
            var reference =
initContext.lookup("test.cluster.loadbalancing.ejb.TestSessionBeanRemote");
            var myGreeterRemote =
(TestSessionBeanRemote)PortableRemoteObject.narrow(reference,
TestSessionBeanRemote.class);

        } catch (Exception e) {}

        for (int i=0; i < 10; i++ ) {
            var message = myGreeterRemote.sayHello(Integer.toString(i));
            System.out.println("got"+": " + message);
        }
    }
}
```

Security Guide

Overview

This security guide provides instructions for configuring and administering basic security concerns in Payara Server.

Administering System Security

This chapter describes general information about administering system security.

Information on application security is contained in "Securing Applications" in the Application Development section.

About System Security in Payara Server

Security is about protecting data, that is, how to prevent unauthorized access or damage to data that is in storage or in transit. Payara Server is built on the Java security model, which uses a sandbox where applications can run safely, without potential risk to systems or users.

System security affects all the applications in a Payara Server environment.

The Jakarta Security specification defines portable, plug-in interfaces for authentication and identity stores, and a new injectable-type `SecurityContext` interface that provides an access point for programmatic security. You can use the built-in implementations of the plug-in SPIs, or write your own custom implementations.

Authentication

Authentication is the way in which an entity (a user, an application, or a component) determines that another entity is who it claims to be. An entity uses security credentials to authenticate itself. The credentials might be a username and password, a digital certificate, or something else.

Usually, servers or applications require clients to authenticate themselves. Additionally, clients might require servers to authenticate themselves. When authentication is bidirectional, it is called **mutual authentication**.

When an entity tries to access a protected resource, Payara Server uses the authentication mechanism configured for that resource to determine whether to grant access. For example, a user can enter a set of credentials in a web browser, and if the application verifies those credentials, the user is authenticated. The user is associated with this authenticated security identity for the remainder of the session.

Authentication Types

Within its deployment descriptors, an application can specify the type of authentication that it uses. The Jakarta Security API provides an alternative mechanism for configuring the type of authentication an application uses.

Payara Server supports specifying the following types of authentication in deployment descriptors:

BASIC

Uses the standard `Basic` Authentication Scheme as described in RFC2617. The communication protocol is HTTP (secure transport is optional).

There is no encryption of user credentials unless using secure transport.

This type is not considered to be a secure method of user authentication unless used in conjunction with an encrypted communications channel, such as that provided by SSL/TLS.

FORM

The application provides its own custom login and error webpages. The communication protocol is HTTP (secure transport is optional).

There is no encryption of user credentials unless using secure transport.

CLIENT-CERT

The server authenticates the client using a public key certificate.The communication protocol is HTTPS (secure transport required).

DIGEST

The server authenticates a user based on a username and a password. Unlike `BASIC`

authentication, the plaintext password is never sent over the network, although a hash of the password combined with other parameters is sent.

While `Digest` Authentication is more secure than `Basic` Authentication, usernames and passwords are not strongly protected, and the use of secure transport is heavily recommended.

Jakarta Security Authentication Mechanisms and Identity Stores

The Jakarta Security API defines the `HttpAuthenticationMechanism` interface, the `IdentityStore` and `IdentityStoreHandler` interfaces.

The `HttpAuthenticationMechanism` interface defines an SPI for writing authentication mechanisms that can be provided with an application and deployed using CDI. Developers can write their own implementations of `HttpAuthenticationMechanism` to support specific authentication token types or protocols. There are also several built-in authentication mechanisms that perform `BASIC`, `FORM`, and Custom `FORM` authentication.

The `HttpAuthenticationMechanism` interface defines three methods - `validateRequest()`, `secureResponse()`, and `cleanSubject()`. These methods align closely with the methods defined by the Jakarta Authentication's `ServerAuth` interface.

The `IdentityStore` interface provides an abstraction of an identity store that holds user account information including name, password, group membership, and other additional attributes. Implementations of the `IdentityStore` interface are used to validate caller credentials, typically username and password, and retrieve and group information. There are built-in implementations of this interface that can validate credentials against external **LDAP** or **Database** identity stores.

`IdentityStore` is intended primarily for use by `HttpAuthenticationMechanism` implementations, but could be used by other authentication mechanisms, such as a Jakarta Authentication `ServerAuthModule` implementation, or a runtime built-in authentication mechanisms. Though `HttpAuthenticationMechanism` implementations can authenticate users in any manner they choose, the `IdentityStore` interface provides a convenient mechanism.

A significant advantage of using `HttpAuthenticationMechanism` and `IdentityStore` over the declarative mechanisms defined by the Jakarta Servlet specification is that it allows an application to control the identity stores that it authenticates against, in a standard, portable way. You can use the built-in implementations of the plug-in SPIs, or define custom implementations.

Passwords

Passwords are your first line of defense against unauthorized access to the components and data of Payara Server. For Information about how to use passwords for Payara Server, see Administering Passwords.

Master Password and Java Keystores

The master password is not tied to a user account, and it is not used for authentication. Instead, Payara Server strictly uses the master password to ONLY encrypt the keystore and truststore used to store keys and certificates for the DAS and instances usage.

When you create a new Payara Server domain, a new self-signed certificate is generated and stored

in the domain keystore and truststore. The DAS needs the master password to open both stores at startup. Similarly, the associated server instances need the master password to open their copy of these stores at startup.

If you use a utility such as `keytool` to modify the keystore or truststore, you must provide the master password in that case as well.

The default master password (unless changed at domain creation) is `changeit`.

The master password is a shared password and must be the same for the DAS and all instances in the domain in order to manage the instances from the DAS. However, because Payara Server never transmits the master password over the network, it is up to you to keep the master password in sync between the DAS and instances.

If you change the master password, you can choose to enter the master password manually when required, or save it in a file.

Understanding Master Password Synchronization

Payara Server keeps the keystore and truststore for the DAS and instances in sync, which guarantees that all copies of the stores are encrypted with the same master password at any given time.

However, Payara Server **does not synchronize** the master password itself, and it is possible that the DAS and instances might attempt to use different master passwords.

Consider the following potential scenario:

1. You create a domain and instances, using the default master password. As a result, the DAS and instances have keystores and truststores encrypted using `changeit`.
2. You use the `change-master-password` subcommand on the DAS to change the master password to `ichangedit`. As a result, the DAS and instance keystores and truststores are encrypted using `ichangedit`.
3. Access to the keystore and truststore from an instance now requires the master password `ichangedit`. You are responsible for changing the master password in each corresponding instance as needed.

If you do not use a master password file, you assume the responsibility for using the `change-master-password` subcommand on the DAS and instances to keep the master passwords in sync.

If you do use a master password file, you assume the responsibility for using the `change-master-password` subcommand on the DAS and instances to keep the master password file in sync.

Using the Default Master Password

Payara Server uses the known text string `changeit` as the default master password. This master password is not stored in a file. The default password is a convenience feature and provides no additional security because it is assumed to be widely known.

It is recommended to change the default master password in most production environment settings to prevent unwanted access to the server's configured keystore and truststores.

All Payara Server subcommands work as expected with the default master password and there are no synchronization issues.

Saving the Master Password to a File

The `change-master-password --savemasterpassword` option indicates whether the master password should be written to the file system in the `master-password` file for the DAS or a node. The default setting is `false`.

- For a domain, the master password is kept in the `domain-dir/master-password` file.
- For a node, the master-password file is kept in `as_install/nodes/<node-name>/agent/master-password`.

  You can set a master password at the node level and all instances created on that node will use that master-password file. To do this, use the `--nodedir` option and provide the corresponding node name.

You might want to save the master password to the file so that the `start-domain` subcommand can start the server without having to prompt the user.

The master-password file is encoded, not encrypted. You must use filesystem permissions to protect the file.

Using the Master Password When Creating a Domain

The `create-domain --usemasterpassword` option specifies whether the keystore and truststore are encrypted with a master password that is built into the system, or by a user-defined master password.

- If `false` (default), the keystore is encrypted with the default master password.
- If `true`, the subcommand obtains the master password from the `AS_ADMIN_MASTERPASSWORD` entry in the password file you specified in the `--passwordfile` option of the `asadmin` utility. Or, if none is defined, the `--usemasterpassword` option prompts the user for the master password.

Administration Password

An administration password, also known as the admin password, is used to invoke the Administration Console and the Asadmin CLI utility. As with the default `admin` username, the default admin password is usually set during installation, but it can be changed.

For instructions, see To Change an Administration Password.

Encoded Passwords

Files that contain encoded passwords need to be protected using file system permissions. These

files include the following:

- `domain-dir/master-password`

  This file contains the encoded master password and should be protected with the default file system permissions set to `600` (in most *Nix systems).

- Any password file created to pass as an argument by using the `--passwordfile` argument to the `asadmin` CLI.

  Additionally, any password file being used for a transient purpose, such as setting up SSH nodes, should be deleted after it has served its purpose.

For instructions, see To Set a Password From a File.

Web Browsers and Password Storage

Most web browsers can save login credentials entered through HTML forms. This function can be configured by the user and also by applications that employ user credentials. If the function is enabled, credentials entered by the user are stored on their local computer and retrieved by the browser on future visits to the same application.

This function is convenient for users, but can also be a security risk. The stored credentials can be captured by an attacker who gains access to the computer, either locally or through some remote compromise. Further, methods have existed whereby a malicious website can retrieve the stored credentials for other applications, by exploiting browser vulnerabilities or through application-level cross-domain attacks.

It is heavily recommended to disable password storage when prompted for the password of the Administration Console's web interface.

Password Aliases

To avoid storing passwords in the domain configuration file in clear text, you can create an alias for a password. This process is also known as encrypting a password. For more information, see Administering Password Aliases.

Authorization

Authorization, also known as access control, is the means by which users are granted permission to access data or perform operations. After a user is authenticated, the user's level of authorization determines what operations they can perform. A user's authorization is based on the user's roles.

Roles

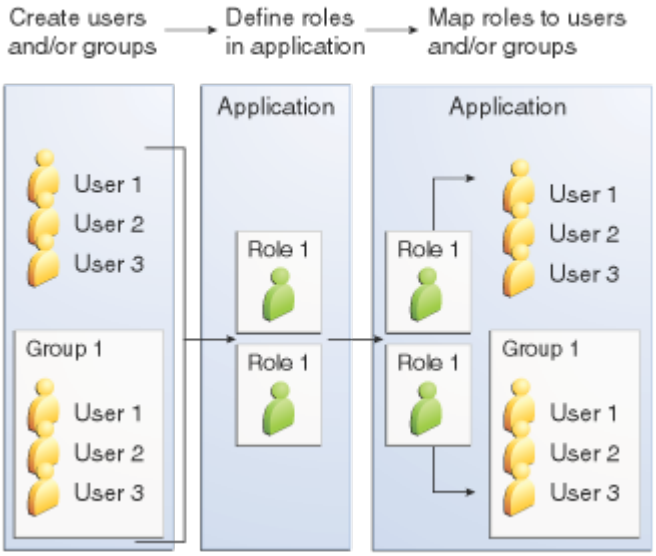
A role defines which applications and what parts of each application users can access and what those users or groups can do with the applications. For example, in a personnel application, all employees might be able to see phone numbers and email addresses, but only managers have access to salary information. This application would define at least two roles: `employee` and `manager`. Only users in the `manager` role are allowed to view salary information.

A role is different from a group in that a role defines a function in an application, while a group is a set of users who are related in some way.

For example, the personnel application specify groups such as`full-time`, `part-time`, and `on-leave`. Users in these groups are all employees (the `employee` role). In addition, each user has its own designation that defines an additional level of employment.

Roles are defined in the standard deployment descriptor for the application. The application developer or deployer maps roles to one or more groups in the deployment descriptor for each application. When the application is being packaged and deployed, the application specifies mappings between users, groups, and roles, like this:

Role Mappings



By default, group principal names are mapped to roles of the same name. Therefore, the Default Principal To Role Mapping setting is enabled by default on the *Security* page of the Administration Console.
With this setting enabled, if the group name defined on Payara Server matches the role name defined in the application, there is no need to use the runtime deployment descriptor to provide a mapping. The application server will implicitly make this mapping, as long as the names of the groups and roles match (case sensitivity considered).

Jakarta Authorization

Jakarta Authorization is the specification that defines an interface for pluggable policy providers. This enables you to set up third-party plug-in modules to perform authorization based on custom policies.

Working With the `server.policy` Policy File

Each Payara Server domain has its own global Java policy file, located in `domain-dir/config`. The file is named `server.policy`.

A sample `server.policy` file is as follows. Comments in the file describe why various permissions

are granted. These permissions are described in more detail in the next section.

```
// classes in lib get all permissions by default
grant codeBase "file:${com.sun.aas.installRoot}/lib/-" {
    permission java.security.AllPermission;
};

// Core server classes get all permissions by default
grant codeBase "file:${com.sun.aas.installRoot}/modules/-" {
    permission java.security.AllPermission;
};

// Apache Felix classes get all permissions by default
grant codeBase "file:${com.sun.aas.installRoot}/osgi/felix/bin/-" {
    permission java.security.AllPermission;
};

// iMQ classes get all permissions by default
grant codeBase "file:${com.sun.aas.imqLib}/-" {
    permission java.security.AllPermission;
};

// H2 driver classes get all permissions by default
grant codeBase "file:${fish.payara.aas.h2Root}/bin/-" {
    permission java.lang.RuntimePermission "createClassLoader";
    permission java.io.FilePermission       "<<ALL FILES>>", "read,write";
};

// Basic set of required permissions granted to all remaining code
// The permission FilePermission "<<ALL FILES>>", "read,write"
// allows all applications to read and write any file in the filesystem.

// It should be changed based on real deployment needs. If you know your
// applications just need to read/write a few directories consider removing
// this permission and adding grants indicating those specific directories.
// against the codebase of your application(s).
grant {
    permission java.util.PropertyPermission "*", "read,write";

    permission java.lang.RuntimePermission  "loadLibrary.*";
    permission java.lang.RuntimePermission  "queuePrintJob";
    permission java.net.SocketPermission    "*", "connect";
    permission java.io.FilePermission       "<<ALL FILES>>", "read,write";

    permission java.io.FilePermission "${java.io.tmpdir}${/}-", "delete";

    permission java.util.PropertyPermission "*", "read";

    permission java.lang.RuntimePermission    "modifyThreadGroup";
    permission java.lang.RuntimePermission    "getClassLoader";
```

```
    permission java.lang.RuntimePermission    "setContextClassLoader";
    permission javax.management.MBeanPermission "[com.sun.messaging.jms.*:*]", "*";
};

// The following grant block is only required by Connectors. If Connectors are not in
use the recommendation is to remove this grant.
grant {
    permission javax.security.auth.PrivateCredentialPermission
"jakarta.resource.spi.security.PasswordCredential * \"*\"","read";
};

// The following grant block is only required for Reflection. If Reflection is not in
use the recommendation is to remove this section.
grant {
    permission java.lang.RuntimePermission "accessDeclaredMembers";
};

// Permissions to invoke CORBA objects in server
grant {
    permission com.sun.enterprise.security.CORBAObjectPermission "*", "*";
};

grant {
    permission java.io.SerializablePermission "enableSubclassImplementation";
};

grant {
    permission javax.management.MBeanPermission "sun.management.*", "*";
    permission javax.management.MBeanPermission "javax.management.*", "*";
    permission javax.management.MBeanPermission "[amx:*]", "*";
    permission javax.management.MBeanPermission "[amx-support:*]", "*";
    permission java.lang.management.ManagementPermission "monitor";
    permission javax.management.MBeanPermission "com.hazelcast.*", "*";
    permission javax.management.MBeanPermission "fish.payara.*", "*";
};

grant  codeBase "file:${com.sun.aas.instanceRoot}/applications/-"{
    permission java.io.FilePermission       "<<ALL FILES>>", "read,write";
};
```

Changing the Default Permissions

The Payara Server internal server code is granted all permissions. These grants are covered by the `AllPermission` grant blocks to various parts of the server infrastructure code. Do not modify these entries.

Application permissions are granted in the default `grant` block. These permissions apply to all code not part of the internal server code listed previously.

The section beginning with the comment *"Basic set of required permissions..."* provides the basic set

of permissions granted to all remaining code.

Specifically, the following permission allows all applications to read and write all properties and read and write all files on the file system:

```
permission java.util.PropertyPermission "*", "read,write";
permission java.io.FilePermission       "<<ALL FILES>>", "read,write";
```

While this grant provides optimum flexibility, it is inherently unsecure. For enhanced security, change this permission based on your real deployment needs.

For example, consider removing this permission and assign default read and write permissions only to the application's install directory (context-root). This example uses `com.sun.aas.instanceRoot`, which specifies the top level directory for a server instance:

```
grant codeBase "file:${com.sun.aas.instanceRoot}/applications/MyApp/-"{
    permission java.io.FilePermission "file:${com.sun.aas.instanceRoot}
/applications/MyApp/-", "read,write";
}
```

For any application that needs to read and write additional directories, you would then have to explicitly allow such permissions by adding specific grants. In general, you should add extra permissions only to the applications or modules that require them, not to all applications deployed to a domain.

Firewalls

A firewall controls the flow of data between two or more networks, and manages communications between the networks. A firewall can consist of both hardware and software elements. The following guidelines pertain primarily to Payara Server:

- In general, firewalls should be configured so that clients can access the necessary TCP/IP ports.

  For example, if the HTTP listener is operating on port `8080`, configure the firewall to allow HTTP requests on port `8080` only. Likewise, if HTTPS requests are set up for port `8081`, you must configure the firewalls to allow HTTPS requests on port `8081`.

- If direct Remote Method Invocations over Internet Inter-ORB Protocol (RMI-IIOP) access from the Internet to EJB modules is required, open the ORB listener port as well.

  Opening the ORB port to all possible clients is strongly discouraged because it creates security risks. Instead, create a valid access list of remote hosts that should access remote EJB modules and configure the firewall to grant them specific access.

- In a "double firewall" architecture, you must configure the outer firewall to allow for HTTP and HTTPS transactions. You must configure the inner firewall to allow the HTTP server plug-in to communicate with Payara Server behind the firewall.

Certificates and Secure Transport

Certificates

Certificates, also known as **digital certificates**, are electronic files that uniquely identify users and resources on the Internet and public networks. Certificates also enable secure, confidential communication between two entities. Usually, there are two different kinds of certificates:

- Personal certificates, used by individuals.
- Server certificates, used to establish secure-transport sessions between the server and clients through secure sockets layer (SSL) and transport layer security (TLS) technologies.

Certificates are based on **public key cryptography**, which uses pairs of digital keys to encrypt, or encode, information so the information can be read only by its intended recipient. The recipient then decrypts the information to read it.

A key pair contains a public key and a private key. The owner distributes the public key and makes it available to anyone, which is embedded on a digital certificate. The private key on the other hand is always kept secret. Because the keys are mathematically related, data encrypted with one key can only be decrypted with the other key in the pair.

Certificates are issued by a trusted third party called a **Certification Authority (CA)**. The CA is analogous to a passport office: it validates the certificate holder's identity and signs the certificate so that it cannot be forged or tampered with. After a CA has signed a certificate, the holder can present it as proof of identity and to establish encrypted, confidential communications.

Most importantly, a certificate binds the owner's public key to the owner's identity.

In addition to the public key, a digital certificate typically includes information such as the following:

- The name of the holder and other identification, such as the URL of the web server using the certificate, or an individual's email address
- The name of the CA that issued the certificate
- The certificate's expiration date

Certificates are governed by the technical specifications of the **X.509 format**. To verify the identity of a user in the `certificate` realm, the authentication service verifies an X.509 certificate, using the common name field (`CN`) of the X.509 certificate as the principal name.

Certificate Chains

A certificate chain is a series of certificates issued by successive CA certificates, eventually ending in a root CA certificate.

Most modern web browsers are preconfigured with a set of root CA certificates that the browser automatically trusts. Any certificates from elsewhere must come with a certificate chain to verify their validity.

When a certificate is first generated, it is a called a **self-signed certificate**. A self-signed certificate

is one for which the issuer (signer) is the same as the subject (the entity whose public key is being authenticated by the certificate). When the owner sends a certificate signing request (CSR) to a CA, then imports the response, the self-signed certificate is replaced by a chain of certificates.

At the bottom of the chain is the certificate (reply) issued by the CA authenticating the subject's public key. The next certificate in the chain is one that authenticates the CA's public key. Usually, this is a self-signed certificate (that is, a certificate from the CA authenticating its own public key) and the last certificate in the chain.

In other cases, the CA can return a chain of certificates. In this situation, the bottom certificate in the chain is the same (a certificate signed by the CA, authenticating the public key of the key entry), but the second certificate in the chain is a certificate signed by a different CA, authenticating the public key of the CA to which you sent the CSR. Then, the next certificate in the chain is a certificate authenticating the second CA's key, and so on, until a self-signed root certificate is reached.

Each certificate in the chain (after the first) thus authenticates the public key of the signer entity of the previous certificate in the chain.

Certificate Files

During Payara Server installation, a self-signed certificate is generated in Java Secure Socket Extension (JSSE) format suitable for internal testing. By default, Payara Server stores its certificate information in certificate databases in the `domain-dir/config` directory:

Keystore file

The `keystore.jks` file contains the certificate, including its private key. The keystore file is protected with a password.
Each keystore entry has a unique alias. After installation, the Payara Server keystore has a single entry with an alias of `s1as` that corresponds to the self-signed certificate and its key.

Truststore file

The `cacerts.p12` file contains trusted certificates, including public keys for other entities. For a trusted certificate, the server has confirmed that the public key in the certificate belongs to the certificate's owner. These trusted certificates generally include those of recognized CAs.

Secure Sockets Layer

Secure Sockets Layer (SSL) is a standard for securing Internet communications and transactions. Secure web applications use HTTPS (HTTP over SSL). The HTTPS protocol uses certificates to ensure confidential and secure communications between server and clients. In an SSL connection, both the client and the server encrypt data before sending it. Data is decrypted upon receipt.

When a Web browser (client) wants to connect to a secure site, an SSL handshake happens, like this:

1. The browser sends a message over the network requesting a secure session (typically, by requesting a URL that begins with `https` instead of `http`).
2. The server responds by sending its certificate (including its public key).
3. The browser verifies that the server's certificate is valid and is signed by a CA whose certificate

is in the browser's database (and who is trusted). It also verifies that the supplied certificate has not expired and is still valid.

4. If the certificate is valid, the browser generates a one-time, unique session key and encrypts it with the server's public key. The browser then sends the encrypted session key to the server so that they both have a copy.
5. The server decrypts the message using its private key and recovers the session key to fully establish the handshake.

After the handshake, the client has verified the identity of the website, and only the client and the Web server have a copy of the session key. From this point forward, the client and the server use the session key to encrypt all their communications with each other. Thus, their communications are ensured to be secure.

To use SSL, Payara Server must have a certificate for each external interface or IP address that accepts secure connections. The HTTPS service of most web servers will not run unless a certificate has been installed. For instructions on applying SSL to HTTP listeners, see "To Configure an HTTP Listener for SSL" in the Payara Server General Administration section.

Ciphers

A cipher is a cryptographic algorithm used for encryption or decryption. SSL and TLS protocols support a variety of ciphers used to authenticate the server and client to each other, transmit certificates, and establish session keys.

Some ciphers are stronger and more secure than others. Clients and servers can support different cipher suites. During a secure connection, the client and the server agree to use the strongest cipher that they both have enabled for communication, so it is usually sufficient to enable all ciphers.

Name-based Virtual Hosts

Using name-based virtual hosts for a secure application can be problematic. This is a design limitation of the SSL protocol itself. The SSL handshake, where the client browser accepts the server certificate, must occur before the HTTP request is accessed. As a result, the request information containing the virtual host name cannot be determined prior to authentication, and it is therefore not possible to assign multiple certificates to a single IP address.

If all virtual hosts on a single IP address need to authenticate against the same certificate, the addition of multiple virtual hosts probably will not interfere with normal SSL operations on the server. Be aware, however, that most browsers will compare the server's domain name against the domain name (corresponding to the `CN` entry) listed in the certificate, if any (applicable primarily to official, CA-signed certificates). If the domain names do not match, most browsers will display a warning and fail the validation. In general, only address-based virtual hosts are commonly used with SSL in a production environment.

Understanding the `AppservCertificateLoginModule` Class

Payara Server provides the `AppservCertificateLoginModule` class to allow developers to implement a custom implementation of a login module that interacts with client certificates. This class provides some convenience methods for accessing the certificates, the application name and so forth, and for

adding the group principals to the subject.

The convenience methods include the following:

`getAppName()`
: Returns the name of the application to be authenticated. This may be useful when a single `LoginModule` has to handle multiple applications that use certificates.

`getCerts()`
: Returns the certificate chain as an array of `java.security.cert.X509Certificate` certificates.

`getX500Principal()`
: Returns the distinguished (`DN`) principal from the first certificate in the chain.

`getSubject()`
: Returns the subject that is being authenticated.

`commitUserAuthentication(final String[] groups)`
: This method sets the authentication status to success if the groups parameter is non-null.

This method is called after the authentication has succeeded. If the authentication failed, do not call this method.

You do not have to extend the convenience base class, you can extend the JAAS LoginModule `javax.security.auth.spi.LoginModule` instead if you so choose.

Example `AppservCertificateLoginModule` Code

The following example shows a custom implementation of a certificate login module using the `AppservCertificateLoginModule` class.

Take note of the following points from the example:

- The `getX500Principal()` method returns the subject(subject distinguished name) value from the first certificate in the client certificate chain as an `X500Principal`.
- From that `X500Principal`, the `getName()` method then returns a string representation of the X.500 distinguished name using the format defined in RFC 2253 (LDAP v3).
- The example uses the `getAppName()` method to determine the application name. It also determines the organizational unit (`OU`) from the distinguished name.
- The example concatenates the application name with the value of `OU`, and uses it as the group name in the `commitUserAuthentication` method.

```
public class CustomCertificateLoginModule extends AppservCertificateLoginModule {

    @Override
    protected void authenticateUser() throws LoginException {
        // Get the distinguished name from the X500Principal.
```

```
        var st = new StringTokenizer(getX500Principal().getName(), "B \t\n\r\f,");
        while (st.hasMoreTokens()) {
            var next = st.nextToken();
            /*
             Set appname:OU as the group name.
             At this point, one has the application name and the DN of
             the certificate. A suitable login decision can be made here.
             */
            if (next.startsWith("OU=")) {
                commitUserAuthentication(new String[]{getAppName() + ":" +
next.substring(3)});
                return;
            }
        }
        throw new LoginException("No OU found in the DN of the supplied certificate");
    }
}
```

Setting the JAAS Context

After you create your LoginModule, you must plug it in to a jaas-context, which you then specify as a parameter to the certificate realm's configuration in Payara Server.

To do this, perform the following steps:

1. Specify a new jaas-context for the Certificate realm in the `domain-dir/config/login.conf` file. Using the previous example configuration would look like this:

   ```
   certRealm {
       fish.payara.security.examples.CustomCertificateLoginModule required;
   };
   ```

2. Specify this jaas-context as a parameter to the `set` subcommand in the `configs.config.server-config.security-service.auth-realm.certificate.property.jaas-context=`<jaas-context-name> property. For example:

   ```
   asadmin set configs.config.server-config.security-service.auth-
   realm.certificate.property.jaas-context=certRealm configs.config.server-
   config.security-service.auth-realm.certificate.property.jaas-context=certRealm

   Command set executed successfully.
   ```

3. Optionally, get the value you just set to make sure that it is correct.

   ```
   asadmin get configs.config.server-config.security-service.auth-
   realm.certificate.property.jaas-context
   ```

```
configs.config.server-config.security-service.auth-realm.certificate.property.jaas-
context=certRealm

Command get executed successfully.
```

Administering Passwords

There are multiple ways to administer passwords. You can rely on administrators to keep passwords secret and change the passwords regularly. You can set up files for storing passwords so that `asadmin` CLI subcommands can access these files rather than having users type the commands.

You can also encrypt passwords by setting up aliases so that sensitive passwords are not clearly visible in the `domain.xml` configuration file.

To Change the Master Password

The master password gives access to the keystore and truststore used by the domain. This password is not tied to an operating system user. You should treat this overall shared password as sensitive data to secure. Payara Server never uses it for authentication and never transmits it over the network.

When a domain is created, you can choose to type its master password manually when required, or to obscure it in a password file. If there is no password file, you are prompted for the master password. If there is a password file, but you want to change access to require prompting, remove the file. The default master password is `changeit`.

When changing the master password, it has to be changed on all configured nodes as well as on the DAS. The master password on nodes is only stored once in the node, for all instances that are on hosted on that node.

Use the `change-master-password` subcommand in local mode to modify the master password.

If you change the master password and are not using a master password file, the `start-instance` and `start-cluster` subcommands are not able to determine the master password. In this case, you must start those instances locally by using the `start-local-instance` command.

When the master password is saved, it is saved in the `domain-dir/config/master-password` file.

Follow these steps to correctly change the master password on an existing domain:

1. Stop the domain first.
2. Change the master password for the domain by using the `change-master-password` subcommand. You will be prompted for the old and new passwords based on whether you have been previously logged into the domain.
3. Start the domain again.

The following example changes the master password for the `custom-domain` domain:

```
asadmin> change-master-password custom-domain
```

If you have already logged into the domain using the `login` subcommand, you are prompted for the new master password:

```
Please enter the new master password>
Please enter the new master password again>
```

If you are not logged into the domain, you are prompted for both the old and the new master passwords:

```
Please enter the master password>
Please enter the new master password>
Please enter the new master password again>
```

Information similar to the following is displayed:

```
Master password changed for domain44ps
```

Additional Considerations when starting instances through CLI subcommands

If you change the master password for the DAS, the `start-domain` and `start-local-instance` subcommands allow you to provide it during domain or instance startup in one of three ways:

- Via the master-password file
- By entering it interactively
- Via the Asadmin CLI `--passwordfile` option

The `start-instance`, `start-cluster` and `start-deployment-group` subcommands require additional considerations. If you create a domain with a master password other than the default, an associated remote instance, cluster or deployment group must have access to the master password in order to properly start.

However, for security reasons Payara Server never transmits the master password or the master password file over the network.

Consider the following scenario:

1. Change the master password on the DAS and save it with the `--savemasterpassword` option.
2. Create an instance on another host using the subcommand `create-instance`. Payara Server then copies the keystore and truststore from the DAS to the remote instance, but it DOES not copy the master password file.
3. Try to start the instance using the `start-instance` subcommand. An error results preventing the instance to correctly start.

The `start-instance` command is looking for the master-password file in the node directory on the instance's host machine, and it is not there by default. Therefore, the subcommand fails.

You can use the `change-master-password` subcommand to make sure the correct password is used in this password file, as described in the following section.

The `start-instance`, `start-cluster` and `start-deployment-group` subcommands do not include any other way for you to provide the password. If you change the master password and are not using a master password file, the `start-instance` and `start-cluster` subcommands will not be able to determine the master password. In this case, you must start the instances locally by using `start-local-instance` command.

Remotely starting an instance using a password file

Assume that you have changed the master password on the DAS and you want to make the same change for all instances.

The `start-instance`, `start-cluster` and `start-deployment-group` subcommands automatically use the master password file if it exists in the instance filesystem. You can use the `change-master-password` subcommand to make sure the password file exists and that the correct password is used.

Here's a concrete set of steps that showcase how to manage the master password from a domain's creation:

1. From the DAS, create a domain and set the master password.

```
asadmin create-domain --savemasterpassword true <domain-name>
```

2. Start the domain.

```
asadmin start-domain <domain-name>
```

3. Create a remote SSH node.

```
asadmin create-node-ssh --nodehost <host-name> --installdir /usr/local/payara
<node-name>
```

4. Create a new instance on the node.

```
asadmin create-instance --node <node-name> <instance-name>
```

5. Before you start the instance, on the node's host machine run the `change-master-password` with the `---savemasterpassword` option to create a file called `master-password` in the `agents` directory so that the instance can correctly start up.

Locally on the remote node's host:

```
asadmin change-master-password --savemasterpassword true --nodedir
/usr/local/payara <node-name>

Enter the current master password>
Enter the new master password>
Enter the new master password again>

Command change-master-password executed successfully.
```

Remember that when you created the domain you specified a new master password. This master password was then used to encrypt the keystore and truststore for the DAS, and these stores were copied to the instance as a result of the `create-instance` subcommand.

Therefore, enter the master password you set when you created the domain as both the current master password and again as the new master password. You enter it as the new master password because you do not want to change the master password for the instance and make it out of sync with the DAS.

6. Run the `start-instance` from the DAS.

```
asadmin start-instance <instance-name>
```

The master password file is associated with the node and not with an instance. After the master password file exists in the node directory on the instance machine, additional instances can be created, started and stopped from the DAS with no additional considerations.

To Change an Administration Password

Use the `change-admin-password` subcommand in remote mode to change an administration password. The default administration user is `admin`. When run, you will be prompted for the old and new admin passwords, with confirmation.

When using the default domains shipped with Payara Server, the default administration user will have a blank password.

If there is a single user called `admin` that does not have a password, you are not prompted for login information when running any Asadmin CLI commands that affect a running domain or access the Admin console.

If secure administration is enabled as described in link:Technical Documentation/Payara Server Documentation/Security Guide/administrative-security.adoc#running-secure-admin[Running Secure Admin], you cannot change an administration password to a blank value under any circumstance.

1. Change the admin password by using the `change-admin-password` subcommand.
2. Enter the old and new admin passwords when prompted.
3. Restart the Payara Server domain.

This example changes the admin password for user anonymous from `adminadmin` to `newadmin`:

```
asadmin change-admin-password --username anonymous
```

You are prompted to enter the old and the new admin passwords:

```
Enter admin password>adminadmin
Enter new admin password>newadmin
Enter new admin password again>newadmin

Command change-admin-password executed successfully.
```

To Set a Password From a File

Instead of typing a specific password (like the admin password or the master password) at the command line, you can supply the password for a command from a text file such as `passwords.txt`.

The `--passwordfile` option of the Asadmin CLI utility takes the name of the file that contains the passwords. The entry for a specific password in the file must have the `AS_ADMIN_` prefix followed by the password name in uppercase letters.

Any password file created to pass as an argument by using the `--passwordfile` argument to the `asadmin` utility should be protected with the corresponding file system permissions. Additionally, any password file being used for a transient purpose, such as setting up SSH among nodes, should be deleted after it has served its purpose.

For a complete list of the types of passwords that can be specified, see the `asadmin` command help page. Here are a couple of examples of password names used by the file.

```
AS_ADMIN_MASTERPASSWORD
AS_ADMIN_USERPASSWORD
AS_ADMIN_ALIASPASSWORD
```

For example, to specify an administrative password, add an entry similar to the following to the password file, where `adminadmin` is the current password:

```
AS_ADMIN_PASSWORD=adminadmin
```

Save your changes. You can now specify the password file in an `asadmin` subcommand. In this

example, `passwords.txt` is the file that contains the password:

+

```
asadmin delete-jdbc-resource --user admin --passwordfile passwords.txt jdbc/CustomPool
```

Administering Password Aliases

A password alias is used to indirectly access a password so that the password itself does not appear in cleartext in the domain's `domain.xml` configuration file.

Storing and passing passwords in cleartext is a security risk, and may violate some corporate security policies. In such cases, you can use password aliases to protect your passwords.

Create a Password Alias

Use the `create-password-alias` subcommand in remote mode to create an alias for a password in the domain. The password corresponding to the alias name is stored in an encrypted form in the domain configuration file.

The `create-password-alias` subcommand takes both a secure interactive form, in which users are prompted for all information, and a more script-friendly form, in which the password is propagated on the command line.

You can also use the `set` subcommand to remove and replace the password in the configuration file. For example:

```
asadmin set --user admin server.jms-service.jms-host.default_JMS_host.
admin-password='${ALIAS=jms-password}'
```

To create a new password alias follow these steps:

1. Run the `create-password-alias` subcommand.
2. Type the password for the alias when prompted.
3. Add the alias to a password file.

   For example, assume the use of a password file such as `passwords.txt`. Assume further that you want to add an alias for the `AS_ADMIN_USERPASSWORD` entry that is read by the `create-file-user` subcommand.

   You would add the following line to the password file:

   ```
   AS_ADMIN_USERPASSWORD=${ALIAS=user-password-alias}
   ```

   Where `user-password-alias` is the new password alias.

4. Now execute the corresponding command that requires the alias in the password file. Here's an

example that uses the `create-file-user` subcommand:

```
asadmin --passwordfile passwords.txt create-file-user user1
```

Here's another example that creates the new `jms-password` alias for the `admin` user:

```
asadmin> create-password-alias --user admin jms-password
```

Then, you are prompted to type the password for the alias:

```
Please enter the alias password> secret-password
Please enter the alias password again> secret-password
Command create-password-alias executed successfully.
```

Here's another example that creates a new password alias using the provided name. The user is then prompted to enter the associated password twice.

```
asadmin> create-password-alias example-alias-name
Enter the alias password>
Enter the alias password again>
Command create-password-alias executed successfully.
```

To List Password Aliases

Use the `list-password-aliases` subcommand in remote mode to list existing the password aliases.

This example lists all existing password aliases:

```
asadmin list-password aliases
jmspassword-alias

Command list-password-aliases executed successfully
```

To Delete a Password Alias

Use the `delete-password-alias` subcommand in remote mode to delete an existing password alias.

This example deletes the password alias `jmspassword-alias`:

```
asadmin> delete-password-alias jmspassword-alias

Command list-password-aliases executed successfully
```

To Update a Password Alias

Use the `update-password-alias` subcommand in remote mode to change the password for an existing password alias. The `update-password-alias` subcommand takes both a secure interactive form, in which the user is prompted for all information, and a more script-friendly form, and the password is propagated on the command line.

This example updates the password for the `jmspassword-alias` alias:

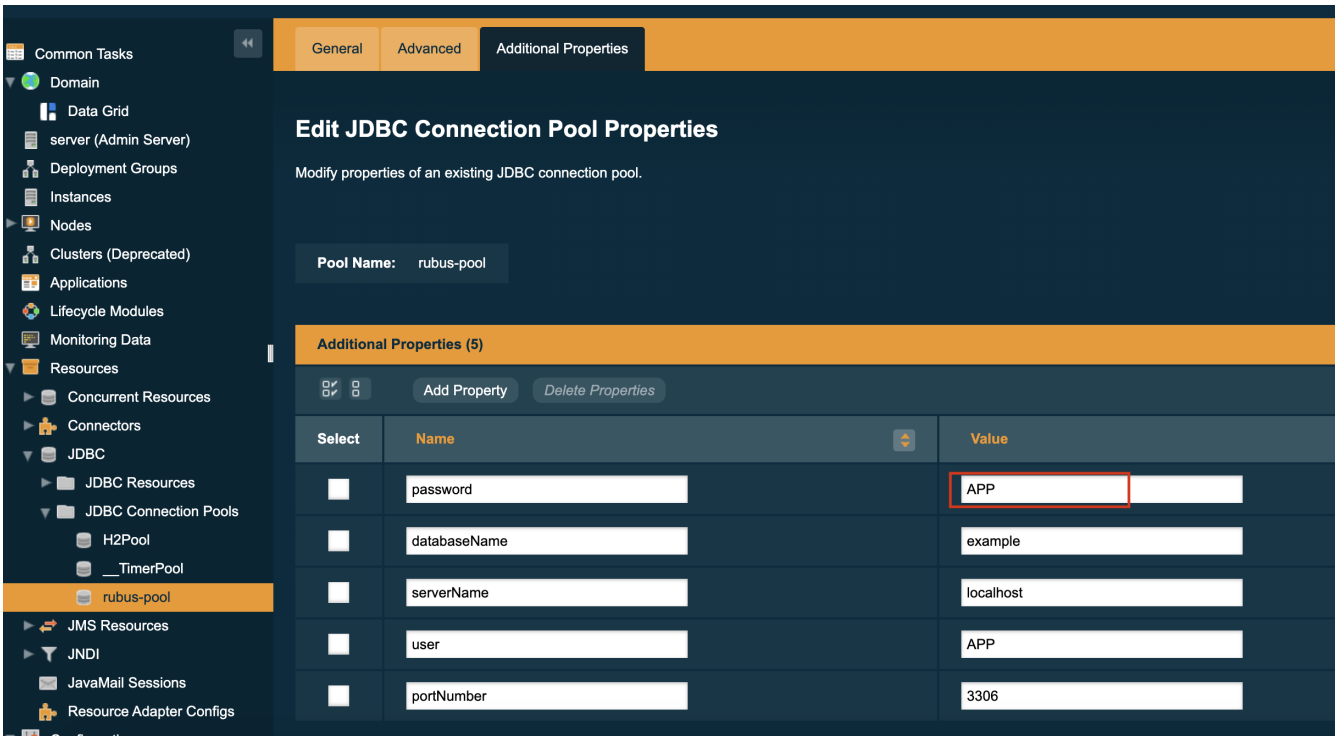
```
asadmin> update-password-alias jsmpassword-alias
```

You are prompted to type the new password for the alias:

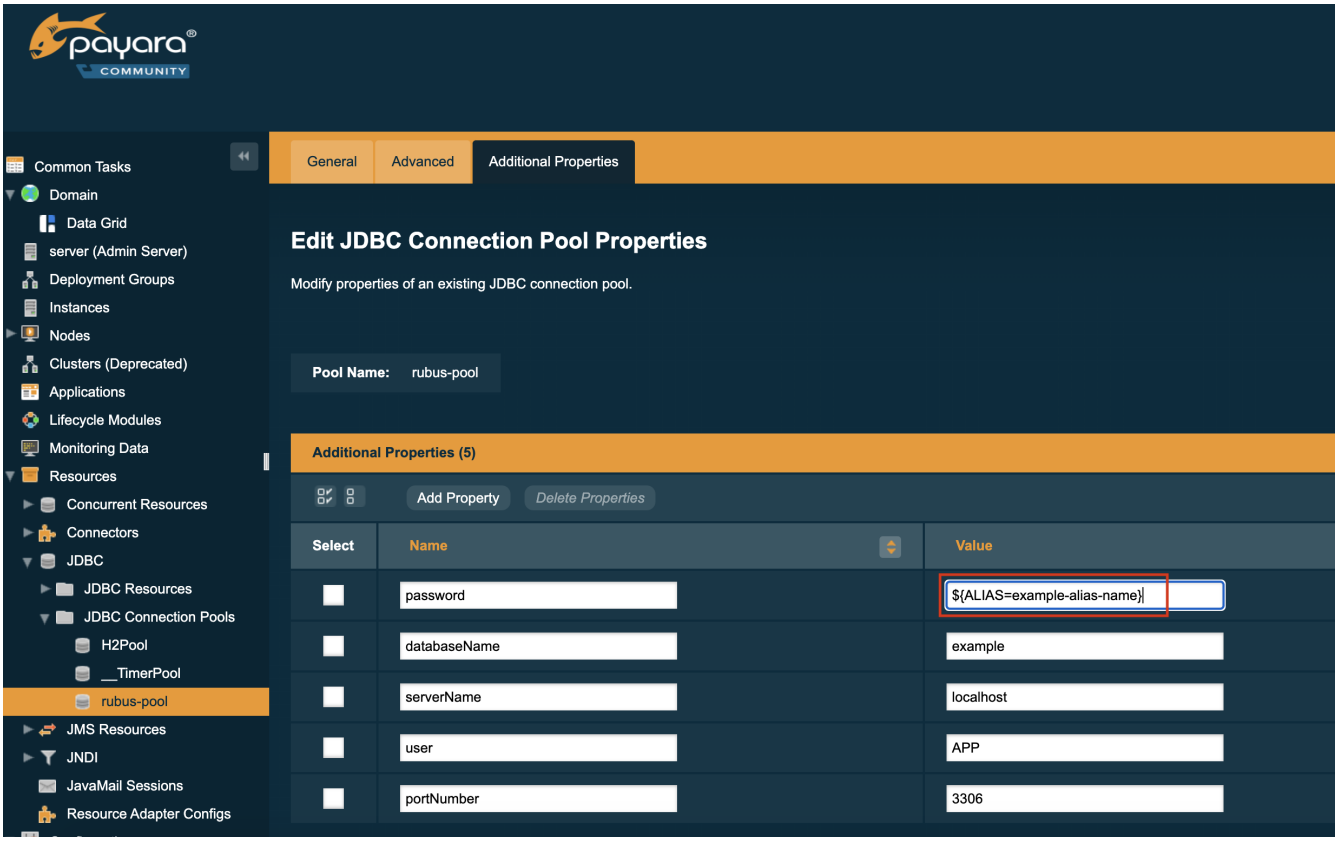
```
Please enter the alias password> new-secret-password
Please enter the alias password again> new-secret-password
Command update-password-alias executed successfully
```

Using a password alias within the Admin Console

To use a password alias, navigate to any configuration view where you would have previously entered a password in plaintext format:



In place of the password, you can enter an alias which corresponds to the password in the form: `${ALIAS=<password-alias-name>}`:

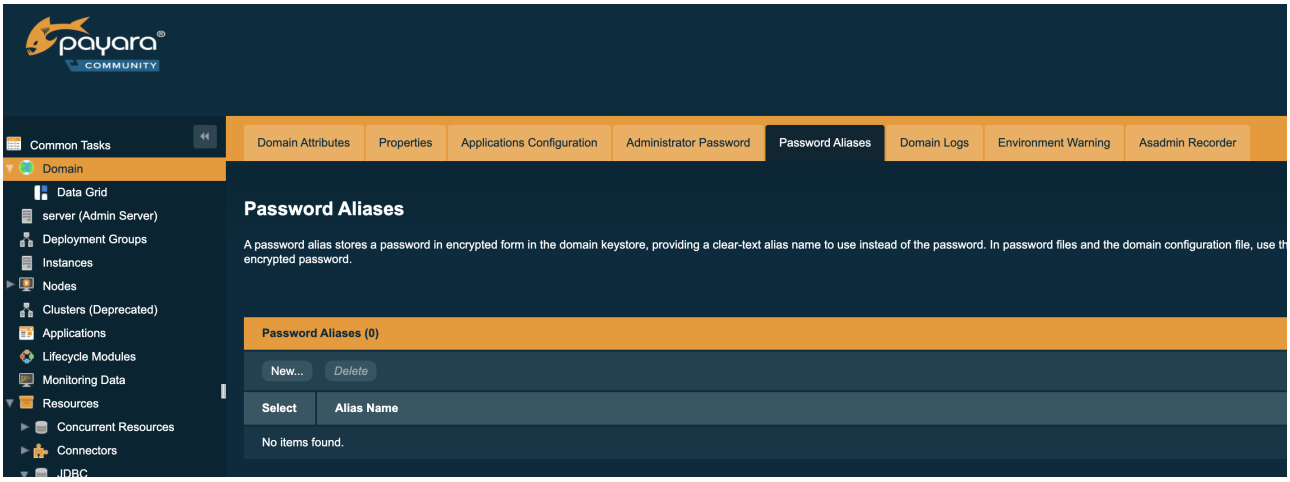


Managing Password Aliases through the Admin Console

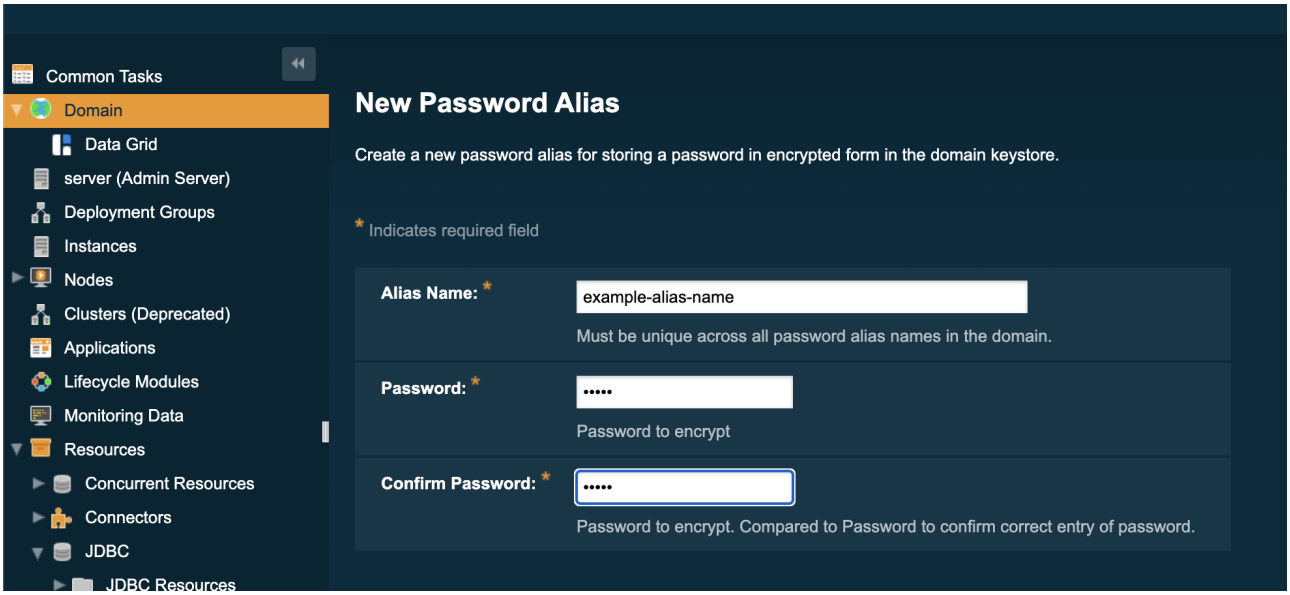
Here are instructions on managing password aliases through the web administration console.

Creating a password alias

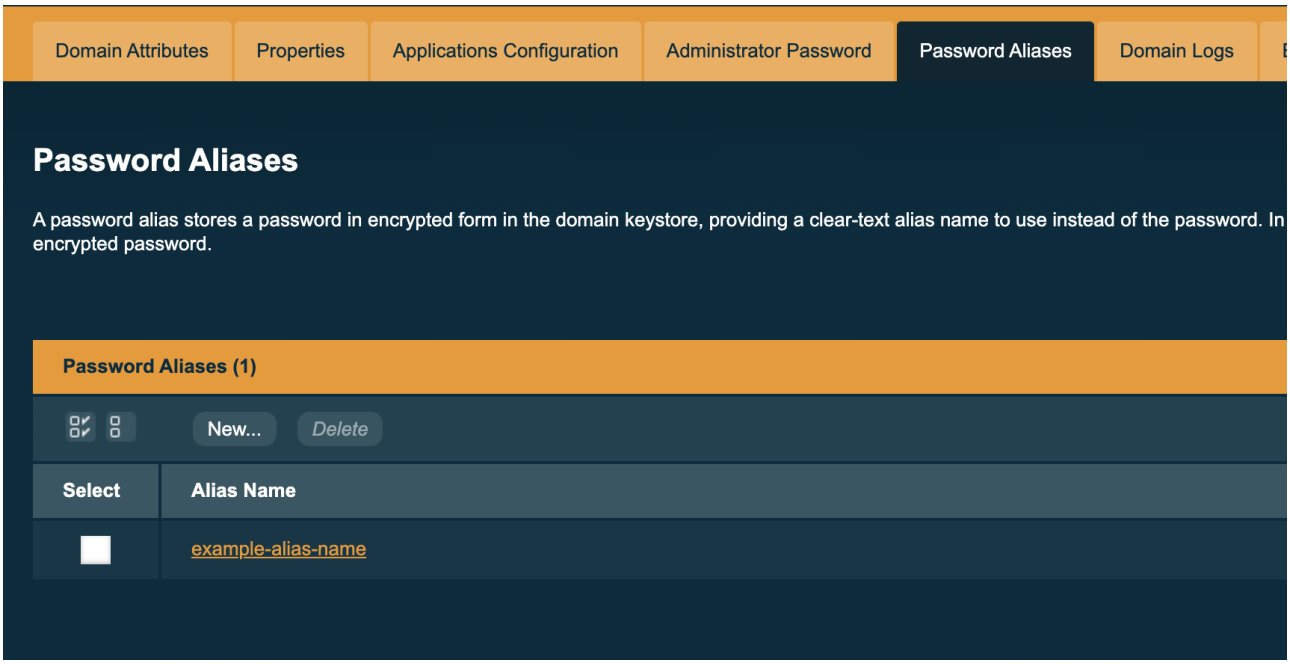
1. To create a new password alias for the domain, select **Domain** on the page tree, then select the **Password Aliases** tab and click the **New** button:



2. On the next page, enter the name of the alias, and the password, twice:



3. Finally, press the **OK** button to create your new alias:

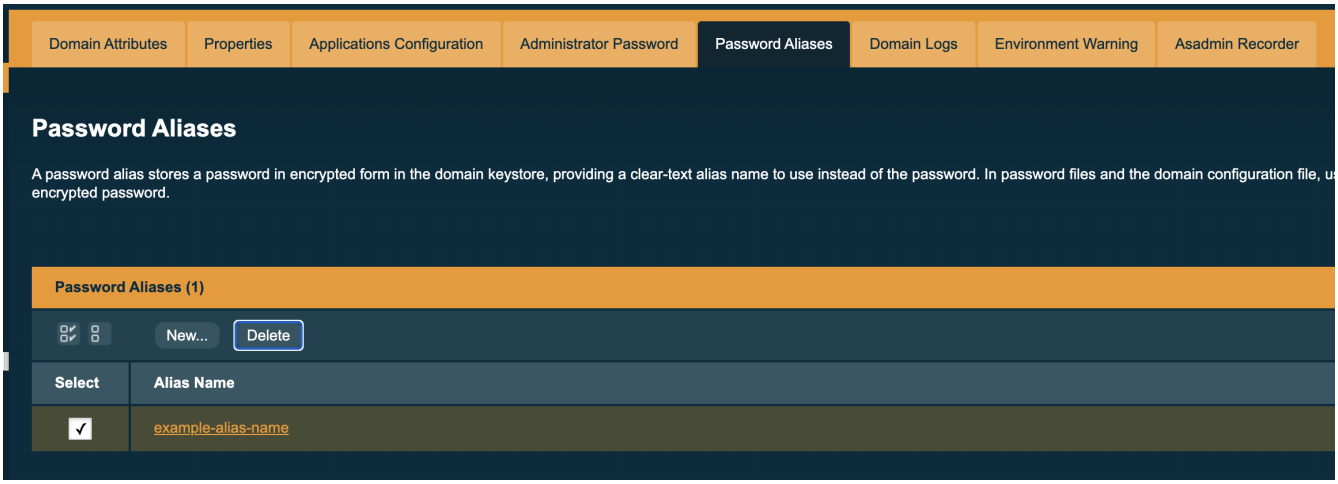


Modifying a password alias

To modify an existing password alias, select it on the **Password Aliases** page. On the **Edit Password Alias** page you are able to change the entered password.

Deleting a password alias

To delete a password alias, go to the **Password Aliases page**, tick the checkbox of the password alias you wish to delete and then press the **Delete** button:



MicroProfile Config support

Password aliases can also be accessed using MicroProfile Config, as detailed link:/Technical Documentation/MicroProfile/Config/Overview.adoc[here,role=unresolved].

Administering JSSE Certificates

The Java SE SDK ships with the `keytool` utility, which enables you to set up and work with Java Secure Socket Extension (JSSE) digital certificates and similar formats. You can administer public/private key pairs and associated certificates, and cache the public keys (in the form of certificates) of their communicating peers.

To Generate a Certificate by Using the `keytool` utility

By default, the `keytool` utility creates a keystore file in the directory where the utility is run. The following are steps to generate a certificate using the `keytool` utility an import it in the domain's keystore and truststore. These commands should be run from the domain's configuration directory.

1. Change to the directory that contains the keystore and truststore files.

   Always generate the certificate in the directory containing the keystore and truststore files.

2. Generate the certificate in the keystore file, `keystore.p12`, using the following command format:

   ```
   keytool -genkey -alias keyAlias -keyalg RSA -keypass changeit -storepass changeit
   -keystore keystore.p12
   ```

   Use any unique name as the alias. If you have changed the keystore or private key password from the default (`changeit`), substitute the new password for `changeit`. The default key password alias is `s1as`.

   A prompt will ask for your name, organization, and other information.

3. Export the generated certificate to the `server.cer` file, using the following command format:

   ```
   keytool -export -alias keyAlias -storepass changeit -file server.cer -keystore
   keystore.p12
   ```

4. If a certificate signed by a certificate authority is required, the following section.
5. Import the certificate to the truststore, using the following command:

   ```
   keytool -import -v -trustcacerts -alias keyAlias -file server.cer -keystore
   cacerts.p12 -storepass changeit -keypass changeit
   ```

   If you have changed the keystore or private key password from the default (`changeit`), substitute the new password.

   Information about the certificate is displayed and a prompt appears asking if you want to trust the certificate.

6. Type `yes`, then press Enter.

   Information similar to the following is displayed:

   ```
   Certificate was added to keystore
   [Saving cacerts.p12]
   ```

7. To apply your changes, restart the Payara Server domain and corresponding instances.

The following is an example on how to create a Self-Signed Certificate in a PKCS12 Keystore by Using an **RSA Key Algorithm**:

```
keytool -genkey -noprompt -trustcacerts -keyalg RSA -alias ${cert.alias} -dname
${dn.name} -keypass ${key.pass} -keystore ${keystore.file} -storepass ${keystore.pass}
```

The following is an example on how to create a Self-Signed Certificate in a PKCS12 Keystore by using the default key algorithm:

```
keytool -genkey -noprompt -trustcacerts -alias ${cert.alias} -dname ${dn.name}
-keypass ${key.pass} -keystore ${keystore.file} -storepass ${keystore.pass}
```

The following command will display detailed information about all certificates present in a keystore:

```
keytool -list -v -keystore ${keystore.file} -storepass ${keystore.pass}
```

The following command will display detailed information about a specific certificate identified by the supplied alias in a keystore:

```
keytool -list -v -alias ${cert.alias} -keystore ${keystore.file}
-storepass ${keystore.pass}
```

Generate and Sign Certificate by Using `keytool`

After creating a certificate, the owner must sign the certificate to prevent forgery. E-commerce sites, or those for which authentication of identity is important, can purchase a signed certificate from a trustworthy Certificate Authority (CA) or third parties associated with one.

If integrity is not a concern (in some rare cases), for example if private secure communications are all that is required, you can save the time and expense involved in obtaining a CA certificate by using a self-signed certificate.

The following steps outline how to create and sign a new certificate:

1. First, delete the default self-signed certificate:

```
keytool -delete -alias s1as -keystore keystore.p12 -storepass <store_passwd>
```

`s1as` is the default alias of the Payara Server keystore.

2. Generate a new key pair to be used by the certificate:

```
keytool -genkeypair -keyalg <key_alg> -keystore keystore.p12 -validity <val_days>
-alias s1as
```

Where `<key_alg>` is the algorithm to be used for generating the key pair, for example `RSA`, and `<val_days>` is the number of days that the certificate should be considered valid.

In addition to generating a key pair, the command wraps the public key into a self-signed certificate and stores the certificate and the private key in a new keystore entry identified by the inputted alias.

For HTTPS hostname verification, it is important to ensure that the name of the certificate (CN) matches the fully-qualified hostname of your site (fully-qualified domain name). If the names do not match, clients connecting to the server will see a security alert stating that the name of the certificate does not match the name of the site.

3. Generate a Certificate Signing Request (CSR):

```
keytool -certreq -alias s1as -file <certreq_file> -keystore keystore.p12 -storepass
<store_passwd>
```

Where `<certreq_file>` is the file in which the CSR is stored (for example, `s1as.csr`) and <store_passwd> is the password for the keystore (which corresponds to the domain's master password).

4. Submit the CSR to a Certificate Authority to get a signed certificate. In response, you should receive a signed server certificate. Make sure to import into your browser the CA certificate of the CA (if not already present) and any intermediate certificates indicated by the CA in the reply.
5. Download the CA certificate and any intermediate CA certificates and store them in local files.
6. Import the CA certificate (if not already present) and any intermediate CA certificates (if not already present) indicated by the CA into the domain's truststore:

```
keytool -import -v -trustcacerts -alias <CA-Name> -file ca.cert -keystore
cacerts.p12 -storepass <store_passwd>
```

7. Replace the original self-signed certificate with the certificate you obtained from the CA, as stored in a file such as `s1as.cert`:

```
keytool -import -v -trustcacerts -alias s1as -file s1as.cert -keystore keystore.jks
-storepass <store_passwd>
```

When you import the certificate using the same original alias `s1as`, the `keytool` utility treats it as a command to replace the original certificate with the certificate obtained as a reply to a CSR.

After running the command, you should see that the certificate `s1as` in the keystore is no longer the original self-signed certificate, but is now the certificate delivered by the CA.

Consider the following example that compares an original `s1as` certificate with a new `s1as` certificate obtained from VeriSign:

```
Original s1as (self-signed):

Owner: CN=demo.payara.fish, OU=Payara, O=Payara Foundation, L=Great Malvern,
ST=Worcestershire, C=UK
Issuer: CN=demo.payara.fish, OU=Payara, O=Payara Foundation, L=Great Malvern,
ST=Worcestershire, C=UK
Serial number: 472acd34
Valid from: Fri Nov 02 12:39:40 GMT+05:30 2023 until: Mon Oct 30 12:39:40 GMT+05:30
2033

New s1as (contains signed cert from CA):

Owner: CN=demo.payara.fish, OU=Payara, O=Payara Foundation, L=Great Malvern,
ST=Worcestershire, C=UK
Issuer: CN=VeriSign Trial Secure Server Test CA, OU=Terms of use at
https://www.verisign.com/cps/testca (c)05, OU="For Test Purposes Only. No
assurances.", O="VeriSign, Inc.", C=US
Serial number: 1375de18b223508c2cb0123059d5c440
Valid from: Sun Nov 11 05:30:00 GMT+05:30 2023 until: Mon Nov 26 05:29:59 GMT+05:30
2025
```

8. To apply your changes, restart the Payara Server domain.

[[Technical Documentation-Payara Server Documentation-Security Guide-Administering System Security:::example-15]] .Example 15 Importing an RFC/Text-Formatted Certificate Into a JKS Keystore

To Delete a Certificate by Using `keytool`

Use the `keytool delete` command to delete an existing certificate.

Here's an example on how to delete an existing certificate from the truststore using the following command:

```
keytool -delete -alias keyAlias -keystore cacerts.p12 -storepass password
```

Administering Jakarta Authorization / JACC Providers

The Jakarta Authorization specification (formerly known as Java Authorization Contract for Containers - JACC) defines an interface for pluggable authorization providers (commonly known as JACC providers) based on policies. This enables the administrator to set up third-party plug-in modules to perform authorization.

Payara Server includes Administration Console support and subcommands to support JACC providers, as follows:

- create `create-jacc-provider`
- delete `delete-jacc-provider`
- list `list-jacc-providers`

Payara Server includes a default JACC provider named `default` which you should not delete under any circumstance.

Payara Server allows Jakarta Authorization compliant JACC providers to be registered, so they can be used as third-party authorization modules for applications deployed on its corresponding domain.

Administering JACC Providers From the Administration Console

To use the Administration Console to administer JACC providers, perform the following steps:

1. Select *Configurations* and expand the entry.
2. Select the server configuration for which you want to administer JACC providers and expand the entry.
3. Select *Security* and expand the entry.
4. Select *JACC Providers*. The existing JACC providers are shown on this page.

5. To create a new provider, click *New*.

   Enter the **Name**, **Policy Configuration** (the class that implements the policy configuration factory) and the **Policy Provider** (the class that implements the policy factory) for the new JACC provider.

   You can also enter optional properties to further configure the provider.

6. To delete an existing JACC provider, select that provider and click Delete.

Administering JACC Providers from the Command Line

To use the Asadmin CLI to administer JACC providers, perform the following steps:

1. To create a JACC provider, use the `create-jacc-provider` subcommand. The following example shows how to create a JACC provider named `testJACC` on the default server target.

```
asadmin create-jacc-provider --policyproviderclass
fish.payara.security.jacc.sample.TestPolicyProvider --policyconfigfactoryclass
fish.payara.security.jacc.provider.PolicyConfigurationFactoryImpl testJACC
```

2. To delete a JACC provider, use the `delete-jacc-provider` subcommand. The following example shows how to delete a JACC provider named `testJACC` from the default domain:

```
asadmin delete-jacc-provider testJACC
```

3. To list the available providers, use the `list-jacc-providers` subcommand. The following example shows how to list JACC providers for a running domain:

```
asadmin> list-jacc-providers
default

Command list-jacc-providers executed successfully.
```

How to install a custom JACC provider per Server (Global)

Having coded a JACC provider, the first thing to do it is to make these classes available for the server. For that purpose, you need to put the implementation JAR, with all its dependencies, under the `as-install/lib` folder.

The next thing to do is to tell Payara you want to use the custom JACC provider. To do this, you have to execute the following administration command:

```
asadmin create-jacc-provider
--policyConfigurationFactoryProvider=com.example.CustomPolicyConfigurationFactory
--policyProvider=com.example.CustomPolicy --target=server-config custom-provider set
configs.config.server-config.security-service.jacc=custom-provider
```

This will result in the following configuration element added to the *domain.xml* file:

```
<security-service jacc="custom-provider">
    <jacc-provider policy-provider="com.example.CustomPolicy" name="custom-provider"
      policy-configuration-factory-
provider="com.example.CustomPolicyConfigurationFactory">
    </jacc-provider>
    <!-- More providers can be defined -->
</security-service>
```

As you can see on the XML excerpt, more JACC providers can be defined (by default, the `simple` and `default` providers are already defined), but only one will be used at runtime, specified by the `jacc` attribute on the `security-service` element.

How to install a custom JACC provider per Application (Local)

With a custom JACC provide per server, applications deployed to a single server can't have their own custom authorization contracts. In this case, having a custom JACC Provider per application makes more sense by using the `fish.payara.jacc.JaccConfigurationFactory` API.

To access this API, you will need to add a dependency to the Payara Public API first.

In the example below, when an application is deployed, a custom JACC provider is registered programmatically using the `JaccConfigurationFactory (consisting of a JACC` `PolicyConfigurationFactory` and `Policy` implementation objects) in the `contextInitialized` method of `ServletContextListener`.

```
@WebListener
public class JaccInstaller implements ServletContextListener {

    @Override
    public void contextInitialized(ServletContextEvent sce) {

        JaccConfigurationFactory
                .getJaccConfigurationFactory()
                .registerContextProvider(
                        getAppContextId(sce.getServletContext()),
                        new CustomPolicyConfigurationFactory(),
                        new CustomPolicy()
                );

    }

    private String getAppContextId(ServletContext servletContext) {
        return servletContext.getVirtualServerName() + " " +
servletContext.getContextPath();
    }
}
```

Administering User Security

This chapter provides instructions for administering user security in the Payara Server environment by using the `asadmin` command-line utility. Payara Server enforces its authentication and authorization policies upon realms, users, and groups. This chapter assumes that you are familiar with security features such as authentication, authorization, and certificates. If you are not, see Administering System Security.

Instructions for accomplishing these tasks by using the Administration Console are contained in the Administration Console online help.

Jakarta Security defines the concept of an Identity Store, and an SPI interface for writing providers that can authenticate users against Identity Stores. It also

provides multiple built-in providers
See Working with Identity Stores in The Jakarta EE Tutorial for more information about Identity Stores.

Administering Security Realms

Overview of Security Realms

A **security authentication realm**, also called a **security policy domain** or **security domain**, is a scope over which the Payara Server defines and enforces a common security policy. Payara Server is preconfigured with the file, certificate, and administration realms. In addition, you can set up LDAP, JDBC, digest, or custom realms. An application can specify which security realm to use in its deployment descriptors.

If the application does not specify a security realm, Payara Server uses its default realm (`file`).

File realm

Payara Server stores user credentials locally in a file named `keyfile`. This is the default realm.

Administration realm

The administration realm is also a file realm and stores administrator user credentials locally in a file named `admin-keyfile`.

Certificate realm

Payara Server stores user credentials in a certificate keystore. When using the certificate realm, the server uses certificates with the HTTPS protocol to authenticate web clients exclusively.

LDAP realm

Payara Server can get user credentials from a Lightweight Directory Access Protocol (LDAP) server.

JDBC realm

Payara Server gets user credentials from a database. The server uses the database information and the enabled JDBC realm option in the configuration file.

Digest realm

Digest Authentication authenticates a user based on a username and a password. However, the authentication is performed by transmitting the password in an encrypted manner using a digest algorithm.

Oracle Solaris realm

Payara Server gets user credentials directly from the Oracle Solaris operating system user accounts.

This realm supports both Oracle Solaris 9 and 10 versions only.

PAM realm

A Pluggable Authentication Module (PAM) realm allows applications deployed on Payara Server

to authenticate users against a native Unix users list. PAM realms are implemented through the `com.sun.enterprise.security.auth.realm.pam.PamRealm` class and the JAAS Context `pamRealm`.

Custom realm

You can create custom realms that retrieve user credentials from other type of repositories for user credentials, such as a NoSQL database or a third-party user management system. For more information about custom realms, see "Creating a Custom Realm" in the Payara Server Application Development section.

The Payara Server authentication service can govern users in multiple realms.

To Create an Authentication Realm

Use the `create-auth-realm` subcommand in remote mode to create an authentication realm.

1. Ensure that the server is running.
2. Create a realm by using the `create-auth-realm` subcommand.

The following example creates a realm named `custom-dbRealm` by using a customized realm implementation class named `fish.payara.security.auth.realm.DB.DatabaseRealm`:

```
asadmin create-auth-realm --classname=fish.payara.security.auth.realm.DB.DatabaseRealm
--property=group-name-column=groupname:user-name-column=username:group
-table=user_groups:user-table=users:datasource-jndi=jdbc\/userDS:password
-column=password:jaas-context=custom-db: --login
-module=fish.payara.support.SaltedSupportJDBCLoginModule custom-dbRealm

Command create-auth-realm executed successfully.
```

You can use the `--login-module` option to automatically register the JAAS login module in the server's policy file when the security realm is created.

Listing Authentication Realms

Use the `list-auth-realms` subcommand in remote mode to list existing authentication realms.

1. Ensure that the server is running.
2. List realms by using the `list-auth-realms` subcommand.

The following example lists the authentication realms registered on the DAS:

```
asadmin list-auth-realms

db
certificate
file
admin-realm
```

```
Command list-auth-realms executed successfully.
```

Updating an Authentication Realm

Use the `set` subcommand to modify an existing authentication realm. You can only modify the realm's configuration properties.

The following example shows how to change the properties of a custom realm named `custom-db-realm`:

```
asadmin set configs.config.server-config.security-service.auth-realm.custom-
dbRealm.property.group-table=user_name_groups

asadmin set configs.config.server-config.security-service.auth-realm.custom-
dbRealm.property.group-name-column=db_group
```

The realm's name and class name cannot be modified once its created.

Delete an Authentication Realm

Use the `delete-auth-realm` subcommand in remote mode to delete an existing authentication realm.

1. Ensure that the server is running,
2. Delete the realm by using the `delete-auth-realm` subcommand.

This example deletes the security realm named `custom-dbRealm`.

```
asadmin delete-auth-realm custom-dbRealm

Command delete-auth-realm executed successfully.
```

To Configure a JDBC or Digest Authentication Realm

Payara Server enables you to specify a database user's credentials (username and password) in the JDBC realm settings directly instead of in the settings of a JDBC resource and its corresponding connection pool. Using the `jdbc` type realm instead of the connection pool prevents other applications from browsing the database tables for user credentials.

The user password credential should be stored using a password alias for better security.

1. Create the database tables in which to store user credentials for the realm.

   How you create the database tables depends on the database that you are using.

2. Add user credentials to the database tables that you created.

How you add user credentials to the database tables depends on the database that you are using.

3. Create a JDBC connection pool for the database.

   See "To Create a JDBC Connection Pool" in the Payara Server General Administration section.

4. Create a JDBC resource for the database.

   See "To Create a JDBC Resource" in the Payara Server General Administration section.

5. Create a new JDBC security realm.

   The JAAS context should be `jdbcDigestRealm` for digest authentication or `jdbcRealm` for other authentication types.

6. Modify the corresponding deployment descriptor that is associated with your application to specify the `jdbc` realm.
   - For an enterprise application in an Enterprise Archive (EAR) file, modify the `payara-application.xml` file.
   - For a web application in a Web Application Archive (WAR) file, modify the `web.xml` file.
   - For an enterprise bean in an EJB JAR file, modify the `payara-ejb-jar.xml` file.

     For more information about how to specify a security realm, see "How to Configure a Realm" in the Payara Server Application Development section.

7. Assign security roles to users in the realm.

   To assign a security role to a user, add a `security-role-mapping` element to the deployment descriptor that you modified.

This example shows a `security-role-mapping` element that assigns the security role `Employee` to a user account named `Calvin`:

```
<security-role-mapping>
    <role-name>Employee</role-name>
    <principal-name>Calvin</principal-name>
  </security-role-mapping>
```

To Enable LDAP Authentication on the Payara Server DAS

This procedure explains how to enable LDAP authentication to account for user logins to the Payara Server Domain Administration Server (DAS). Login in to the DAS is typically only performed by Payara Server administrators who want to use the Administration Console or the Asadmin CLI.

Ensure that you have properly configured an LDAP server that will host the user credentials with the administrators that will log in to the server's DAS.

Use the `asadmin configure-ldap-for-admin` subcommand to enable user authentication to the Payara Server DAS.

The command uses following syntax:

```
asadmin configure-ldap-for-admin --basedn "dn-list" --url [ldap|ldaps]://ldap-url
--ldap-group group-name
```

Where the arguments are defined as follows:

dn-list
: LDAP BaseDN parameters

ldap-url
: URL and port number for the LDAP server; can use standard (`ldap`) or secure (`ldaps`) protocol

group-name
: LDAP group name for allowed users, as defined on the LDAP server.

For example:

```
asadmin configure-ldap-for-admin --basedn "dc=fish,dc=payara" \
--url ldap://payara.fish:3060 --ldap-group das-admins

asadmin configure-ldap-for-admin --basedn "dc=fish,dc=payara" \
--url ldaps://payara.fish:7501 --ldap-group das-admins
```

Be careful when running this command as once LDAP access is set up in this manner, it will prove challenging to revert this configuration, so it is encouraged to properly test these settings before running them in a production environment.

Administering File Users

When using a file security realm, as its administrator, you are responsible for integrating users into the Payara Server environment so that their credentials are securely established, and they can access the applications and services that they are entitled to use.

The file security realm is a good solution to consider when the user base of a business domain is sufficiently small and user identity administration doesn't require a complex setup. However, for most production environments it is recommended to use a robust solution using either an LDAP or relational database storage.

To Create a File User

Use the `create-file-user` subcommand in remote mode to create a new user by adding a new entry to the `keyfile`. The entry includes the username, password, and any groups that the user belongs to.

Multiple groups can be specified by using a colon(`:`) separated string.

If secure administration is enabled as described in Running Secure Admin, you cannot create an administrative user using a blank password.

Creating a new `file` realm user is a dynamic event and does not require server restart.

1. Ensure that the server is running.
2. Review the current groups of the security realm by using the `list-file-groups` subcommand.
3. Create a file user by using the `create-file-user` subcommand.

This example create user `jennifer` on the default realm `file` (no groups are specified).

The `asadmin --passwordfile` option specifies the name of a file that contains the password entries in a specific format. The entry for a password must have the `AS_ADMIN_` prefix followed by the password name in uppercase letters, an equals sign, and the password. See the `asadmin` documentation for more information.

```
asadmin create-file-user --user admin --passwordfile=asadminpassword.txt jennifer

Command create-file-user executed successfully.
```

To List File Users

Use the `list-file-users` subcommand in remote mode to list the users that are in the `keyfile`.

This example lists file users on the default `file` realm file:

```
asadmin list-file-users

jennifer

Command list-file-users executed successfully.
```

To List File Groups

A group is a category of users classified by common traits, such as job title or customer profile. For example, users of an e-commerce application might belong to the `customer` group, and the big spenders might also belong to the `preferred` group. Categorizing users into groups makes it easier to control the access of large numbers of users.

A group is different from a role in that a role defines a function in an application, while a group is a set of users who are related in some way. For example, in the personnel application there might be groups such as `full-time`, `part-time`, and `on-leave`.

Users in these groups are all employees (the `employee` role). In addition, each user has its own designation that defines an additional level of employment.

Use the `list-file-groups` subcommand in remote mode to list groups for a specific user, or all file groups if the `--name` option is not specified.

This example lists the groups for user `joe`.

```
asadmin> list-file-groups --name joe

staff
manager

Command list-file-groups executed successfully
```

To Update a File User

Use the `update-file-user` subcommand in remote mode to modify the information for a specified user.

If secure administration is enabled as described in Running Secure Admin, you cannot update an administrative user to have a blank password.

1. Ensure that the server is running.
2. Update the user information by using the `update-file-user` subcommand.

The following command updates the groups for user `jennifer`:

```
asadmin update-file-user --passwordfile asadminpassword.txt --groups
staff:manager:engineer Jennifer

Command update-file-user executed successfully.
```

To Delete a File User

Use the `delete-file-user` subcommand in remote mode to remove a user entry from the `keyfile` by specifying the username.

1. Ensure that the server is running.
2. List users by using the `list-file-users` subcommand.
3. Delete the user by using the `delete-file-user` subcommand.

This example deletes user `jennifer` from the default `file` realm.

```
asadmin> delete-file-user jennifer

Command delete-file-user executed successfully.
```

Administering Message Security

This chapter provides information and procedures on configuring the message layer security for SOAP web services in a Payara Server environment.

Message security is supported only in the Full Profile of Payara Server, not in the Web Profile.

Materials in this chapter assumes a basic understanding of security and web services concepts. For more information about security, see About System Security in Payara Server.

About Message Security in Payara Server

Message security enables a server to perform end-to-end authentication of web service invocations and responses at the message layer. Security information is inserted into messages so that it travels through the networking layers and arrives with the intact message at the message destination(s). Message security differs from transport layer security in that message security can be used to decouple message protection from message transport so that messages remain protected after transmission.

SOAP Web services deployed on Payara Server are secured by binding SOAP layer message security providers and message protection policies to the containers in which the applications are deployed, or to web service endpoints served by the applications. SOAP layer message security functionality is configured in the client-side containers of Payara Server by binding SOAP layer message security providers and message protection policies to the client containers or to the portable service references declared by client applications.

Message-level security can be configured for the entire Payara Server or for specific applications or methods. Configuring message security at the application level is discussed in the Application Development section.

Security Tokens and Security Mechanisms

WS-Security is a specification that provides a communications protocol for applying security to web services. The security mechanisms implement the specification. Web Services Interoperability Technologies (WSIT) implements WS-Security to provide interoperable message content integrity and confidentiality, even when messages pass through intermediary nodes before reaching their destination endpoint.

WS-Security as provided by WSIT is in addition to existing transport-level security, which can still be used.

The Simple Object Access Protocol (SOAP) layer message security providers installed with Payara Server can be used to employ username/password and X.509 certificate security tokens to authenticate and encrypt SOAP web services messages.

Username Tokens

Payara Server uses username tokens in SOAP messages to authenticate the message sender. The recipient of a message containing a username token (within embedded password) validates that

the message sender is authorized to act as the user (identified in the token) by confirming that the sender knows the password of the user.

When using a username token, a valid user database must be configured on Payara Server.

Digital Signatures

Payara Server uses XML digital signatures to bind an authentication identity to message content. Clients use digital signatures to establish their caller identity. Digital signatures are verified by the message receiver to authenticate the source of the message content (which might be different from the sender of the message.)

When using digital signatures, valid keystore and truststore files must be configured on Payara Server.

Encryption

The purpose of encryption is to modify the data so that it can only be understood by its intended audience. This is accomplished by substituting an encrypted element for the original content. When based on public key cryptography, encryption can be used to establish the identity of the parties who are authorized to read a message.

When using encryption, a Java Cryptography Extension (JCE) provider that supports the corresponding encryption algorithm suites must be installed.

Authentication Providers

The authentication layer is the message layer on which authentication processing must be performed. Payara Server enforces web services message security at the SOAP layer. The types of authentication that are supported include the following:

- Sender authentication, including username-password authentication
- Content authentication, including XML digital signatures

Payara Server invokes authentication providers to process SOAP message layer security. The message security providers provide information such as the type of authentication that is required for the request and response messages. The following message security providers are included with Payara Server:

- Client-side Provider: A client-side provider establishes (by signature or username/password) the source identity of request messages and/or protects (by encryption) request messages such that they can only be viewed by their intended recipients. A client-side provider also establishes its container as an authorized recipient of a received response (by successfully decrypting it) and validates passwords or signatures in the response to authenticate the source identity associated with the response. Client-side providers configured in Payara Server can be used to protect the request messages sent and the response messages received by server-side components (servlets and EJB components) acting as clients of other services.

  The default client provider is used to identify the client—side provider to be invoked for any application for which a specific client provider has not been bound.

- Server-side Provider: A server-side provider establishes its container as an authorized recipient

of a received request (by successfully decrypting it), and validates passwords or signatures in the request to authenticate the source identity associated with the request. A server-side provider also establishes (by signature or username/password) the source identity of response messages and/or protects (by encryption) response messages such that they can only be viewed by their intended recipients. Server-side providers are only invoked by server-side containers.

The default server provider is used to identify the server—side provider to be invoked for any application for which a specific server provider has not been bound.

Message Protection Policies

A request policy defines the authentication policy requirements associated with request processing performed by the authentication provider. Policies are expressed in message sender order such that a requirement that encryption occur after content would mean that the message receiver would expect to decrypt the message before validating the signature. The response policy defines the authentication policy requirements associated with response processing performed by the authentication provider.

Message protection policies are defined for request message processing and response message processing. The policies are expressed in terms of requirements for source and/or recipient authentication. The providers apply specific message security mechanisms to cause the message protection policies to be realized in the context of SOAP web services messages.

- Source Authentication Policy: A source authentication policy represents a requirement that the identity of the entity that sent a message or that defined the content of a message be established in the message such that it can be authenticated by the message receiver.
- Recipient Authentication Policy. A recipient authentication policy represents a requirement that the message be sent such that the identity of the entities that can receive the message can be established by the message sender.

Request and response message protection policies are defined when a security provider is configured into a container. Application-specific message protection policies (at the granularity of the web service port or operation) can also be configured within the Payara Server deployment descriptors of the application or application client. In any situation where message protection policies are defined, the request and response message protection policies of the client must be equivalent t) the request and response message protection policies of the server.

For more information about defining application-specific message protection policies, see "Securing Applications" in the Application Development section.

Application-Specific Web Services Security

Application-specific web services security functionality is configured (at application assembly) by defining the `message-security-binding` elements in the Payara Server deployment descriptors of the application. These `message-security-binding` elements are used to associate a specific security provider or message protection policy with a web service endpoint or service reference, and might be qualified so that they apply to a specific port or method of the corresponding endpoint or referenced service.

For information about defining application-specific message protection policies, see "Securing

Applications" in the Application Development section.

Message Security Administration

When Payara Server is installed or a new domain is created, SOAP layer message security providers are configured in the client and server-side containers of Payara Server, where they are available for binding for use by the containers, or by individual applications or clients deployed in the containers.

Default providers are configured with a simple message protection policy that, if bound to a container, or to an application or client in a container, would cause the source of the content in all request and response messages to be authenticated by XML digital signature.

Payara Server administrative interfaces can be used as follows:

- To modify the message protection policies enforced by the providers
- To bind the existing providers for use by the server-side containers of Payara Server
- To create new security provider configurations with alternative message protection policies

Analogous administrative operations can be performed on the SOAP message layer security configuration of the application client container. If you want web services security to protect all web services applications deployed on Payara Server, see Enabling Message Security for Application Clients.

Message Security Tasks

The general implementation tasks for message security include some or all of the following:

1. If you are using a username token, verifying that a user database is configured for an appropriate security realm

When using a username/password token, an appropriate realm must be configured and a user database must be configured for the realm.

2. Managing certificates and private keys, if necessary
3. Enabling the Payara Server default providers
4. Configuring new message security providers

Message Security Roles

In a traditional Payara Server management infrastructure, the administrator and the application deployer are expected to take primary responsibility for configuring message security.

System Administrator

The system administrator is responsible for the following message security tasks:

- Administering server security settings and certificate databases
- Administering keystore and truststore files

- Configuring message security providers on Payara Server
- Turning on message security

Application Deployer

The application deployer is responsible for the following message security tasks:

- Specifying (at application reassembly) any required application-specific message protection policies if such policies have not already been specified by the developer/assembler.
- Modifying Payara Server deployment descriptors to specify application-specific message protection policies information (message-security-binding elements) to web service endpoint and service references.

Application Developer

The application developer is responsible for the following message security tasks:

- Determining if an application-specific message protection policy is required by the application

  If so, the developer ensures that the required policy is specified at application assembly time.

- Specifying how SOAP web services should be set up for message security.

Message security can be set up by the administrator so that all web services are secured, or by the application deployer when the security provider or protection policy bound to the application must be different from that bound to the container.

- Turning on message security if authorized to do so by the administrator.

Enabling Default Message Security Providers for SOAP Web Services

By default, message security is disabled on Payara Server. Default message security providers have been created, but are not active until you enable them. After the providers have been enabled, message security is enabled.

To Enable a Default Server Provider

To enable message security for web services endpoints deployed in Payara Server, you must specify a security provider to be used by default on the server side. If you enable a default provider for message security, you also need to enable providers to be used by clients of the web services deployed in Payara Server.

1. Specify the default server provider by using the `set` subcommand.

   Use the following syntax:

```
asadmin set --port admin-port server-config.security-service.message-security-
config.SOAP.default_provider=ServerProvider
```

2. To apply your changes to applications that are already running, restart the server instance.

To Enable a Default Client Provider

To enable message security for web service invocations originating from deployed endpoints, you must specify a default client provider. If you enabled a default client provider for Payara Server, you must ensure that any services invoked from endpoints deployed in Payara Server are compatibly configured for message layer security.

1. Specify the default client provider by using the `set` subcommand.

   Use the following syntax:

   ```
   asadmin set --port admin-port server-config.security-service.message-security-
   config.SOAP.default_client_provider=ClientProvider
   ```

2. To apply your changes to applications that are already running, restart the server instance.

Configuring Message Protection Policies

Message protection policies are defined for request message processing and response message processing. The policies are expressed in terms of requirements for source and/or recipient authentication.

The providers apply specific message security mechanisms to cause the message protection policies to be realized in the context of SOAP web services messages.

Message Protection Policy Mapping

The following table shows message protection policy configurations and the resulting message security operations performed by the WS-Security SOAP message security providers for that configuration.

Table 158. Message Protection Policy Mapping to WS-Security SOAP Operations

Message Protection Policy	Resulting WS-Security SOAP Message Protection Operations
`auth-source="sender"`	The message contains a `wsse:Security` header that contains a `wsse:UsernameToken` (with password).
`auth-source="content"`	The content of the SOAP message Body is signed. The message contains a `wsse:Security` header that contains the message body signature represented as a `ds`:`Signature`.

Message Protection Policy	Resulting WS-Security SOAP Message Protection Operations
auth-source="sender" auth-recipient="before-content" OR auth-recipient="after-content"	The content of the SOAP message Body is encrypted and replaced with the resulting xend:EncryptedData. The message contains a wsse:Security header that contains a wsse:UsernameToken (with password) and an xenc:EncryptedKey. The xenc:EncryptedKey contains the key used to encrypt the SOAP message body. The key is encrypted in the public key of the recipient.
auth-source="content" auth-recipient="before-content"	The content of the SOAP message body is encrypted and replaced with the resulting xend:EncryptedData. The xenc:EncryptedData is signed.The message contains a wsse:Security header that contains an xenc:EncryptedKey and a ds:`Signature`. The xenc:EncryptedKey contains the key used to encrypt the SOAP message body. The key is encrypted in the public key of the recipient.
auth-source="content" auth-recipient="after-content"	The content of the SOAP message Body is signed, then encrypted, and then replaced with the resulting xend:EncryptedData. The message contains a wsse:Security header that contains an xenc:EncryptedKey and a ds:Signature. The xenc:EncryptedKey contains the key used to encrypt the SOAP message body. The key is encrypted in the public key of the recipient.
auth-recipient="before-content" OR auth-recipient="after-content"	The content of the SOAP message Body is encrypted and replaced with the resulting xend:EncryptedData. The message contains a wsse:Security header that contains an xenc:EncryptedKey. The xenc:EncryptedKey contains the key used to encrypt the SOAP message body. The key is encrypted in the public key of the recipient.
No policy specified.	No security operations are performed by the modules.

To Configure the Message Protection Policies for a Provider

Typically, you would not reconfigure a provider. However, if needed for your situation, you can modify a provider's message protection policies by changing provider type, implementation class, and provider-specific configuration properties. To understand the results of different combinations, see the table in the above section.

Use the `set` subcommand to set the response policy, then replace the word `request` in the following commands with the word `response`.

1. Add a request policy to the client and set the authentication source by using the `set` subcommand.

   For example:

   ```
   asadmin set server-config.security-service.message-security-config.SOAP.provider-
   config.ClientProvider.request-policy.auth_source=[sender | content]
   ```

2. Add a request policy to the server and set the authentication source by using the `set` subcommand.

   For example:

   ```
   asadmin set server-config.security-service.message-security-config.SOAP.provider-
   config.ServerProvider.request-policy.auth_source=[sender | content]
   ```

3. Add a request policy to the client and set the authentication recipient by using the `set` subcommand:

   For example:

   ```
   asadmin set server-config.security-service.message-security-config.SOAP.provider-
   config.ClientProvider.request-policy.auth_recipient=[before-content | after-
   content]
   ```

4. Add a request policy to the server and set the authentication recipient by using the `set` subcommand:

   For example:

   ```
   asadmin set server-config.security-service.message-security-config.SOAP.provider-
   config.ServerProvider.request-policy.auth_recipient=[before-content | after-
   content]
   ```

Setting the Request and Response Policy for the Application Client Configuration

The request and response policies define the authentication policy requirements associated with request and response processing performed by the authentication provider.

Policies are expressed in message sender order such that a requirement that encryption occur after content would mean that the message receiver would expect to decrypt the message before validating the signature.

To achieve message security, the request and response policies must be enabled on both the server and client. When configuring the policies on the client and server, make sure that the client policy matches the server policy for request/response protection at application-level message binding.

To set the request policy for the application client configuration, modify the Payara Server-specific configuration for the application client container as described in Enabling Message Security for Application Clients.

Message Security Policy Setting Example

In the application client configuration file, the `request-policy` and `response-policy` elements are used to set the request policy, as shown in the following code snippet.

Additional code in the snippet is provided as illustration and might differ slightly in your environment.

```
<client-container>
  <target-server name="your-host" address="your-host"  port="your-port"/>
  <log-service file="" level="WARNING"/>
  <message-security-config auth-layer="SOAP" default-client-provider="ClientProvider">
    <provider-config class-name="com.sun.enterprise.security.jauth.ClientAuthModule"
provider-id="clientprovider" provider-type="client">
      <request-policy auth-source="sender | content" auth-recipient="after-content |
before-content"/>
      <response-policy auth-source="sender | content" auth-recipient="after-content |
before-content"/>
       <property name="security.config" value="as-install/lib/appclient/wss-client-
config.xml"/>
    </provider-config>
  </message-security-config>
</client-container>
```

Valid values for `auth-source` include `sender` and `content`. Valid values for `auth-recipient` include `before-content` and `after-content`. A table describing the results of various combinations of these values can be found in Configuring Message Protection Policies.

To not specify a request or response policy, leave the element with no content:

```
<response-policy/>
```

Administering Non-default Message Security Providers

To Create a Message Security Provider

Use the `create-message-security-provider` subcommand in remote mode to create a new message provider for the security service. If the message layer does not exist, the message layer is created, and the provider is created under it.

1. Ensure that the server is running.
2. Create the message security provider by using the `create-message-security-provider` subcommand.
3. If needed, restart the server, as some properties require server restart.

This example creates the new message security provider name `mySecurityProvider`:

```
asadmin create-message-security-provider --classname
com.sun.enterprise.security.jauth.ClientAuthModule --providertype client
mySecurityProvider

Command create-message-security-provider executed successfully.
```

To List Message Security Providers

Use the `list-message-security-providers` subcommand in remote mode to list the message providers for the security layer.

1. Ensure that the server is running.
2. List the message security providers by using the `list-message-security-providers` subcommand.

This example lists the message security providers for a message layer.

```
asadmin list-message-security-providers --layer SOAP

XWS_ClientProvider
ClientProvider
XWS_ServerProvider
ServerProvider

Command list-message-security-providers executed successfully.
```

To Update a Message Security Provider

1. Ensure that the server is running.
2. List the message security providers by using the `list-message-security-providers` subcommand.
3. Modify the values for the specified message security provider by using the `set` subcommand.

   The message security provider is identified by its **dotted name**.

To Delete a Message Security Provider

Use the `delete-message-security-provider` subcommand in remote mode to remove a message security provider.

1. Ensure that the server is running.

2. List the message security providers by using the `list-message-security-providers` subcommand.
3. Delete the message security provider by using the `delete-message-security-provider` subcommand.

This example deletes the `myServerityProvider` message security provider.

```
asadmin delete-message-security-provider --layer SOAP myServerityProvider

Command delete-message-security-provider executed successfully.
```

To Configure a Servlet Layer Server Authentication Module (SAM)

You can configure a Jakarta Authentication Server Authentication Module (SAM) as an HTTP Servlet-layer message security provider, either through the Administration Console or with the `create-message-security-provider` subcommand.

1. Ensure that the server is running.
2. Create the message security provider by using the `create-message-security-provider` subcommand.
3. Bind the message security provider for use with your application.

   You do this by defining the `httpservlet-security-provider` attribute in the `glassfish-web.xml` (deprecated) or `payara-web.xml` deployment descriptor corresponding to your application.

   Set the value of the attribute to the provider name you assigned to the message security provider. For example, if you use MySAM when you create the message security provider the entry would be `httpservlet-security-provider="MySAM"`.

4. Restart the server instance.

This example creates a new message security provider named `mySAM`.

```
asadmin create-message-security-provider --layer=HttpServlet --classname
com.sun.glassfish.oamsam.OAMAuthenticatorSAM --providertype server --property
oam.resource.hostid.variation="your-host-system.com" mySAM

Creation of message security provider named mySAM completed successfully

Command create-message-security-provider executed successfully.
```

The subcommand results in the following `domain.xml` configuration entry:

```
<message-security-config auth-layer="HttpServlet">
    <provider-config provider-type="server" provider-id="mysam"  class-
name="com.sun.glassfish.oamsam.OAMAuthenticatorSAM">
        <property name="oam.resource.hostid.variation" value="your-host-
system.com"></property>
```

```
        <request-policy></request-policy>
        <response-policy></response-policy>
    </provider-config>
</message-security-config>
```

To list the HttpServlet message security providers, use the `list-message-security-providers` subcommand:

```
asadmin list-message-security-providers --layer HttpServlet

list-message-security-providers successful
GFConsoleAuthModule
mySAM

Command list-message-security-providers executed successfully.
```

Enabling Message Security for Application Clients

The message protection policies of client providers must be configured such that they are equivalent to the message protection policies of the server-side providers they will be interacting with. This is already the situation for the providers configured (but not enabled) when Payara Server is installed or a new domain is created.

To enable message security for client applications, modify the Payara Server specific configuration for the application client container. The process is analogous to the process in Configuring Message Protection Policies.

Security in High-Availability Environments

This chapter describes important information about administering security in a high availability environment (using traditional clusters or deployment groups).

This chapter assumes that you are familiar with security features such as authentication, authorization, and certificates. If you are not, see Administering System Security.

Configuring Certificates in Cluster Mode

The sections Certificates and Secure Transport and Administering JSSE Certificates describe the relevant concepts and use of certificates in Payara Server.

By default, Payara Server uses self-signed certificates. The self-signed certificates that Payara Server uses will not be trusted by clients by default because a certificate authority does not vouch for the authenticity of the certificate.

You can instead use your own certificates, as described in Using Your Own Certificates.

Dynamic Reconfiguration

Administrative commands that you execute on the domain administration server (DAS) must either

be replicated on the affected server instances, or on all server instances that are part of a cluster or deployment group.

Payara Server replicates the commands by sending the same administration command request that was sent to the DAS to the server instances. As a result of replicating the commands on the DAS and the individual instances, the DAS and the instances make the same changes to their respective copies of the domain's configuration.

It is recommended that you enable secure admin as described in Managing Administrative Security so that Payara Server securely transfers these files on the network.

Dynamic reconfiguration refers to using the `--target` operand to CLI subcommands to make a change to a server instance (if the user-specified target is a server instance), or all server instances that are part of a cluster or deployment group (if the user-specified target is a cluster or deployment group).

For example, in the following command:

```
asadmin create-jdbc-resource some-options --target some-target
```

The `--target` operand allows the following values:

- `server` - Performs the command on the default server instance. This is the default value.
- `configuration_name` - Performs the command in the specified configuration.
- `cluster_name` - Performs the command on all server instances in the specified cluster.
- `deployment_group_name` - Performs the command on all server instances in the specified deployment group.
- `instance_name` - Performs the command on a specified server instance.

If a command fails while targeting a cluster or deployment group, the status shows all server instances where dynamic reconfiguration failed, and suggests corrective measures to make progress.

The command status also shows when a restart is required for each server instance.

Enabling Dynamic Configuration

Dynamic configuration is enabled by default and no additional action is required. Use the following command to enable dynamic configuration from the command line:

```
asadmin --user user --passwordfile password-file set <cluster-name-config>.dynamic-
reconfiguration-enabled=true
```

To enable dynamic configuration from the Administration Console, perform the following steps:

1. Expand the *Configurations* node.
2. Click the name of the cluster's configuration or a shared configuration object used by the instances of a deployment group.
3. On the *System Properties* page, check the *Dynamic Reconfiguration* Enabled box.
4. Save your changes.

The dynamic reconfiguration feature applies only to server instances, not the DAS. Therefore, you cannot "disable" dynamic reconfiguration on the DAS.
Some commands and changes done in the DAS may be applied dynamically on the DAS, so consult the documentation on the command reference to find out if they support dynamic re-configuration on the DAS/

Understanding Synchronization

As described in "Resynchronizing Payara Server Instances and the DAS" in the High Availability section, configuration data for a Payara Server instance is stored in the repository of the DAS and in a cache on the host that is local to the instance.

The configuration data in these locations must be synchronized. The cache is synchronized only when a user uses the administration tools to start or restart an instance.

Managing Administrative Security

This chapter describes how to manage administrative security by using Payara Server's secure administration feature.

This chapter assumes that you are familiar with security features such as authentication, authorization, and certificates. If you are not, first see Administering System Security.

Secure Administration Overview

The secure administration feature allows an administrator to secure all administrative communication between the domain administration server (DAS), any remote instances, and administration clients such as the `asadmin` CLI utility, the administration console's web interface, and REST clients using the Management API.

In addition, secure administration helps to prevent DAS-to-DAS and instance-to-instance traffic, and carefully restricts administration-client-to-instance traffic.

The secure administration feature, which is henceforth referred to as **secure admin**, provides a secure environment, in which you can be confident that rogue users or processes cannot intercept or corrupt administration traffic or impersonate legitimate Payara Server components.

When you install Payara Server or create a new domain, secure admin is disabled by default. When secure admin is disabled, Payara Server does not encrypt administrative communication among the system components, but it **does not accept administrative connections from remote hosts**.

The following subcommands enable and disable secure admin:

`enable-secure-admin`

The `enable-secure-admin` subcommand turns on secure admin. Payara Server uses SSL/TLS encryption to protect subsequent administrative traffic and will ALSO accept remote administrative connections. Enabling secure admin affects the entire domain, including the DAS and all of its instances. The DAS must be running to run `enable-secure-admin`.

You must restart the DAS immediately after enabling secure admin, and then start any instances you want to run.

The `enable-secure-admin` subcommand fails if ANY administrator users have an empty password credential assigned. Before retrying the command, ALL administrator users should have non-empty passwords assigned.

`disable-secure-admin`

The `disable-secure-admin` subcommand turns off secure admin. Payara Server no longer encrypts administrative messages and will no longer accept remote administration connections. Disabling secure admin affects the entire domain, including the DAS and all instances. The DAS must be running to run `disable-secure-admin`.

You must restart the DAS immediately after disabling secure admin, and then start any instances you want to run.

If secure admin is not enabled, this subcommand has no effect.

This section describes how to use these commands to run secure admin, and the implications of doing so.

How Secure Admin Works: The Big Picture

Secure admin is a domain-wide setting. It affects the DAS and all instances and all administration clients.

Functions Performed by Secure Admin

The `enable-secure-admin` subcommand performs the following functions. Subsequent sections describe these functions in more detail.

- Enables the secure admin behavior, optionally setting which **aliases** are to be used for identifying the DAS and instance certificates.
- Adjusts all configurations in the domain, including the `default-config` template configuration.
- Adjusts HTTP settings:
  - SSL/TLS is enabled in the DAS' admin listener and the instances' admin listeners configurations.
  - Port unification (that is, HTTP and HTTPS are handled by the same port), http—to—https redirection, and client authentication (`client-auth=want`) are enabled.
  - Configures SSL to use the administration truststore.
  - Configures SSL to use the administration keystore and the correct alias (for the self-signed

cert) for authenticating itself. (You can use a CA-issued certificate instead, as described in Using Your Own Certificates.

HTTP configuration on the DAS and each instance is identical, with the exception that the DAS uses the `s1as` alias for SSL/TLS authentication and the instances use the `glassfish-instance` alias by default.

A server restart is required to apply the aforementioned changes. The restart also synchronizes the restarted instances.

Which Administration Account is Used?

If only one administration account exists in the default `admin` realm, Payara Server treats that account as the current default administration account. In this case, when you run an `asadmin` command, you do not need to specify a username. If a password for that username is required, you need to specify it, typically by using the `--passwordfile` option or by letting `asadmin` prompt you for it.

By default, Payara Server includes a single account for user `admin` which has an empty password.

If multiple admin accounts exist, then Payara Server does not recognize any administrator username as the default. You must then specify a valid username via the `--user` option when you use the `asadmin` command (or by or defining the `AS_ASDMIN_USER` environment variable), and its associated password (if it is not empty).

The username and password used for a login attempt must match the username and password (if required) for an account defined in the `admin` realm, and you must have set up the account as a member of the `admin` group.

What Authentication Methods Are Used for Secure Administration?

The secure admin feature enforces security via the following authentication methods:

- The DAS and instances authenticate to each other via mutual (two-way) SSL/TLS certificate authentication. The DAS authenticates to clients via one-way SSL/TLS certificate authentication.

The domain creation process creates a default keystore and truststore, plus a default private key for the DAS. Secure admin uses this initial configuration to set up the default truststore so that the DAS and instances always trust each other.

- Remote administration clients (the Asadmin CLI, the web administration console, and IDE extension plugins) must accept the public certificate presented by the DAS. If accepted, remote administration clients then send a username and password (via HTTP `Basic` authentication). The receiving DAS or instance makes sure those credentials are valid in its configured `admin` realm, and authenticates and authorizes the user.
- A locally-running Asadmin CLI (that is, connecting to an instance on the same host) authenticates and authorizes to the co-located instance using a locally-provisioned password.

- Credentials or other sensitive information sent over the network are always encrypted if secure admin is enabled. No credentials are sent in the clear if secure admin is enabled. (If secure admin is disabled, credentials are sent in clear text.)

  Messages between administration clients and the DAS, between the DAS and remote instances, and between local administration clients and instances are encrypted using SSL/TLS. This is true even if you explicitly set the `asadmin --secure` option to `false`.

The following table shows which authentication methods are employed when secure admin is enabled or disabled.

Table 159. Authentication Methods Employed

Access Method	Secure Admin is Disabled	Secure Admin is Enabled
Remote administration access to the DAS	Rejected.	Username/password authentication. (Client must also accept server certificate.)
Communication between DAS and instances	Cleartext messages. No mutual authentication.	SSL-encrypted messages. SSL mutual authentication using certificates.
Communication between administration clients and DAS	Cleartext messages. No DAS authentication.	SSL-encrypted messages. DAS uses SSL certificate server authentication.
Local asadmin client to instance on same node	Cleartext messages. Locally-provisioned password mechanism is used.	SSL-encrypted messages. Locally-provisioned password mechanism is used.

Understanding How Certificate Authentication is Performed

The domain creation process creates a primary (private) key and a self-signed certificate for the DAS, and a separate private key and self-signed certificate for remote instances.

Then, when you enable secure admin, the following actions are performed:

- Both private keys are stored in the domain-wide DAS keystore file, `keystore.p12`.
- Both public certificates are stored in the domain-wide DAS truststore file, `cacerts.p12`.

When the DAS sends a message to an instance:

1. The instance asks the DAS to provide an SSL/TLS certificate.
2. The DAS sends the certificate with the alias you specified using the `--adminalias` option when you ran the `enable-secure-admin` subcommand.
3. The instance makes sure the certificate is valid and Payara Server makes sure that the security `Principal` associated with the incoming request (provided automatically by the HTTP engine and the SSL/TLS implementation provided by the Java runtime) matches the `Principal` associated with the `adminalias` from the instance's truststore.

What Certificates Are Used?

When you enable secure admin, you can optionally set the `--adminalias` and `--instancealias` options that tell secure admin which aliases to use for the DAS and instance certificates.

The DAS uses the alias associated with the `--instancealias` option to check incoming requests that use SSL/TLS cert authentication. Conversely, instances use the alias associated with the `--adminalias` option to check incoming requests with certificate authentication.

By default, `--adminalias` of the `enable-secure-admin` subcommand uses the `s1as` alias, and the `--instancealias` option uses the `glassfish-instance` alias, both of which identify the default self-signed certificates.

You can use your tool of choice, such as `keytool`, to list the default self-signed certificates in the keystore, similar to the following:

```
keytool -list -keystore keystore.p12

Enter keystore password:

Keystore type: PKCS12
Keystore provider: SUN

Your keystore contains 2 entries

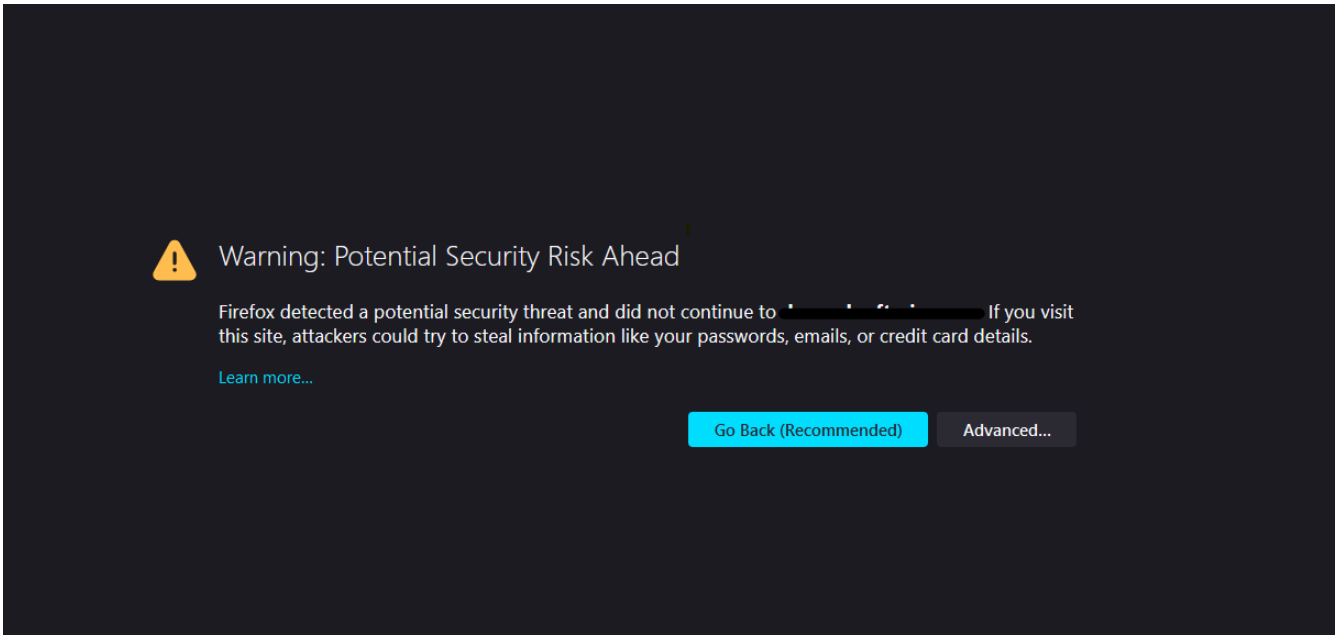
glassfish-instance, Jan 3, 2023, PrivateKeyEntry,
Certificate fingerprint (MD5): 06:A4:83:84:57:52:9C:2F:E1:FD:08:68:BB:2D:ED:E8
s1as, Jan 3, 2023, PrivateKeyEntry,
Certificate fingerprint (MD5): 8B:7D:5A:4A:32:36:1B:5D:6A:29:66:01:B0:A3:CB:85
```

The `--adminalias` and `--instancealias` values are maintained. Because of this design, normal instance creation operations (create-instance over SSH and create-local-instance) apply the up-to-date keystore, truststore, and configuration to each instance.

Self-Signed Certificates and Trust

The self-signed certificates that Payara Server uses will not be trusted by clients by default because a certificate authority (CA)) does not vouch for the authenticity of the certificate.

If you enable secure admin and then contact the DAS using an administration client, that client will detect whether the certificate is automatically trusted. Most modern web browsers will deny access to the web interface of the Admin console and reject any communication until the user explicitly creates an exception to continue. And example is shown in the following figure:



Similarly, the first time the Asadmin CLI receives an untrusted certificate, it displays the certificate and lets you accept it or reject it, as follows:

```
> asadmin enable-secure-admin
Command enable-secure-admin executed successfully.

> asadmin restart-domain domain1
...
Command start-domain executed successfully.

> asadmin list-applications

]
Do you trust the above certificate [y|N] -->
```

When accepted for the first time, the certificate will be automatically accepted in subsequent Asadmin CLI operations.

The Asadmin CLI locally saves accepted certificates in the `.gf-client/truststore` file in the OS user's home directory. You do not generally need to work with the file directly, but if you delete or move the file, `asadmin` will prompt you again when it receives untrusted certificates.

Some `asadmin` commands can contact an instance directly to retrieve information (but not to make configuration changes). The instances do not use the same certificate as the DAS, so in these cases the command will also prompt you to accept or reject the specific instance certificate.

Using Your Own Certificates

By default, `--adminalias` of the `enable-secure-admin` subcommand uses the `s1as` alias, and the `--instancealias` option uses the `glassfish-instance` alias, both of which identify default self-signed certificates prepared by the domain at its creation.

You can instead have Payara Server use your own certificates for this purpose by first importing your certificates to the keystore and truststore, and then enabling secure admin and specify the aliases for your custom certificates.

In general, in most cases it is recommended to use custom certificates for the DAS as remote access is usually done on un-restricted environments.

It is also possible to use `s1as` and `glassfish-instance` as the alias names for your own certificates when importing them to the keystore and truststore. A benefit of doing so is that you would not have to specify alias names with the `enable-secure-admin` subcommand.

In addition, your own certificate identified by the `s1as` alias would be used in all other cases within the domain where the `s1as` alias is used (by default), such as in the SSL configuration of the IIOP and `http-listener-2` listeners, and as the `encryption.key.alias` and `signature.key.alias` used for provider configuration in the SOAP authentication layer for Message Security configuration.

You may find the wide-reaching effect of using the `s1as` alias with your own certificate to be either a useful feature or an unintended consequence. Therefore, you should understand the implications of using the `s1as` alias before doing so.

If you decide to use the `s1as` and `glassfish-instance` aliases with your own certificates, you will first need to disable secure admin (if enabled) and then change or delete the exiting `s1as` alias from both the `keystore.p12` keystore and `cacerts.p12` truststore for the DAS.

You can also use the `--changealias` or`--delete` option of `keytool` to accomplish this. After that import your own certificates.

When renewing an expired certificate (since most CA-issued certificates would have a lifetime of a year in general), you must first disable secure admin, replace the certificates in the keystore and truststore with the renewed certificates and then re-enable secure admin to correctly re-established secure administration to the domain and its instances.

An Alternate Approach: Using Distinguished Names to Specify Certificates

By default, the DAS uses the alias associated with the `--instancealias` option to check incoming requests that use SSL/TLS cert authentication. Conversely, instances use the alias associated with the `--adminalias` option to check incoming requests with certificate authentication.

The `enable-secure-admin-principal` subcommand provides an alternate approach. `enable-secure-admin-principal` instructs Payara Server to accept admin requests when accompanied by an SSL certificate with the specified distinguished name (DN).

Any certificate you specify with `enable-secure-admin-principal` must either be issued by a trusted certificate authority or, if it is self-signed, must already be imported in the server's truststore.

For example, assume that you write your own admin client that uses the REST interface. When your client establishes the connection, it can choose which certificate to use for its client cert. You would then specify the DN of this certificate to `enable-secure-admin-principal`.

You must specify either the DN or the `--alias` option of the `enable-secure-admin-principal` subcommand.

If you specify the DN, Payara Server records the value you specify as the DN. You specify the DN as a comma-separated list in quotes. For example, `"CN=sample.payara.fish,OU=Payara,O=Payara Foundation,L=Great Malvern,ST=Worcestershire,C=UK"`.

The `enable-secure-admin-principal` subcommand accepts the string you enter and does not immediately validate it. However, secure admin must be able to match

> the DN you specify in order to use it.

If you have sufficient privileges to view the content of the keystore, you can use keytool to display the DN of a certificate:

```
keytool -v -list -keystore keystore.p12

Keystore type: PKCS12
Keystore provider: SUN

Your keystore contains 2 entries

Alias name: glassfish-instance
Creation date: Jul 7, 2023

    ]
]
```

If you use the `--alias aliasname` form, then Payara Server looks in its truststore for a certificate with the specified alias and uses the DN associated with that certificate. `aliasname` must be an alias associated with a certificate currently in the truststore.

If you have sufficient privileges to view the contents of the truststore, you can use keytool to display the alias of a certificate:

```
keytool -v -list -keystore cacerts.p12

Alias name: glassfish-instance
```

```

```

When you run `enable-secure-admin`, Payara Server automatically records the DNs for the admin alias and the instance alias, whether you specify those values or use the defaults. You do not need to run `enable-secure-admin-principal` yourself for those certificates.

Other than these certificates, you must run `enable-secure-admin-principal` for any other DN that Payara Server should authorize to send admin requests. This includes DNs corresponding to trusted certificates (those with a certificate chain to a trusted authority.)

You can run `enable-secure-admin-principal` multiple times so that Payara Server accepts admin requests from a client sending a certificate with any of the DNs you specify.

The following example shows how to specify a `DN` for authorizing access in secure administration:

```
asadmin enable-secure-admin-principal
"CN=sample.payara.fish,OU=Payara,O=Payara Foundation,L=Great
Malvern,ST=Worcestershire,C=UK"

Command enable-secure-admin-principal executed successfully.
```

You can use the `disable-secure-admin-principal` subcommand to disable a specific certificate for authenticating and authorizing access in secure admin. You must specify either the DN or the `--alias` option of the `disable-secure-admin-principal` subcommand. To disable multiple certificates for authenticating and authorizing access in secure admin, run the `disable-secure-admin-principal` subcommand multiple times.

You can use the `list-secure-admin-principals` subcommand to list the certificates for which Payara Server accepts admin requests from clients.

Guarding Against Unwanted Connections

Secure admin guards against unwanted connections in several ways:

- **DAS-to-DAS, instance-to-instance**:
  - The DAS and the instances have copies of the same truststore, which contains the public certificate of the DAS and the separate public certificate that is used by all instances. In addition, Payara Server includes a unique, generated "domain ID" that servers use to ensure that admin requests from other Payara Servers originate from the correct domain.
  - DAS-to-other-DAS communication is not authenticated because each different DAS will have its own self-signed certificate that is not in the truststore of the other DAS.
  - DAS-to-itself communication is unlikely unless you were to mis-configure the admin listener port for an instance on the same host, so it is the same as for the DAS. Similarly, instance-to-instance traffic is unlikely unless you were to mis-configure listener ports for instances on the same host.

    To prevent both of these situations, both cases are handled by making sure that the connecting `Principal` (alias) is not the running `Principal`. Secure admin ensures that if the client has authenticated using SSL/TLS client authentication that the `Principal` associated with the remote client is not the same as the current process. That is, the DAS makes sure that the `Principal` is not itself. Similarly, each instance ensures that the client is not an instance. (The instances share the same self-signed certificate and therefore are mapped to the same `Principal`)

- Remote client-to-instance:

  Remote `asadmin` clients are unable to connect directly to instances. If the user on host "test1" runs a local command but specifies a remote instance on host "test2," `asadmin` on "test1" will read and send that locally-provisioned password. The instance on "test2" will have a different locally-provisioned password and so the authentication attempt will fail.

  Therefore, a user on "test1" will not be able to run a remote command targeting an instance on "test2."

Considerations When Running Payara Server With Default Security

In Payara Server, the default admin account has the username "admin" with an empty password credentials. By default, admin clients provide empty credentials or none at all, and all are authenticated and authorized as that default admin user. None of the participants (clients, DAS, or instances) encrypts network messages.

If this level of security is acceptable in your environment, no changes are needed, you do not need to enable secure administration.

Imposing a heightened level of security is optional, but recommended on most public-facing production environments.

However, consider the following table, which shows which operations are accepted and rejected when secure admin is disabled.

When secure admin is disabled, Payara Server does allow remote monitoring (read-only) access via the REST interface.

Table 160. Accepted and Rejected Operations if Secure Admin is Disabled

Operation	Run Locally	Run Remotely
`start-local-instance`	Functions as expected	Cannot sync with DAS. The instance starts but cannot communicate with the DAS. DAS will not properly recognize the instance and synchronize with it.
Any other `asadmin` subcommand	Functions as expected	Rejected. The user sees the credentials prompt, but even correct entries are rejected.
Commands that use SSH. For example, `create-instance`.	Functions as expected but requires prior SSH configuration.	Functions as expected but requires prior SSH configuration.

Running Secure Admin

This section describes how to run secure admin. The section begins with prerequisites for running secure admin.

Prerequisites for Running Secure Admin

Before running Payara Server with secure admin enabled, you must make sure that:

1. The DAS is initialized and running.
2. If one or more remote instances are installed and initialized, they must not be running.
3. Any administration clients you require are installed.
4. The username and password sent by remote administration clients (`asadmin`, administration console, browsers, and IDEs) must exist in the realm and be in the admin group.
5. The keystore and truststore for the domain exist. (They are created by default when you create the domain)

If you are not using the default self-signed certificates, you must add your own valid certificates (including CA root certificates) in the keystore and truststore, respectively.

6. If you are not using the default self-signed certificates, create two aliases corresponding to certificates in the keystore and truststore: one that the DAS will use for authenticating itself in administration traffic, and one that the instances will use for authenticating itself in

administration traffic.

For convenience, you can use the same certificate alias for both DAS access and DAS-to-instance communication.

An Alternate Approach: Using A Username and Password for Internal Authentication and Authorization

By default, secure admin uses the Payara Server self-signed certificates, via the aliases corresponding to these certificates, to authenticate the DAS and instances with each other and to authorize secure admin operations. Specifically, the DAS uses the (`s1as`) alias for authenticating itself and authorizing access in administration traffic, and instances use the (`glassfish-instance`) alias for authenticating themselves and authorizing access in secure admin traffic.

As described in Using Your Own Certificates, you can instead use your own certificates and their associated aliases for authenticating and authorizing the DAS and instances in administration traffic and communication.

As an alternative to this certificate-based authentication and authorization, you can instead use the `enable-secure-admin-internal-user` subcommand to instruct all servers in the domain to authenticate to each other, and to authorize admin operations submitted to each other, using an existing admin username and password rather than certificates.

If secure admin is enabled, all Payara Server processes continue to use SSL encryption to secure the content of the admin messages, regardless of how they authenticate to each other.

You might want to use the `enable-secure-admin-internal-user` subcommand if your use case favors the use of a username and password combination over the use of SSL certificates and aliases.

This generally means that you must:

1. Create a valid admin user.

```
asadmin> create-file-user --authrealmname admin-realm --groups
asadmin newAdminUsername
```

2. Create a password alias for the password credential of the newly created user.

```
asadmin> create-password-alias passwordAliasName
```

The following example allows secure admin to use a username and password alias for authentication and authorization between the DAS and instances, instead of certificates.

```
asadmin> enable-secure-admin-internal-user --passwordalias passwordAliasName
newAdminUsername
```

If Payara Server finds at least one secure admin internal user, then if secure admin is enabled Payara Server processes will not use SSL authentication and authorization with each other and will instead use basic authentication through username and password credentials.

Most users who use this subcommand will need to set up only one secure admin internal user. If you set up more than one secure admin internal user, you should not make any assumptions about which username and password pair Payara Server will choose to use for any given admin request.

As a general practice, you should not use the same username and password pair for internal admin communication and for admin user login. That is, always create at least one admin account specifically for internal admin communication if you prefer to use this method.

You can use the `disable-secure-admin-internal-user` subcommand to disable secure admin from using the username/password credentials to authenticate the DAS and instances with each other and to authorize admin operations.

To disable multiple usernames for authenticating and authorizing access in secure admin, run the `disable-secure-admin-internal-user` subcommand multiple times.

You can use the `list-secure-admin-internal-users` subcommand to list the usernames for which Payara Server authenticate the DAS and instances with each other and authorizes admin operations.

Additional Considerations When Creating Local Instances

If you use `*-local-instance` variant commands to set up local instances (which are run locally from within the node host where the instance has been installed), either leave secure admin disabled, or enable it before you create or start the instances and leave it that way.

However, if you use `*-instance` variant commands over SSH to manage remote instances (which are run from the DAS), you can enable and disable secure admin, although this is not recommended because it can result in an inconsistent security model.

Secure Admin Use Case

This section describes a simple secure admin use case.

In the `asadmin --secure=false --user me --passwordfile myFile.txt cmd ⋯` use case, the user submits a command with `--secure` set to false, and supplies password credentials.

The important concept to note is that `asadmin` uses HTTPS because of the DAS redirection, even though the command sets `--secure` to false. `asadmin` sends the HTTP Authorization header along with the redirected request.

In addition to the flow described here, certificate authentication is also performed as described in the following table. Also, the credentials that the user supplies are assumed to be valid administrator credentials for the DAS.

Table 161. asadmin --secure=false, With Username and Password

asadmin	HTTP Engine	AdminAdapter
Sends HTTP request, no authorization header (because the transport is not secure).	+	+
+	Returns 3xx status and redirects HTTP to HTTPS.	+
Follows redirection, this time adding the Authorization header (because transport is now HTTPS).	+	+
+	+	Authenticates admin user and password from HTTP Authorization header in the realm Executes command, and responds with success status.

Running in a Secure Environment

This chapter describes important information about running Payara Server in a secure environment.

This chapter assumes that you are familiar with security features such as authentication, authorization and certificates. If you are not, see Administering System Security first.

Determining Your Security Needs

Before you deploy Payara Server and your Jakarta EE applications into a production environment, determine your security needs and make sure that you take the appropriate security measures.

Understand Your Environment

To better understand your security needs, ask yourself the following questions:

Which resources am I protecting?

Many resources in the production environment can be protected, including information in databases accessed by Payara Server and the availability, performance, applications, and the integrity of the website.

Consider the resources you want to protect when deciding the level of security you must provide.

From whom am I protecting the resources?

For most websites, resources must be protected from everyone on the Internet. But should the website be protected from the employees on an intranet in your enterprise infrastructure?

Should your employees have access to all resources within the server environment?

Should the system administrators have access to all Payara Server resources?

Should the system administrators be able to access all data?

You might consider giving access to highly confidential data or strategic resources to only a few well trusted system administrators. Perhaps it would be best to disallow system administrators access to the data or resources.

What will happen if the protections on strategic resources fail?

In some cases, a fault in your security scheme is easily detected and considered nothing more than an inconvenience. In other cases, a fault might cause great damage to companies or individual clients that use the website.

Understanding the security ramifications of each resource will help you protect it properly.

Installing Payara Server in a Secure Environment

This section describes recommendations for installing Payara Server in a secure environment.

Enable the Secure Administration Feature

The secure administration feature allows an administrator to secure all administrative communication between the domain administration server (DAS), any remote instances, and administration clients such as the asadmin utility, the administration console, and REST clients.

In addition, secure administration helps to prevent DAS-to-DAS and instance-to-instance traffic, and carefully restricts administration-client-to-instance traffic.

When you install Payara Server or create a new domain, secure admin is disabled by default. Payara Server does not encrypt administrative communication among the system components and does not accept administrative connections from remote hosts.

Imposing a heightened level of security is optional.

See Managing Administrative Security for information on enabling the secure administration feature.

Run on the Web Profile if Possible

If your applications can run without issues on Payara Server's Web Profile, use that instead of the Full Profile. As the web profile is a subset of the full feature set of the Payara Platform, it has fewer features that require extra considerations for security (like ORB listeners, Web Services, Message Queue Brokers) which reduces the overall risks of the server's installation.

Securing the Payara Server Host Machine

A Payara Server production environment is only as secure as the security of the machine on which it is running. It is important that you secure the physical machine, the operating system, and all other software that is installed on the host machine.

The following are basic recommendations for securing a Payara Server host in a production environment. Also check with the manufacturer of the machine and operating system for recommended security measures.

The domain and server configuration files should be accessible only by the operating system users who configure or execute Payara Server processes.

Table 162. Securing the Payara Server Host Machine

Security Action	Description
Physically secure the hardware.	Keep your hardware in a secured area to prevent unauthorized operating system users from tampering with the deployment machine or its network connections.
Log out of the Administration Console before navigating to a non-secure site.	If you are logged on to the Administration Console, be sure to log out completely before browsing to an unknown or non-secure website.
Secure networking services that the operating system provides.	Have a security professional review network services such as e-mail programs or directory services to ensure that a malicious attacker cannot access the operating system or system-level commands. These actions depend on the operating system used by the host machine. Sharing a file system with other machines in the enterprise network imposes risks of a remote attack on the file system. Be certain that the remote machines and the network are secure before sharing the file systems from the machine.
Use a file system that can prevent unauthorized access.	Make sure that the file system on each Payara Server host can prevent unauthorized access to protected resources. For example, on a Windows host, use only exFAT.
Set file access permissions for data stored on disk.	Set operating system file access permissions to restrict access to data stored on disk. This data includes, but is not limited to, the following: • The database files. Payara Server includes an integrated H2 database,however, you can use any JDBC-compliant database. • The directory and filename location of a private keystore, such as `keystore.p12` • The directory and filename location of a Root Certificate Authority (CA) truststore, such as `cacerts.p12`. *Nix operating systems provide utilities such as `umask` and `chmod` to set the file access permissions. At a minimum, consider using `umask 066`, which denies read and write permission to the group owner and other users.

Security Action	Description
Set file access permission for the Payara Server installation.	The directory structure in which Payara Server is located, including all files, should be protected from access by unprivileged users. Taking this step helps ensure that unprivileged users cannot insert code that can potentially be executed by Payara Server.
Limit the number of user accounts on the host machine.	Avoid creating more user accounts than you need on host machines, and limit the file access privileges granted to each account. On operating systems that allow more than one system administrator user, the host machine should have two user accounts with system administrator privileges and one user with sufficient privileges to run Payara Server. Having two system administrator users provides a backup at all times. The Payara Server user should be a restricted user, not a system administrator user. One of the system administrator users can always create a new Payara Server user if needed. Domain and server configuration files should be accessible only by the operating system users who configure or execute Payara Server. Review active user accounts regularly and according to your organisation account management policies. Configuration data and some URL (Web) resources, including Java Server Pages (JSPs) and HTML pages, are stored in clear text on the file system. A sophisticated user or intruder with read access to files and directories might be able to defeat any security mechanisms you establish with authentication and authorization schemes.
For your system administrator user accounts, choose names that are not obvious.	For additional security, avoid choosing an obvious name such as "system," "admin," or "administrator" for your system administrator user accounts.
Safeguard passwords.	The passwords for user accounts on production machines should be robust, difficult to guess and should be guarded carefully. Set a policy to expire passwords periodically based on your organisation account management policies. Never code passwords in client applications.

Security Action	Description
Safeguard password files	The `-passwordfile` option of the `asadmin` command specifies the name of a file that contains password entries in a specific format. These password entries are stored in clear text in the password file, and rely on file system mechanisms for protection. Therefore, any password file created for use with the `-passwordfile` option should be protected with file system permissions. Additionally, any password file being used for a transient purpose, such as setting up SSH among nodes, should be deleted after it has served its purpose.
Use password aliases	A password alias stores a password in encrypted form in the domain keystore, providing a clear-text alias name to use instead of the password. To provide additional security, use the `create-password-alias` subcommand to create an alias for the password. The password for which the alias is created is stored in an encrypted form.
Do not run Payara Server as root	Payara Server should run only as an unprivileged user, never as the `root` in *Nix systems or as an Administrator user in Windows systems.
Do not develop code on a production machine.	Develop your applications first on a development machine and then move code to the production machine when it is completed and tested. This process prevents bugs in the development environment from affecting the security of the production environment.
Do not install development or sample software on a production machine.	Do not install development tools on production machines. Keeping development tools off the production machine reduces the leverage intruders have should they get partial access to a production machine.
Enable security auditing.	If the operating system on which Payara Server runs supports security auditing of file and directory access, it is recommended using audit logging to track any denied directory or file access violations. Administrators should ensure that sufficient disk space is available for the audit log.

Security Action	Description
Consider using additional software to secure your operating system.	Most operating systems can run additional software to secure a production environment. For example, an Intrusion Detection System (IDS) can detect attempts to modify the production environment. Refer to the vendor of your operating system for information about available software that can be used for this purpose.
Apply operating system patch sets and security patches.	Refer to the vendor of your operating system for a list of recommended patch sets and security-related patches.
Apply Java runtime security patches.	Refer to your official Java runtime version for a list of recommended security-related patches. In general, whenever possible it is recommended to upgrade the Java runtime to its latest security patch on its corresponding major version.

Securing Payara Server

Payara Server provides a powerful and flexible set of software tools for securing the subsystems and applications that run on a server instance. The following table provides a checklist of essential features recommended to secure your production environment.

Table 163. Securing Payara Server

Security Action	Description
Enable Secure Admin.	The secure administration feature allows an administrator to secure all administrative communication between the domain administration server (DAS), any remote instances, and administration clients such as the `asadmin` utility, the administration console, and REST clients. In addition, secure administration helps to prevent DAS-to-DAS and instance-to-instance traffic, and carefully restricts administration-client-to-instance traffic. The secure administration feature provides a secure environment, in which you can be confident that rogue users or processes cannot intercept or corrupt administration traffic or impersonate legitimate Payara Server components. See Managing Administrative Security.

Security Action	Description
Protect the `.asadminpass` file	If you create a domain with the `--savelogin` option, `create-domain` saves the administration username and password in the `.asadminpass` file in the user's home directory. Make sure that this file remains protected. Information stored in this file will be used by `asadmin` commands to manage the domain.
Safeguard password files	The `-passwordfile` option of the `asadmin` command specifies the name of a file that contains password entries in a specific format. These password entries are stored in clear text in the password file, and rely on file system mechanisms for protection. Therefore, any password file created for use with the `-passwordfile` option should be protected with file system permissions. Additionally, any password file being used for a transient purpose, such as setting up SSH among nodes, should be deleted after it has served its purpose. To provide additional security, create a password alias.
Use SSL/TLS secured transport, but do not use the self-signed certificates in a production environment.	To prevent sensitive data from being compromised, secure data transfers by using HTTPS. By default, Payara Server uses self-signed certificates. The self-signed certificates that Payara Server uses will not be trusted by clients by default because a certificate authority does not vouch for their authenticity. You can instead use your own custom CA-issued certificates, as described in Using Your Own Certificates.
Restrict the size and the time limit of requests on external channels to prevent **Denial of Service (DoS) attacks**.	To prevent some Denial of Service (DoS) attacks, restrict the size of a message as well as the maximum time it takes a message to arrive. The default setting for maximum post size is `2097152` bytes and `900` seconds for the request timeout.
Set appropriate logging for security and SSL log entries.	Consider setting module log levels for the `javax.enterprise.system.ssl.security.` and `javax.enterprise.system.core.security.` You can set a level from `SEVERE` to `FINEST` (the default is `INFO`), but be aware that the finer logging levels may produce a large log file. By default, Payara Server logging messages are recorded in the server log, and you can set the file rotation limit, as described in `rotate-log`

Security Action	Description
Ensure that you have correctly assigned users to the correct groups.	Make sure you have assigned the desired set of users to the right groups. In particular, make sure that users assigned to the `asadmin` group need to be members of that group.
Create no fewer than two user accounts in the `asadmin` group.	The default `admin` user is created when you install Payara Server or create a new domain and accept its default username. For production environments, create at least one other account in the `asadmin` group in case one account password is compromised. When creating asadmin users give them unique names that cannot be easily guessed.

Securing Applications

Although much of the responsibility for securing Payara Server resources in a domain fall within the scope of the server, some security responsibilities lie within the scope of individual applications.

For some security options, Payara Server enables you to determine whether the server or individual applications are responsible. For each application that you deploy in a production environment, review the items in the following table to verify that you have properly secured its resources.

Table 164. Securing Applications

Security Action	Description
Use JSP comment tags instead of HTML comment tags.	Comments in JSP files that might contain sensitive data and or other comments that are not intended for the end user should use the JSP syntax of `<%/* xxx */%>` instead of the HTML syntax `<!-- xxx -->`. JSP comments, unlike HTML comment blocks, are deleted when the JSP is compiled and therefore cannot be viewed in a web browser.
Do not install un-compiled JSPs and other source code on a production machine.	Always keep source code off of the production machine. Getting access to your source code allows an intruder to find security holes. Consider pre-compiling JSPs and installing only the compiled JSPs on the production machine. To do this, set the `deploy` subcommand `-precompilejsp` option to true for the component. When set to true, the `deploy` and `redeploy` subcommands `-precompilejsp` option compiles JSPs during deploy time. If set to `false` (the default), JSPs are compiled during runtime.
Configure your applications to use secure transport.	Set the `transport-guarantee` to `CONFIDENTIAL` in the `user-data-constraint` element of the `web.xml` deployment descriptor whenever appropriate.

Security Action	Description
Examine applications for security.	There are instances where an application's code can lead to a security vulnerability. Of particular concern is code that uses Java native interface (JNI) because Java positions native code outside the scope of the Java security model. If Java native code behaves in an errant manner, it is only constrained by the operating system. That is, the Java native code can do anything Payara Server itself can do. This potential vulnerability is further complicated by the fact that buffer overflow errors are common in native code and can be used to run arbitrary code.
If your applications contain untrusted code, enable the Java security manager.	The Java security manager defines and enforces permissions for classes that run within a JVM. In many cases, where the threat model does not include malicious code being run in the JVM, the Java security manager is unnecessary. However, when third parties use Payara Server and untrusted classes are being run, the Java security manager may be useful. See "Enabling and Disabling the Security Manager" in the Application Development section.
Replace HTML special characters when servlets or JSPs return user-supplied data.	The ability to return user-supplied data can present a security vulnerability called cross-site scripting (XSS), which can be exploited to steal a user's security authorization. To remove this security vulnerability, before you return data that a user has supplied, scan the data for HTML special characters. If you find any such characters, replace them with their HTML entity or character reference. Replacing the characters prevents the browser from executing the user-supplied data as HTML. Using third-party libraries that can sanitize the content of an HTML-formatted set of data is recommended in most cases.

SSL Certificate Management

As a reminder, Payara Server uses the following PKCS12 keystore files to manage SSL/TLS certificates required for secure communications:

`keystore.p12`

: Java Keystore formatted file containing the Cryptographic keys, like the private keys associated with the certificates.

`cacerts.p12`

Java Keystore formatted file used as Trust Store file holding the X.509 certificates.

These keystores are protected with the Master Password of your domain.

Adding a new SSL Certificate

To add your SSL Certificate to the Payara Server configuration files, you need:

- The private key associated with your certificate.
- The Certificate you received from the Certificate Authority based on your Certificate Signing Request (CSR).

You can generate a self-signed certificate using the `generate-self-signed-certificate` command:

```
asadmin generate-self-signed-certificate --dn "CN=test.payara.fish,IP=127.0.0.1"
mydomain_certificate
```

Alternatively

You can find the detailed steps of adding a self-signed certificate into Payara Server for testing purposes using `keytool` and `openssl` here.

The private key can be stored in various formats. We assume that the key is in a format which can be read by the Java key tool program, such as PKCS12.

First, you'll have to combine the Private key and the Certificate you generated into a single file. This file can then be used to merge our data into the files used by the server.

Then specify an alias name for your key/certificate. This alias name is important as it will be used to refer to the SSL Certificate as a complete unit.

The command to perform this combination is the following with OpenSSL:

```
openssl pkcs12 -export -in mycert.crt -inkey mycert.key -out mycert.p12 -name
mydomain_certificate
```

The resulting P12 bundle file can then be added to the keystore and truststore in Payara Server as described in the following sections.

Import into the Keystore

The information needs to be imported into the `keystore.p12` file of your Payara Server domain which will use it.

Using Asadmin CLI

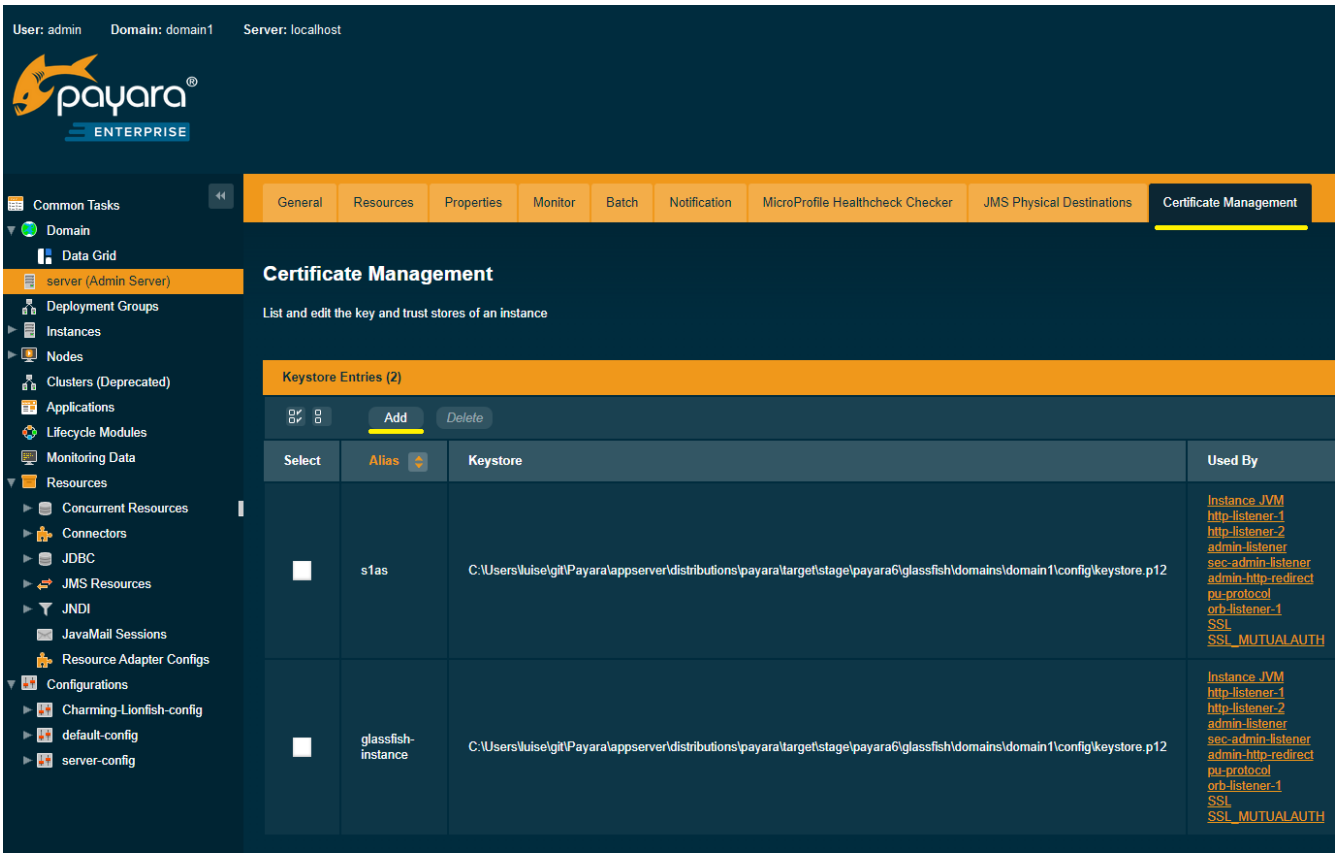
You can use the `add-to-keystore` command:

```
asadmin add-to-keystore --file mycert.p12 mydomain_certificate
```

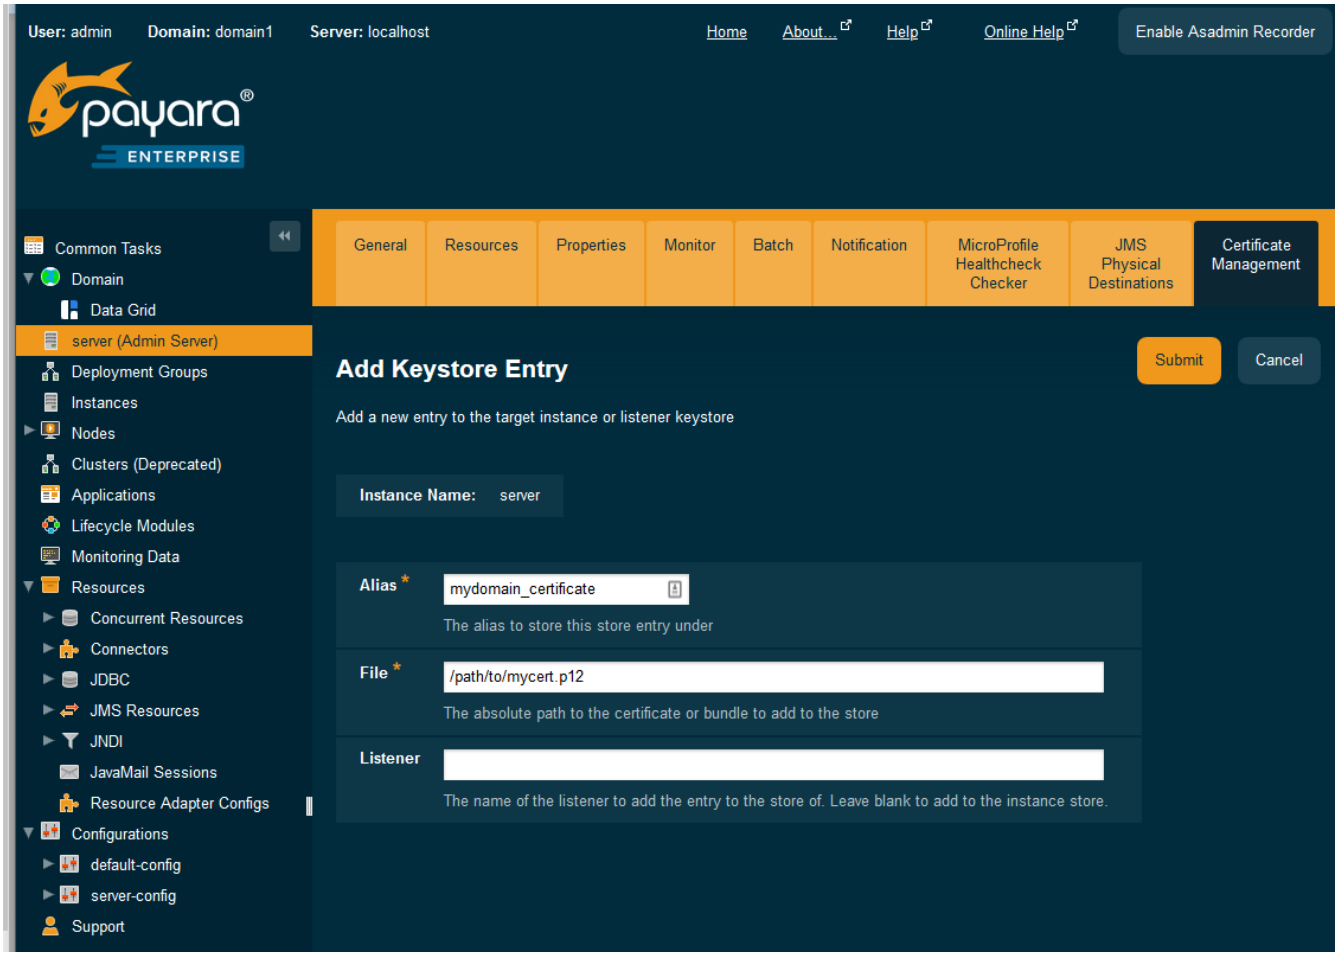
Using the Admin Console

From the Admin Console, open the instance details page (e.g. on the navigation bar select *Instances* → *$instanceName*) and navigate to the *Certificate Management* tab.

From here, Click on the *Add* button of the keystore table (highlighted):



You can then enter the alias name and the path to the certificate bundle:



Using the `keytool` command

You can also use the `keytool` command of the JDK:

```
keytool -importkeystore -destkeystore keystore.p12 -srckeystore mycert.p12
-srcstoretype PKCS12 -alias mydomain_certificate
```

Import into the Truststore

A similar command is used to import the information into the Trust Store file so that our certificate is trusted by the JVM.

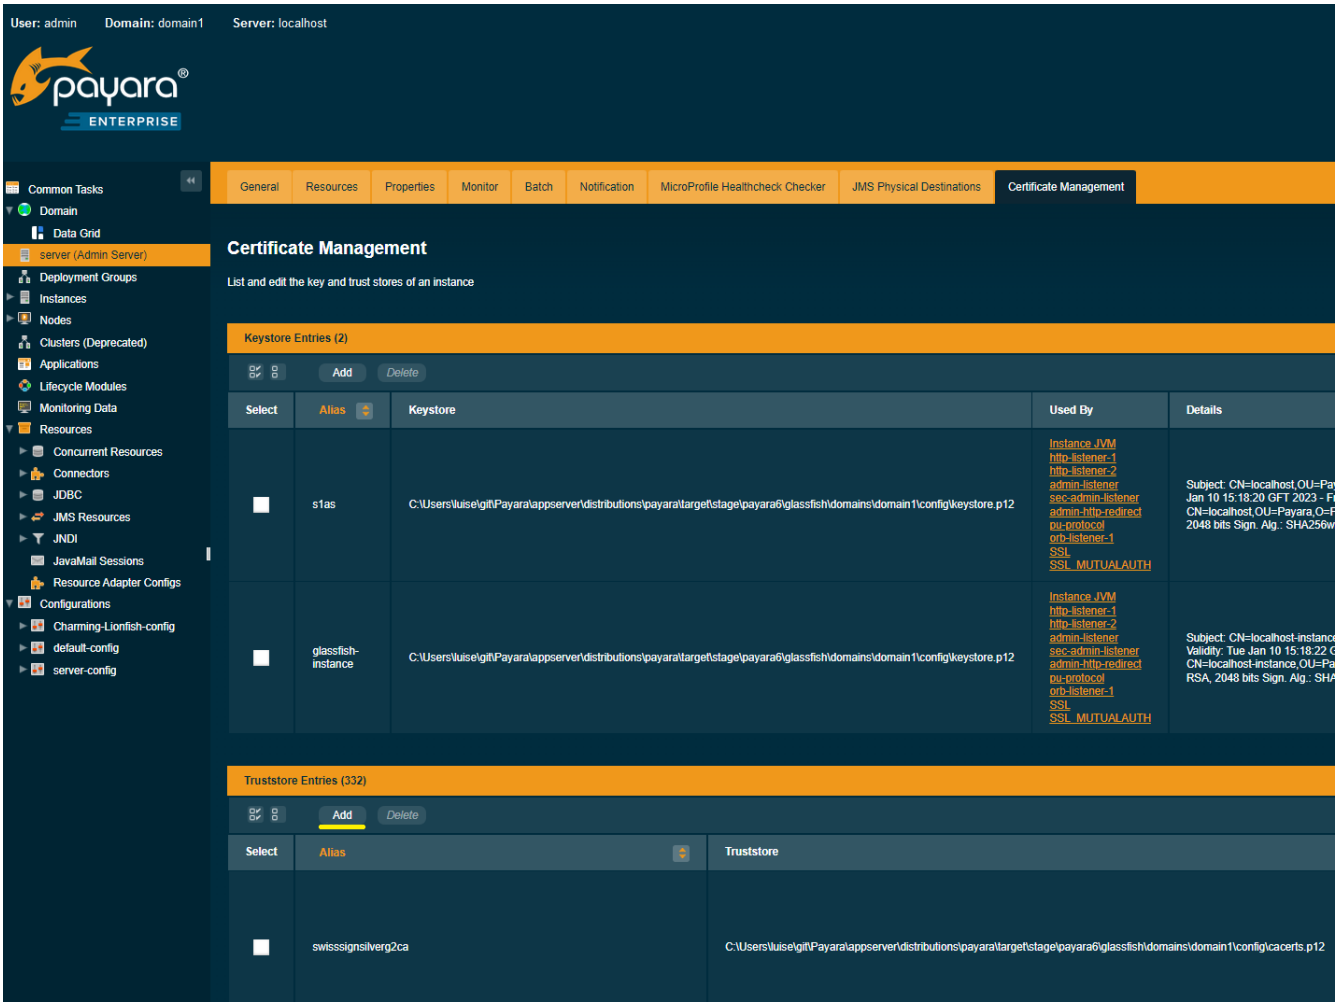
Using Asadmin CLI

You can use the `add-to-truststore` command:

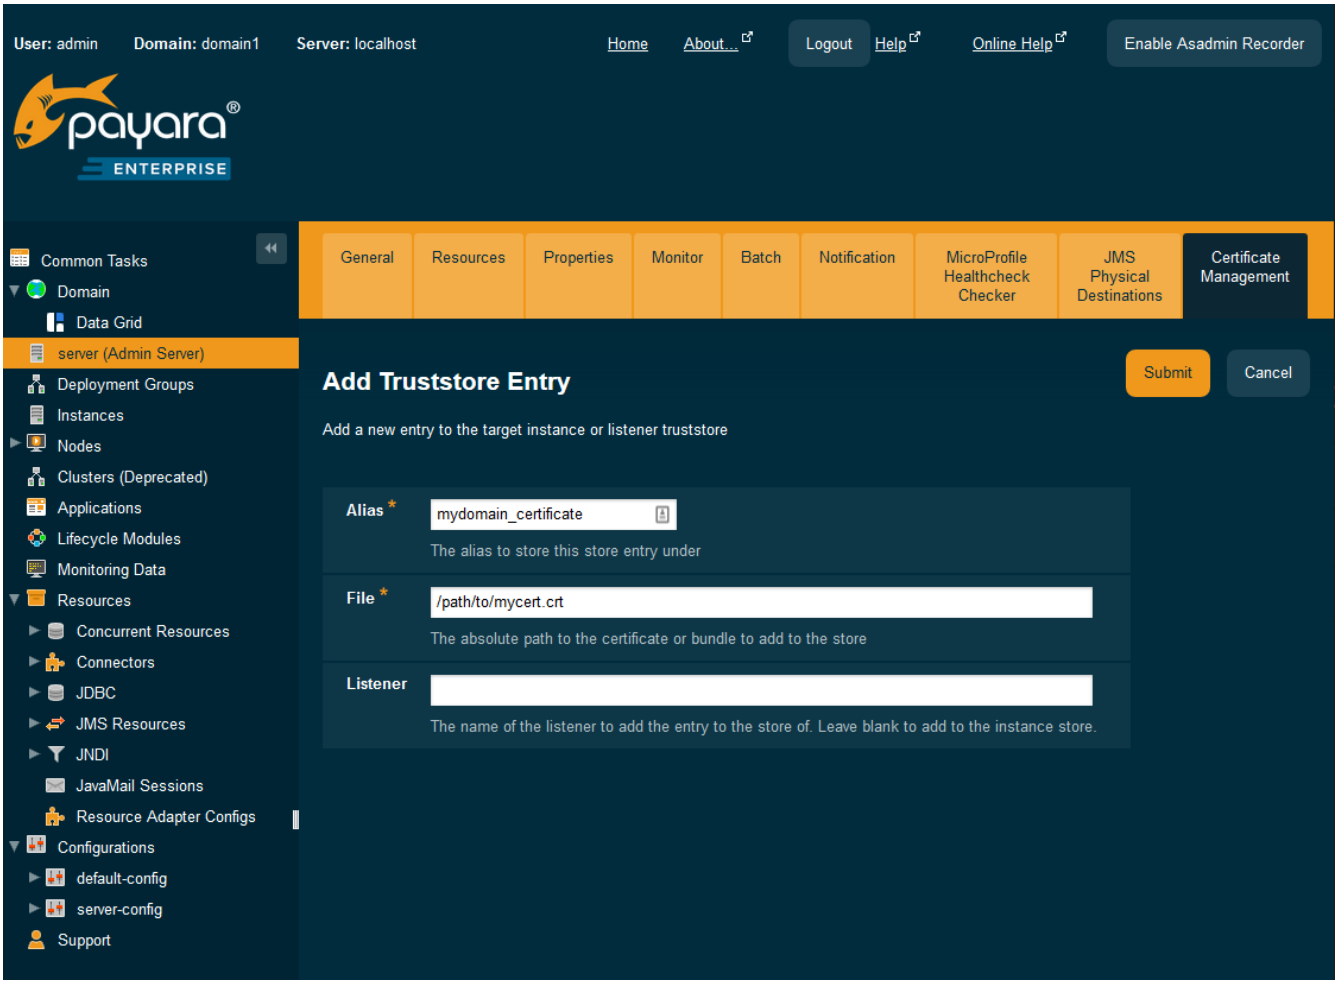
```
asadmin add-to-truststore --file mycert.crt mydomain_certificate
```

Using the Admin Console

You can also follow the same steps as done for adding the bundle to the keystore via the admin console, though selecting the **Add** button of the truststore table



And then specifying the `mycert.crt` file.



Using the `keytool` command

You can also use the `keytool` command of the JDK:

```
keytool -importcert -trustcacerts -destkeystore cacerts.p12 -file mycert.crt -alias
mydomain_certificate
```

Update HTTP Listeners

The last step you have to perform is to configure which certificate needs to be used when the server receives an SSL/TLS request. This can be done by specifying the alias name we have used when we integrated the required information into the key store files of the domain.

Using Asadmin CLI

This information can be set via the CLI:

```
asadmin set configs.config.server-config.network-config.protocols.protocol.http-
listener-2.ssl.cert-nickname=mydomain_certificate
```

In a default installation, the `http-listener-2` listener is responsible for handling the secure connections on port **8181**. The above command sets the alias name so

that the system knows which certificate needs to be used.

Using the Admin Console

The information can also be entered in the Web Administration console, by navigating to the page Configurations → `server-config` → HTTP Service → HTTP Listeners → `http-listener-2`.

Loading Certificates From Multiple Keystores

All additional keystores must have the same password as your domain master password.

To add additional keystores to Payara Server you will need to have your keystore and truststore files in a local directory. You can then configure this using the admin console or asadmin commands. If you want to load more than one additional keystore, you will need to use a delimiter between the paths to the additional keystores. This is different depending on your OS, Windows uses ';' and Linux uses ':'.

When specifying the key or trust store for a specific listener, this is deemed as an absolute and any additional key or trust stores are not considered.

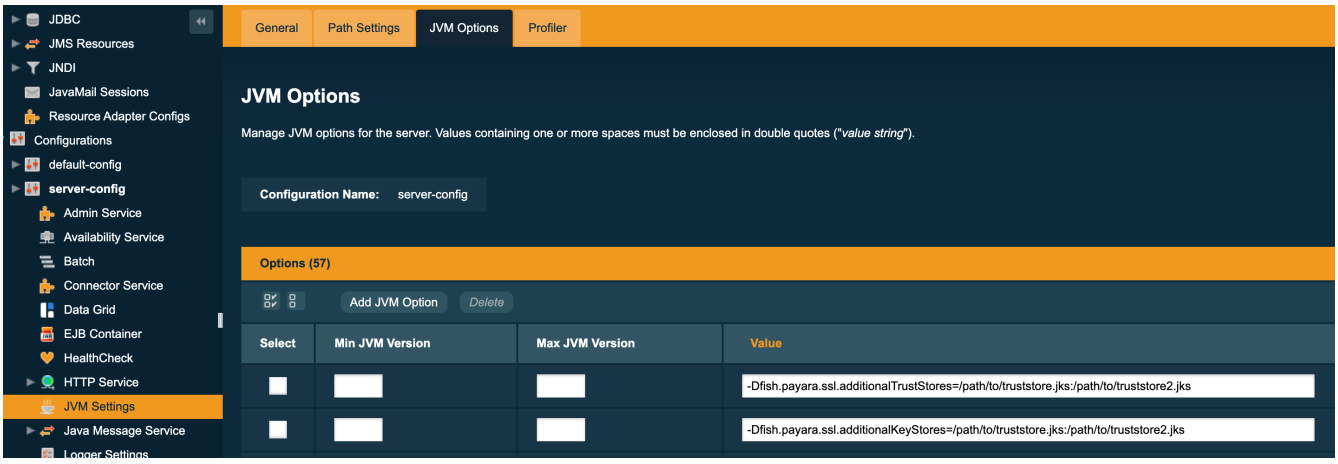
The new JVM properties used to add additional keystores are:

```
-Dfish.payara.ssl.additionalKeyStores
-Dfish.payara.ssl.additionalTrustStores
```

Using the Admin Console

To configure the additional keystore locations in the admin console, head to the **Configurations** → <**instance configuration**> → **JVM Settings** and on the **JVM Options** tab click **Add JVM Option**.

You can add the new JVM property and the relative paths to your keystores or truststores here.



Using Asadmin CLI

JVM options can be configured using the `create-jvm-options` asadmin command, you can configure your additional keystore and truststore files using this command. If you are loading in multiple

additional keystores via asadmin commands, you will need to prefix the appropriate delimiter for your OS with \ to avoid creating multiple JVM options.

Additional Keystores

```
asadmin create-jvm-options "-
Dfish.payara.ssl.additionalKeyStores=/path/to/keystore.p12\:/path2/to/keystore2.p12"
```

Additional Truststores

```
asadmin create-jvm-options "-
Dfish.payara.ssl.additionalTrustStores=/path/to/truststore.p12\:/path2/to/truststore2.
p12"
```

If you load multiple keystores with the same alias, the server will use the first keystore with that alias, starting with the default and then the additional keystores in the order they are listed in the JVM option.

Certificate expiration

All X.509 certificates have a validity period when they can be used. Once this validity period is passed, the users will see a warning or error message depending on the browser that the certificate is no longer valid.

Within the server log file, the expired certificates are listed when the system encounters one. Besides your custom certificates which are added as described in a previous chapter, the Trust Store also contains certificates from recognized Certificate Authorities, which can also expire in due time and thus can be listed as entries in the log file too.

The log level of the expired certificates is of type **WARNING**.

Removing expired certificates

Using Asadmin CLI

If you wish to remove all expired certificates, you can use the following Asadmin CLI subcommands:

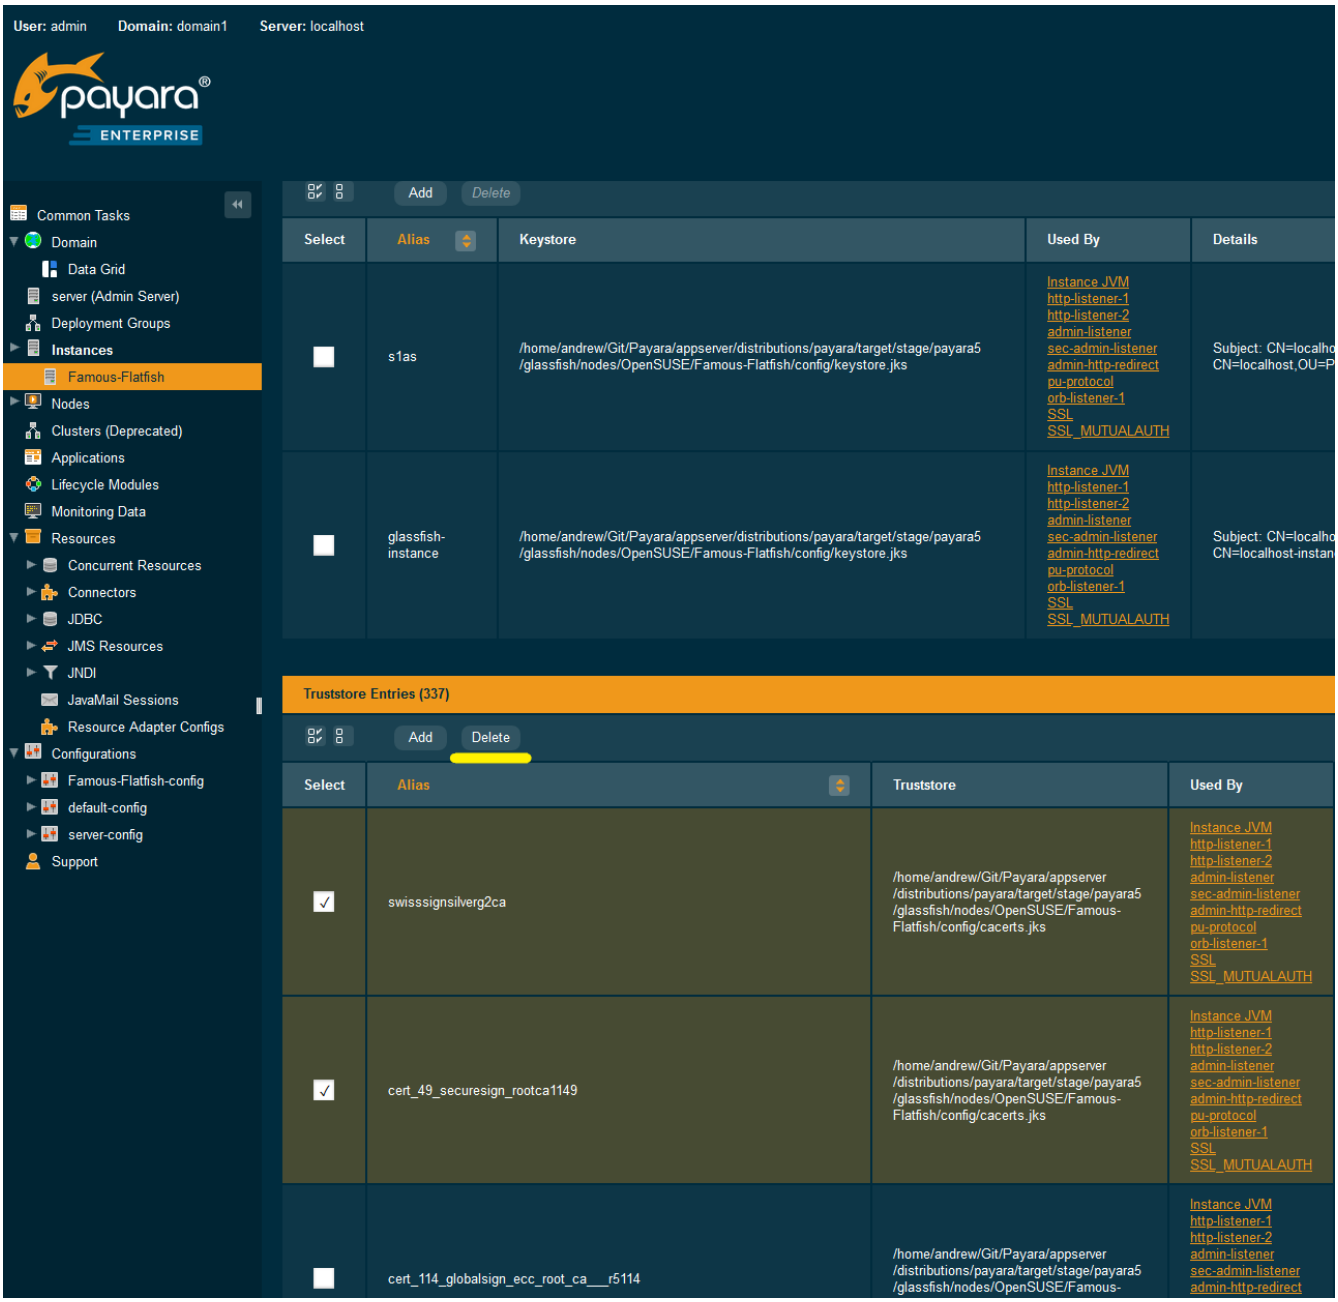
- `remove-expired-certificates`,
- `remove-from-keystore`, and
- `remove-from-truststore` respectively.

```
asadmin remove-expired-certificates
asadmin remove-from-keystore mydomain_certificate
asadmin remove-from-truststore mydomain_certificate
```

Using the Admin Console

You can also remove individual or groups of certificates using the admin console Certificate Management tab (*Instances → $instanceName → Certificate Management*).

Select the desired certificates from the keystore **or** truststore entries table (not both), and click on the *Delete* button:



Printing Certificate Data

The `print-certificate` asadmin subcommand is useful to print legible and detailed information of one or multiple SSL certificate and key entries.

Since the output generated by the standard `keytool` utility is not standardized (especially distinguished names since they usually they use RFC 1779), it is recommended to use this command instead.

This command prints the certificate's distinguished name in RFC 2253 format, which is used by the

Payara Platform, so it can be directly used for principal and role mappings when using client certificate authentication, for example.

The command supports only X.509 certificates files with the following extensions:

- Keystore format: `p12`, `pkcs12`, `pfx`, `jks`, `jceks`
- PEM or DER encoded certificates: `.cer`, `.cert`, `.crt`, `.der`, `.pem`

If the file contains more certificates, the command prints only the first one.

Usage

The `print-certificate` is an offline command (it doesn't need a running domain or server instance as target) that prints data of a selected certificate in RFC 2253 format.

The details that are printed out by the command are the following :

1. Validity dates
2. Serial number
3. Version
4. Issuer's distinguished name (DN)
5. Public key's algorithm and size
6. Signature algorithm including OI

The command will not be successful in one of the following cases:

1. The file cannot be read (permission issues or I/O errors)
2. The file extension is not supported by the command
3. The file type is not supported by the JDK
4. The keystore password is not correct
5. The keystore does not contain a certificate entry under the given alias
6. The certificate type is not supported

See the `print-certificate` documentation in the Command Reference for more information on its structure.

Examples

DER/PEM Encoded Certificate

Here's an example for printing a DER certificate with one entry:

```
asadmin print-certificate ./certificate.der

Found Certificate:
Subject:    UID=LDAP-
```

```
Test,EMAILADDRESS=nobody@nowhere.space,CN=PrintCertificateCommandTest,OU=Test Test\,
Test,O=Payara Foundation,L=Pilsen,C=CZ
Validity:   Thu Aug 01 02:00:00 CEST 2019 - Fri Aug 02 02:00:00 CEST 2019
S/N:        1
Version:    3
Issuer:     UID=LDAP-
Test,EMAILADDRESS=nobody@nowhere.space,CN=PrintCertificateCommandTest,OU=Test Test\,
Test,O=Payara Foundation,L=Pilsen,C=CZ
Public Key: RSA, 2048 bits
Sign. Alg.: SHA256withRSA (OID: 1.2.840.113549.1.1.11)
Command print-certificate executed successfully.
```

Keystore

Here's an example for printing a specific certificate using a P12 format keystore:

```
asadmin print-certificate --certificatealias s1as ./keystore.p12

Keystore Password>
Found Certificate:
Subject:    CN=localhost,OU=Payara,O=Payara Foundation,L=Great
Malvern,ST=Worcestershire,C=UK
Validity:   Tue Aug 06 14:06:14 CEST 2019 - Fri Aug 03 14:06:14 CEST 2029
S/N:        886895448
Version:    3
Issuer:     CN=localhost,OU=Payara,O=Payara Foundation,L=Great
Malvern,ST=Worcestershire,C=UK
Public Key: RSA, 2048 bits
Sign. Alg.: SHA256withRSA (OID: 1.2.840.113549.1.1.11)
Command print-certificate executed successfully.
```

Alternative Provider

It is possible to plug a different `java.security.Provider` implementation to get different outputs when running the `print-certificate` command.

In this example, we use the **BouncyCastle** third-party security provider, which leads to one significant difference: A highlighted, uppercase signature's algorithm name.

```
#Copy the library to the asadmin lib directory first
cp bcprov-jdk15on-1.62.jar ./payara7/glassfish/lib/asadmin/

#Then run the command
asadmin print-certificate --providerclass
org.bouncycastle.jce.provider.BouncyCastleProvider ./certificate.der

Found Certificate:
Subject:    UID=LDAP-
Test,EMAILADDRESS=nobody@nowhere.space,CN=PrintCertificateCommandTest,OU=Test Test\,
```

```
Test,O=Payara Foundation,L=Pilsen,C=CZ
Validity:   Thu Aug 01 02:00:00 CEST 2019 - Fri Aug 02 02:00:00 CEST 2019
S/N:        1
Version:    3
Issuer:     UID=LDAP-
Test,EMAILADDRESS=nobody@nowhere.space,CN=PrintCertificateCommandTest,OU=Test Test\,
Test,O=Payara Foundation,L=Pilsen,C=CZ
Public Key: RSA, 2048 bits
Sign. Alg.: SHA256WITHRSA (OID: 1.2.840.113549.1.1.11)
Command print-certificate executed successfully.
```

The asadmin command has its own classpath, so first you need to add the provider's library to the asadmin utility's classpath as shown above.

Command Reference

Overview

This section contains reference collection of all Asadmin CLI subcommands available for the Administration interface of Payara Server and a comprehensive detail of what each command does and how it operates.

Here's a brief description of the structure each command page section and the information it references:

Name

This section gives the names of the commands or functions documented, followed by a brief description of what they do.

Synopsis

This section shows the syntax of commands or functions.

The following special characters are used in this section:

`[ ]`

Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.

`|`

Separator. Only one of the arguments separated by this character can be specified at a time.

Description

This section defines the functionality and behavior of the service. Thus, it describes concisely what the command does. It does not discuss options or cite examples .

Options

This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the Synopsis section.

Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

Operands

This section lists the command operands and describes how they affect the actions of the command.

Examples

This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the Synopsis, Description, Options, and Usage sections.

Exit Status

This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero (`0`) is returned for successful completion, and values other than zero for various error conditions.

See Also

This section lists references to other man pages, in-house documentation, and outside publications.

Notes

This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest.

Domain

domain

Domains have their own configurations.

Description

A domain provides a common authentication and administration point for a collection of zero or more server instances. The administration domain encompasses several manageable resources, including instances, clusters, and their individual resources. A manageable resource, such as a server instance, may belong to only one domain.

See Also

`asadmin`

Instance

An instance in Payara Server has its own Jakarta EE configuration, Jakarta EE resources, application deployment areas, and server configuration settings.

Description

Payara Server creates one server instance, called `server` at the time of installation. You can delete the server instance and create a new instance with a different name.

For many users, one server instance meets their needs. However, depending upon your environment, you might want to create additional server instances. For example, in a development environment you can use different server instances to test different Payara Server configurations, or to compare and test different application deployments.

Because you can easily add or delete a server instance, you can use them to create temporary "sandbox" areas to experiment with while developing.

Configuration

The data set that determines how a Payara Server instance operates.

Description

The configuration of Payara Server is the data set that determines how it operates. Parts of this configuration determine the operation of specific parts of Payara Server, such as the following:

- Services, such as the transaction service
- Resources, such as databases
- Deployed applications or modules, such as web applications
- Clusters and server instances

The term configuration is also used to describe a part of the overall configuration, such as the transaction service configuration or the configuration of a database. In clustered environments, clusters, deployment groups or server instances can share configurations.

Examples of configuration data are port numbers, flags that enable or disable processes, application names, and so on. Most of these data points are name/value pairs, either hard-coded attributes or more flexibly defined properties.

The hierarchical structure of the configuration is explained in the dotted names page. You can view and change most of the Payara Server configuration using either the Administration Console or the `asadmin` utility and its subcommands.

To list the structure of all or part of the configuration, use the `list` subcommand. To view the value of one or more attributes or properties, use the `get` subcommand. To change the value of an attribute or property, use the `set` subcommand.

Dotted Names

Syntax for using periods to separate name elements.

Description

A dotted name is an identifier for a particular Payara Server element, such as a configurable or a monitorable object. A dotted name uses the period (`.`), known as dot, as a delimiter to separate the parts of an element name. The period in a dotted name is similar to the slash (`/`) character that delimits the levels in the absolute path name of a file in the UNIX file system.

The subcommands of the `asadmin` utility use dotted names as follows:

- The `list` subcommand provides the fully qualified dotted names of the management components' attributes.
- The `get` subcommand provides access to the attributes.
- The `set` subcommand enables you to modify configurable attributes and set properties.

The configuration hierarchy is loosely based on the domain's schema document, and the attributes are modifiable. The attributes of the monitoring hierarchy are read-only.

The following format is used for configuration dotted names:

```
config-name.config-element-name.primary-key.attribute-name | instance-name.config-
element-name.primary-key.attribute-name
```

The following format is used for resource dotted names:

```
server-name.resource-name.primary-key.attribute-name | domain.resources.resource-
name.primary-key.attribute-name
```

The following rules apply to forming dotted names:

- The top-level is configuration, server, or domain name. For example, `server-config` (default configuration), `server` (default server), or `domain1` (default domain).
- A dot (.) always separates two sequential parts of the name.
- A part of the name usually identifies a server subsystem or its specific instance. For example, `web-container`, `log-service`, `thread-pool-1`.
- If any part of the name itself contains a dot (`.`), then the dot must be escaped with a leading `\` (backslash) so that the `.` (dot) does not act like a delimiter. For further information on escape characters, see the `asadmin` help page.
- An `*` (asterisk) character can be used anywhere in the dotted name and acts like the wildcard

character in regular expressions. Additionally, an `\*` can collapse all the parts of the dotted name.

For example, a long dotted name such as `this.is.really.long.hierarchy` can be abbreviated to `th*.hierarchy`. The `.` (dot) always delimits the parts of the dotted name.

Characters that have special meaning to the shell or command interpreter, such as `\*` (asterisk), should be quoted or escaped as appropriate to the shell, for example, by enclosing the argument in quotes. In multimode, quotes are needed only for arguments that include spaces, quotes, or backslash.

- The `--monitor` option of the `get` and `list` subcommands selects the monitoring or configuration hierarchy. If the subcommand specifies `--monitor=false` (the default), the configuration hierarchy is selected. If the subcommand specifies `--monitor=true`, the monitoring hierarchy is selected.
- If you know the complete dotted name and do not need to use a wildcard, the `list`, `get`, and `set` subcommands treat the name differently:
  - The `list` subcommand treats a complete dotted name as the name of a parent node in the abstract hierarchy. When you specify this name to the `list` subcommand, the names of the immediate children at that level are returned. For example, the following command lists all the web modules deployed to the domain or the default server:

    ```
    asadmin> list server.applications.web-module
    ```

  - The `get` and `set` subcommands treat a complete dotted name as the fully qualified name of the attribute of a node (whose dotted name itself is the name that you get when you remove the last part of this dotted name). When you specify this name to the `get` or `set` subcommand, the subcommand acts on the value of that attribute, if such an attribute exists. You will never start with this case because in order to find out the names of attributes of a particular node in the hierarchy, you must use the * wildcard character.

    For example, the following dotted name returns the context root of the web application deployed to the domain or default server:

    ```
    server.applications.web-module.JSPWiki.context-root
    ```

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-Dotted Names:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-Dotted Names:::example-1] **Example 1 Listing All Configurable Elements**

This example lists all the configurable elements.

```
asadmin> list *
```

Output similar to the following is displayed:

```

Example 2 Listing All the Monitorable Objects

The following example lists all the monitorable objects.

```
asadmin> list --monitor *
```

Output similar to the following is displayed:

```
server
server.jvm
server.jvm.class-loading-system
server.jvm.compilation-system
server.jvm.garbage-collectors
server.jvm.garbage-collectors.Copy
server.jvm.garbage-collectors.MarkSweepCompact
server.jvm.memory
server.jvm.operating-system
server.jvm.runtime
server.network
server.network.admin-listener
server.network.admin-listener.connections
server.network.admin-listener.file-cache
server.network.admin-listener.keep-alive
server.network.admin-listener.thread-pool
server.network.http-listener-1
server.network.http-listener-1.connections
server.network.http-listener-1.file-cache
server.network.http-listener-1.keep-alive
server.network.http-listener-1.thread-pool
server.transaction-service
Command list executed successfully.
```

Deployment Group

A deployment group is a loose grouping of Payara Server instances that can be used as a target for **deployments**. Deployment Groups consist of one or more standalone instances and each instance can belong to one or more deployment groups.

Description

Deployment groups are effective and more flexible replacements for traditional clusters, as they can be used to effectively manage the lifecycle of multiple server instances at once.

When you create a Deployment Group you can add and remove existing standalone instances from the group. However, Deployment Groups provide greater flexibility than traditional clusters:

- An instance can be in many different deployment groups.
- You can add an instance to a deployment group at any time and any targeted applications or resources will automatically be deployed.
- You can also remove an instance from a deployment group and applications and resources will be un-deployed.

Payara Server instances in the deployment group are not hidden in the administration console and are still visible for management under the 'Instances' section of the admin console navigation tree.

Application

Server-side Jakarta EE applications and web services.

Description

The Jakarta EE platform enables applications to access systems that are outside of the application server. Applications connect to these systems through resources.

The Payara Server infrastructure supports the deployment of many types of distributed applications and is an ideal foundation for building applications based on Service Oriented Architectures (SOA). SOA is a design methodology aimed at maximizing the reuse of application services. These features enable you to run scalable and highly available Jakarta EE applications.

See Also

- `create-application-ref`,
- `deploy`,
- `list-applications`

Auto Naming

Auto naming is an `asadmin` feature added to help with the naming of instances, deployment groups, and other resources by resolving name conflicts and auto-generating names for dynamic resources.

Usage

The `autoname` option is enabled either by specifying `--autoname` or `-a` on the command line before or after the command name. This is technically an `asadmin` option rather than a command parameter so should be specified before the command name - it will however still accept being specified after the command name (see examples below).

There are some circumstances in which specifying the `--autoname` or `-a` option after

> the command name will result in the option not taking effect, which is why we recommend that you place it always before the command name.

When enabled, this feature allows commands that accept `String` names as their primary parameter (the parameter that you don't have to specify, e.g. the `instancename` parameter for the `create-instance` command) to generate a name. To automatically generate a name for your instances or resources, simply enable the `autoname` option and omit providing a name.

Specifically for the `create-instance` and `create-local-instance` commands, the `autoname` option can also be used to automatically resolve any name conflicts. When resolving a name conflict, Payara Server will simply append a new name to the existing name, like so: `instance1-BamboozledBarracuda`.

When creating an instance from the admin console, there is a new **Auto Name** checkbox present, which performs the same conflict resolution function as the `autoname` CLI option.

This checkbox does not currently allow you to generate an instance name from scratch - it simply resolves any name conflicts.

It should be stressed that these options are optional and disabled by default - if you wish to retain the original behaviour of prompting for a name or refusing to create an instance due to a name conflict, no action is necessary.

Examples

Example 1 - Name generation:

```
asadmin -a create-instance --node localhost-domain1
-> BemusedCatfish created

asadmin create-local-instance --node localhost-domain1 --autoname
-> ConfusedCarp created

asadmin create-instance --node localhost-domain1
Please enter an instance name: instance1
-> instance1 created

asadmin create-instance --node localhost-domain1
Please enter an instance name: instance1

-> command failed: instance name already in use
```

Example 2 - Name conflict resolution:

```
asadmin --autoname create-instance --node localhost-domain1 instance1
-> instance1 created

asadmin create-instance --node localhost-domain1 --autoname instance1
-> instance1-BemusedCatfish created
```

```
asadmin create-instance --node localhost-domain1 instance1
-> command failed: instance name already in use
```

Logging

Capturing information on Payara Server runtime events.

Description

Logging is the process by which Payara Server captures data about events that occur during Payara Server operation. Payara Server components and application components generate logging data, which is saved in the server log, typically `domain-dir/logs/server.log`.

The server log is the first source of information if Payara Server problems occur.

The server log is rotated when the file reaches the specified size in bytes, or the specified time has elapsed. The file can also be rotated manually by using the `rotate-log` subcommand.

In addition to the server log, the `domain-dir/logs` directory contains two other kinds of logs:

- HTTP service access logs, located in the `/access` subdirectory
- Transaction service logs, located in the `/tx` subdirectory

Logging levels can be configured by using the Administration Console or the `set-log-levels` subcommand.

Additional properties can be set by using the Administration Console or by editing the `logging.properties`file. The default `logging.properties` file is typically located in domain-dir`/config`.

See Also

- `list-log-levels`,
- `rotate-log`,
- `set-log-levels`
- `asadmin`
- Administering the Logging Service in Payara Server General Administration section

Security

Secure and administer Payara Server applications.

Description

Security is about protecting data: how to prevent unauthorized access or damage to it in storage or transit. Payara Server has a dynamic, extensible security architecture based on the Jakarta EE standard. Built-in security features include cryptography, authentication and authorization, and public key infrastructure. Payara Server is built on the Java security model, which uses a sandbox

where applications can run safely, without potential risk to systems or users.

add-instance-to-deployment-group

Adds a standalone instance to an existing deployment group.

Synopsis

```
asadmin [asadmin-options] add-instance-to-deployment-group [--help]
[--instance instanceName]
[--deploymentgroup deploymentGroupName]
```

Description

The `add-instance-to-deployment-group` subcommand will add the referenced instance to the referenced deployment group.

This command will only work with standalone instances (see here for more information).

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--instance`

The name of the standalone instance that will be added to the deployment group. The command will fail if the name doesn't match to an existing standalone instance.

`--deploymentGroup`

The name of the deployment group to which the standalone instance will be added. The command will fail if the name doesn't match to an existing deployment group.

Examples

Example 1 Add an instance to a Deployment Group

This example adds an instance named `test-instance-1` to a deployment group named `test-dgroup`:

```
asadmin add-instance-to-deployment-group --instance=test-instance-1
--deploymentGroup=test-dgroup

Command add-instance-to-deployment-group executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-deployment-group`,
- `delete-deployment-group`,
- `list-deployment-groups`
- `remove-instance-from-deployment-group`

add-library

Adds one or more library JAR files to Payara Server

Synopsis

```
asadmin [asadmin-options]
add-library
[--help]
[--type={common|ext|app}]
[--upload={false|true}]
[library-file-path ...]
```

Description

The `add-library` subcommand adds one or more library archive files to Payara Server.

The `--type` option specifies the library type and the Payara Server directory to which the library is added.

The library-file-path operand is the path to the JAR file that contains the library to be added.To specify multiple libraries, specify multiple paths separated by spaces.

The library archive file is added to the DAS. For common and extension libraries, you must restart the DAS so the libraries are picked up by the server runtime.

To add the libraries to other server instances, synchronize the instances with the DAS by restarting them.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--type`

Specifies the library type and the Payara Server directory to which the library is added. Valid values are as follows:

`common`

Adds the library files to the Common class loader directory, `domain-dir/lib`. This is the default.

`ext`

Adds the library files to the Java optional package directory, `domain-dir/lib/ext`.

`app`

Adds the library files to the application-specific class loader directory, `domain-dir/lib/applibs`.

For more information about these directories, see Class Loaders in the Payara Server Application Development section.

`--upload`

Specifies whether the subcommand uploads the file to the DAS. In most situations, this option can be omitted.

If a directory filepath is specified, this option is ignored.

Valid values are as follows:

`false`

The subcommand does not upload the file and attempts to access the file through the specified file name. If the DAS cannot access the file, the subcommand fails.

For example, the DAS might be running as a different user than the administration user and does not have read access to the file. In this situation, the subcommand fails if the `--upload` option is `false`.

`true`

The subcommand uploads the file to the DAS over the network connection.

The default value depends on whether the DAS is on the host where the subcommand is run or is on a remote host.

- If the DAS is on the host where the subcommand is run, the default is `false`.
- If the DAS is on a remote host, the default is `true`.

Operands

library-file-path

The paths to the archive files that contain the libraries that are to be added. You can specify an absolute path or a relative path.
If the `--upload` option is set to `true`, this is the path to the file on the local client machine. If the `--upload` option is set to `false`, this is the path to the file on the server machine.

Examples

Example 1 Adding Libraries

This example adds the library in the archive file `mylib.jar` to the application-specific class loader directory on the default server instance.

```
asadmin add-library --type app /tmp/mylib.jar
Command add-library executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

add-resources

Creates the resources specified in an XML file.

Synopsis

```
asadmin [asadmin-options] add-resources [--help]
[--target target]
[--upload={false|true}] xml-file-name
```

Description

The `add-resources` subcommand creates the resources named in the specified XML file. The resources that can be created with this subcommand are listed in S ee Also in this help page.

The `--target` option specifies the target for which you are creating the resources. If this option specifies the domain, the resources are added only to the configuration of the domain administration server (DAS). If this option specifies any other target, the resources are added to the configuration of the DAS and references are added to the resources from the specified target.

The xml-file-name operand is the path to the XML file that contains the resources to be created. The `DOCTYPE` must be specified as `https://docs.payara.fish/schemas/payara-resources_1_8.dtd` in the `resources.xml` file.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which you are creating the resources.
Valid values are as follows:

`server`

Creates the resources for the default server instance `server` and is the default value.

`domain`

Creates the resources for the domain.

cluster-name

Creates the resources for every server instance in the cluster.

instance-name

Creates the resources for a particular Payara Server instance.

`--upload`

Specifies whether the subcommand uploads the file to the DAS. In most situations, this option can be omitted.
Valid values are as follows:

`false`

The subcommand does not upload the file and attempts to access the file through the specified file name. If the DAS cannot access the file, the subcommand fails.
For example, the DAS might be running as a different user than the administration user and does not have read access to the file. In this situation, the subcommand fails if the `--upload` option is `false`.

`true`

The subcommand uploads the file to the DAS over the network connection.
The default value depends on whether the DAS is on the host where the subcommand is run or is on a remote host.

- If the DAS is on the host where the subcommand is run, the default is `false`.
- If the DAS is on a remote host, the default is `true`.

Operands

xml-file-name

The path to the XML file that contains the resources that are to be created. You can specify an absolute path, only the file name, or a relative path.

- If you specify an absolute path, the XML file can be anywhere.
- If you specify only the file name, the XML file must reside in the domain-dir`/config`

directory on the DAS host. This requirement must be met even if you run the subcommand from another host.

- If you specify a relative path, the XML file must be in the relative directory.
  An example XML file follows.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE resources PUBLIC
  "-//Payara.fish//DTD Payara Server 4 Resource Definitions//EN"
  "http://docs.payara.fish/schemas/payara-resources_1_8.dtd">
<resources>
 <jdbc-connection-pool name="SPECjPool" steady-pool-size="100"
   max-pool-size="150" max-wait-time-in-millis="60000"
   pool-resize-quantity="2" idle-timeout-in-seconds="300"
   is-isolation-level-guaranteed="true"
   is-connection-validation-required="false"
   connection-validation-method="auto-commit"
   fail-all-connections="false"
   datasource-classname="oracle.jdbc.pool.OracleDataSource">
  <property name="URL"
    value="jdbc:oracle:thin:@iasperfsol12:1521:specdb"/>
  <property name="User" value="spec"/>
  <property name="Password" value="spec"/>
  <property name="MaxStatements" value="200"/>
  <property name="ImplicitCachingEnabled" value="true"/>
 </jdbc-connection-pool>
 <jdbc-resource enabled="true" pool-name="SPECjPool"
   jndi-name="jdbc/SPECjDB"/>
</resources>
```

Examples

Example 1 Adding Resources

This example creates resources using the contents of the XML file `resource.xml`.

```
asadmin> add-resources resource.xml
Command : Connector connection pool jms/testQFactoryPool created.
Command : Administered object jms/testQ created.
Command : Connector resource jms/testQFactory created.
Command : Resource adapter config myResAdapterConfig created successfully
Command : JDBC connection pool DerbyPoolA created successfully.
Command : JDBC resource jdbc/__defaultA created successfully.
Command add-resources executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

add-to-keystore

Adds the specified keystore bundle to a target domain keystore.

Synopsis

```
asadmin add-to-keystore [--help]
[--reload={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[--file=<file-path>]
[alias]
```

Description

This command adds a certificate bundle (e.g. `.p12` or `.jks` file) to the target instance or listener's key store using the provided alias.

If the instance or listener is configured to use the default key store, the command will instead synchronize the instance with the DAS (under the assumption the certificate has been added to the default key store of the DAS), since any certificates added to the instance stores would be lost upon next synchronisation.

This will overwrite an entry already present with the same alias. A certificate without a private key cannot be used by an HTTP listener and will generate a

warning.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are adding to its keystore. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--reload`

Whether the HTTP listeners should be reloaded. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

`--file`

The bundle file to add to the target keystore.

Operands

alias

The alias name to store the certificate bundle in the keystore under.

Examples

Example 1 Add the specified P12 bundle under the `mycert` alias

```
asadmin add-to-keystore --file mycert.p12 mycert
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- SSL Certificate Management,
- `add-to-truststore`

add-to-truststore

Adds the specified certificate to a target domain truststore.

Synopsis

```
asadmin add-to-truststore [--help]
[--reload={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[--file=<file-path>]
[alias]
```

Description

This command adds a certificate (e.g. `.cer`/`.pem` file) to the target instance or listener's trust store or listener's trust store using the provided alias.

If the instance or listener is configured to use the default trust store, the command will instead synchronize the instance with the DAS (under the assumption the certificate has been added to the default trust store of the DAS), since any certificates added to the instance stores would be lost upon

next synchronisation.

This will overwrite an entry already present with the same alias.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are adding the certificate. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--reload`

Whether the HTTP listeners should be reloaded. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

`--file`

The certificate file to add to the target truststore.

Operands

alias

The alias name to store the certificate in the truststore under.

Examples

Example 1 Add the specified certificate under the `mycert` alias

```
asadmin add-to-truststore --file mycert.pem mycert
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

appclient

Launches the Application Client Container and invokes the client application typically packaged in the application JAR file.

Synopsis

```
appclient [client_application_classfile | -client client_application_jar]
[-mainclass main_class_name | -name display_name]
[-xml sun-acc.xml file] [-textauth]
[-targetserver host[:port][,host[:port]...]]
[-user username] [-passwordfile password_file]
[application-options]

appclient [jvm-options]
[-mainclass main_class_name | -name display_name]
[-xml client_config_xml_file] [-textauth]
[-targetserver host[:port][,host[:port]...]]
[-user username] [-passwordfile password_file]
class-selector [application-options]
```

Description

Use the `appclient` command to launch the Application Client Container and invoke a client application that is typically packaged in an application JAR file. The application client JAR file is specified and created during deployment by the Administration Console or the `asadmin deploy` command with the `--retrieve` option. You can also retrieve the client JAR file using the `asadmin get-client-stubs` command.

The Application Client Container is a set of Java classes, libraries, and other files that are required to execute a first-tier application client program on a Virtual Machine for the Java platform (JVM machine). The Application Client Container communicates with the server using RMI-IIOP.

The client JAR file that is retrieved after deploying an application should be passed with the `-client` or `-jar` option when running the `appclient` utility. The client JAR file name is of the form app-name`Client.jar`. For multiple application clients in an EAR file, you must use the `-mainclass` or `-name` option to specify which client to invoke.

If the application client is a stand-alone module or the only client in an EAR file, the Application Client Container can find the client without using the `-mainclass` or `-name` options. If you provide a `-mainclass` or `-name` value that does not match what is in the client, the Application Client Container launches the client anyway but issues a warning that the selection did not match the information in the client. The warning also displays what the actual main class and name values are for the client.

Options

jvm-options

optional; you can set JVM options for the client application. These can be any valid `java` command options except `-client` or `-jar`. JVM options can be intermixed with other `appclient` command options as long as both types of options appear before the class-selector.

client_application_classfile

optional; the file system pathname of the client application `.class` file. A relative pathname must be relative to the current directory. This class file must contain the `main()` method to be invoked by the Application Client Container.
If you use client_application_classfile and the class is dependent on other user classes, you must also set the classpath. You can either use the `-classpath` JVM option in the `appclient` command or set the `CLASSPATH` environment variable. For more information about setting a classpath, see Setting the Class Path, Oracle Solaris Version (`http://docs.oracle.com/javase/6/docs/technotes/tools/solaris/classpath.html`) or Setting the Class Path, Windows Version (`http://docs.oracle.com/javase/6/docs/technotes/tools/windows/classpath.html`).

`-client`

optional; the name and location for the client JAR file.

`-mainclass`

optional; the full classname of the main client application as specified in the `Main-Class` entry in the `MANIFEST.MF` file. Used for a multiple client applications. By default, uses the class specified in the `client jar`. For example, `com.example.test.AppClient`.

`-name`

optional; the display name for the client application. Used for multiple client applications. By default, the display name is specified in the client jar `application-client.xml` file which is identified by the `display-name` attribute.

`-xml`

optional if using the default domain, instance, and name (`sun-acc.xml`), otherwise it is required; identifies the name and location of the client configuration XML file. If not specified, defaults to the `sun-acc.xml` file in the domain-dir`/config` directory.

`-textauth`

optional; used to specify using text format authentication when authentication is needed.

`-targetserver`

optional; a comma-separated list of one or more server specifications for ORB endpoints. Each server specification must include at least the host. Optionally, a server specification can include the port as well. If the port is omitted from a server specification, the default value, `3700`, is used for that host.

`-user`

optional; the application user who is authorized to have access to particular guarded components in the application, such as EJB components.

`-passwordfile`

optional; specifies the name, including the full path, of a file that contains the password for application clients in the following format:

```
PASSWORD=appclient-password
```

If this option is omitted, the password is specified interactively at the command prompt.

Avoid specifying a password interactively at the command prompt. Such a password can be seen by users who can run commands to display running processes and the commands to start them, such as `ps`.

```
  For security reasons, a password that is specified as an environment variable is not
read by the `appclient` utility.
class-selector::
  required; you must specify the client application class using one of the following
class selectors. +
  `-jar` jar-file;;
    the name and location of the client JAR file. The application client JAR file is
specified and created during deployment by the `asadmin deploy` command. If specified,
the `-classpath` setting is ignored in deference to the `Class-Path` setting in the
client JAR file's manifest.
  class-name;;
    the fully qualified name of the application client's main class. The Application
```

```
Client Container invokes the `main` method of this class to start the client. For
example, `com.example.test.AppClient`. +
    If you use class-name as the class selector, you must also set the classpath. You
can either use the `-classpath` JVM option in the `appclient` command or set the
`CLASSPATH` environment variable. For   more information about setting a classpath,
see Setting the Class Path, Oracle Solaris Version
(`http://docs.oracle.com/javase/6/docs/technotes/tools/solaris/classpath.html`) or
Setting the Class Path, Windows Version
(`http://docs.oracle.com/javase/6/docs/technotes/tools/windows/classpath.html`).
application-options::
  optional; you can set client application arguments.
```

Examples

Example 1 Using the `appclient` command

```
appclient -xml sun-acc.xml -jar myclientapp.jar scott sample
```

Where: `sun-acc.xml` is the name of the client configuration XML file, `myclientapp.jar` is the client application `.jar` file, and `scott` and `sample` are arguments to pass to the application. If `sun-acc.xml` and `myclientapp.jar` are not in the current directory, you must give the absolute path locations; otherwise the relative paths are used. The relative path is relative to the directory where the command is being executed.

asadmin-recorder-enabled

Returns whether the Asadmin Recorder service is enabled .

Synopsis

```
asadmin [asadmin-options] asadmin-recorder-enabled [--help]
```

Description

The `asadmin-recorder-enabled` command checks if the Asadmin Recorder feature is active in Payara Server, simply returning a true or false status.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1

Returns whether the Asadmin Recorder Service is enabled or not.

```
asadmin> asadmin-recorder-enabled
Asadmin Recorder Service is enabled
Command asadmin-recorder-enabled executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

asadmin

Utility for performing administrative tasks for Payara Server.

Synopsis

```
asadmin
[--host host]
```

```
[--port port]
[--user admin-user]
[--passwordfile filename]
[--terse={true|false}]
[--extraterse={true|false}]
[--secure={false|true}]
[--echo={true|false}]
[--interactive={true|false}]
[--detach={true|false}]
[--autoname={true|false}]
[--help]
[subcommand [options] [operands]]
```

Description

Use the `asadmin` utility to perform administrative tasks for Payara Server. You can use this utility instead of the Administration Console interface.

Subcommands of the asadmin Utility

The subcommand identifies the operation or task that you are performing. Subcommands are case-sensitive. Each subcommand is either a local subcommand or a remote subcommand.

- A local subcommand can be run without a running domain administration server (DAS). However, to run the subcommand and have access to the installation directory and the domain directory, the user must be logged in to the machine that hosts the domain.
- A remote subcommand is always run by connecting to a DAS and running the subcommand there. A running DAS is required.

asadmin Utility Options and Subcommand Options

Options control the behavior of the `asadmin` utility and its subcommands. Options are also case-sensitive.

The `asadmin` utility has the following types of options:

- `asadmin` utility options. These options control the behavior of the `asadmin` utility, not the subcommand. The `asadmin` utility options may precede or follow the subcommand, but `asadmin` utility options after the subcommand are deprecated. All `asadmin` utility options must either precede or follow the subcommand. If `asadmin` utility options are specified both before and after the subcommand, an error occurs. For a description of the `asadmin` utility options, see the "Options" section of this help information.
- Subcommand options. These options control the behavior of the subcommand, not the `asadmin` utility. Subcommand options must follow the subcommand. For a description of a subcommand's options, see the help information for the subcommand.

A subcommand option may have the same name as an `asadmin` utility option, but the effects of the two options are different.

The `asadmin` utility options and some subcommand options have a long form and a short form.

- The long form of an option has two dashes (`--`) followed by an option word.
- The short form of an option has a single dash (`-`) followed by a single character.

For example, the long form and the short form of the option for specifying terse output are as follows:

- Long form: `--terse`
- Short form: `-t`

Most options require argument values, except Boolean options, which toggle to enable or disable a feature.

Operands of asadmin Subcommands

Operands specify the items on which the subcommand is to act. Operands must follow the argument values of subcommand options, and are set off by a space, a tab, or double dashes (`--`). The `asadmin` utility treats anything that follows the subcommand options and their values as an operand.

Escape Characters in Options for the asadmin Utility

Escape characters are required in options of the `asadmin` utility for the following types of characters:

- Meta characters in the UNIX operating system. These characters have special meaning in a shell. Meta characters in the UNIX operating system include:

  ```
  `\/,.!$%^&*|{}[]"'~;`.
  ```

  To disable these characters, use the backslash (`\`) escape character or enclose the entire command-line argument in single quote (`\'`) characters.

  The following examples illustrate the effect of escape characters on the`*` character. In these examples, the current working directory is the `domains` directory.

  - The following command, without the escape character, echoes all files in the current directory:

    ```
    prompt% echo *
    domain1 domain2
    ```

  - The following command, in which the backslash (`\`) escape character precedes the `*` character, echoes the `*` character:

    ```
    prompt% echo \*
    *
    ```

  - The following command, in which the `*` character is enclosed in single quote (`\'`) characters,

echoes the * character:

```
prompt% echo '*'
*
```

The escape character is also a special character in the UNIX operating system and in the Java language. Therefore, in the UNIX operating system and in multimode, you must apply an additional escape character to every escape character in the command line. This requirement does not apply to the Windows operating system.

For example, the backslash (\) UNIX operating system meta character in the option argument `Test\Escape\Character` is specified on UNIX and Windows systems as follows:

- On UNIX systems, each backslash must be escaped with a second backslash:

```
Test\\Escape\\Character
```

- On Windows systems, no escape character is required:

```
Test\Escape\Character
```

In contexts where meta characters in the UNIX operating system are unambiguous, these characters do not require escape characters. For example, in the `set` subcommand, the value that is to be set is specified as `name=value`.
Because name can never include an equals sign, no escape character is required to disable the equals sign. Therefore, everything after the equals sign is an uninterpreted string that the `set` subcommand uses unchanged.

- Spaces. The space is the separator in the command-line interface. To distinguish a space in a command-line argument from the separator in the command-line interface, the space must be escaped as follows:
  - For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, use the backslash (\) escape character or enclose the entire command-line argument in single quote (\') characters or double quote (") characters.
  - For the Windows operating system in single mode, enclose the entire command-line argument in double quote (") characters.
- Option delimiters. The `asadmin` utility uses the colon character (:) as a delimiter for some options. The backslash (\) escape character is required if the colon is part of the following items:
  - A property
  - An option of the Virtual Machine for the Java platform (Java Virtual Machine or JVM machine)

For example, the operand of the subcommand `create-jvm-options` specifies JVM machine options in the following format:

```
(jvm-option-name[=jvm-option-value])
[:jvm-option-name[=jvm-option-value]]*
```

Multiple JVM machine options in the operand of the `create-jvm-options` subcommand are separated by the colon (`:`) delimiter. If jvm-option-name or jvm-option-value contains a colon, the backslash (`\`) escape character is required before the colon.

The backslash (`\`) escape character is also required before a single quote (`\'`) character or a double quote (`"`) character in an option that uses the colon as a delimiter.

When used without single quote (`\'`) characters, the escape character disables the option delimiter in the command-line interface.

For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, the colon character and the backslash character in an option that uses the colon as a delimiter must be specified as follows:

- To pass a literal backslash to a subcommand, two backslashes are required. Therefore, the colon (`:`) must be escaped by two backslashes (`\\`).
- To prevent a subcommand from treating the backslash as a special character, the backslash must be escaped. As a result, two literal backslashes (`\\`) must be passed to the subcommand. To prevent the shell from interpreting these backslashes as special characters, each backslash must be escaped. Therefore, the backslash must be specified by a total of four backslashes (`\\\\`).

  For the Windows operating system in single mode, a backslash (`\`) is required to escape the colon (`:`) and the backslash (`\`) in an option that uses the colon as a delimiter.

Instead of using the backslash (`\`) escape character, you can use the double quote ("") character or single quote (') character. The effects of the different types of quote characters on the backslash (`\`) character are as follows:

- Between double quote (") characters, the backslash (`\`) character is a special character.
- Between single quote (') characters, the backslash (`\`) character is not a special character.

Requirements for Using the `--secure` Option

The requirements for using the `--secure` option are as follows:

- The domain that you are administering must be configured for security.
- The `security-enabled` attribute of the `http-listener` element in the DAS configuration must be set to `true`.

  To set this attribute, use the `set` subcommand.

Server Restart After Creation or Deletion

When you use the `asadmin` subcommands to create or delete a configuration item, you must restart the DAS for the change to take effect. To restart the DAS, use the `restart-domain` subcommand.

Help Information for Subcommands and the asadmin Utility

To obtain help information for an `asadmin` utility subcommand, specify the subcommand of interest as the operand of the `help` subcommand. For example, to obtain help information for the `start-domain` subcommand, type:

```
asadmin help start-domain
```

If you run the `help` subcommand without an operand, this help information for the `asadmin` utility is displayed.

To obtain a listing of available `asadmin` subcommands, use the `list-commands` subcommand.

Options

`--host`

`-H`

The machine name where the DAS is running. The default value is `localhost`.

`--port`

`-p`

The HTTP port or HTTPS port for administration. This port is the port in the URL that you specify in your web browser to manage the domain. For example, in the URL `http://localhost:4949`, the port is 4949.

The default port number for administration is 4848.

`--user`

`-u`

The username of the authorized administrative user of the DAS.

If you have authenticated to a domain by using the `asadmin login` command, you need not specify the `--user` option for subsequent operations on the domain.

`--passwordfile`

`-W`

Specifies the name, including the full path, of a file that contains password entries in a specific format.

Any password file created to pass as an argument by using the `--passwordfile` option should be protected with file system permissions. Additionally, any password file being used for a transient purpose, such as setting up SSH among nodes, should be deleted after it has served its purpose.

The entry for a password must have the `AS_ADMIN_` prefix followed by the password name in uppercase letters, an equals sign, and the password.

The entries in the file that are read by the `asadmin` utility are as follows:

- `AS_ADMIN_PASSWORD`=administration-password
- `AS_ADMIN_MASTERPASSWORD`=master-password
  The entries in this file that are read by subcommands are as follows:
- `AS_ADMIN_NEWPASSWORD=\`new-administration-password\`` (read by the `start-domain` subcommand)
- `AS_ADMIN_USERPASSWORD=\`user-password\`` (read by the `create-file-user` subcommand)
- `AS_ADMIN_ALIASPASSWORD=\`alias-password\`` (read by the `create-password-alias` subcommand)
- `AS_ADMIN_MAPPEDPASSWORD=\`mapped-password\`` (read by the `create-connector-security-map` subcommand)
- `AS_ADMIN_SSHPASSWORD=\`sshd-password\`` (read by the `create-node-ssh`, `install-node`, `install-node-ssh`, and `update-node-ssh` subcommands)
- `AS_ADMIN_SSHKEYPASSPHRASE=\`sshd-passphrase\`` (read by the `create-node-ssh`, `install-node`, `install-node-ssh`, and `update-node-ssh` subcommands)
- `AS_ADMIN_JMSDBPASSWORD=` jdbc-user-password (read by the `configure-jms-cluster` subcommand)

  These password entries are stored in clear text in the password file. To provide additional security, the `create-password-alias` subcommand can be used to create aliases for passwords that are used by remote subcommands. The password for which the alias is created is stored in an encrypted form. If an alias exists for a password, the alias is specified in the entry for the password as follows:

  ```
  AS_ADMIN_password-name=${ALIAS=password-alias-name}
  ```

  For example:

  ```
  AS_ADMIN_SSHPASSWORD=${ALIAS=ssh-password-alias}
  AS_ADMIN_SSHKEYPASSPHRASE=${ALIAS=ssh-key-passphrase-alias}
  ```

  In domains that do not allow unauthenticated login, all remote subcommands must specify the administration password to authenticate to the DAS. The password can be specified by one of the following means:

- Through the `--passwordfile` option
- Through the link:Technical Documentation/Payara Server Documentation/Command Reference/login#login[`login`] subcommand
- Interactively at the command prompt

  The `login` subcommand can be used to specify only the administration password. For other

passwords that remote subcommands require, use the `--passwordfile` option or specify them at the command prompt.

After authenticating to a domain by using the `asadmin login` command, you need not specify the administration password through the `--passwordfile` option for subsequent operations on the domain. However, only the `AS_ADMIN_PASSWORD` option is not required. You still must provide the other passwords, for example, `AS_ADMIN_USERPASSWORD`, when required by individual subcommands, such as link:Technical Documentation/Payara Server Documentation/Command Reference/update-file-user#update-file-user[`update-file-user`].

For security reasons, a password that is specified as an environment variable is not read by the `asadmin` utility.

The master password is not propagated on the command line or an environment variable, but can be specified in the file that the `--passwordfile` option specifies.

The default value for `AS_ADMIN_MASTERPASSWORD` is `changeit`.

`--terse`

`-t`

If true, output data is very concise and in a format that is optimized for use in scripts instead of for reading by humans. Typically, descriptive text and detailed status messages are also omitted from the output data.

Default is `false`.

`--extraterse`

`-T`

Currently, this option only works with the `create-instance` and `create-local-instance` commands.

If `true`, the `create-instance` and `create-local-instance` commands should only return the name of the instance created.

See `extraterse` for more information.

The `extraterse` option implicitly enables the `terse` option - this is true for **all** commands (not just `create-instance` and `create-local-instance`).

Defaults to `false`.

`--secure`

`-s`

If set to `true`, uses SSL/TLS to communicate with the DAS.

The default is `false`.

`--echo`

`-e`

If set to `true`, the command-line statement is echoed on the standard output. The default is `false`.

`--interactive`

`-I`

If set to `true`, only the required options are prompted.

The default depends on how the `asadmin` utility is run:

- If the `asadmin` utility is run from a console window, the default is `true`.
- If the `asadmin` utility is run without a console window, for example, from within a script, the default is `false`.

`--detach`

If set to `true`, the specified `asadmin` subcommand is detached and executed in the background in detach mode. The default value is `false`.

The `--detach` option is useful for long-running subcommands and enables you to execute several independent subcommands from one console or script.

The `--detach` option is specified before the subcommand. For example, in single mode, `asadmin --detach` subcommand.

Job IDs are assigned to subcommands that are started using `asadmin --detach`. You can use the `list-jobs` subcommand to view the jobs and their job IDs, the `attach` subcommand to reattach to the job and view its status and output, and the `configure-managed-jobs` subcommand to configure how long information about the jobs is kept.

`--autoname`

`-a`

If `true`, this option allows the specified `asadmin` subcommand that accept `String` names as their primary parameter (the parameter that you don't have to specify, e.g. the `instancename` parameter for the `create-instance` command) to generate a name.

Specifically for the `create-instance` and `create-local-instance` commands, the `autoname` option can also be used to automatically resolve any name conflicts. See `auto-naming` for more information.

Default to `false`.

`--help`

`-?`

Displays the help text for the `asadmin` utility.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-

asadmin:::example-1] **Example 1 Running an `asadmin` Utility Subcommand in Single Mode**

This example runs the `list-applications` subcommand in single mode. In this example, the default values for all options are used.

The example shows that the application `hello` is deployed on the local host.

```
asadmin list-applications
hello <web>

Command list-applications executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-2]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-2] **Example 2 Specifying an `asadmin` Utility Option With a Subcommand**

This example specifies the `--host asadmin` utility option with the list-applications` subcommand in single mode. In this example, the DAS is running on the host `srvr1.example.com`.

The example shows that the applications `basic-ezcomp`, `scrumtoys`, `ejb31-war`, and `automatic-timer-ejb` are deployed on the host `srvr1.example.com`.

```
asadmin --host srvr1.example.com list-applications

basic-ezcomp <web>
scrumtoys <web>
ejb31-war <ejb, web>
automatic-timer-ejb <ejb>

Command list-applications executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-3]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-3] **Example 3 Specifying an `asadmin` Utility Option and a Subcommand Option**

This example specifies the `--host asadmin` utility option and the `--type` subcommand option with the `list-applications` subcommand in single mode. In this example, the DAS is running on the host `srvr1.example.com` and applications of type `web` are to be listed.

```
asadmin --host srvr1.example.com list-applications --type web

basic-ezcomp <web>
scrumtoys <web>
ejb31-war <ejb, web>

Command list-applications executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-4]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-4] **Example 4 Escaping a Command-Line Argument With Single Quote Characters**

The commands in this example specify the backslash (`\`) UNIX operating system meta character and the colon (`:`) option delimiter in the property value `c:\extras\pmdapp`.

For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, the backslash (`\`) is required to escape the backslash (`\`) meta character and the colon (:) option delimiter:

```
asadmin deploy --property extras.home='c\:\\extras\\pmdapp' pmdapp.war

Application deployed with name pmdapp.
Command deploy executed successfully
```

For the Windows operating system in single mode, the single quote (`'`) characters eliminate the need for other escape characters:

```
asadmin deploy --property extras.home='c:\extras\pmdapp' pmdapp.war

Application deployed with name pmdapp.
Command deploy executed successfully
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-5]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-5] **Example 5Specifying a UNIX Operating System Meta Character in an Option**

The commands in this example specify the backslash (`\`) UNIX operating system meta character in the option argument `Test\Escape\Character`.

For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, the backslash (`\`) is required to escape the backslash (`\`) meta character:

```
asadmin --user admin --passwordfile gfpass create-jdbc-connection-pool
--datasourceclassname sampleClassName --description Test\\Escape\\Character
sampleJDBCConnectionPool
```

For the Windows operating system in single mode, no escape character is required:

```
asadmin --user admin --passwordfile gfpass create-jdbc-connection-pool
--datasourceclassname sampleClassName --description Test\Escape\Character
sampleJDBCConnectionPool
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-6]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-6] **Example 6 Specifying a Command-Line Argument That Contains a Space**

The commands in this example specify spaces in the operand `C:\Documents and Settings\gfuser\apps\hello.war`.

For all operating systems in single mode or multimode, the entire operand can be enclosed in double quote (") characters:

```
asadmin deploy "C:\Documents and Settings\gfuser\apps\hello.war"

Application deployed with name hello.
Command deploy executed successfully.
```

For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, the entire command-line argument can be enclosed in single quote (') characters:

```
asadmin deploy 'C:\Documents and Settings\gfuser\apps\hello.war'

Application deployed with name hello.
Command deploy executed successfully.
```

Alternatively, for the UNIX operating system in single mode and multimode, and for all operating systems in multimode, the backslash (\) escape character can be used before each space in the operand. In this situation, the backslash (\) escape character is required before each backslash in the operand:

```
asadmin deploy C:\\Documents\ and\ Settings\\gfuser\\apps\\hello.war

Application deployed with name hello.
Command deploy executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-7]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-7] **Example 7 Specifying a Meta Character and an Option Delimiter Character in a Property**

The commands in this example specify the backslash (\) UNIX operating system meta character and the colon (:) option delimiter character in the `--property`option of the `create-jdbc-connection-pool` subcommand.

The name and value pairs for the `--property` option are as follows:

```
user=dbuser
passwordfile=dbpasswordfile
```

```
DatabaseName=jdbc:h2
server=http://localhost:9092
```

For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, a backslash (\) is required to escape the colon (:) and the backslash (\):

```
asadmin --user admin --passwordfile gfpass create-jdbc-connection-pool
--datasourceclassname org.h2.jdbcx.JdbcDataSource --property
user=dbuser:passwordfile=dbpasswordfile:DatabaseName=jdbc\\:h2:server=http\\://localho
st\\:9092 h2-pool
```

Alternatively, the entire argument to the `--property` option can be enclosed in single quote (') characters:

```
asadmin --user admin --passwordfile gfpass create-jdbc-connection-pool
--datasourceclassname org.h2.jdbcx.JdbcDataSource --property
'user=dbuser:passwordfile=dbpasswordfile:DatabaseName="jdbc:h2":server="http://localho
st:9092"' h2-pool
```

For the Windows operating system in single mode, a backslash (\) is required to escape only the colon (:), but not the backslash (\):

```
asadmin --user admin --passwordfile gfpass create-jdbc-connection-pool
--datasourceclassname org.h2.jdbcx.JdbcDataSource --property user-dbuser:passwordfile-
dbpasswordfile:DatabaseName=jdbc\:h2:server=http\://localhost\:9092 h2-pool
```

For all operating systems, the need to escape the colon (:) in a value can be avoided by enclosing the value in double quote characters or single quote characters:

```
asadmin --user admin --passwordfile gfpass create-jdbc-connection-pool
--datasourceclassname org.h2.jdbcx.JdbcDataSource --property
user=dbuser:passwordfile=dbpasswordfile:DatabaseName=\"jdbc:h2\":server=\"http://local
host:9092\" h2-pool
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-8]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-8] **Example 8 Specifying an Option Delimiter and an Escape Character in a JVM Machine Option**

The commands in this example specify the following characters in the `-Dlocation=c:\payara\appserver` JVM machine option:

- The colon (:) option delimiter
- The backslash (\) escape character

For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, these characters must be specified as follows:

- To pass a literal backslash to a subcommand, two backslashes are required. Therefore, the colon (`:`) must be escaped by two backslashes (`\\`).
- To prevent the subcommand from treating the backslash as a special character, the backslash must be escaped. As a result, two literal backslashes (`\\`) must be passed to the subcommand. To prevent the shell from interpreting these backslashes as special characters, each backslash must be escaped. Therefore, the backslash must be specified by a total of four backslashes (`\\\\`).

The resulting command is as follows:

```
asadmin create-jvm-options --target test-server -e
-Dlocation=c\\:\\\\payara\\\\appserver
```

For the Windows operating system in single mode, a backslash (`\`) is required to escape the colon (`:`) and the backslash (`\`):

```
asadmin create-jvm-options --target test-server -e -Dlocation=c\:\\payara\\appserver
```

[[Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-9]#Technical Documentation-Payara Server Documentation-Command Reference-asadmin:::example-9] **Example 9 Specifying an Option That Contains an Escape Character**

The commands in this example specify the backslash (`\`) character and the double quote (`"`) characters in the `description` argument.

For the UNIX operating system in single mode and multimode, and for all operating systems in multimode, a backslash (`\`) is required to escape the double quote character (`"`) and the backslash (`\`):

```
asadmin set-web-env-entry --name="Hello User" --type=java.lang.String
--value=techscribe --description=\"Hello\\App\"\\authentication hello
```

For the Windows operating system in single mode, a backslash (`\`) is required to escape only the double quote (`"`), but not the backslash (`\`):

```
asadmin set-web-env-entry --name="Hello User" --type=java.lang.String
--value=techscribe --description=\"Hello\App\"\authentication hello
```

Environment Variables

Environment variables modify the default values of `asadmin` utility options as shown in the following table.

Environment Variable	`asadmin` Utility Option
AS_ADMIN_TERSE	--terse
AS_ADMIN_EXTRATERSE	--extraterse
AS_ADMIN_ECHO	--echo
AS_ADMIN_INTERACTIVE	--interactive
AS_ADMIN_HOST	--host
AS_ADMIN_PORT	--port
AS_ADMIN_SECURE	--secure
AS_ADMIN_USER	--user
AS_ADMIN_PASSWORDFILE	--passwordfile
AS_ADMIN_HELP	--help

attach

Attaches to subcommands that were started using `asadmin --detach` or that contain progress information.

Synopsis

```
asadmin [asadmin-options] attach [--help]
job_id
```

Description

The `attach` subcommand attaches to subcommands that were started using the `asadmin` utility option `--detach` or that contain progress information. The `--detach` option detaches long-running subcommands and executes them in the background in detach mode.

Job IDs are assigned to the subcommands (jobs), and can be used to view the status of a job and its output. Use the `list-jobs` subcommand to view the jobs and their job IDs, and the `configure-managed-jobs` subcommand to configure how long information about the jobs is kept.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the link:Technical Documentation/Payara Server Documentation/Command Reference/asadmin#asadmin-1m[`asadmin`] help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

job_id

The ID of the job for which you want to view status and output.

Examples

Example 1: Attaching to a Subcommand and Checking Its Status

This example attaches to the `deploy` subcommand with a job ID of `20` and shows that the job is finished. If a subcommand is still in progress, the output displays the current status, for example, `64%: Uploading bits`.

```
asadmin> attach 20
Finished execution of deploy
```

```
Command attach executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `configure-managed-jobs`,
- `list-jobs`

backup-domain

Performs a backup on the domain.

Synopsis

```
asadmin [asadmin-options] backup-domain [--help]
[--long[={false|true}]]
[--description description-text]
[--domaindir domain-root-dir]
[--backupdir backup-directory]
[--backupconfig backup-config-name]
[domain_name]
```

Description

The `backup-domain` subcommand backs up files under the named domain.

To complete the command, however, **the domain must be stopped first**. This will mean that any application deployed to the DAS is unavailable while the backup takes place.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Displays detailed information about the backup operation.

The default value is `false`.

`--description`

Specifies a description to store in the backup file. The description is displayed as part of the information about a backup file.

The default value has this form:

```
domain-name_YYYY_MM_DD_backup-number
```

`--domaindir`

Specifies the domain root directory, the parent directory of the domain to back up.

The default value is `as-install/domains`.

`--backupdir`

Specifies the directory under which the backup file is to be stored.

The default value is `as-install/domains/domain-dir/backups`. If the domain is not in the default location, the location is `domain-dir/backups`.

Operands

domain-name

Specifies the name of the domain to be backed up.

This operand is optional if only one domain exists in the Payara Server installation.

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-backups`,
- `restore-domain`

capture-schema

Stores the database metadata (schema) in a file for use in mapping and execution.

Synopsis

```
capture-schema -username name -password password
[-dburl url] [-driver jdbc_driver_classname]
[-schemaname schemaname] [-table tablename]
-out filename]
```

Description

Stores the database metadata (schema) in a file.

Run `capture-schema` as the same database user that owns the table(s), and use that same username with the `-username` option (and `-schemaname`, if required).

When running `capture-schema` against an Oracle database, you should grant the database user running the `capture-schema` command the `ANALYZE ANY TABLE` privilege.

Options

`-username`
: user name for authenticating access to a database.

`-password`
: password for accessing the selected database.

`-dburl`
: JDBC URL required by the driver for accessing a database.

`-driver`
: JDBC driver classname in your `CLASSPATH`.

`-schemaname`
: name of the user schema being captured. If not specified, the default will capture metadata for all tables from all the schemas accessible to this user.
Specifying this parameter is highly recommended.
The specified schema name must be uppercase.

`-table`
: name of a table; multiple table names can be specified. If no table is specified, all the tables in the database or named schema are captured.
The specified table name or names are case sensitive. Be sure to match the case of the previously created table names.

`-out`
: name of the output file. This option is required. If the specified output file does not contain the

.dbschema suffix, it will be appended to the filename.

Examples

Example 1 Using the `capture-schema` command

```
capture-schema -username cantiflas -password enigma
-dburl jdbc:oracle:thin:@sadbuttrue:1521:ora817
-driver oracle.jdbc.driver.OracleDriver
-schemaname CANTIFLAS -out cantiflas.dbschema
```

Where: `sun-acc.xml` is the name of the client configuration XML file, `myclientapp.jar` is the client application `.jar` file, and `scott` and `sample` are arguments to pass to the application. If `sun-acc.xml` and `myclientapp.jar` are not in the current directory, you must give the absolute path locations; otherwise the relative paths are used. The relative path is relative to the directory where the command is being executed.

See Also

- `asadmin`

change-admin-password

Changes the administrator password.

Synopsis

```
asadmin [asadmin-options] change-admin-password [--help]
[--domaindir domain-root-dir [--domain_name domain-name]]
```

Description

The `change-admin-password` subcommand modifies the administrator password. The `change-admin-password` subcommand is interactive because the subcommand prompts the user for the old administrator password, for the new administrator password, and for confirmation of the new administrator password. The new password must contain at least 8 characters.

If the only user is an anonymous user without a password, this subcommand fails.

If a blank password is provided, this subcommand fails if secure administration is enabled.

For security purposes, create a password-protected user account with administrator privileges. To create this account, use the `create-file-user` or the Administration Console. After creating this user account, remove the anonymous user to restrict access to Payara Server settings.

If more than one administrator is configured for Payara Server, you must run the `asadmin` command with the `--user` option to change the password for that user. For more information, see the examples in this help page.

This subcommand is supported in local mode and remote mode. If the `--domaindir` or `--domain_name` option is specified, the `change-admin-password` subcommand operates in local mode. If neither option is specified, the `change-admin-password` subcommand first attempts to operate in remote mode. If neither option is specified and the DAS is not running, the `change-admin-password` subcommand operates in local mode, using the default values for the `--domaindir` and `--domain_name` options.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--domaindir`

Specifies the parent directory of the domain specified in the `--domain_name` option. When this option is used, the `change-admin-password` subcommand operates in local mode.

`--domain_name`

Specifies the domain of the admin user.
This option is not required if the directory specified by the `--domaindir` option contains only one domain.

Examples

Example 1 Changing the Administrator Password For a Single User in Multimode

```
asadmin --user admin
asadmin> change-admin-password
Please enter the old admin password>
Please enter the new admin password>
Please enter the new admin password again>
Command change-admin-password executed successfully.
```

Example 2 Changing the Administrator Password For a Single User in Single Mode

```
asadmin --user admin change-admin-password
Please enter the old admin password>
Please enter the new admin password>
Please enter the new admin password again>
Command change-admin-password executed successfully.
```

Exit Status

0

command executed successfully

1

command failed

- `list-password-aliases`,
- `update-password-alias`

change-master-broker

Changes the master broker in a Message Queue cluster providing JMS services for a Payara Server cluster.

Synopsis

```
asadmin [asadmin-options] change-master-broker [--help]
clustered-instance-name
```

Description

The `change-master-broker` subcommand changes the master broker in a Message Queue cluster that is the JMS provider for a Payara Server cluster. By default, the master broker is the one associated with the first instance configured in the Payara Server cluster.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

clustered-instance-name

The name of the server instance whose Message Queue broker is to become the master broker of the Message Queue cluster. This server instance must be an instance in a Payara Server cluster.

Examples

Example 1 Changing the master broker

The following subcommand changes the Message Queue master broker to the one for the `clustinst3` clustered instance.

```
asadmin> change-master-broker clustinst3
Command change-master-broker executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

change-master-password

Changes the master password.

Synopsis

```
asadmin [asadmin-options] change-master-password [--help]
[--nodedir node-dir] [--domaindir domain-dir]
[--savemasterpassword={false|true}] [--masterpasswordlocation filepath]
[domain-name|node-name]
```

Description

The `change-master-password` subcommand is used to modify the master password. The `change-master-password` subcommand is interactive in that the user is prompted for the old master password, as well as the new master password. This subcommand will not work unless the server is stopped. In a distributed environment, this command must run on each machine in the domain.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodedir`

The name of the directory containing the node instance for which the password will be changed. If this option is omitted, the change is applied to the entire domain.

`--domaindir`

The name of the domain directory used for this operation. By default, the `--domaindir` option is `$AS_DEF_DOMAINS_PATH`, which is an environment variable defined in the file `asenv.bat` or `asenv.conf`.

`--savemasterpassword`

This option indicates whether the master password should be written to the file system. This is necessary so that the `start-domain` command can start the server without having to prompt the user.
The default is `false`.

`--masterpasswordlocation`

This is the absolute filepath that the master password will be written to. This parameter is only active when `--savemasterpassword` is active.
If this parameter is unused, then the master password will be saved to the default location.

Saving the master password on disk is extremely insecure and should be avoided.

If the `--savemasterpassword` option is not set, the master password file, if it exists, will be deleted.

Operands

domain-name|node-name

This name of the domain or node for which the password will be changed. If there is only a single domain, this is optional.

Examples

Example 1 Changing the Master Password

This example shows how to changed the master password for the `domain44ps` domain.

```
asadmin>change-master-password domain44ps
Please enter the new master password>
Please enter the new master password again>
Master password changed for domain44ps
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- `delete-password-alias`,
- `list-password-aliases`,
- `start-domain`,
- `update-password-alias`

clean-jbatch-repository

Deletes records of Jakarta Batch job executions.

Synopsis

```
asadmin [asadmin-options] clean-jbatch-repository
[--status={COMPLETED|ALL}]
[--days] days
[job_name]
```

Description

The `clean-jbatch-repository` subcommand will remove the history of all job records related to an specific Jakarta Batch execution job.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--status`

The status of batch jobs executions to which delete the records of. Valid values are as follows:

`COMPLETED`

Only job executions that successfully completed will be deleted.

`ALL`

All job executions will be deleted, regardless of status.

`--days`

The number of days previous that the end time of the job execution must be to get deleted.

Defaults to 1 day

Operands

job_name

The name of the Jakarta Batch job that will be cleared in the repository.

Examples

The following command will delete all job records for the `testjob` job that were executed before 7 days ago.

```
asadmin > clean-jbatch-repository --status=ALL --days=7 testjob
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `list-batch-jobs`,
- `list-batch-job-executions`,
- `list-batch-job-steps`,
- `list-batch-runtime-configuration`,
- `purge-jbatch-repository`

clear-cache

Clears a Hazelcast or JCache IMap.

Synopsis

```
asadmin [asadmin-options] clear-cache
[--help]
[--target target]
[--cachename cachename]
```

Description

This command can be used to clear a Hazelcast or JCache IMap.

Use of this command removes all data from a cache and therefore can result in unexpected behaviour if a system cache is cleared.
Clearing a cache containing web session data will result in all users losing their sessions, for example.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are executing this operation. Valid values are:

`server`

Applies to the default server instance. This is the default value.

instance_name

Applies to a specified server instance.

`--cachename`

Name of the cache/map to clear.

Examples

Example 1 Clears a Hazelcast or JCache IMap

```
asadmin> clear-cache --cachename payara.instance.store
Cleared Cache payara.instance.store
Command clear-cache executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

collect-diagnostics

Collects data used for the diagnostics and troubleshooting of Payara Server incidents.

Synopsis

```
asadmin [asadmin-options] collect-diagnostics [--help]
[--domainDir=directory]
[--nodeDir=directory]
[--target=target]
[--dir=<file-path>]
[--serverLog={false|true}]
[--accessLog={false|true}]
[--notificationLog={false|true}]
[--domainXml={false|true}]
[--threadDump={false|true}]
[--heapDump={false|true}]
[--jvmReport={false|true}]
[--obfuscate={true|false}]
[domainName]
```

Description

This command will collect useful information for diagnosing incidents within a Payara Server domain. It can collect from both remote and local instances.

Among the data collected is the following information:

- `domain.xml` configuration file
- Server logs
- Access logs
- Notification logs
- A JVM thread dump.
- A JVM Heap Dump
- JVM Report

The data collected is stored in a ZIP file in your user home directory, the output directory by default.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which data is collected. Valid values are:

deployment_group_name

Applies to every server instance in the specified deployment group.

cluster_name

Applies to every server instance in the specified cluster.

instance_name

Applies to a specific sever instance.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

`--dir`

The directory path where the ZIP file will be stored. Defaults to `${user.home}`

`--domainXml`

Whether to collect the `domain.xml` configuration file. Defaults to `true`.

`--serverLog`

Whether to collect server logs. Defaults to `true`

`--accessLog`

Whether to collect access logs. Defaults to `true`

`--notificationLog`

Whether to collect notification logs. Defaults to `true`

`--heapDump`

Whether to collect a heap dump. Defaults to `true`

`--threadDump`

Whether to collect a thread dump. Defaults to `true`

`--jvmReport`

Whether to collect the JVM report. Defaults to `true`

`--obfuscate`

Whether to obfuscate data in `domain.xml`. Defaults to `true`

Operands

domainName

The name of the domain that will be scanned.

Defaults to `domain1`.

Examples

Example 1 Collect Diagnostics

The following example shows how to collect the data of all instances that belong to the `deploymentGroup1` deployment group in the `mydomain` domain:

```
asadmin collect-diagnostics --target deploymentGroup1 mydomain

Directory selected /home/user/payara/diagnostics/mydomain-2024-04-15T11-42-36Z
Collecting domain.xml from instance2
Attempting to create missing path at /home/user/payara/diagnostics/mydomain-2024-04-
15T11-42-36Z/deploymentGroup1/instance1
Collecting logs from instance2
Collecting jvm report from instance2
Collecting thread dump from instance2
Collecting Heap Dump from instance2
This version of Payara does not support heap dump generation.
Collecting domain.xml from instance1
Attempting to create missing path at /home/user/payara/diagnostics/mydomain-2024-04-
15T11-42-36Z/deploymentGroup1/instance1
Collecting logs from instance1
Collecting jvm report from instance1
Collecting thread dump from instance1
Collecting Heap Dump from instance1

Command collect-diagnostics executed successfully.
```

Example 2 Collect only a Heap Dump

The following example shows how to just collect a Heap dump of all instances in the `mydomain` domain:

```
asadmin collect-diagnostics --target deploymentGroup1 --threadDump=false
--domainXml=false --jvmReport=false --serverLog=false mydomain

Directory selected /home/user/payara/diagnostics/mydomain-2024-04-15T11-42-36Z
Collecting domain.xml from instance2
Attempting to create missing path at /home/user/payara/diagnostics/mydomain-2024-04-
15T11-42-36Z/deploymentGroup1/instance1
Collecting Heap Dump from instance2
This version of Payara does not support heap dump generation.
Collecting domain.xml from instance1
Attempting to create missing path at /home/user/payara/diagnostics/mydomain-2024-04-
15T11-42-36Z/deploymentGroup1/instance1
Collecting Heap Dump from instance1

Command collect-diagnostics executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- Diagnostics Tool

collect-log-files

Creates a ZIP archive of all available log files.

Synopsis

```
asadmin [asadmin-options] collect-log-files [--help]
[--target target]
[--retrieve={false|true}] [retrievefilepath]]
```

Description

The `collect-log-files` subcommand collects all available log files for the domain administration server (DAS), the specified cluster, or the specified Payara Server instance and creates a single ZIP archive of the log files. If a cluster is specified, the ZIP archive also contains the log file for the DAS.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--retrieve`

Specifies whether the ZIP archive is created in a directory other than the default directory.
By default the ZIP archive is created in the `domain-dir/collected-logs` directory. The ZIP file names are constructed from the specified target and timestamp, as follows:

```
log_yyyy-mm-dd_hh-min-sec.zip
```

Possible values are as follows:

`false`

The ZIP archive will be created in the default directory. If omitted, the `--retrieve` option defaults to `false`.

`true`

The ZIP archive will be created in the directory that the retrievefilepath operand specifies. If retrievefilepath is omitted, the ZIP archive will be created in the default directory.

`--target`

Specifies the target for which log files will be collected.
Possible values are as follows:

`server`

The log files will be collected for the DAS (default).

`instance-name`

The log files will be collected for the specified Payara Server instance.

`cluster-name`

The log files will be collected for the specified cluster and the DAS.

Operands

retrievefilepath

The name of the directory in which the ZIP archive will be created. If this operand is omitted, the ZIP archive will be created in the default directory. If the `--retrieve` option is `false`, this operand is ignored.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-collect-log-files:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-collect-log-files:::example-1] **Example 1 Collecting Log Files for the Default Server**

This example generates a ZIP archive from the log files for the default server.

```
asadmin> collect-log-files
Created Zip file under /space/gfv3/v3setup/payara7/glassfish/domains/domain1/\
collected-logs/log_2010-12-15_15-46-23.zip.
Command collect-log-files executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-collect-log-files:::example-2]#Technical Documentation-Payara Server Documentation-Command Reference-collect-log-files:::example-2] **Example 2 Collecting Log Files for a Cluster**

This example generates a ZIP archive from the log files for a cluster named `cluster1` and the two server instances running in the cluster.

```
asadmin> collect-log-files --target cluster1
Log files are downloaded for instance1.
Log files are downloaded for instance2.
Created Zip file under /space/gfv3/v3setup/payara7/glassfish/domains/domain1/\
collected-logs/log_2010-12-15_15-54-06.zip.
Command collect-log-files executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-collect-log-files:::example-3]#Technical Documentation-Payara Server Documentation-Command Reference-collect-log-files:::example-3] **Example 3 Collecting Log Files in a Directory Other Than the Default for a Cluster**

This example generates a ZIP archive from the log files for a cluster named `cluster1` and its two server instances, and saves the archive in a directory named `/space/output`.

```
asadmin> collect-log-files --target cluster1 --retrieve true /space/output
Log files are downloaded for instance1.
Log files are downloaded for instance2.
Created Zip file under /space/output/log_2010-12-15_15-55-54.zip.
Command collect-log-files executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,

configure-jms-cluster

Configures the Message Queue cluster providing JMS services to a Payara Server cluster.

Synopsis

```
asadmin [asadmin-options] configure-jms-cluster [--help]
[--clustertype={conventional|enhanced}]
[--configstoretype={masterbroker|shareddb}]
[--messagestoretype={file|jdbc}]
[--dbvendor database-vendor]
[--dbuser database-user]
[--dburl database-url]
[--property (name=value)[:name=value]*]
cluster-name
```

Description

The `configure-jms-cluster` configures the Message Queue cluster providing JMS services to a Payara Server cluster.

This subcommand should be used before the Payara Server cluster is started for the first time. Otherwise, follow the instructions in Administering the Java Message Service (JMS) in Payara Server General Administration section.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--clustertype`

The type of Message Queue cluster to configure. The value `conventional` specifies a conventional cluster, and the value `enhanced` specifies an enhanced, high-availability cluster.
The default value is `conventional`.
If `enhanced` is specified, the `configstoretype` and `messagestoretype` options are ignored.

`--configstoretype`

The type of data store for configuration data in a conventional cluster. The value `masterbroker` specifies the use of a master broker to store and manage the configuration data. The value `shareddb` specifies the use of a shared database to store the configuration data.
The default value is `masterbroker`.
This option is ignored if `clustertype` is set to `enhanced`.

`--messagestoretype`

The type of data store for message data in brokers in a conventional cluster. The value `file` specifies a file store. The value `jdbc` specifies a JDBC store.
The default value is `file`.
This option is ignored if `clustertype` is set to `enhanced`.

`--dbvendor`

`--dbuser`

`--dburl`

The database vendor, user, and access url of the JDBC database to use in any of these situations:

- When `clustertype` is set to `enhanced`
- When `configstoretype` is set to `shareddb`
- When `messagestoretype` is set to `jdbc`

To specify the password of the JDBC database user, use the `--passwordfile` utility option of the `asadmin` command after adding the entry `AS_ADMIN_JMSDBPASSWORD` to the password file.

`--property`

A list of additional database-vendor-specific properties to configure the JDBC database for use by the Message Queue cluster. Specify properties as a colon (`:`) separated list of property names and values in the form:

```
prop1name=prop1value:prop2name=prop2value
```

Operands

cluster-name

The name of the Payara Server cluster for which the Message Queue cluster is to provide JMS services.
Because Payara Server uses the cluster name to uniquely identify database tables the Message Queue cluster might require, the length of the name is restricted in the following situations:

- If `clustertype` is set to `enhanced`, the name can be no longer than n–21 characters, where n is the maximum table name length allowed by the database.
- If `configstoretype` is set to `shareddb`, the name can be no longer than n–19 characters, where n is the maximum table name length allowed by the database.

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- `asadmin`

configure-lb-weight

configure-ldap-for-admin

Configures the authentication realm named admin-realm for the given LDAP.

Synopsis

```
asadmin [asadmin-options] configure-ldap-for-admin [--help]
```

Description

The `configure-ldap-for-admin` subcommand configures the authentication realm named `admin-realm` for the given LDAP. The `configure-ldap-for-admin` subcommand is interactive. The subcommand prompts the user for the `basedn` and `ldap-group` options.

This command is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Configuring the LDAP Authentication Realm

```
asadmin> configure-ldap-for-admin
Enter the value for the basedn option>
Enter the value for the ldap-group option>
The LDAP Auth Realm admin-realm was configured correctly
in admin server's configuration.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `change-admin-password`,
- `create-auth-realm`,
- `list-auth-realms`

configure-managed-jobs

Configures how long information about subcommands that were started using `asadmin --detach` or that contain progress information is kept.

Synopsis

```
asadmin [asadmin-options] configure-managed-jobs [--help]
[--in-memory-retention-period in-memory-retention-period]
[--job-retention-period job-retention-period]
[--cleanup-initial-delay cleanup-initial-delay]
[--cleanup-poll-interval cleanup-poll-interval]
```

Description

The `configure-managed-jobs` subcommand configures how long information about subcommands (jobs) that were started using the `asadmin` utility option `--detach` or that contain progress information is kept. The `--detach` option detaches long-running subcommands and executes them

in the background in detach mode. Job information includes subcommand progress and status.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--in-memory-retention-period`

Specifies how long a completed job is kept in memory after the job is finished. The default value is 1 hour.

`--job-retention-period`

Specifies how long a job is stored. The default value is 24 hours.

`--cleanup-initial-delay`

After server startup, specifies the initial delay after which the cleanup service starts purging jobs. The default value is 5 minutes.

`--cleanup-poll-interval`

Specifies the time interval after which the cleanup service polls for expired jobs. The default value is 20 minutes.

Examples

Example 1 Configuring the Job Retention Period

This example sets the job retention period to 36 hours. Time periods can be specified in Hh|Mm|Ss for hours, minutes, or seconds.

```
asadmin> configure-managed-jobs --job-retention-period=36h
Command configure-managed-jobs executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,

- `list-jobs`

copy-config

Copies an existing named configuration to create another configuration.

Synopsis

```
asadmin [asadmin-options] copy-config [--help]
[--systemproperties (name=value)[:name=value]*]
source-configuration-name destination-configuration-name
```

Description

The `copy-config` subcommand creates a named configuration in the configuration of the domain administration server (DAS) by copying an existing configuration. The new configuration is identical to the copied configuration, except for any properties that you specify in the `--systemproperties` option.

The `default-config` configuration is copied when a standalone sever instance or standalone cluster is created.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--systemproperties`

Optional attribute name-value pairs for the configuration. These properties override port settings in the configuration.
The following properties are available:

`ASADMIN_LISTENER_PORT`

This property specifies the port number of the HTTP port or HTTPS port through which the DAS connects to the instance to manage the instance. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTP requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTPS requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_LISTENER_PORT`

This property specifies the port number of the port that is used for IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used for secure IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_MUTUALAUTH_PORT`

This property specifies the port number of the port that is used for secure IIOP connections with client authentication. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JAVA_DEBUGGER_PORT`

This property specifies the port number of the port that is used for connections to the Java Platform Debugger Architecture (JPDA) (http://www.oracle.com/technetwork/java/javase/tech/jpda-141715.html) debugger. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMS_PROVIDER_PORT`

This property specifies the port number for the Java Message Service provider. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMX_SYSTEM_CONNECTOR_PORT`

This property specifies the port number on which the JMX connector listens. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`OSGI_SHELL_TELNET_PORT`

This property specifies the port number of the port that is used for connections to the Apache Felix Remote Shell (`http://felix.apache.org/site/apache-felix-remote-shell.html`). This shell uses the Felix shell service to interact with the OSGi module management subsystem. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

Operands

source-configuration-name

The name of the configuration that you are copying.

destination-configuration-name

The name of the configuration that you are creating by copying the source configuration. The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Hyphen
  - Period
  - Underscore
- The name must be unique in the domain and must not be the name of a another named configuration, a cluster, a Payara Server instance, or a node.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.

Examples

Example 1 Copying a Configuration

This example copies the `default-config` configuration to the `pmdsaconfig` configuration, overriding the settings for the following ports:

- HTTP listener port
- HTTPS listener port

```
asadmin> copy-config
--systemproperties HTTP_LISTENER_PORT=2000:HTTP_SSL_LISTENER_PORT=3000
default-config pmdsaconfig

Command copy-config executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `delete-config`,
- `list-configs`

create-admin-object

Adds the administered object with the specified JNDI name for a resource adapter.

Synopsis

```
asadmin [asadmin-options] create-admin-object [--help]
[--target target]
--restype restype
[--classname classname]
--raname raname
[--enabled={true|false}]
[--description description]
[--property name=value[:name=value]*]
jndi_name
```

Description

The `create-admin-object` subcommand creates the administered object with the specified JNDI name and the interface definition for a resource adapter.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which you are creating the administered object. Valid values are as follows:

`server`

Creates the administered object for the default server instance `server` and is the default value.

configuration_name

Creates the administered object for the named configuration.

cluster_name

Creates the administered object for every server instance in the cluster.

instance_name

Creates the administered object for a particular server instance.

The resource is always created for the domain as a whole, but the `resource-ref` for the resource is only created for the specified `--target`. This means that although the resource is defined at the domain level, it is only available at the specified target level. Use the `create-resource-ref` subcommand to refer to the resource in multiple targets if needed.

`--restype`

Specifies the interface definition for the administered object. The resource type must be an interface definition that is specified in the `ra.xml` file of the resource adapter.

`--classname`

Specifies the class name of the administered object. Required if multiple administered objects use the same interface definition.

`--raname`

Specifies the name of the resource adapter associated with this administered object.

`--enabled`

Specifies if this object is enabled. Default is true.

`--description`

Text string describing the administered object.

`--property`

Description of the name/values pairs for configuring the resource. Dependent on the resource adapter. For JMS properties, see `create-jms-resource` for JMS destination resources.

Operands

jndi_name

JNDI name of the administered object to be created.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-create-admin-object:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-create-admin-object:::example-1] **Example 1 Creating an Administered Object**

In this example, `jmsra` is a system resource adapter with the admin object interfaces, `jakarta.jms.Queue` and `jakarta.jms.Topic`.

```
asadmin> create-admin-object --restype jakarta.jms.Queue
--raname jmsra --description "sample administered object"
--property Name=sample_jmsqueue jms/samplequeue
Command create-admin-object executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-resource-ref`,
- `delete-admin-object`,
- `list-admin-objects`

create-application-ref

Creates a reference to an application.

Synopsis

```
asadmin [asadmin-options] create-application-ref [--help]
[--target target]
[--virtualservers virtual_servers] [--enabled=true]
[--lbenabled=true] reference_name
```

Description

The `create-application-ref` subcommand creates a reference from a cluster or an unclustered server instance to a previously deployed application element (for example, a Java EE application, a Web module, or an enterprise bean module). This effectively results in the application element being deployed and made available on the targeted instance or cluster.

The target instance or instances making up the cluster need not be running or available for this subcommand to succeed. If one or more instances are not available, they will receive the new application element the next time they start.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which you are creating the application reference. Valid values are

- `server` - Specifies the default server instance as the target for creating the application reference. `server` is the name of the default server instance and is the default value for this option.
- cluster_name - Specifies a particular cluster as the target for creating the application reference.
- instance_name - Specifies a particular stand-alone server instance as the target for creating the application reference.

`--virtualservers`

Specifies a comma-separated list of virtual server IDs on which to deploy. This option applies only to Web modules (either standalone or in a Java EE application). If this option is not specified, the application is deployed to all virtual servers except the administrative server, `__asadmin`.

`--enabled`

Indicates whether the application should be enabled (that is, loaded). This value will take effect only if the application is enabled at the global level. The default is `true`.

`--lbenabled`

Controls whether the deployed application is available for load balancing. The default is true.

Operands

reference_name

The name of the application or module, which can be a Java EE application, Web module, EJB module, connector module or application client module.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (_), dash (`-`), and period (`.`) characters. If the `--enabled` option is set to false, you can create references to multiple disabled versions by using an asterisk (`*`) as a wildcard character. For more information about module and application versions, see "Module and Application Versions" in Payara Server Application Deployment section.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-create-application-ref:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-create-application-ref:::example-1] **Example 1 Creating an Application Reference**

The following example creates a reference to the Web module `MyWebApp` on the unclustered server instance `NewServer`.

```
asadmin> create-application-ref --target NewServer MyWebApp
```

```
Command create-application-ref executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

[[Technical Documentation-Payara Server Documentation-Command Reference-create-application-ref:::sthref130]]

See Also

- `asadmin`
- `delete-application-ref`,
- `list-application-refs`
- Payara Server Application Deployment

create-auth-realm

Adds the named authentication realm.

Synopsis

```
asadmin [asadmin-options] create-auth-realm [--help]
--classname realm_class [--property(name=value)[:name=value]*]
[--target target_name] auth_realm_name
```

Description

The `create-auth-realm` subcommand adds the named authentication realm.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which you are creating the realm. Valid values are

`server`

Creates the realm on the default server instance. This is the default value.

configuration_name

Creates the realm in the specified configuration.

cluster_name

Creates the realm on all server instances in the specified cluster.

instance_name

Creates the realm on a specified server instance.

`--classname`

Java class which implements this realm. These include `com.sun.enterprise.security.auth.realm.file.FileRealm`, `com.sun.enterprise.security.auth.realm.certificate.CertificateRealm`, `com.sun.enterprise.security.auth.realm.jdbc.JDBCRealm`, `com.sun.enterprise.security.auth.realm.ldap.LDAPRealm`, `com.sun.enterprise.security.auth.realm.ldap.PamRealm`, and `com.sun.enterprise.security.auth.realm.solaris.SolarisRealm`, or a custom realm.

`--property`

Optional attribute name-value pairs for configuring the authentication realm. Authentication realms require provider-specific properties, which vary based on implementation.
The following properties are common to all of the supported realms, which include `FileRealm`, `CertificateRealm`, `JDBCRealm`, `LDAPRealm`, PamRealm, and `SolarisRealm`.

`jaas-context`

Specifies the Java Authentication and Authorization Service (JAAS) context.

`assign-groups`

(Optional) If this property is set, its value is taken to be a comma-separated list of group names. All clients who present valid certificates are assigned membership to these groups for the purposes of authorization decisions in the web and EJB containers.
Specific to each realm, you can specify the following properties.

- You can specify the following properties for `FileRealm`:

`file`

Specifies the file that stores usernames, passwords, and group names. The default is domain-dir`/config/keyfile`.

- You can specify the following properties for `CertificateRealm`:

`LoginModule`

Specifies the name of a JAAS `LoginModule` to use for performing authentication. To use a JAAS `LoginModule`, you must first create an implementation of the javax.security.auth.spi.LoginModule interface, and then plug the module into a `jaas-context`.

- You can specify the following properties for `JDBCRealm`:

`datasource-jndi`

Specifies the `jndi-name` of the `jdbc-resource` for the database.

`user-table`

Specifies the name of the user table in the database.

`user-name-column`

Specifies the name of the user name column in the database's user table.

`password-column`

Specifies the name of the password column in the database's user table.

`group-table`

Specifies the name of the group table in the database.

`group-table`

Specify the group table for an authentication realm of class `JDBCRealm`.

`group-name-column`

Specifies the name of the group name column in the database's group table.

`db-user`

(Optional) Allows you to specify the database username in the realm instead of the `jdbc-connection-pool`. This prevents other applications from looking up the database, getting a connection, and browsing the user table. By default, the `jdbc-connection-pool` configuration is used.

`db-password`

(Optional) Allows you to specify the database password in the realm instead of the `jdbc-connection-pool`. This prevents other applications from looking up the database, getting a connection, and browsing the user table. By default, the `jdbc-connection-pool` configuration is used.

`group-table`

Specifies the name of the group table in the database.

`digest-algorithm`

(Optional) Specifies the digest algorithm. The default is `SHA-256`. You can use any algorithm supported in the JDK, or none.

If you have applications that depend on the `MD5` algorithm, you can override the default `SHA-25` algorithm by using the `asadmin set` subcommand:

```
asadmin> set server.security-service.property.default-digest-
algorithm=MD5
```

You can use the `asadmin get` subcommand to determine what algorithm is currently being used:

```
asadmin> get server.security-service.property.default-digest-algorithm
```

`digestrealm-password-enc-algorithm`

(Optional) Specifies the algorithm for encrypting passwords stored in the database.

It is a security risk not to specify a password encryption algorithm.

`encoding`

(Optional) Specifies the encoding. Allowed values are `Hex` and `Base64`. If digest-algorithm is specified, the default is `Hex`. If `digest-algorithm` is not specified, by default no encoding is specified.

`charset`

(Optional) Specifies the `charset` for the digest algorithm.

- You can specify the following properties for `LDAPRealm`:

`directory`

Specifies the LDAP URL to your server.

`base-dn`

Specifies the LDAP base DN for the location of user data. This base DN can be at any level above the user data, since a tree scope search is performed. The smaller the search tree, the better the performance.

`search-filter`

(Optional) Specifies the search filter to use to find the user. The default is `uid=%s` (`%s` expands to the subject name).

`group-base-dn`

(Optional) Specifies the base DN for the location of groups data. By default, it is same as the `base-dn`, but it can be tuned, if necessary.

`group-search-filter`

(Optional) Specifies the search filter to find group memberships for the user. The default is `uniquemember=%d` (`%d` expands to the user `elementDN`).

`group-target`

(Optional) Specifies the LDAP attribute name that contains group name entries. The default is `CN`.

`search-bind-dn`

(Optional) Specifies an optional DN used to authenticate to the directory for performing the search-filter lookup. Only required for directories that do not allow anonymous search.

`search-bind-password`

(Optional) Specifies the LDAP password for the DN given in `search-bind-dn`.

Operands

auth_realm_name

A short name for the realm. This name is used to refer to the realm from, for example, `web.xml`.

Examples

Example 1 Creating a New Authentication Realm

This example creates a new file realm.

```
asadmin> create-auth-realm
--classname com.sun.enterprise.security.auth.realm.file.FileRealm
--property file=${com.sun.aas.instanceRoot}/config/admin-keyfile:jaas-
context=fileRealm file
Command create-auth-realm executed successfully
```

Where `file` is the authentication realm created.

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-cluster

Creates a Payara Server cluster.

Synopsis

```
asadmin [asadmin-options] create-cluster [--help]
[--config config-name]
[--systemproperties (name=value)[:name=value]*]
[--properties (name=value)[:name=value]*]
[--gmsenabled={true|false}]
[--multicastport multicast-port]
```

```
[--multicastaddress multicast-address]
[--bindaddress bind-address]
cluster-name
```

Description

The `create-cluster` subcommand creates a Payara Server cluster. Initially the cluster contains no Payara Server instances, applications, or resources.

A cluster requires a reference to the named configuration that defines the configuration of all instances that are added to the cluster. The configuration can be specified in the command to create the cluster, but is not required. If no configuration is specified, the subcommand creates a configuration that is named cluster-name`-config` for the cluster. The cluster that is created is a standalone cluster because the cluster's configuration is not shared with any other clusters or standalone instances.

To add instances to the cluster, set the `--cluster` option to the name of the cluster when using either of the following subcommands:

- `create-instance`
- `create-local-instance`

To delete server instances from the cluster at any time, use one of the following subcommands:

- `delete-instance`
- `delete-local-instance`

To associate applications and resources with all instances in the cluster, set the `--target` option to the name of the cluster when performing the following operations:

- Deploying applications by using the `deploy` subcommand
- Creating resources by using subcommands such as `create-jdbc-resource`
- Creating references to applications that are already deployed in other targets by using the `create-application-ref` subcommand
- Creating references to resources that are already created in other targets by using the `create-resource-ref` subcommand

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--config`

Specifies the named configuration that the cluster references. The configuration must exist and must not be named `default-config` or `server-config`. Specifying the `--config` option creates a shared cluster. If this option is omitted, a standalone cluster is created.

`--systemproperties`

Defines system properties for the configuration that is created for the cluster. These properties override the property values in the `default-config` configuration. The following properties are available:

`ASADMIN_LISTENER_PORT`

This property specifies the port number of the HTTP port or HTTPS port through which the DAS connects to the instance to manage the instance. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTP requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTPS requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_LISTENER_PORT`

This property specifies the port number of the port that is used for IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used for secure IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_MUTUALAUTH_PORT`

This property specifies the port number of the port that is used for secure IIOP connections with client authentication. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JAVA_DEBUGGER_PORT`

This property specifies the port number of the port that is used for connections to the Java Platform Debugger Architecture (JPDA) (http://www.oracle.com/technetwork/java/javase/tech/jpda-141715.adoc) debugger. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMS_PROVIDER_PORT`

This property specifies the port number for the Java Message Service provider. Valid values

are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMX_SYSTEM_CONNECTOR_PORT`

This property specifies the port number on which the JMX connector listens. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`OSGI_SHELL_TELNET_PORT`

This property specifies the port number of the port that is used for connections to the Apache Felix Remote Shell (http://felix.apache.org/site/apache-felix-remote-shell.html). This shell uses the Felix shell service to interact with the OSGi module management subsystem. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`--properties`

Defines properties for the cluster. The following properties are available:

`GMS_DISCOVERY_URI_LIST`

The locations of Payara Server instances in the cluster to use for discovering the cluster. This property is required only if the Group Management Service (GMS) is not using multicast for broadcasting messages.

Valid values for this property are as follows:

- A comma-separated list of uniform resource identifiers (URIs). Each URI must locate a Payara Server instance or the DAS. This format is required if multiple Payara Server instances are running on the same host.

  The format of each URI in the list is as follows:

  scheme `://` host-name-or -IP-address `:` port

  - scheme is the URI scheme, which is `tcp`.
  - host-name-or -IP-address is the host name or IP address of the host on which the instance is running.
  - port is the port number of the port on which the instance listens for messages from GMS. The system property `GMS_LISTENER_PORT-` clustername must be set for the instance.
- A comma-separated list of IP addresses or host names on which the DAS or the instances are running. The list can contain a mixture of IP addresses and host names. This format can be used only if one clustered instance is running on each host. The value of the `GMS_LISTENER_PORT` property must be unique for each cluster in a domain.
- The keyword `generate`. This format can be used only if one instance in a cluster is running on each host and the DAS is running on a separate host. Multiple instances on the same host cannot be members of the same cluster. The value of the `GMS_LISTENER_PORT` property must be unique for each cluster in a domain.

`GMS_LISTENER_PORT`

The port number of the port on which the cluster listens for messages from GMS.

The default value is a reference to the `GMS_LISTENER_PORT-` cluster-name system property. By default, this system property is not set. In this situation, GMS selects a free port from the range that is defined by the properties `GMS_TCPSTARTPORT` and `GMS_TCPENDPORT`. By default, this range is 9090-9200. In most situations, the default behavior should suffice.

However, if GMS is not using multicast for broadcasting messages, the `GMS_LISTENER_PORT` property must specify a port number that is valid for all Payara Server instances in the cluster. To use the default value to meet this requirement, use a system property to set the port number individually for each instance.

For example, use the `create-system-properties` subcommand to create the system property `GMS_LISTENER_PORT-` cluster-name for the DAS. Then, for each instance in the cluster, set the `GMS_LISTENER_PORT-` cluster-name system property to the port number on which the instance listens for messages from GMS. The default value of the `GMS_LISTENER_PORT` property for the cluster references this system property.

`GMS_LOOPBACK`

Specifies whether an instance may receive from itself application-level messages that the instance broadcasts to the cluster.

Possible values are as follows:

`false`

The instance may not receive messages from itself (default).

`true`

The instance may receive messages from itself. Use this setting for testing an instance when the instance is the only instance in a cluster.

`GMS_MULTICAST_TIME_TO_LIVE`

The maximum number of iterations or transmissions that a multicast message for the following types of events can experience before the message is discarded:

- Group discovery
- Member heartbeats
- Membership changes

To match the configuration of the network on which the DAS and clustered instances are deployed, set this value as low as possible. To determine the lowest possible value for your system, use the `validate-multicast` subcommand.

A value of 0 ensures that multicast messages never leave the host from which they are broadcast.

A value of 1 might prevent the broadcast of messages between hosts on same subnet that are connected by a switch or a router.

The default is 4, which ensures that messages are successfully broadcast to all cluster members in networks where hosts are connected by switches or routers.

`GMS_TCPENDPORT`

The highest port number in the range from which GMS selects a free port if the `GMS_LISTENER_PORT-`cluster-name system property is not set. The default is 9200.

`GMS_TCPSTARTPORT`

The lowest port number in the range from which GMS selects a free port if the `GMS_LISTENER_PORT-`cluster-name system property is not set. The default is 9090.

`--gmsenabled`

Specifies whether GMS is enabled for the cluster.

Possible values are as follows:

`true`

GMS is enabled for the cluster (default).

When GMS is enabled for a cluster, GMS is started in each server instance in the cluster and in the DAS. The DAS participates in each cluster for which this option is set to `true`.

`false`

GMS is disabled for the cluster.

`--multicastaddress`

The address on which GMS listens for group events. This option must specify a multicast address in the range 224.0.0.0 through 239.255.255.255. The default is 228.9.XX.YY, where XX and YY are automatically generated independent values between 0 and 255.

`--multicastport`

The port number of communication port on which GMS listens for group events. This option must specify a valid port number in the range 2048-49151. The default is an automatically generated value in this range.

`--bindaddress`

The Internet Protocol (IP) address of the network interface to which GMS binds. This option must specify the IP address of a local network interface. The default is all public network interface addresses.

On a multihome machine, this option configures the network interface that is used for the GMS. A multihome machine possesses two or more network interfaces.

To specify an address that is valid for all Payara Server instances in the cluster, use a system property to set the address individually for each instance.

For example, use the `create-system-properties` subcommand to create the system property `GMS-BIND-INTERFACE-ADDRESS-` cluster-name. Then set the `--bindaddress` option of this subcommand to `${GMS-BIND-INTERFACE-ADDRESS-` cluster-name `}` to specify the system property.

Finally, for each instance in the cluster, set the `GMS-BIND-INTERFACE-ADDRESS-` cluster-name system property to the required network interface address on the instance's machine.

Operands

cluster-name

The name of the cluster.

The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Hyphen
  - Period
  - Underscore
- The name must be unique in the domain and must not be the name of another cluster, a named configuration, a Payara Server instance, or a node.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.
  If the `configure-jms-cluster` subcommand is to be used to configure a Message Queue cluster to provide JMS services to the Payara Server cluster, the length of the Payara Server cluster name is might be restricted:
- If `clustertype` is set to `enhanced` in the `configure-jms-cluster` subcommand, the name can be no longer than n–21 characters, where n is the maximum table name length allowed by the database.
- If `configstoretype` is set to `shareddb` in the `configure-jms-cluster` subcommand, the name can be no longer than n–19 characters, where n is the maximum table name length allowed by the database.

Examples

Example 1 Creating a Cluster

This example creates a cluster that is named `ltscluster` for which port 1169 is to be used for secure IIOP connections. Because the `--config` option is not specified, the cluster references a copy of the named configuration `default-config` that is named `ltscluster-config`.

```
asadmin> create-cluster
--systemproperties IIOP_SSL_LISTENER_PORT=1169
ltscluster
```

```
Command create-cluster executed successfully.
```

Example 2 Creating a Cluster With a List of URIs for Discovering the Cluster

This example creates a cluster that is named `tcpcluster`. In this example, GMS is not using multicast for broadcasting messages and multiple instances reside on the same host. Therefore, the `GMS_DISCOVERY_URI_LIST` property is set to the locations of the Payara Server instances to use for discovering the cluster. These instances reside on the host whose IP address is `10.152.23.224` and listen for GMS events on ports 9090, 9091, and 9092.

To distinguish colon (`:`) characters in URIs from separators in a property list, colons in URIs are escaped with single quote characters (`'`) and backslash (`\`) characters. For more information about escape characters in options for the `asadmin` utility, see the `asadmin` help page.

This example assumes that the port on which each instance listens for GMS messages is set independently for the instance through the `GMS_LISTENER_PORT-tcpcluster` system property.

```
asadmin> create-cluster --properties GMS_DISCOVERY_URI_LIST=
tcp'\\:'//10.152.23.224'\\:'9090,
tcp'\\:'//10.152.23.224'\\:'9091,
tcp'\\:'//10.152.23.224'\\:'9092 tcpcluster
Command create-cluster executed successfully.
```

Example 3 Creating a Cluster With a List of IP Addresses for Discovering the Cluster

This example creates a cluster that is named `ipcluster`. In this example, GMS is not using multicast for broadcasting messages and only one clustered instance resides on each host. Therefore, the `GMS_DISCOVERY_URI_LIST` property is set to the IP addresses of the hosts where instances to use for discovering the cluster are running. The cluster listens for messages from GMS on port 9090.

```
asadmin> create-cluster --properties 'GMS_DISCOVERY_URI_LIST=
10.152.23.225,10.152.23.226,10.152.23.227,10.152.23.228:
GMS_LISTENER_PORT=9090' ipcluster
Command create-cluster executed successfully.
```

Example 4 Creating a Cluster With a Generated List of Instances for Discovering the Cluster

This example creates a cluster that is named `gencluster`. In this example, GMS is not using multicast for broadcasting messages, one instance in the cluster is running on each host and the DAS is running on a separate host. Therefore, the `GMS_DISCOVERY_URI_LIST` property is set to the keyword `generate` to generate a list of instances to use for discovering the cluster. The cluster listens for messages from GMS on port 9090.

```
asadmin> create-cluster --properties 'GMS_DISCOVERY_URI_LIST=generate:
GMS_LISTENER_PORT=9090' gencluster
Command create-cluster executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

create-connector-connection-pool

Adds a connection pool with the specified connection pool name.

Synopsis

```
asadmin [asadmin-options] create-connector-connection-pool [--help]
--raname raname
--connectiondefinition connectiondefinitionname
[--steadypoolsize steadypoolsize]
[--maxpoolsize maxpoolsize]
[--maxwait maxwait]
[--poolresize poolresize]
```

```
[--idletimeout idletimeout]
[--isconnectvalidatereq={false|true}]
[--failconnection={false|true}]
[--leaktimeout=timeout]
[--leakreclaim={false|true}]
[--creationretryattempts=attempts]
[--creationretryinterval=interval]
[--lazyconnectionenlistment={false|true}]
[--lazyconnectionassociation={false|true}]
[--associatewiththread={false|true}]
[--matchconnections={true|false}]
[--maxconnectionusagecount=count]
[--validateatmostonceperiod=interval]
[--transactionsupport transactionsupport]
[--descrip[tion description]
[--ping {false|true}]
[--pooling {true|false}]
[--property (name=value)[:name=value]*]
poolname
```

Description

The `create-connector-connection-pool` subcommand defines a pool of connections to an enterprise information system (EIS). The named pool can be referred to by multiple connector resources. Each defined pool is instantiated at server startup, and is populated when accessed for the first time. If two or more connector resources point to the same connector connection pool, they are using the same pool of connections at run time. There can be more than one pool for a connection definition in a single resource adapter.

A connector connection pool with authentication can be created either by using a `--property` option to specify user, password, or other connection information, or by specifying the connection information in the XML descriptor file.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--associatewiththread`

Specifies whether a connection is associated with the thread to enable the thread to reuse the connection. If a connection is not associated with the thread, the thread must obtain a connection from the pool each time that the thread requires a connection. Possible values are as follows:

`false`

A connection is not associated with the thread (default).

`true`

A connection is associated with the thread.

`--connectiondefinition`

The name of the connection definition.

`--creationretryattempts`

Specifies the maximum number of times that the server retries to create a connection if the initial attempt fails.
Default value is 0, which specifies that the server does not retry to create the connection.

`--creationretryinterval`

Specifies the interval, in seconds, between successive attempts to create a connection.
If `--creationretryattempts` is 0, the `--creationretryinterval` option is ignored. Default value is 10.

`--description`

Text providing descriptive details about the connector connection pool.

`--failconnection`

If set to true, all connections in the pool are closed if a single validation check fails. This parameter is mandatory if the `--isconnectvalidatereq` option is set to true. Default value is false.

`--idletimeout`

The maximum time that a connection can remain idle in the pool. After this amount of time, the pool can close this connection. Default value is 300.

`--isconnectvalidatereq`

If the value is set to true, the connections will be checked to see if they are usable, before they are given out to the application. Default value is false.

`--lazyconnectionenlistment`

Specifies whether a resource to a transaction is enlisted only when a method actually uses the resource. Default value is false.

`--lazyconnectionassociation`

Specifies whether a physical connection should be associated with the logical connection only when the physical connection is used, and disassociated when the transaction is completed. Such association and dissociation enable the reuse of physical connections. Possible values are as follows:

`false`

A physical connection is associated with the logical connection even before the physical connection is used, and is not disassociated when the transaction is completed (default).

`true`

A physical connection is associated with the logical connection only when the physical connection is used, and disassociated when the transaction is completed. The `--lazyconnectionenlistment` option must also be set to `true`.

`--leakreclaim`

Specifies whether leaked connections are restored to the connection pool after leak connection tracing is complete. Possible values are as follows:

`false`

Leaked connections are not restored to the connection pool (default).

`true`

Leaked connections are restored to the connection pool.

`--leaktimeout`

Specifies the amount of time, in seconds, for which connection leaks in a connection pool are to be traced.
If connection leak tracing is enabled, you can use the Administration Console to enable monitoring of the JDBC connection pool to get statistics on the number of connection leaks. Default value is 0, which disables connection leak tracing.

`--matchconnections`

Specifies whether a connection that is selected from the pool should be matched with the resource adaptor. If all connections in the pool are identical, matching between connections and resource adapters is not required. Possible values are as follows:

`true`

A connection should be matched with the resource adaptor (default).

`false`

A connection should not be matched with the resource adaptor.

`--maxconnectionusagecount`

Specifies the maximum number of times that a connection can be reused.
When this limit is reached, the connection is closed. Default value is 0, which specifies no limit on the number of times that a connection can be reused.

`--maxpoolsize`

The maximum number of connections that can be created to satisfy client requests. Default value is 32.

`--maxwait`

The amount of time, in milliseconds, that a caller must wait before a connection is created, if a connection is not available. If set to 0, the caller is blocked indefinitely until a resource is available or until an error occurs. Default value is 60000.

`--ping`

A pool with this attribute set to true is contacted during creation (or reconfiguration) to identify and warn of any erroneous values for its attributes. Default value is false.

`--pooling`

When set to false, this attribute disables connection pooling. Default value is true.

`--poolresize`

Quantity by which the pool will scale up or scale down the number of connections. Scale up: When the pool has no free connections, pool will scale up by this quantity. Scale down: All the invalid and idle connections are removed, sometimes resulting in removing connections of quantity greater than this value. The number of connections that is specified by `--steadypoolsize` will be ensured. Possible values are from 0 to `MAX_INTEGER`. Default value is 2.

`--property`

Optional attribute name/value pairs for configuring the pool.

`--raname`

The name of the resource adapter.

`--steadypoolsize`

The minimum and initial number of connections maintained in the pool. Default value is 8.

`--transactionsupport`

Indicates the level of transaction support that this pool will have. Possible values are `XATransaction`, `LocalTransaction` and `NoTransaction`. This attribute can have a value lower than or equal to but not higher than the resource adapter's transaction support attribute. The resource adapter's transaction support attribute has an order of values, where `XATransaction` is the highest, and `NoTransaction` the lowest.

`--validateatmostonceperiod`

Specifies the time interval in seconds between successive requests to validate a connection at most once. Setting this attribute to an appropriate value minimizes the number of validation requests by a connection. Default value is 0, which means that the attribute is not enabled.

Operands

poolname

The name of the connection pool to be created.

Examples

Example 1 Creating a Connector Connection Pool

This example creates a new connector connection pool named `jms/qConnPool`.

```
asadmin> create-connector-connection-pool --raname jmsra
--connectiondefinition jakarta.jms.QueueConnectionFactory --steadypoolsize 20
```

```
--maxpoolsize 100 --poolresize 2 --maxwait 60000 jms/qConnPool
Command create-connector-connection-pool executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- `ping-connection-pool`

create-connector-resource

Registers the connector resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] create-connector-resource [--help]
--poolname connectorConnectionPoolName
[--enabled={true|false}]
[--description description]
[--objecttype ovjecttype]
[--property (name=value)[:name=value]*]
[--target target]
jndi_name
```

Description

The `create-connector-resource` subcommand registers the connector resource with the specified JNDI name.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--poolname`

The name of the connection pool. When two or more resource elements point to the same connection pool element, they use the same pool connections at runtime.

`--enabled`

This option determines whether the resource is enabled at runtime. The default value is true.

`--objecttype`

Defines the type of the connector resource. Default is user. Allowed values are:

`system-all`

A system resource for all server instances and the domain administration server (DAS).

`system-admin`

A system resource only for the DAS.

`system-instance`

A system resource for all server instances only.

`user`

A user resource.

`--description`

Text providing details about the connector resource.

`--property`

Optional attribute name value pairs for configuring the resource.

`--target`

This option specifies the ending location of the connector resources. Valid targets are:

`server`

Creates the connector resource in the default server instance. This is the default value.

`domain`

Creates the connector resource in the domain.

cluster_name

Creates the connector resource in every server instance in the cluster.

instance_name

Creates the connector resource in the specified server instance.

The resource is always created for the domain as a whole, but the `resource-ref` for

> the resource is only created for the specified `--target`. This means that although the resource is defined at the domain level, it is only available at the specified target level. Use the `create-resource-ref` subcommand to refer to the resource in multiple targets if needed.

Operands

jndi_name

The JNDI name of this connector resource.

Examples

Example 1 Creating a Connector Resource

This example creates a connector resource named `jms/qConnFactory`.

```
asadmin> create-connector-resource --poolname jms/qConnPool
--description "sample connector resource" jms/qConnFactory
Command create-connector-resource executed successfully
```

Example 2 Using the create-connector-resource subcommand

This example shows the usage of this subcommand.

```
asadmin> create-connector-resource --target server --poolname jms/qConnPool
--description "sample connector resource" jms/qConnFactory
Command create-connector-resource executed successfully
```

Where `jms/qConnFactory` is the sample connector resource that is created.

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-connector-security-map

Creates a security map for the specified connector connection pool.

Synopsis

```
asadmin [asadmin-options] create-connector-security-map [--help]
--poolname connector_connection_pool_name
[--principals principal-name1[,principal-name2]*]
[--usergroups user-group1[,user-group2]*]
[--mappedusername user-name]
mapname
```

Description

The `create-connector-security-map` subcommand creates a security map for the specified connector connection pool. If the security map is not present, a new one is created. This subcommand can also map the caller identity of the application (principal or user group) to a suitable enterprise information system (EIS) principal in container-managed authentication scenarios. The EIS is any system that holds the data of an organization. It can be a mainframe, a messaging system, a database system, or an application. One or more named security maps can be associated with a connector connection pool. The connector security map configuration supports the use of the wild card asterisk (*) to indicate all users or all user groups.

To specify the EIS password, you can add the `AS_ADMIN_MAPPEDPASSWORD` entry to the password file, then specify the file by using the `--passwordfile` `asadmin` utility option.

For this subcommand to succeed, you must have first created a connector connection pool using the `create-connector-connection-pool` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--poolname`

Specifies the name of the connector connection pool to which the security map belongs.

`--principals`

Specifies a list of backend EIS principals. More than one principal can be specified using a comma-separated list. Use either the `--principals` or `--usergroups` options, but not both in the same command.

`--usergroups`

Specifies a list of backend EIS user group. More than one user groups can be specified using a comma separated list. Use either the `--principals` or `--usergroups` options, but not both in the same command.

`--mappedusername`

Specifies the EIS username.

Operands

mapname

The name of the security map to be created.

Examples

Example 1 Creating a Connector Security Map

This example creates `securityMap1` for the existing connection pool named `connector-pool1`.

```
asadmin> create-connector-security-map --poolname connector-pool1
--principals principal1,principal2 --mappedusername backend-username securityMap1
Command create-connector-security-map executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `delete-connector-security-map`,
- `list-connector-security-maps`,
- `update-connector-security-map`

create-connector-work-security-map

Creates a work security map for the specified resource adapter.

Synopsis

```
asadmin [asadmin-options] create-connector-work-security-map [--help]
--raname raname
[--principalsmap eis-principal1=principal_name1[, eis-principal2=principal_name2]*
|--groupsmap eis-group1=server-group1[, eis-group2=server-group2]*}
```

```
[--description description]
mapname
```

Description

The `create-connector-work-security-map` subcommand maps the caller identity of the work submitted by the resource adapter EIS principal or EIS user group to a suitable principal or user group in the Payara Server security domain. One or more work security maps may be associated with a resource adapter. The connector work security map configuration supports the use of the wild card asterisk (`*`) to indicate all users or all user groups.

The enterprise information system (EIS) is any system that holds the data of an organization. It can be a mainframe, a messaging system, a database system, or an application.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--description`

Text providing descriptive details about the connector work security map.

`--groupsmap`

Specifies a map of the backend EIS user group to the Payara Server user group. Use a comma-separated list to specify more than one mapping. Use either the `--principalsmap` option or the `--groupsmap` option, but not both.

`--principalsmap`

Specifies a map of the backend EIS principal to the Payara Server principal. Use a comma-separated list to specify more than one mapping. Use either the `--principalsmap` option or the `--groupsmap` option, but not both.

`--raname`

Indicates the connector module name, which is the name of the resource adapter.

Operands

mapname

The name of the work security map to be created.

Examples

Example 1 Creating a Connector Work Security Map (Principal)

This example creates connector work security map `workSecurityMap1` that maps the backend EIS principal to the Payara Server principal.

```
asadmin create-connector-work-security-map --raname my-resource-adapter
--principalsmap eis-principal-1=server-principal-1,eis-principal-2
=server-principal-2,eis-principal-3=server-principal-1
workSecurityMap1
Command create-connector-work-security-map executed successfully.
```

Example 2 Creating a Connector Work Security Map (Group)

This example creates connector work security map `workSecurityMap2` that maps the backend EIS user group to the Payara Server user group.

```
asadmin create-connector-work-security-map --raname my-resource-adapter
--groupsmap eis-group-1=server-group-1,eis-group-2=server-group-2,
eis-group-3=server-group-1 workSecurityMap2
Command create-connector-work-security-map executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-context-service

The `create-context-service` asadmin command creates a context service resource.

Synopsis

```
asadmin [asadmin-options] create-context-service [--help]
        [--enabled={false|true}]
        [--contextinfoenabled={false|true}]
        [--contextinfo={Classloader|JNDI|Security|WorkArea}]]
        [--description description]
        [--property property]
        [--target target]
```

```
        jndi_name
```

Description

The `create-context-service` subcommand creates a context service resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Determines whether the resource is enabled at runtime.

The default value is `true`.

`--contextinfoenabled`

Determines whether container contexts are propagated to threads. If set to `true`, the contexts specified in the `--contextinfo` option are propagated. If set to `false`, no contexts are propagated and the `--contextinfo` option is ignored.

The default value is `true`.

`--contextinfo`

Specifies individual container contexts to propagate to threads. Valid values are Classloader, JNDI, Security, and WorkArea. Values are specified in a comma-separated list and are case-insensitive.

All contexts are propagated by default.

`--description`

Descriptive details about the resource.

`--property`

Optional attribute name/value pairs for configuring the resource.

Payara Server does not define any additional properties for this resource. Moreover, this resource does not currently use any additional properties.

`--target`

Specifies the target for which you are creating the resource. Valid targets are:

`server`

Creates the resource for the default server instance.

This is the default value.

`domain`

Creates the resource for the domain.

cluster_name

Creates the resource for every server instance in the specified cluster.

instance_name

Creates the resource for the specified server instance.

Operands

jndi_name

The JNDI name of this resource.

Examples

Example 1 Creating a Context Service Resource

This example creates a context service resource named `concurrent/myContextService`.

```
asadmin> create-context-service --description "context example" --property name=Jose
--target domain concurrent/myContextService
Context service concurrent/myContextService created successfully.
Command create-context-service executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `delete-context-service`,
- `list-context-services`

create-custom-resource

Creates a custom resource.

Synopsis

```
asadmin [asadmin-options] create-custom-resource [--help]
--restype type --factoryclass classname
[--enabled={true|false}] [--description text]
[--property (name=value)[:name=value]*] jndi-name
[--target target]
```

Description

The `create-custom-resource` subcommand creates a custom resource. A custom resource specifies a custom server-wide resource object factory that implements the `javax.naming.spi.ObjectFactory` interface.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The target on which the custom resource you are creating will be available. Valid values are:

`server`

The resource will be available on the default server instance and all domains hosted on the instance. This is the default value.

`domain`

The resource will be available on the specified domain only.

cluster_name

The resource will be available on every server instance in the cluster.

instance_name

The resource will be available on the specified server instance only.

The resource is always created for the domain as a whole, but the `resource-ref` for the resource is only created for the specified `--target`. This means that although the resource is defined at the domain level, it is only available at the specified target level. Use the `create-resource-ref` subcommand to refer to the resource in multiple targets if needed.

`--restype`

The type of custom resource to be created. Specify a fully qualified type definition, for example `javax.naming.spi.ObjectFactory`. The resource type definition follows the format, xxx`.`xxx.

`--factoryclass`

Factory class name for the custom resource. This class implements the `javax.naming.spi.ObjectFactory` interface.

`--enabled`

Determines whether the custom resource is enable at runtime. Default is true.

`--description`

Text providing details about the custom resource. This description is a string value and can include a maximum of 250 characters.

`--property`

Optional attribute name/value pairs for configuring the resource.

Operands

jndi-name

The JNDI name of this resource.

Examples

Example 1 Creating a Custom Resource

This example creates a custom resource.

```
asadmin> create-custom-resource --restype topic
--factoryclass com.imq.topic
Custom Resource mycustomresource created.
Command create-custom-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `delete-custom-resource`,
- `list-custom-resources`,

- `create-resource-ref`

create-deployment-group

Creates a Payara Server deployment group.

Synopsis

```
asadmin [asadmin-options] create-deployment-group [--help]
name
```

Description

The `create-deployment-group` subcommand creates a Payara Server deployment group. Initially the deployment group contains no Payara Server instances, applications, or resources.

To add instances to the cluster, use the `add-instance-to-deployment-group`.

- Deploying applications by using the `deploy` subcommand
- Creating resources by using subcommands such as `create-jdbc-resource`
- Creating references to applications that are already deployed in other targets by using the `create-application-ref` subcommand
- Creating references to resources that are already created in other targets by using the `create-resource-ref` subcommand

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

name

The name of the deployment group.

The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters

    - Uppercase letters
    - Numbers
    - Hyphen
    - Period
    - Underscore
- The name must be unique in the domain and must not be the name of another cluster, a named configuration, a Payara Server instance, or a node.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.

Examples

Example 1 Creating a Deployment Group

This example creates a deployment group that is named `test-dgroup`:

```
asadmin create-deployment-group test-dgroup
Command create-deployment-group executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

create-domain

Creates a domain.

Synopsis

```
asadmin [asadmin-options] create-domain [--help]
[--adminport adminport]
[--instanceport instanceport]
[--portbase portbase]
[--template template-name]
[--domaindir domaindir]
[--savemasterpassword={false|true}]
[--masterpasswordlocation filepath]
[--usemasterpassword={false|true}]
[--domainproperties (name=value)[:name=value]*]
[--keytooloptions (name=value)[:name=value]*]
[--savelogin={false|true}]
[--checkports={true|false}]
[--nopassword={false|true}]
[--hazelcastdasport hazelcastdasport]
[--hazelcaststartport hazelcaststartport]
[--hazelcastautoincrement hazelcastautoincrement]
domain-name
```

Description

The `create-domain` subcommand creates a Payara Server domain. A domain in Payara Server is an administrative namespace that complies with the Jakarta EE standard. Every domain has a configuration, which is stored in a set of files. Any number of domains, each of which has a distinct administrative identity, can be created in a given installation of Payara Server. A domain can exist independently of other domains.

Any user who has access to the `asadmin` utility on a given system can create a domain and store its configuration in a folder of the user's choosing. By default, the domain configuration is created in the default directory for domains. You can override this location to store the configuration elsewhere.

If domain customizers are found in JAR files in the `as-install/modules` directory when the `create-domain` subcommand is run, the customizers are processed. A domain customizer is a class that implements the `DomainInitializer` interface.

The `create-domain` subcommand creates a domain with a single administrative user specified by the

`asadmin` utility option `--user`. If the `--user` option is not specified, and the `--nopassword` option is set to true, the default administrative user, `admin`, is used. If the `--nopassword` option is set to false (the default), a username is required. In this case, if you have not specified the user name by using the `--user` option, you are prompted to do so.

You choose an appropriate profile for the domain, depending on the applications that you want to run on your new domain. You can choose the developer, cluster, or enterprise profile for the domain you create. This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--adminport`

The HTTP port or the HTTPS port for administration. This port is the port in the URL that you specify in your web browser to manage the domain, for example, `http://localhost:4949`. The `--adminport` option cannot be used with the `--portbase` option. The default value is 4848.
The `--adminport` option overrides the `domain.adminPort` property of the `--domainproperties` option.

`--instanceport`

The domain provides services so that applications can run when deployed. This HTTP port specifies where the web application context roots are available for a web browser to connect to. This port is a positive integer and must be available at the time of domain creation. The `--instanceport` option cannot be used with the `--portbase` option. The default value is 8080.
The `--instanceport` option overrides the `domain.instancePort` property of the `--domainproperties` option.

`--portbase`

Determines the number with which port assignments should start. A domain uses a certain number of ports that are statically assigned. The portbase value determines where the assignment should start. The values for the ports are calculated as follows:

- Administration port: portbase + 48
- HTTP listener port: portbase + 80
- HTTPS listener port: portbase + 81
- JMS port: portbase + 76
- IIOP listener port: portbase + 37
- Secure IIOP listener port: portbase + 38
- Secure IIOP with mutual authentication port: portbase + 39
- JMX port: portbase + 86

- JPDA debugger port: portbase + 9
- Felix shell service port for OSGi module management: portbase + 66
  When the `--portbase` option is specified, the output of this subcommand includes a complete list of used ports.
  The `--portbase` option cannot be used with the `--adminport`, `--instanceport`, or the `--domainproperties` option.

`--template`

The file name, including a relative or absolute path, of a domain configuration template to use for creating the domain. If a relative path is specified, the subcommand appends the path to the as-install`/lib/templates` directory to locate the file. If it is an absolute pathname, the subcommand locates the file in the specified path.
This option enables domains of different types to be created and custom domain templates to be defined.

`--domaindir`

The directory where the domain is to be created. If specified, the path must be accessible in the filesystem. If not specified, the domain is created in the default domain directory, as-install`/domains`.

`--savemasterpassword`

Setting this option to `true` allows the master password to be written to the file system. If this option is `true`, the `--usemasterpassword` option is also true, regardless of the value that is specified on the command line. The default value is `false`.
A master password is really a password for the secure key store. A domain is designed to keep its own certificate (created at the time of domain creation) in a safe place in the configuration location. This certificate is called the domain's SSL server certificate. When the domain is contacted by a web browser over a secure channel (HTTPS), this certificate is presented by the domain. The master password is supposed to protect the store (a file) that contains this certificate. This file is called `keystore.jks` and is created in the configuration directory of the domain created. If however, this option is chosen, the master password is saved on the disk in the domain's configuration location. The master password is stored in a file called `master-password`, which is a Java JCEKS type keystore. The reason for using the `--savemasterpassword` option is for unattended system boots. In this case, the master password is not prompted for when the domain starts because the password will be extracted from this file.
It is best to create a master password when creating a domain, because the master password is used by the `start-domain` subcommand. For security purposes, the default setting should be false, because saving the master password on the disk is an insecure practice, unless file system permissions are properly set. If the master password is saved, then `start-domain` does not prompt for it. The master password gives an extra level of security to the environment.

`--masterpasswordlocation`

Only applies if the `--savemasterpassword` parameter is set to true. This parameter receives an absolute filepath that the master password will be saved to.
If this parameter is omitted, the default location will be used.

`--usemasterpassword`

Specifies whether the key store is encrypted with a master password that is built into the system

or a user-defined master password.
If `false` (default), the keystore is encrypted with a well-known password that is built into the system. Encrypting the keystore with a password that is built into the system provides no additional security.
If `true`, the subcommand obtains the master password from the `AS_ADMIN_MASTERPASSWORD` entry in the password file or prompts for the master password. The password file is specified in the `--passwordfile` option of the `asadmin`utility.
If the `--savemasterpassword` option is `true`, this option is also true, regardless of the value that is specified on the command line.

`--domainproperties`

Setting the optional name/value pairs overrides the default values for the properties of the domain to be created. The list must be separated by the colon (:) character. The `--portbase` options cannot be used with the `--domainproperties` option. The following properties are available:

`domain.adminPort`

This property specifies the port number of the HTTP port or the HTTPS port for administration. This port is the port in the URL that you specify in your web browser to manage the instance, for example, `http://localhost:4949`. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.
The `domain.adminPort` property is overridden by the `--adminport` option.

`domain.instancePort`

This property specifies the port number of the port that is used to listen for HTTP requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.
The `domain.instancePort` property is overridden by `--instanceport` option.

`domain.jmxPort`

This property specifies the port number on which the JMX connector listens. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`http.ssl.port`

This property specifies the port number of the port that is used to listen for HTTPS requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`java.debugger.port`

This property specifies the port number of the port that is used for connections to the Java Platform Debugger Architecture (JPDA) debugger. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`jms.port`

This property specifies the port number for the Java Message Service provider. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`orb.listener.port`

This property specifies the port number of the port that is used for IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`orb.mutualauth.port`

This property specifies the port number of the port that is used for secure IIOP connections with client authentication. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`orb.ssl.port`

This property specifies the port number of the port that is used for secure IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`osgi.shell.telnet.port`

This property specifies the port number of the port that is used for connections to the Apache Felix Remote Shell. This shell uses the Felix shell service to interact with the OSGi module management subsystem. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`hazelcast.das.port`

This property specifies the port number of the port the DAS use to run the Data Grid (Hazelcast) on. The `hazelcast.das.port` property is overridden by the `--hazelcastdasport` option.

`hazelcast.start.port`

This property specifies the port number of the port the other Payara Server instances use to run the Data Grid (Hazelcast) on. The `hazelcast.start.port` property is overridden by the `--hazelcaststartport` option.

`hazelcast.auto.increment`

This property specifies whether to use the next unoccupied port that is available starting with the start port. When auto-increment is turned off an occupied start port results in a startup failure instead. The `hazelcast.auto.increment` property is overridden by the `--hazelcastautoincrement` option.

`--keytooloptions`

Specifies an optional list of name-value pairs of keytool options for a self-signed server certificate. The certificate is generated during the creation of the domain. Each pair in the list must be separated by the colon (:) character.

Allowed options are as follows:

`CN`

Specifies the common name of the host that is to be used for the self-signed certificate. This option name is case insensitive.

By default, the name is the fully-qualified name of the host where the `create-domain` subcommand is run.

`--savelogin`

If set to true, this option saves the administration user name and password. Default value is false. The username and password are stored in the `.asadminpass` file in user's home directory. A domain can only be created locally. Therefore, when using the `--savelogin` option, the host name saved in `.asadminpass` is always `localhost`. If the user has specified default administration port while creating the domain, there is no need to specify `--user`, `--passwordfile`, `--host`, or `--port` on any of the subsequent `asadmin` remote commands. These values will be obtained automatically.

When the same user creates multiple domains that have the same administration port number on the same or different host (where the home directory is NFS mounted), the subcommand does not ask if the password should be overwritten. The password will always be overwritten.

`--checkports`

Specifies whether to check for the availability of the administration, HTTP, JMS, JMX, and IIOP ports. The default value is `true`.

`--nopassword`

Specifies whether the administrative user will have a password. If false (the default), the password is specified by the `AS_ADMIN_PASSWORD` entry in the `asadmin` password file (set by using the `--passwordfile` option). If false and the `AS_ADMIN_PASSWORD` is not set, you are prompted for the password.

If `true`, the administrative user is created without a password.

If a username for the domain is not specified by using the `--user` option, and the `--nopassword` option is set to `true`, the default username, `admin`, is used.

`--hazelcastdasport`

The port to run the Data Grid (Hazelcast) on for the DAS. If this port is busy and auto-increment option is enabled, the port specified will be incremented until a valid port is found.

The `--hazelcastdasport` option cannot be used with the `--portbase` option.

The `--hazelcastdasport` option overrides the `hazelcast.das.port` property of the `--domainproperties` option. The default value is `4900`.

`--hazelcaststartport`

The port the other Payara Server instances use to run the Data Grid (Hazelcast) on.

If this port is busy and the `--hazelcastautoincrement` option is enabled, the port specified will be incremented until a valid port is found. The `--hazelcaststartport` option cannot be used with the `--portbase` option. The `--hazelcaststartport` option overrides the `hazelcast.start.port` property of the `--domainproperties` option.

The default value is `5900`.

If the port base options are used, the values for the ports of the Hazelcast DAS start port and the Hazelcast start Port are calculated as follows:
Hazelcast DAS start port = `portbase + 49` and Hazelcast Instance start port= `portbase + 59`.

`--hazelcastautoincrement`

By default, the Data Grid (Hazelcast) uses the next unoccupied port that is available starting with the start port.

When auto-increment is turned off an occupied start port results in a startup failure instead. The `--hazelcastautoincrement` option overrides the `hazelcast.auto.inrement` property of the `--domainproperties` option.

The default value is `5900`.

Operands

domain-name

The name of the domain to be created. The name may contain only ASCII characters and must be a valid directory name for the operating system on the host where the domain is created.

Examples

Example 1 Creating a Domain

This example creates a domain named `domain4`.

```
asadmin> create-domain --adminport 4848 domain4
Enter admin user name [Enter to accept default "admin" / no password]>
Using port 4848 for Admin.
Using default port 8080 for HTTP Instance.
Using default port 7676 for JMS.
Using default port 3700 for IIOP.
Using default port 8181 for HTTP_SSL.
Using default port 3820 for IIOP_SSL.
Using default port 3920 for IIOP_MUTUALAUTH.
Using default port 8686 for JMX_ADMIN.
Using default port 6666 for OSGI_SHELL.
Distinguished Name of the self-signed X.509 Server Certificate is:
[CN=sr1-usca-22,OU=Payara,O=Payara Foundation,L==Great Malvern,ST=Worcestershire,C=UK]
No domain initializers found, bypassing customization step
Domain domain4 created.
Domain domain4 admin port is 4848.
Domain domain4 allows admin login as user "admin" with no password.
Command create-domain executed successfully.
```

Example 2 Creating a Domain in an Alternate Directory

This example creates a domain named `sampleDomain` in the `/home/someuser/domains` directory.

```
asadmin> create-domain --domaindir /home/someuser/domains --adminport 7070
--instanceport 7071 sampleDomain
Enter admin user name [Enter to accept default "admin" / no password]>
Using port 7070 for Admin.
Using port 7071 for HTTP Instance.
Using default port 7676 for JMS.
Using default port 3700 for IIOP.
Using default port 8181 for HTTP_SSL.
Using default port 3820 for IIOP_SSL.
Using default port 3920 for IIOP_MUTUALAUTH.
Using default port 8686 for JMX_ADMIN.
Using default port 6666 for OSGI_SHELL.
Enterprise ServiceDistinguished Name of the self-signed X.509 Server Certificate is:
[CN=sr1-usca-22,OU=Payara,O=Payara Foundation,L==Great Malvern,ST=Worcestershire,C=UK]
No domain initializers found, bypassing customization step
Domain sampleDomain created.
Domain sampleDomain admin port is 7070.
Domain sampleDomain allows admin login as user "admin" with no password.
Command create-domain executed successfully.
```

Example 3 Creating a Domain and Saving the Administration User Name and Password

This example creates a domain named `myDomain` and saves the administration username and password.

```
asadmin> create-domain --adminport 8282 --savelogin=true myDomain
Enter the admin password [Enter to accept default of no password]>
Enter the master password [Enter to accept default password "changeit"]>
Using port 8282 for Admin.
Using default port 8080 for HTTP Instance.
Using default port 7676 for JMS.
Using default port 3700 for IIOP.
Using default port 8181 for HTTP_SSL.
Using default port 3820 for IIOP_SSL.
Using default port 3920 for IIOP_MUTUALAUTH.
Using default port 8686 for JMX_ADMIN.
Using default port 6666 for OSGI_SHELL.
Enterprise ServiceDistinguished Name of the self-signed X.509 Server Certificate is:
[CN=sr1-usca-22,OU=Payara,O=Payara Foundation,L==Great Malvern,ST=Worcestershire,C=UK]
No domain initializers found, bypassing customization step
Domain myDomain created.
Domain myDomain admin port is 8282.
Domain myDomain allows admin login as user "admin" with no password.
Login information relevant to admin user name [admin]
for this domain [myDomain] stored at
[/home/someuser/.asadminpass] successfully.
Make sure that this file remains protected.
```

```
Information stored in this file will be used by
asadmin commands to manage this domain.
Command create-domain executed successfully.
```

Example 4 Creating a Domain and Designating the Certificate Host

This example creates a domain named `domain5`. The common name of the host that is to be used for the self-signed certificate is `trio`.

```
asadmin> create-domain --adminport 9898 --keytooloptions CN=trio domain5
Enter the admin password [Enter to accept default of no password]>
Enter the master password [Enter to accept default password "changeit"]>
Using port 9898 for Admin.
Using default port 8080 for HTTP Instance.
Using default port 7676 for JMS.
Using default port 3700 for IIOP.
Using default port 8181 for HTTP_SSL.
Using default port 3820 for IIOP_SSL.
Using default port 3920 for IIOP_MUTUALAUTH.
Using default port 8686 for JMX_ADMIN.
Using default port 6666 for OSGI_SHELL.
Distinguished Name of the self-signed X.509 Server Certificate is:
[CN=trio,OU=Payara,O=Payara Foundation.,L==Great Malvern,ST=Worcestershire,C=UK]
No domain initializers found, bypassing customization step
Domain domain5 created.
Domain domain5 admin port is 9898.
Domain domain5 allows admin login as user "admin" with no password.
Command create-domain executed successfully.
```

Example 5 Creating a Domain with Hazelcast specific domain properties

This example creates a domain named `testDomain` with the port to run Hazelcast on for the DAS set to 7900 and the port the other Payara Server instances use to run Hazelcast set to 8900.

```
asadmin> asadmin create-domain --hazelcastdasport 7900 --hazelcaststartport 8900
testDomain
Using default port 4848 for Admin.
Using default port 8080 for HTTP Instance.
Using default port 7676 for JMS.
Using default port 3700 for IIOP.
Using default port 8181 for HTTP_SSL.
Using default port 3820 for IIOP_SSL.
Using default port 3920 for IIOP_MUTUALAUTH.
Using default port 8686 for JMX_ADMIN.
Using default port 6666 for OSGI_SHELL.
Using default port 9009 for JAVA_DEBUGGER.
Using port 7900 for Hazelcast DAS.
Using port 8900 for Hazelcast Start.
Distinguished Name of the self-signed X.509 Server Certificate is:
```

```
[CN=dev,OU=Payara,O=Payara Foundation,L=Great Malvern,ST=Worcestershire,C=UK]
Distinguished Name of the self-signed X.509 Server Certificate is:
[CN=dev-instance,OU=Payara,O=Payara Foundation,L=Great Malvern,ST=Worcestershire,C=UK]
Domain testDomain created.
Domain testDomain admin port is 4848.
Domain testDomain allows admin login as user "admin" with no password.
Command create-domain executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-file-user

Creates a new file user.

Synopsis

```
asadmin [asadmin-options] create-file-user [--help]
[--authrealmnameauth_realm_name]
[--target target
[--groups user_groups[:user_groups]*] user_name
```

Description

The `create-file-user` subcommand creates an entry in the keyfile with the specified username, password, and groups. Multiple groups can be created by separating them with a colon (`:`). If auth_realm_name is not specified, an entry is created in the keyfile for the default realm.

If auth_realm_name is specified, an entry is created in the keyfile using the `auth_realm_name`.

You can use the `--passwordfile` option of the `asadmin` command to specify the password for the user. The password file entry must be of the form `AS_ADMIN_USERPASSWORD`=user-password.

If a password is not provided, this subcommand fails if secure administration is enabled and the user being created is an administrative user.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This is the name of the target on which the command operates. The valid targets are config, instance, cluster, or server. By default, the target is the server.

`--groups`

This is the group associated with this file user.

`--authrealmname`

The name of the realm in which the new user is created. If you do not specify this option, the user is created in the "file" realm.

Operands

user_name

This is the name of file user to be created.

Examples

Example 1 Creating a User in the File Realm

This example creates a file realm user named `sample_user`. It is assumed that an authentication realm has already been created using the `create-auth-realm` subcommand.

```
asadmin> create-file-user
--groups staff:manager
--authrealmname auth-realm1 sample_user
Command create-file-user executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-http-health-checker

create-http-lb-config

create-http-lb-ref

create-http-lb

create-http-listener

Adds a new HTTP network listener socket.

Synopsis

```
asadmin [asadmin-options] create-http-listener [--help]
--listeneraddress address
--listenerport listener-port
{--default-virtual-server} virtual-server
[--servername server-name]
[--acceptorthreads acceptor-threads]
[--securityenabled={false|true}]
[--enabled={true|false}]
[--target target]
listener-id
```

Description

The `create-http-listener` subcommand creates an HTTP network listener. This subcommand is supported in remote mode only.

If you edit the special HTTP network listener named `admin-listener`, you must

restart the server for the changes to take effect. The Administration Console does not tell you that a restart is required in this case.

This subcommand is provided for backward compatibility and as a shortcut for creating network listeners that use the HTTP protocol. Behind the scenes, this subcommand creates a network listener and its associated protocol, transport, and HTTP configuration.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--listeneraddress`

The IP address or the hostname (resolvable by DNS).

`--listenerport`

The port number to create the listen socket on. Legal values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges. Configuring an SSL listen socket to listen on port 443 is recommended.

`--default-virtual-server`

The ID attribute of the default virtual server for this listener.

`--servername`

Tells the server what to put in the host name section of any URLs it sends to the client. This affects URLs the server automatically generates; it doesn't affect the URLs for directories and files stored in the server. This name should be the alias name if your server uses an alias. If a colon and port number are appended, that port will be used in URLs that the server sends to the client.

`--acceptorthreads`

The number of acceptor threads for the listener socket. The recommended value is the number of processors in the machine. The default value is 1.

`--securityenabled`

If set to true, the HTTP listener runs SSL. You can turn SSL2 or SSL3 ON or OFF and set ciphers using an SSL element. The security setting globally enables or disables SSL by making certificates available to the server instance. The default value is `false`.

`--enabled`

If set to true, the listener is enabled at runtime. The default value is `true`.

`--target`

Creates the HTTP listener only on the specified target. Valid values are as follows:

`server`

Creates the HTTP listener on the default server instance. This is the default value.

configuration-name

Creates the HTTP listener in the specified configuration.

cluster-name

Creates the HTTP listener on all server instances in the specified cluster.

standalone-instance-name

Creates the HTTP listener on the specified standalone server instance.

Operands

listener-id

The listener ID of the HTTP network listener.

Examples

Example 1 Creating an HTTP Network Listener

The following command creates an HTTP network listener named `sampleListener` that uses a non-default number of acceptor threads and is not enabled at runtime:

```
asadmin> create-http-listener --listeneraddress 0.0.0.0 --listenerport 7272
--default-virtual-server server --servername host1.sun.com --acceptorthreads 100
--securityenabled=false --enabled=false sampleListener
Command create-http-listener executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

create-http-redirect

Adds a new HTTP redirect.

Synopsis

```
asadmin [asadmin-options] create-http-redirect [--help]
[--redirect-port redirect-port]
[--secure-redirect={false|true}]
[--target target]
protocol-name
```

Description

The `create-http-redirect` subcommand creates an HTTP redirect. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--redirect-port`

Port number for redirects. If the HTTP listener is supporting non-SSL requests, and a request is received for which a matching security-constraint requires SSL transport, Payara Server automatically redirects the request to this port number.

`--secure-redirect`

If set to true, the HTTP redirect runs SSL. The default value is `false`.

`--target`

Creates the HTTP redirect only on the specified target. Valid values are as follows:

`server`

Creates the HTTP redirect on the default server instance. This is the default value.

configuration-name

Creates the HTTP redirect in the specified configuration.

cluster-name

Creates the HTTP redirect on all server instances in the specified cluster.

standalone-instance-name

Creates the HTTP redirect on the specified standalone server instance.

Operands

protocol-name

The name of the protocol to which to apply the redirect.

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `delete-http-redirect`

create-http

Sets HTTP parameters for a protocol.

Synopsis

```
asadmin [asadmin-options] create-http [--help]
--default-virtual-server virtual-server
[--request-timeout-seconds timeout]
[--timeout-seconds timeout]
[--max-connection max-keepalive]
[--dns-lookup-enabled={false|true}]
[--servername server-name]
[--target target]
protocol-name
```

Description

The `create-http` subcommand creates a set of HTTP parameters for a protocol, which in turn configures one or more network listeners. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--default-virtual-server`

The ID attribute of the default virtual server for the associated network listeners.

`--request-timeout-seconds`

The time in seconds at which the request times out. If you do not set this option, the request times out in 30 seconds.

`--timeout-seconds`

The maximum time in seconds for which a keep alive connection is kept open. A value of `0` or less means keep alive connections are kept open indefinitely. The default is `30`.

`--max-connection`

The maximum number of HTTP requests that can be pipelined until the connection is closed by the server. Set this property to `1` to disable HTTP/1.0 keep-alive, as well as HTTP/1.1 keep-alive and pipelining. The default is `256`.

`--dns-lookup-enabled`

If set to `true`, looks up the DNS entry for the client. The default is `false`.

`--servername`

Tells the server what to put in the host name section of any URLs it sends to the client. This affects URLs the server automatically generates; it doesn't affect the URLs for directories and files stored in the server. This name should be the alias name if your server uses an alias. If a colon and port number are appended, that port will be used in URLs that the server sends to the client.

`--target`

Creates the set of HTTP parameters only on the specified target. Valid values are as follows:

`server`

Creates the set of HTTP parameters on the default server instance. This is the default value.

configuration-name

Creates the set of HTTP parameters in the specified configuration.

cluster-name

Creates the set of HTTP parameters on all server instances in the specified cluster.

standalone-instance-name

Creates the set of HTTP parameters on the specified standalone server instance.

Operands

protocol-name

The name of the protocol to which this HTTP parameter set applies.

Examples

Example 1 Using the `create-http` Subcommand

The following command creates an HTTP parameter set for the protocol named `http-1`:

```
asadmin> create-http --timeout-seconds 60 --default-virtual-server server http-1
Command create-http executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `create-network-listener`,
- `create-protocol`,
- `create-virtual-server`,
- `delete-http`

create-iiop-listener

Adds an IIOP listener.

Synopsis

```
asadmin [asadmin-options] create-iiop-listener [--help]
--listeneraddress address
[--iiopport iiop-port-number] [--securityenabled={false|true}] [--
enabled={true|false}]
[--property (name=value)[:name=value]*]
[--target target] listener_id
```

Description

The `create-iiop-listener` subcommand creates an IIOP listener. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--listeneraddress`

Either the IP address or the hostname (resolvable by DNS).

`--iiopport`

The IIOP port number. The default value is 1072.

`--securityenabled`

If set to true, the IIOP listener runs SSL. You can turn SSL2 or SSL3 ON or OFF and set ciphers using an SSL element. The security setting globally enables or disables SSL by making certificates available to the server instance. The default value is `false`.

`--enabled`

If set to true, the IIOP listener is enabled at runtime. The default value is `true`.

`--property`

Optional attribute name/value pairs for configuring the IIOP listener.

`--lazyInit`

Whether to lazily initialise the listener. The default value is `false`.

`--target`

Specifies the target for which you are creating the IIOP listener. Valid values are:

`server`

Creates the listener for the default server instance `server` and is the default value.

configuration_name

Creates the listener for the named configuration.

cluster_name

Creates the listener for every server instance in the cluster.

stand-alone_instance_name

Creates the listener for a particular standalone server instance.

Operands

listener_id

A unique identifier for the IIOP listener to be created.

Examples

Example 1 Creating an IIOP Listener

The following command creates an IIOP listener named `sample_iiop_listener`:

```
asadmin> create-iiop-listener --listeneraddress 192.168.1.100
--iiopport 1400 sample_iiop_listener
Command create-iiop-listener executed successfully.
```

Example 2 Creating an IIOP Listener with a Target Cluster

The following command creates an IIOP listener named `iiop_listener_2` for the cluster `mycluster`. It uses the target option.

```
asadmin> create-iiop-listener --listeneraddress 0.0.0.0 --iiopport 1401
--target mycluster iiop_listener_2
Command create-iiop-listener executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-ssl`,
- `delete-iiop-listener`,
- `list-iiop-listeners`

create-instance

Creates a Payara instance.

Synopsis

```
asadmin [asadmin-options] create-instance [--help]
--node node-name
[--config config-name | --cluster cluster-name]
[--lbenabled={true|false}]
[--portbase=port-number] [--checkports={true|false}]
[--systemproperties (name=value)[:name=value]* ]
[--dataGridStartPort startPort]
```

```
instance-name
```

Description

The `create-instance` subcommand creates a Payara instance. This subcommand requires the secure shell (SSH) to be configured on the host where the domain administration server (DAS) is running and on the host that is represented by the node where the instance is to reside.

SSH is not required if the instance is to reside on a node of type `CONFIG` that represents the local host. A node of type `CONFIG` is not enabled for remote communication over SSH.

You may run this command from any host that can contact the DAS.

A Payara Server instance is a single Virtual Machine for the Java platform (Java Virtual Machine or JVM machine) on a single node in which Payara is running. A node defines the host where the Payara Server instance resides. The JVM machine must be compatible with the Java Platform, Enterprise Edition (Java EE).

A Payara Server instance requires a reference to the following items:

- The node that defines the host where the instance resides. The node must be specified in the command to create the instance.
- The named configuration that defines the configuration of the instance. The configuration can be specified in the command to create the instance, but is not required. If no configuration is specified for an instance that is not joining a cluster, the subcommand creates a configuration for the instance. An instance that is joining a cluster receives its configuration from its parent cluster.

Each Payara Server instance is one of the following types of instance:

Standalone instance

A standalone instance does not share its configuration with any other instances or clusters. A standalone instance is created if either of the following conditions is met:

- No configuration or cluster is specified in the command to create the instance.
- A configuration that is not referenced by any other instances or clusters is specified in the command to create the instance.

  When no configuration or cluster is specified, a copy of the `default-config` configuration is created for the instance. The name of this configuration is instance-name`-config`, where instance-name represents the name of an un-clustered server instance.

Shared instance

A shared instance shares its configuration with other instances or clusters. A shared instance is created if a configuration that is referenced by other instances or clusters is specified in the command to create the instance.

Clustered instance

A clustered instance inherits its configuration from the cluster to which the instance belongs and shares its configuration with other instances in the cluster. A clustered instance is created if a cluster is specified in the command to create the instance.

Any instance that is not part of a cluster is considered an un-clustered server instance. Therefore, standalone instances and shared instances are un-clustered server instances.

By default, this subcommand attempts to resolve possible port conflicts for the instance that is being created. The subcommand also assigns ports that are currently not in use and not already assigned to other instances on the same node. The subcommand assigns these ports on the basis of an algorithm that is internal to the subcommand.

Use the `--systemproperties` option to resolve port conflicts for additional instances on the same node. System properties of an instance can be manipulated by using the `create-system-properties` subcommand and the `delete-system-property` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--node`

The name of the node that defines the host where the instance is to be created. The node must already exist. If the instance is to be created on the host where the domain administration server (DAS) is running, use the predefined node `localhost-`domain.

`--config`

Specifies the named configuration that the instance references. The configuration must exist and must not be named `default-config` or `server-config`. Specifying the `--config` option creates a shared instance. The `--config` option and the `--cluster` option are mutually exclusive. If both options are omitted, a standalone instance is created.

`--cluster`

Specifies the cluster from which the instance inherits its configuration. Specifying the `--cluster` option creates a clustered instance. The `--config` option and the `--cluster` option are mutually exclusive. If both options are omitted, a standalone instance is created.

`--lbenabled`

Specifies whether the instance is enabled for load balancing. Possible values are as follows:

`true`

The instance is enabled for load balancing (default). When an instance is enabled for load

balancing, a load balancer sends requests to the instance.

`false`

The instance is disabled for load balancing. When an instance is disabled for load balancing, a load balancer does not send requests to the instance.

`--portbase`

Determines the number with which the port assignment should start. An instance uses a certain number of ports that are statically assigned. The `portbase` value determines where the assignment should start. The values for the ports are calculated as follows:

- Administration port: `portbase + 48`
- HTTP listener port: `portbase + 80`
- HTTPS listener port: `portbase + 81`
- JMS port: `portbase + 76`
- IIOP listener port: `portbase + 37`
- Secure IIOP listener port: `portbase + 38`
- Secure IIOP with mutual authentication port: `portbase + 39`
- JMX port: `portbase + 86`
- JPA debugger port: `portbase + 9`
- Felix shell service port for OSGi module management: `portbase + 66`

When the `--portbase` option is specified, the output of this subcommand includes a complete list of used ports.

`--checkports`

Specifies whether to check for the availability of the administration, HTTP, JMS, JMX, and IIOP ports. The default value is `true`.

`--systemproperties`

Defines system properties for the instance. These properties override property definitions for port settings in the instance's configuration. Predefined port settings must be overridden if, for example, two clustered instances reside on the same host. In this situation, port settings for one instance must be overridden because both instances share the same configuration. The following properties are available:

`ASADMIN_LISTENER_PORT`

This property specifies the port number of the HTTP port or HTTPS port through which the DAS connects to the instance to manage the instance. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTP requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTPS requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_LISTENER_PORT`

This property specifies the port number of the port that is used for IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used for secure IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_MUTUALAUTH_PORT`

This property specifies the port number of the port that is used for secure IIOP connections with client authentication. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JAVA_DEBUGGER_PORT`

This property specifies the port number of the port that is used for connections to the Java Platform Debugger Architecture (JPDA)(http://www.oracle.com/technetwork/java/javase/tech/jpda-141715.html) debugger. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMS_PROVIDER_PORT`

This property specifies the port number for the Java Message Service provider. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMX_SYSTEM_CONNECTOR_PORT`

This property specifies the port number on which the JMX connector listens. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`OSGI_SHELL_TELNET_PORT`

This property specifies the port number of the port that is used for connections to the Apache Felix Remote Shell (`http://felix.apache.org/site/apache-felix-remote-shell.html`). This shell uses the Felix shell service to interact with the OSGi module management subsystem. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`--dataGridStartPort`

Sets Data Grid (Hazelcast) instance's starting port.

If set to `0` the Domain wide start port will be used instead.

The default value is `0`.

Operands

instance-name

The name of the instance that is being created.

The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Hyphen
  - Period
  - Underscore
- The name must be unique in the domain and must not be the name of another Payara instance, a cluster, a named configuration, or a node.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.

Examples

Example 1 Creating a Standalone Payara Instance

This example creates the standalone Payara instance `pmdsainst` in the domain `domain1` on the local host.

```
asadmin> create-instance --node localhost-domain1 pmdsainst
Port Assignments for server instance pmdsainst:
JMX_SYSTEM_CONNECTOR_PORT=28688
JMS_PROVIDER_PORT=27678
ASADMIN_LISTENER_PORT=24850
HTTP_LISTENER_PORT=28082
IIOP_LISTENER_PORT=23702
IIOP_SSL_LISTENER_PORT=23822
HTTP_SSL_LISTENER_PORT=28183
IIOP_SSL_MUTUALAUTH_PORT=23922

Command create-instance executed successfully.
```

Example 2 Creating a Standalone Payara Instance With Custom Port Assignments

This example creates the standalone Payara instance `pmdcpinst` in the domain `domain1` on the local host. Custom port numbers are assigned to the following ports:

- HTTP listener port
- HTTPS listener port
- IIOP connections port
- Secure IIOP connections port
- Secure IIOP connections port with mutual authentication
- JMX connector port

```
asadmin> create-instance --node localhost-domain1
--systemproperties HTTP_LISTENER_PORT=58294:
HTTP_SSL_LISTENER_PORT=58297:
IIOP_LISTENER_PORT=58300:
IIOP_SSL_LISTENER_PORT=58303:
IIOP_SSL_MUTUALAUTH_PORT=58306:
JMX_SYSTEM_CONNECTOR_PORT=58309 pmdcpinst
Port Assignments for server instance pmdcpinst:
JMS_PROVIDER_PORT=27679
ASADMIN_LISTENER_PORT=24851

Command create-instance executed successfully.
```

Example 3 Creating a Shared Payara Server Instance

This example creates the shared Payara instance `pmdsharedinst1` in the domain `domain1` on the local host. The shared configuration of this instance is `pmdsharedconfig`.

```
asadmin> create-instance --node localhost-domain1 --config pmdsharedconfig
pmdsharedinst1
Port Assignments for server instance pmdsharedinst1:
JMX_SYSTEM_CONNECTOR_PORT=28687
JMS_PROVIDER_PORT=27677
ASADMIN_LISTENER_PORT=24849
HTTP_LISTENER_PORT=28081
IIOP_LISTENER_PORT=23701
IIOP_SSL_LISTENER_PORT=23821
HTTP_SSL_LISTENER_PORT=28182
IIOP_SSL_MUTUALAUTH_PORT=23921

Command create-instance executed successfully.
```

Example 4 Creating a Clustered Payara Server Instance

This example creates the clustered Payara instance `pmdinst1` in the domain `domain1` on the local host. The instance is a member of the cluster `pmdclust1`.

```
asadmin> create-instance --node localhost-domain1 --cluster pmdclust pmdinst1
Port Assignments for server instance pmdinst1:
```

```
JMX_SYSTEM_CONNECTOR_PORT=28686
JMS_PROVIDER_PORT=27676
HTTP_LISTENER_PORT=28080
ASADMIN_LISTENER_PORT=24848
IIOP_SSL_LISTENER_PORT=23820
IIOP_LISTENER_PORT=23700
HTTP_SSL_LISTENER_PORT=28181
IIOP_SSL_MUTUALAUTH_PORT=23920

Command create-instance executed successfully.
```

Example 5 Creating a Standalone Payara Server Instance with Specific Data Grid Start Port

This example creates a Standalone Payara instance `instance1` in the domain `domain1` on the local host. Setting the Data Grid Start Port when an instance is created to `2900`.

```
asadmin> create-instance --dataGridStartPort 2900 --node localhost-domain1 instance1
Command _create-instance-filesystem executed successfully.
Port Assignments for server instance instance1:
OSGI_SHELL_TELNET_PORT=26666
JAVA_DEBUGGER_PORT=29009
JMS_PROVIDER_PORT=27676
HTTP_LISTENER_PORT=28080
IIOP_SSL_LISTENER_PORT=23820
ASADMIN_LISTENER_PORT=24848
IIOP_SSL_MUTUALAUTH_PORT=23920
JMX_SYSTEM_CONNECTOR_PORT=28686
HTTP_SSL_LISTENER_PORT=28181
IIOP_LISTENER_PORT=23700
The instance, instance1, was created on host localhost
Command create-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

create-jacc-provider

Enables administrators to create a JACC provider that can be used by third-party authorization modules for applications running in Payara Server.

Synopsis

```
asadmin [asadmin-options] create-jacc-provider [--help]
[--policyproviderclass pol-provider-class]
[--policyconfigfactoryclass pc-factory-class]
[--property name=value)[:name=value]*]
[--target target] jacc-provider-name
```

Description

The `create-jacc-provider` subcommand creates a JSR-115—compliant Java Authorization Contract for Containers (JACC) provider that can be used for authorization of applications running in Payara. The JACC provider is created as a `jacc-provider` element within the `security-service` element in the domain's `domain.xml` file.

The default Payara installation includes two JACC providers, named `default` and `simple`. Any JACC providers created with the `create-jacc-provider` subcommand are in addition to these two default providers. The default Payara JACC providers implement a simple, file-based authorization engine that complies with the JACC specification. The `create-jacc-provider` subcommand makes it possible to specify additional third-party JACC providers.

You can create any number of JACC providers within the `security-service` element, but the Payara runtime uses only one of them at any given time. The `jacc-provider` element in the `security-service` element points to the name of the provider that is currently in use by Payara. If you change this element to point to a different JACC provider, restart Payara.

This command is supported in remote mode only.

Options

If an option has a short option name, then the short option precedes the long option name. Short options have one dash whereas long options have two dashes.

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--policyproviderclass`

Specifies the fully qualified class name for the `javax.security.jacc.policy.provider` that implements the `java.security.Policy`.

`--policyconfigfactoryclass`

Specifies the fully qualified class name for the `javax.security.jacc.PolicyConfigurationFactory.provider` that implements the provider-specific `javax.security.jacc.PolicyConfigurationFactory`.

`--property`

Optional attribute name/value pairs for configuring the JACC provider. The following properties are available:

`repository`

The directory containing the JACC policy file. For the `default` Payara JACC provider, the default directory is `${com.sun.aas.instanceRoot}/generated/policy`. This property is not defined by default for the `simple` Payara JACC provider.

`--target`

Specifies the target for which you are creating the JACC provider. The following values are valid:

`server`

Creates the JACC provider on the default server instance. This is the default value.

configuration_name

Creates the JACC provider in the specified configuration.

cluster_name

Creates the JACC provider on all server instances in the specified cluster.

instance_name

Creates the JACC provider on a specified server instance.

Operands

jacc-provider-name

The name of the provider used to reference the `jacc-provider` element in `domain.xml`.

Examples

Example 1 Creating a JACC Provider

The following example shows how to create a JACC provider named `testJACC` on the default `server` target.

```
asadmin> create-jacc-provider
--policyproviderclass org.glassfish.exousia.modules.locked.SimplePolicyProvider
--policyconfigfactoryclass
org.glassfish.exousia.modules.locked.SimplePolicyConfigurationFactory
testJACC

Command create-jacc-provider executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `delete-jacc-provider`,
- `list-jacc-providers`

create-javamail-resource

Creates a JavaMail session resource.

Synopsis

```
asadmin [asadmin-options] create-javamail-resource [--help]
[--target target] --mailhost hostname
--mailuser username --fromaddress address [--storeprotocol storeprotocol]
[--storeprotocolclass storeprotocolclass] [--transprotocol transprotocol]
[--transprotocolclass transprotocolclass] [--debug={false|true}] [--
enabled={true|false}]
[--description resource-description] [--property (name=value)[:name=value]*] jndi-name
```

Description

The `create-javamail-resource` subcommand creates a JavaMail session resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target for which you are creating the JavaMail session resource. Valid values are:

`server`

Creates the resource for the default server instance. This is the default value.

`domain`

Creates the resource for the domain.

cluster_name

Creates the resource for every server instance in the cluster.

instance_name

Creates the resource for a particular server instance.

`--mailhost`

The DNS name of the default mail server. The connect methods of the Store and Transport objects use this value if a protocol-specific host property is not supplied. The name must be resolvable to an actual host name.

`--mailuser`

The name of the mail account user provided when connecting to a mail server. The connect methods of the Store and Transport objects use this value if a protocol-specific username property is not supplied.

`--fromaddress`

The email address of the default user, in the form username`@`host.`domain.

`--storeprotocol`

The mail server store protocol. The default is `imap`. Change this value only if you have reconfigured the Payara Server's mail provider to use a non-default store protocol.

`--storeprotocolclass`

The mail server store protocol class name. The default is `org.eclipse.angus.mail.imap.IMAPStore`. Change this value only if you have reconfigured the Payara Server's mail provider to use a nondefault store protocol.

`--transprotocol`

The mail server transport protocol. The default is `smtp`. Change this value only if you have reconfigured the Payara Server's mail provider to use a nondefault transport protocol.

`--transprotocolclass`

The mail server transport protocol class name. The default is

`org.eclipse.angus.mail.smtp.SMTPTransport`. Change this value only if you have reconfigured the Payara Server's mail provider to use a nondefault transport protocol.

`--debug`

If set to true, the server starts up in debug mode for this resource. If the JavaMail log level is set to `FINE` or `FINER`, the debugging output will be generated and will be included in the server log file. The default value is false.

`--enabled`

If set to true, the resource is enabled at runtime. The default value is true.

`--description`

Text providing some details of the JavaMail resource.

`--property`

Optional attribute name/value pairs for configuring the JavaMail resource. The Payara Server-specific `mail-` prefix is converted to the standard mail prefix. The JavaMail API documentation lists the properties you might want to set.

Operands

jndi-name

The JNDI name of the JavaMail resource to be created. It is a recommended practice to use the naming subcontext prefix `mail/` for JavaMail resources.

Examples

Example 1 Creating a JavaMail Resource

This example creates a JavaMail resource named `mail/MyMailSession`. The JNDI name for a JavaMail session resource customarily includes the `mail/` naming subcontext.

```
asadmin> create-javamail-resource --mailhost localhost
--mailuser sample --fromaddress sample@sun.com mail/MyMailSession
Command create-javamail-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

[--wrapjdbcobjects={false|true}]
[--description description]
[--property name=value)[:name=value]*]
[--skipclientinfovalidation={false|true}]
connectionpoolid
```

Description

The `create-jdbc-connection-pool` subcommand registers a new Java Database Connectivity ("JDBC") software connection pool with the specified JDBC connection pool name.

A JDBC connection pool with authentication can be created either by using a `--property` option to specify user, password, or other connection information, or by specifying the connection information in the XML descriptor file.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--datasourceclassname`

The name of the vendor-supplied JDBC datasource resource manager. An XA or global transactions capable datasource class will implement the `javax.sql.XADatasource` interface. Non-XA or exclusively local transaction datasources will implement the `javax.sql.Datasource` interface. `--restype`
Required when a datasource class implements two or more interfaces (`javax.sql.DataSource`, `javax.sql.XADataSource`, or `javax.sql.ConnectionPoolDataSource`), or when a driver classname must

be provided.

- If `--restype` = `java.sql.Driver`, then the `--driverclassname` option is required.
- If `--restype` = `javax.sql.DataSource`, `javax.sql.XADataSource`, or `javax.sql.ConnectionPoolDataSource`, then the `--datasourceclassname` option is required.
- If `--restype` is not specified, then either the `--driverclassname` or `--datasourceclassname` option must be specified, but not both.

`--steadypoolsize`

The minimum and initial number of connections maintained in the pool. The default value is 8.

`--maxpoolsize`

The maximum number of connections that can be created. The default value is 32.

`--maxwait`

The amount of time, in milliseconds, that a caller will wait before a connection timeout is sent. The default is 60000 (60 seconds). A value of 0 forces the caller to wait indefinitely.

`--poolresize`

Number of connections to be removed when `idle-timeout-in-seconds` timer expires. This is the quantity by which the pool will scale up or scale down the number of connections. Scale up:

When the pool has no free connections, pool will scale up by this quantity. Scale down: All the invalid and idle connections are removed, sometimes resulting in removing connections of quantity greater than this value. Connections that have been idle for longer than the timeout are candidates for removal. Steadypoolsize will be ensured. Possible values are from 0 to `MAX_INTEGER`. The default value is 2.

`--idletimeout`

The maximum time, in seconds, that a connection can remain idle in the pool. After this time, the implementation can close this connection. This timeout value must be kept shorter than the database server side timeout value to prevent the accumulation of unusable connections in the application. The default value is 300.

`--initsql`

An SQL string that is executed whenever a connection is created from the pool. If an existing connection is reused, this string is not executed. Connections that have idled for longer than the timeout are candidates for removal. This option has no default value.

`--isolationlevel`

The transaction-isolation-level on the pooled database connections. This option does not have a default value. If not specified, the pool operates with the default isolation level that the JDBC driver provides. You can set a desired isolation level using one of the standard transaction isolation levels: `read-uncommitted`, `read-committed`, `repeatable-read`, `serializable`. Applications that change the isolation level on a pooled connection programmatically risk polluting the pool. This could lead to program errors.

`--isisolationguaranteed`

This is applicable only when a particular isolation level is specified for transaction-isolation-level. The default value is true. This option assures that every time a connection is obtained from the pool, isolation level is set to the desired value. This could have some performance impact on some JDBC drivers. Administrators can set this to false when the application does not change `--isolationlevel` before returning the connection.

`--isconnectvalidatereq`

If set to true, connections are validated or checked to see if they are usable before giving out to the application. The default value is false.

`--validationmethod`

Type of validation to be performed when `is-connection-validation-required` is true. Valid settings are: `auto-commit`, `meta-data`, `table`, or `custom-validation`. The default value is `table`.

`--validationtable`

The name of the validation table used to perform a query to validate a connection. If `is-connection-validation-required` is set to true and connection-validation-type set to table, this option is mandatory.

`--failconnection`

If set to true, all connections in the pool must be closed when a single validation check fails. The default value is false. One attempt is made to reestablish failed connections.

`--allownoncomponentcallers`

A pool with this property set to true can be used by non-Jakarta EE components, that is, components other than EJBs or Servlets. The returned connection is enlisted automatically with the transaction context obtained from the transaction manager. Connections obtained by non-component callers are not automatically cleaned by the container at the end of a transaction. These connections need to be explicitly closed by the caller.

`--nontransactionalconnections`

A pool with this property set to true returns non-transactional connections. This connection does not get automatically enlisted with the transaction manager.

`--validateatmostonceperiod`

Specifies the time interval in seconds between successive requests to validate a connection at most once. Setting this attribute to an appropriate value minimizes the number of validation requests by a connection. Default value is 0, which means that the attribute is not enabled.

`--leaktimeout`

Specifies the amount of time, in seconds, for which connection leaks in a connection pool are to be traced. When a connection is not returned to the pool by the application within the specified period, it is assumed to be a potential leak, and stack trace of the caller will be logged. This option only detects if there is a connection leak. The connection can be reclaimed only if `connection-leak-reclaim` is set to true. If connection leak tracing is enabled, you can use the Administration Console to enable monitoring of the JDBC connection pool to get statistics on the number of connection leaks. The default value is 0, which disables connection leak tracing.

`--leakreclaim`

Specifies whether leaked connections are restored to the connection pool after leak connection tracing is complete. Possible values are as follows:

`false`

Leaked connections are not restored to the connection pool (default).

`true`

Leaked connections are restored to the connection pool.

`--statementleaktimeout`

Specifies the amount of time, in seconds, after which any statements that have not been closed by an application are to be detected. Applications can run out of cursors if statement objects are not properly closed. This option only detects if there is a statement leak. The statement can be reclaimed only if `statement-leak-reclaim` is set to true. The leaked statement is closed when it is reclaimed. The stack trace of the caller that creates the statement will be logged when a statement leak is detected. If statement leak tracing is enabled, you can use the Administration Console to enable monitoring of the JDBC connection pool to get statistics on the number of statement leaks. The default value is 0, which disables statement leak tracing. The following limitations apply to the statement leak timeout value:

- The value must be less than the value set for the connection `leak-timeout`.
- The value must be greater than the value set for `statement-timeout`.

`--statementleakreclaim`

Specifies whether leaked statements are reclaimed after the statements leak. Possible values are as follows:

`false`

Leaked statements are not reclaimed (default).

`true`

Leaked statements are reclaimed.

`--creationretryattempts`

Specifies the maximum number of times that Payara retries to create a connection if the initial attempt fails. The default value is 0, which specifies that Payara does not retry to create the connection.

`--creationretryinterval`

Specifies the interval, in seconds, between successive attempts to create a connection. If `--creationretryattempts` is 0, the `--creationretryinterval` option is ignored. The default value is 10.

`--sqltracelisteners`

A list of one or more custom modules that provide custom logging of database activities. Each module must implement the `org.glassfish.api.jdbc.SQLTraceListener` public interface. When set to an appropriate value, SQL statements executed by applications are traced. This option has no default value.

`--statementtimeout`

Specifies the length of time in seconds after which a query that is not completed is terminated. A query that remains incomplete for a long period of time might cause the application that submitted the query to hang. To prevent this occurrence, use this option set a timeout for all statements that will be created from the connection pool that you are creating. When creating a statement, Payara sets the `QueryTimeout` property on the statement to the length of time that is specified. The default value is -1, which specifies that incomplete queries are never terminated.

`--lazyconnectionenlistment`

Specifies whether a resource to a transaction is enlisted only when a method actually uses the resource. Possible values are as follows:

`false`

Resources to a transaction are always enlisted and not only when a method actually uses the resource (default).

`true`

Resources to a transaction are enlisted only when a method actually uses the resource.

`--lazyconnectionassociation`

Specifies whether a physical connection should be associated with the logical connection only when the physical connection is used, and disassociated when the transaction is completed. Such

association and dissociation enable the reuse of physical connections. Possible values are as follows:

`false`

A physical connection is associated with the logical connection even before the physical connection is used, and is not disassociated when the transaction is completed (default).

`true`

A physical connection is associated with the logical connection only when the physical connection is used, and disassociated when the transaction is completed. The `--lazyconnectionenlistment` option must also be set to `true`.

`--associatewiththread`

Specifies whether a connection is associated with the thread to enable the thread to reuse the connection. If a connection is not associated with the thread, the thread must obtain a connection from the pool each time that the thread requires a connection. Possible values are as follows:

`false`

A connection is not associated with the thread (default).

`true`

A connection is associated with the thread.

`--driverclassname`

The name of the vendor-supplied JDBC driver class. This driver should implement the `java.sql.Driver` interface.

`--matchconnections`

Specifies whether a connection that is selected from the pool should be matched by the resource adaptor. If all the connections in the pool are homogenous, a connection picked from the pool need not be matched by the resource adapter, which means that this option can be set to false. Possible values are as follows:

`false`

A connection should not be matched by the resource adaptor (default).

`true`

A connection should be matched by the resource adaptor.

`--maxconnectionusagecount`

Specifies the maximum number of times that a connection can be reused. When this limit is reached, the connection is closed. By limiting the maximum number of times that a connection can be reused, you can avoid statement leaks. The default value is 0, which specifies no limit on the number of times that a connection can be reused.

`--ping`

Specifies if the pool is pinged during pool creation or reconfiguration to identify and warn of

any erroneous values for its attributes. Default value is false.

`--pooling`

Specifies if connection pooling is enabled for the pool. The default value is true.

`--statementcachesize`

The number of SQL statements to be cached using the default caching mechanism (Least Recently Used). The default value is 0, which indicates that statement caching is not enabled.

`--validationclassname`

The name of the class that provides custom validation when the value of `validationmethod` is `custom-validation`. This class must implement the `org.glassfish.api.jdbc.ConnectionValidation` interface, and it must be accessible to Payara. This option is mandatory if the connection validation type is set to custom validation.

`--wrapjdbcobjects`

Specifies whether the pooling infrastructure provides wrapped JDBC objects to applications. By providing wrapped JDBC objects, the pooling infrastructure prevents connection leaks by ensuring that applications use logical connections from the connection pool, not physical connections. The use of logical connections ensures that the connections are returned to the connection pool when they are closed. However, the provision of wrapped JDBC objects can impair the performance of applications. The default value is true.
The pooling infrastructure provides wrapped objects for implementations of the following interfaces in the JDBC API:

- `java.sql.CallableStatement`
- `java.sql.DatabaseMetaData`
- `java.sql.PreparedStatement`
- `java.sql.ResultSet`
- `java.sql.Statement`

  Possible values of `--wrapjdbcobjects` are as follows:

  `false`

  The pooling infrastructure does not provide wrapped JDBC objects to applications. (default).

  `true`

  The pooling infrastructure provides wrapped JDBC objects to applications.

`--description`

Text providing details about the specified JDBC connection pool.

`--property`

Optional attribute name/value pairs for configuring the pool. The following properties are available:

`user`

Specifies the username for connecting to the database.

`password`

Specifies the password for connecting to the database.

`databaseName`

Specifies the database for this connection pool.

`serverName`

Specifies the database server for this connection pool.

`port`

Specifies the port on which the database server listens for requests.

`networkProtocol`

Specifies the communication protocol.

`roleName`

Specifies the initial SQL role name.

`datasourceName`

Specifies an underlying `XADataSource`, or a `ConnectionPoolDataSource` if connection pooling is done.

`description`

Specifies a text description.

`url`

Specifies the URL for this connection pool. Although this is not a standard property, it is commonly used.

`dynamic-reconfiguration-wait-timeout-in-seconds`

Used to enable dynamic reconfiguration of the connection pool transparently to the applications that are using the pool, so that applications need not be re-enabled for the attribute or property changes to the pool to take effect. Any in-flight transaction's connection requests will be allowed to complete with the old pool configuration as long as the connection requests are within the timeout period, so as to complete the transaction. New connection requests will wait for the pool reconfiguration to complete and connections will be acquired using the modified pool configuration.

`Prefer-Validate-Over-Recreate`

Specifies whether pool resizer should validate idle connections before destroying and recreating them. The default value is true.

`time-to-keep-queries-in-minutes`

Specifies the number of minutes that will be cached for use in calculating frequently used queries. Takes effect when SQL tracing and monitoring are enabled for the JDBC connection

pool. The default value is 5 minutes.

`number-of-top-queries-to-report`

Specifies the number of queries to list when reporting the top and most frequently used queries. Takes effect when SQL tracing and monitoring are enabled for the JDBC connection pool. The default value is 10 queries.

If an attribute name or attribute value contains a colon, the backslash (\) must be used to escape the colon in the name or value. Other characters might also require an escape character. For more information about escape characters in command options, see the `asadmin` man page.

`--skipclientinfovalidation`

Determines whether to skip the validation of client info properties. Default is false.

Skipping client info validation may improve the performance of persistent operations when pooling is disabled and managed by the JDBC driver.

Operands

connectionpoolid

The name of the JDBC connection pool to be created.

Examples

Example 1 Creating a JDBC Connection Pool

This example creates a JDBC connection pool named `sample_derby_pool`.

```
asadmin> create-jdbc-connection-pool
  --datasourceclassname org.h2.Driver
  --restype javax.sql.XADataSource
  --property
portNumber=1527:password=APP:user=APP:serverName=localhost:databaseName=sun-appserv-
samples sample_h2_pool
Command create-jdbc-connection-pool executed successfully
```

The escape character backslash (\) is used in the `--property` option to distinguish the semicolon (`;`). Two backslashes (\\) are used to distinguish the equal sign (`=`).

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-jdbc-resource

Creates a JDBC resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] create-jdbc-resource [--help]
--connectionpoolid connectionpoolid
[--enabled={false|true}]
[--description description]
[--property (property=value)[:name=value]*]
[--target target]
jndi_name
```

Description

The `create-jdbc-resource` subcommand creates a new JDBC resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--connectionpoolid`

The name of the JDBC connection pool. If two or more JDBC resource elements point to the same connection pool element, they use the same pool connection at runtime.

`--enabled`

Determines whether the JDBC resource is enabled at runtime. The default value is true.

`--description`

Text providing descriptive details about the JDBC resource.

`--property`

Optional attribute name/value pairs for configuring the resource.

`--target`

This option helps specify the target to which you are deploying. Valid values are:

`server`

Deploys the component to the default server instance. This is the default value.

`domain`

Deploys the component to the domain.

cluster_name

Deploys the component to every server instance in the cluster.

instance_name

Deploys the component to a particular server instance.

The resource is always created for the domain as a whole, but the `resource-ref` for the resource is only created for the specified `--target`. This means that although the resource is defined at the domain level, it is only available at the specified target level. Use the `create-resource-ref` subcommand to refer to the resource in multiple targets if needed.

Operands

jndi_name

The JNDI name of this JDBC resource.

Examples

Example 1 Creating a JDBC Resource

This example creates a JDBC resource named `jdbc/DerbyPool`.

```
asadmin> create-jdbc-resource
--connectionpoolid sample_h2_pool jdbc/H2Pool
Command create-jdbc-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-resource-ref`,

- `delete-jdbc-resource`,
- `list-jdbc-resources`

create-jms-host

Creates a JMS host.

Synopsis

```
asadmin [asadmin-options] create-jms-host [--help]
--mqhost mq-host --mqport mq-port
--mquser mq-user --mqpassword mq-password
[--target target]
[--force={false|true}]
jms_host_name
```

Description

Creates a Java Message Service (JMS) host within the JMS service.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

`--mqhost`
: The host name for the JMS service.

`--mqport`
: The port number used by the JMS service.

`--mquser`
: The user name for the JMS service.

`--mqpassword`
: The password for the JMS service.

`--target`
: Creates the JMS host only for the specified target. Valid values are as follows:

`server`

Creates the JMS host for the default server instance. This is the default value.

configuration-name

Creates the JMS host in the specified configuration.

cluster-name

Creates the JMS host for every server instance in the specified cluster.

instance-name

Creates the JMS host for the specified server instance.

`--force`

Specifies whether the subcommand overwrites the existing JMS host of the same name. The default value is `false`.

Operands

jms_host_name

A unique identifier for the JMS host to be created.

Examples

Example 1 Creating a JMS host using a non-default port

The following command creates a JMS host named `MyNewHost` on the system `pigeon`.

```
asadmin> create-jms-host --mqhost pigeon.example.com --mqport 7677
--mquser admin --mqpassword admin MyNewHost
Jms Host MyNewHost created.
Command create-jms-host executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `delete-jms-host`,
- `jms-ping`,
- `list-jms-hosts`

create-jms-resource

Creates a JMS resource.

Synopsis

```
asadmin [asadmin-options] create-jms-resource [--help]
--restype type
[--target target]
[--enabled={true|false}]
[--description text]
[--property (name=value)[:name=value]*]
[--force={false|true}]
jndi_name
```

Description

The `create-jms-resource` subcommand creates a Java Message Service (JMS) connection factory resource or a JMS destination resource.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--restype`

The JMS resource type, which can be `jakarta.jms.Topic`, `jakarta.jms.Queue`, `jakarta.jms.ConnectionFactory`, `jakarta.jms.TopicConnectionFactory`, or `jakarta.jms.QueueConnectionFactory`.

`--target`

Creates the JMS resource only for the specified target. Valid values are as follows:

The resource is always created for the domain as a whole, but the `<resource-ref>` element for the resource is only created for the specified `--target`. This means that although the resource is defined at the domain level, it is only active at the specified `--target`.

`server`

Creates the JMS resource for the default server instance. This is the default value.

`domain`

Creates the JMS resource for the domain.

cluster-name

Creates the JMS resource for every server instance in the specified cluster.

instance-name

Creates the JMS resource for the specified server instance.

`--enabled`

If set to true (the default), the resource is enabled at runtime.

`--description`

Text providing details about the JMS resource.

`--property`

Optional attribute name/value pairs for configuring the JMS resource. You can specify the following properties for a connection factory resource:

`ClientId`

A client ID for a connection factory that will be used by a durable subscriber.

`AddressList`

A comma-separated list of message queue addresses that specify the host names (and, optionally, port numbers) of a message broker instance or instances with which your application will communicate. For example, the value could be `earth` or `earth:7677`. Specify the port number if the message broker is running on a port other than the default (7676). The default value is an address list composed of the JMS hosts defined in the server's JMS service configuration. The default value is `localhost` and the default port number is 7676. The client will attempt a connection to a broker on port 7676 of the local host.

`UserName`

The username for the connection factory. The default value is `guest`.

`Password`

The password for the connection factory. The default value is `guest`.

`ReconnectEnabled`

A value of `true` indicates that the client runtime attempts to reconnect to a message server (or the list of addresses in the `AddressList`) when a connection is lost. The default value is `false`.

`ReconnectAttempts`

The number of attempts to connect (or reconnect) for each address in the `AddressList` before the client runtime tries the next address in the list. A value of -1 indicates that the number of reconnect attempts is unlimited (the client runtime attempts to connect to the first address until it succeeds). The default value is 6.

`ReconnectInterval`

The interval in milliseconds between reconnect attempts. This applies to attempts on each address in the `AddressList` and for successive addresses in the list. If the interval is too short, the broker does not have time to recover. If it is too long, the reconnect might represent an unacceptable delay. The default value is 30,000 milliseconds.

`AddressListBehavior`

Specifies whether connection attempts are in the order of addresses in the `AddressList` (`PRIORITY`) or in a random order (`RANDOM`). `PRIORITY` means that the reconnect will always try to connect to the first server address in the `AddressList` and will use another one only if the first broker is not available. If you have many clients attempting a connection using the same connection factory, specify `RANDOM` to prevent them from all being connected to the same address. The default value is the `AddressListBehavior` value of the server's JMS service configuration.

`AddressListIterations`

The number of times the client runtime iterates through the `AddressList` in an effort to establish (or re-establish) a connection). A value of -1 indicates that the number of attempts is unlimited. The default value is -1.

Additionally, you can specify `connector-connection-pool` attributes as connector resource properties. For a list of these attributes, see "connector-connection-pool" in Payara Server Application Deployment section.

You can specify the following properties for a destination resource:

`Name`

The name of the physical destination to which the resource will refer. The physical destination is created automatically when you run an application that uses the destination resource. You can also create a physical destination with the `create-jmsdest` subcommand. If you do not specify this property, the JMS service creates a physical destination with the same name as the destination resource (replacing any forward slash in the JNDI name with an underscore).

`Description`

A description of the physical destination.

`--force`

Specifies whether the subcommand overwrites the existing JMS resource of the same name. The default value is `false`.

Operands

jndi_name

The JNDI name of the JMS resource to be created.

Examples

Example 1 Creating a JMS connection factory resource for durable subscriptions

The following subcommand creates a connection factory resource of type `jakarta.jms.ConnectionFactory` whose JNDI name is `jms/DurableConnectionFactory`. The `ClientId` property sets a client ID on the connection factory so that it can be used for durable subscriptions.

The JNDI name for a JMS resource customarily includes the `jms/` naming subcontext.

```
asadmin> create-jms-resource --restype jakarta.jms.ConnectionFactory
--description "connection factory for durable subscriptions"
--property ClientId=MyID jms/DurableConnectionFactory
Connector resource jms/DurableConnectionFactory created.
Command create-jms-resource executed successfully.
```

Example 2 Creating a JMS destination resource

The following subcommand creates a destination resource whose JNDI name is `jms/MyQueue`. The `Name` property specifies the physical destination to which the resource refers.

```
asadmin> create-jms-resource --restype jakarta.jms.Queue
--property Name=PhysicalQueue jms/MyQueue
Administered object jms/MyQueue created.
Command create-jms-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `delete-jms-resource`,
- `list-jms-resources`

create-jmsdest

Creates a JMS physical destination.

Synopsis

```
asadmin [asadmin-options] create-jmsdest [--help]
--desttype dest_type
[--property (name=value)[:name=value]*]
[--target target]
[--force={false|true}]
dest_name
```

Description

The `create-jmsdest` subcommand creates a Java Message Service (JMS) physical destination. Typically, you use the `create-jms-resource` subcommand to create a JMS destination resource that has a `Name` property that specifies the physical destination. The physical destination is created automatically when you run an application that uses the destination resource. Use the `create-jmsdest` subcommand if you want to create a physical destination with non-default property settings.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--desttype`

The type of the JMS destination. Valid values are `topic` and `queue`.

`--property`

Optional attribute name/value pairs for configuring the physical destination. You can specify the following properties for a physical destination.

`MaxNumMsgs`

The maximum number of unconsumed messages permitted for the destination. A value of -1 denotes an unlimited number of messages. The default value is -1. For the dead message queue, the default value is 1000. If the `limitBehavior` property is set to `FLOW_CONTROL`, it is possible for the specified message limit to be exceeded because the broker cannot react quickly enough to stop the flow of incoming messages. In such cases, the value specified for `maxNumMsgs` serves as merely a hint for the broker rather than a strictly enforced limit.

`MaxBytesPerMsg`

The maximum size, in bytes, of any single message. Rejection of a persistent message is reported to the producing client with an exception; no notification is sent for non-persistent messages.

The value may be expressed in bytes, kilobytes, or megabytes, using the following suffixes:

`b`

Bytes

`k`

Kilobytes (1024 bytes)

`m`

Megabytes (1024 x 1024 = 1,048,576 bytes)
A value with no suffix is expressed in bytes; a value of -1 denotes an unlimited message size. The default value is -1.

`MaxTotalMsgBytes`

The maximum total memory, in bytes, for unconsumed messages. The default value is -1. The syntax is the same as for `maxBytesPerMsg`. For the dead message queue, the default value is `10m`.

`LimitBehavior`

The behavior of the message queue broker when the memory-limit threshold is reached.+

Valid values are as follows.

`REJECT_NEWEST`

Reject newest messages and notify the producing client with an exception only if the message is persistent. This is the default value.

`FLOW_CONTROL`

Slow the rate at which message producers send messages.

`REMOVE_OLDEST`

Throw out the oldest messages.

`REMOVE_LOW_PRIORITY`

Throw out the lowest-priority messages according to age, with no notification to the producing client. If the value is `REMOVE_OLDEST` or `REMOVE_LOW_PRIORITY` and the `useDMQ` property is set to `true`, excess messages are moved to the dead message queue. For the dead message queue itself, the default limit behavior is `REMOVE_OLDEST`, and the value cannot be set to `FLOW_CONTROL`.

`MaxNumProducers`

The maximum number of message producers for the destination. When this limit is reached, no new producers can be created. A value of -1 denotes an unlimited number of producers. The default value is 100. This property does not apply to the dead message queue.

`ConsumerFlowLimit`

The maximum number of messages that can be delivered to a consumer in a single batch. A value of -1 denotes an unlimited number of messages. The default value is 1000. The client runtime can override this limit by specifying a lower value on the connection factory object.
In load-balanced queue delivery, this is the initial number of queued messages routed to active consumers before load balancing begins.

`UseDMQ`

If set to `true`, dead messages go to the dead message queue. If set to `false`, dead messages are discarded. The default value is `true`.

`ValidateXMLSchemaEnabled`

If set to `true`, XML schema validation is enabled for the destination. The default value is `false`. When XML validation is enabled, the Message Queue client runtime will attempt to validate

an XML message against the specified XSDs (or against the DTD, if no XSD is specified) before sending it to the broker. If the specified schema cannot be located or the message cannot be validated, the message is not sent, and an exception is thrown.
This property should be set when a destination is inactive: that is, when it has no consumers or producers and when there are no messages in the destination. Otherwise, the producer must reconnect.

`XMLSchemaURIList`

A space-separated list of XML schema document (XSD) URI strings. The URIs point to the location of one or more XSDs to use for XML schema validation, if `validateXMLSchemaEnabled` is set to `true`. The default value is `null`. Use double quotes around this value if multiple URIs are specified, as in the following example:

```
"http://foo/flap.xsd http://test.com/test.xsd"
```

If this property is not set or `null` and XML validation is enabled, XML validation is performed using a DTD specified in the XML document. If an XSD is changed as a result of changing application requirements, all client applications that produce XML messages based on the changed XSD must reconnect to the broker.
To modify the value of these properties, you can use the `as-install/mq/bin/imqcmd` command. See the **Physical Destination Property Reference** in the Open Message Queue Administration Guide for more information. `--target`:: Creates the physical destination only for the specified target. Although the `create-jmsdest` subcommand is related to resources, a physical destination is created using the JMS Service (JMS Broker), which is part of the configuration. A JMS Broker is configured in the config section of `domain.xml`. Valid values are as follows:
`server`;; Creates the physical destination for the default server instance. This is the default value. configuration-name;; Creates the physical destination in the specified configuration. cluster-name;; Creates the physical destination for every server instance in the specified cluster. instance-name;; Creates the physical destination for the specified server instance. `--force`:: Specifies whether the subcommand overwrites the existing JMS physical destination of the same name. The default value is `false`.

Operands

dest_name

A unique identifier for the JMS destination to be created.

Examples

Example 1 Creating a JMS physical destination

The following subcommand creates a JMS physical queue named `PhysicalQueue` with non-default property values.

```
asadmin> create-jmsdest --desttype queue
--property maxNumMsgs=1000:maxBytesPerMsg=5k PhysicalQueue
Command create-jmsdest executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-jms-resource`,
- `delete-jmsdest`,
- `flush-jmsdest`,

create-jndi-resource

Registers a JNDI resource.

Synopsis

```
asadmin [asadmin-options] create-jndi-resource [--help]
[--target target]
--restype restype --factoryclass factoryclass
--jndilookupname jndilookupname [--enabled={true|false}]
[--description description]
[--property (name=value)[:name=value]*]
jndi-name
```

Description

The `create-jndi-resource` subcommand registers a JNDI resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target for which you are registering a JNDI resource. Valid values for target are described below.

The resource is always created for the domain as a whole, but the `resource-ref` for the resource is only created for the specified `--target`. This means that although the resource is defined at the domain level, it is only available at the specified target level. Use the `create-resource-ref` subcommand to refer to the resource in multiple targets if needed.

`server`

Creates the resource for the default server instance. This value is the default.

`domain`

Creates the resource for the domain

cluster-name

Creates the resource for every server instance in the cluster

instance-name

Creates the resource for a particular server instance

`--restype`

The JNDI resource type. Valid values are `topic` or `queue`.

`--factoryclass`

The class that creates the JNDI resource.

`--jndilookupname`

The lookup name that the external container uses.

`--enabled`

Determines whether the resource is enabled at runtime. Default is true.

`--description`

The text that provides details about the JNDI resource.

`--property`

Optional properties for configuring the resource. Each property is specified as a name-value pair. The available properties are specific to the implementation that is specified by the `--factoryclass` option and are used by that implementation. Payara Server itself does not define any properties for configuring a JNDI resource.

Operands

jndi-name

The unique name of the JNDI resource to be created.

Examples

Example 1 Creating a JNDI Resource

This example creates the JNDI resource `my-jndi-resource` for the default server instance.

```
asadmin> create-jndi-resource
--restype com.example.jndi.MyResourceType
--factoryclass com.example.jndi.MyInitialContextFactoryClass
--jndilookupname remote-jndi-name
--description "sample JNDI resource" my-jndi-resource
JNDI resource my-jndi-resource created.
Command create-jndi-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-resource-ref`,
- `delete-jndi-resource`,
- `list-jndi-resources`

create-jvm-option

Create options for the Java application launcher.

Synopsis

```
asadmin [asadmin-options] create-jvm-option [--help]
[--target target]
(assignment=jvm-option)
```

Description

The `create-jvm-options` subcommand creates a single command-line option that is passed to the Java application launcher when Payara Server is started. The options that this subcommand creates are in addition to the options that are preset with Payara Server. Java application launcher options are stored in the Java configuration `java-config` element of the `domain.xml` file. The options are sent to the command line in the order they appear in the `java-config` element in the `domain.xml` file.

This subcommand can be used to create the following types of options:

- Java system properties. These options are set through the `-D` option of the Java application launcher. For example:
  `-Djava.security.manager`
  `-Denvironment=Production`

- Startup parameters for the Java application launcher. These options are preceded by the dash character (-). For example:
  `--XX:PermSize=\`size`
  `` `-Xmx1024m ``
  `-d64`

If the subcommand specifies an option that already exists, the command does not re-create it.

Ensure that any option that you create is valid. The subcommand might allow you to create an invalid option, but such an invalid option can cause startup to fail.

An option can be verified by examining the server log after Payara Server starts. Options for the Java application launcher are written to the `server.log` file before any other information when Payara Server starts.

The addition of some options requires a server restart for changes to become effective. Other options are set immediately in the environment of the domain administration server (DAS) and do not require a restart. Whether a restart is required depends on the type of option.

- Restart is not required for Java system properties whose names do not start with `-Djava.` or `-Djavax.` (including the trailing period). For example, restart is not required for the following Java system property:
  `-Denvironment=Production`
- Restart is required for the following options:
  - Java system properties whose names start with `-Djava.` or `-Djavax.` (including the trailing period). For example:
    `-Djava.security.manager`
  - Startup parameters for the Java application launcher. For example:
    `-client`
    `-Xmx1024m`
    `-d64`

To restart the DAS, use the `restart-domain` command.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which you are creating Java application launcher options.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Operands

jvm-option-name

A single option where the format depends on the following:

- If the option has a name and a value, the format is option-name=value.
- If the option has only a name, the format is option-name. For example, `-Xmx2048m`.
- If the first option name could be misinterpreted as one or more `asadmin` short options, the format is `--` option-name. For example, `-server` in the following command could be misinterpreted as `-se`, the `asadmin` short forms for `--secure` and `--echo`:

```
create-jvm-option -server
```

To create the JVM option `-server`, instead use the command:

```
create-jvm-option -- -server
```

Examples

Example 1 Setting A Java System Property

```
asadmin> create-jvm-option -Dunixlocation=/root/example
Successfully created JVM option: -Dunixlocation=/root/example
Command create-jvm-option executed successfully.
```

Example 2 Setting a Startup Parameter for the Java Application Launcher

This example sets the maximum available heap size to 1024.

```
asadmin> create-jvm-option -Xmx1024m
Successfully added JVM option: -Xmx1024m
Command create-jvm-option executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jvm-options`,
- `delete-jvm-options`,
- `list-jvm-options`,
- `restart-domain`

For more information about the Java application launcher, see the reference page for the operating system that you are using:

- https://docs.oracle.com/en/java/javase/11/ [Windows: java - the Java application launcher] (`https://docs.oracle.com/en/java/javase/11/`)

create-jvm-options

Create options for the Java application launcher.

Synopsis

```
asadmin [asadmin-options] create-jvm-options [--help]
[--target target]
(jvm-option-name=jvm-option-value) [:jvm-option-name=jvm-option-value*]
```

Description

The `create-jvm-options` subcommand creates command-line options that are passed to the Java application launcher when Payara Server is started. The options that this subcommand creates are in addition to the options that are preset with Payara Server. Java application launcher options are stored in the Java configuration `java-config` element of the `domain.xml` file. The options are sent to the command line in the order they appear in the `java-config` element in the `domain.xml` file.

This subcommand can be used to create the following types of options:

- Java system properties. These options are set through the `-D` option of the Java application launcher. For example:
  `-Djava.security.manager`
  `-Denvironment=Production`
- Startup parameters for the Java application launcher. These options are preceded by the dash character (`-`). For example:

```
--XX:PermSize=`size
`-Xmx1024m
-d64
```

If the subcommand specifies an option that already exists, the command does not re-create it.

Ensure that any option that you create is valid. The subcommand might allow you to create an invalid option, but such an invalid option can cause startup to fail.

An option can be verified by examining the server log after Payara Server starts. Options for the Java application launcher are written to the `server.log` file before any other information when Payara Server starts.

The addition of some options requires a server restart for changes to become effective. Other options are set immediately in the environment of the domain administration server (DAS) and do not require a restart. Whether a restart is required depends on the type of option.

- Restart is not required for Java system properties whose names do not start with `-Djava.` or `-Djavax.` (including the trailing period). For example, restart is not required for the following Java system property:
  `-Denvironment=Production`
- Restart is required for the following options:
  - Java system properties whose names start with `-Djava.` or `-Djavax.` (including the trailing period). For example:
    `-Djava.security.manager`
  - Startup parameters for the Java application launcher. For example:
    `-client`
    `-Xmx1024m`
    `-d64`

To restart the DAS, use the `restart-domain` command.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which you are creating Java application launcher options.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Operands

jvm-option-name

One or more options delimited by a colon (:). The format of an option depends on the following:

- If the option has a name and a value, the format is option-name=value.
- If the option has only a name, the format is option-name. For example, `-Xmx2048m`.
- If the first option name could be misinterpreted as one or more `asadmin` short options, the format is `--` option-name. For example, `-server` in the following command could be misinterpreted as `-se`, the `asadmin` short forms for `--secure` and `--echo`:

```
create-jvm-options -server
```

To create the JVM option `-server`, instead use the command:

```
create-jvm-options -- -server
```

If an option name or option value contains a colon, the backslash (\) must be used to escape the colon in the name or value. Other characters might also require an escape character. For more information about escape characters in subcommand options, see the `asadmin` man page.

Examples

Example 1 Setting Java System Properties

This example sets multiple Java system properties.

```
asadmin> create-jvm-options -Dunixlocation=/root/example:
-Dvariable=\$HOME:-Dwindowslocation=d\:\\sun\\appserver:-Doption1=-value1
created 4 option(s)
Command create-jvm-options executed successfully.
```

Example 2 Setting a Startup Parameter for the Java Application Launcher

This example sets the maximum available heap size to 1024.

```
asadmin> create-jvm-options -Xmx1024m
created 1 option(s)
Command create-jvm-options executed successfully.
```

Example 3 Setting Multiple Startup Parameters for the Java Application Launcher

This example sets the maximum available heap size to 1024 and requests details about garbage collection.

```
asadmin> create-jvm-options "-Xmx1024m:-XX\:+PrintGCDetails"
created 1 option(s)
Command create-jvm-options executed successfully.
```

In this case, one of the two parameters already exists, so the subcommand reports that only one option was set.

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- https://docs.oracle.com/en/java/javase/11/ [Windows: java - the Java application launcher] (`https://docs.oracle.com/en/java/javase/11/`)

create-local-instance

Creates a Payara Server instance on the host where the subcommand is run.

Synopsis

```
asadmin [asadmin-options] create-local-instance [--help]
[--node node-name] [--nodedir node-dir]
[--config config-name | --cluster cluster-name]
[--lbenabled={true|false}]
[--portbase port-number] [--checkports={true|false}]
[--savemasterpassword={false|true}]
[--masterpasswordlocation filepath]
[--usemasterpassword={false|true}]
[--systemproperties (name=value)[:name=value]* ]
[--dataGridStartPort startPort]
instance-name
```

Description

The `create-local-instance` subcommand creates a Payara Server instance on the node that represents the host where the subcommand is run. This subcommand does not require the secure shell (SSH) to be configured.

You must run this subcommand from the host that is represented by the node where the instance is to reside. To contact the domain administration server (DAS), this subcommand requires the name of the host where the DAS is running.

If a non-default port is used for administration, this subcommand also requires the port number. If you are adding the first instance to a node, you must provide this information through the `--host` option and the `--port` option of the `asadmin` utility. For the second and later instances, this information is obtained from the DAS properties of the node.

A Payara Server instance is a single Virtual Machine for the Java platform (Java Virtual Machine or JVM machine) on a single node in which Payara Server is running. A node defines the host where the Payara Server instance resides. The JVM machine must be compatible with the Java Platform, Enterprise Edition (Jakarta EE).

A Payara Server instance requires a reference to the following items:

- The node that defines the host where the instance resides. The node can be specified in the command to create the instance, but is required only if more than one node exists in the directory where files for nodes are stored. If no node is specified, the behavior of the subcommand depends on the number of existing nodes in the directory where nodes are stored:
    - If no nodes exist, the subcommand creates a node for the instance. The name of the node is the name of the host on which the subcommand is run.
    - If only one node exists, the subcommand creates a reference to the existing node for the instance.
    - If two or more nodes exist, an error occurs.
- The named configuration that defines the configuration of the instance. The configuration can be specified in the command to create the instance, but is not required. If no configuration is specified for an instance that is not joining a cluster, the subcommand creates a configuration

for the instance. An instance that is joining a cluster receives its configuration from its parent cluster.

Each Payara Server instance is one of the following types of instance:

Standalone instance

A standalone instance does not share its configuration with any other instances or clusters. A standalone instance is created if either of the following conditions is met:

- No configuration or cluster is specified in the command to create the instance.
- A configuration that is not referenced by any other instances or clusters is specified in the command to create the instance.

  When no configuration or cluster is specified, a copy of the `default-config` configuration is created for the instance. The name of this configuration is instance-name`-config`, where instance-name represents the name of an unclustered server instance.

Shared instance

A shared instance shares its configuration with other instances or clusters. A shared instance is created if a configuration that is referenced by other instances or clusters is specified in the command to create the instance.

Clustered instance

A clustered instance inherits its configuration from the cluster to which the instance belongs and shares its configuration with other instances in the cluster. A clustered instance is created if a cluster is specified in the command to create the instance.

Any instance that is not part of a cluster is considered an unclustered server instance. Therefore, standalone instances and shared instances are unclustered server instances.

By default, this subcommand attempts to resolve possible port conflicts for the instance that is being created. The subcommand also assigns ports that are currently not in use and not already assigned to other instances on the same node.

The subcommand assigns these ports on the basis of an algorithm that is internal to the subcommand. Use the `--systemproperties` option to resolve port conflicts for additional instances on the same node. System properties of an instance can be manipulated by using the `create-system-properties` subcommand and the `delete-system-property` subcommand.

When creating an instance, the subcommand retrieves the files that are required for secure synchronization with the domain administration server (DAS). The instance is synchronized with the DAS when the instance is started

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--node`

The name of the node that defines the host where the instance is to be created. The node must be specified only if more than one node exists in the directory where nodes are stored. Otherwise, the node may be omitted. If a node is specified, the node must exist. If no node is specified, the behavior of the subcommand depends on the number of existing nodes in the directory where nodes are stored:

- If no nodes exist, the subcommand creates a node for the instance. The name of the node is the name of the host on which the subcommand is run.
- If only one node exists, the subcommand creates a reference to the existing node for the instance.
- If two or more nodes exist, an error occurs.

`--nodedir`

The path to the directory in which the files for instance's node is to be stored. The default is as-install`/nodes`.

`--config`

Specifies the named configuration that the instance references. The configuration must exist and must not be named `default-config` or `server-config`. Specifying the `--config` option creates a shared instance. The `--config` option and the `--cluster` option are mutually exclusive. If both options are omitted, a standalone instance is created.

`--cluster`

Specifies the cluster from which the instance inherits its configuration. Specifying the `--cluster` option creates a clustered instance. The `--config` option and the `--cluster` option are mutually exclusive. If both options are omitted, a standalone instance is created.

`--lbenabled`

Specifies whether the instance is enabled for load balancing. Possible values are as follows:

`true`

The instance is enabled for load balancing (default). When an instance is enabled for load balancing, a load balancer sends requests to the instance.

`false`

The instance is disabled for load balancing. When an instance is disabled for load balancing, a load balancer does not send requests to the instance.

`--portbase`

Determines the number with which the port assignment should start. An instance uses a certain number of ports that are statically assigned. The `portbase` value determines where the assignment should start. The values for the ports are calculated as follows:

- Administration port: `portbase + 48`
- HTTP listener port: `portbase + 80`
- HTTPS listener port: `portbase + 81`
- JMS port: `portbase + 76`
- IIOP listener port: `portbase + 37`
- Secure IIOP listener port: `portbase + 38`
- Secure IIOP with mutual authentication port: `portbase + 39`
- JMX port: `portbase + 86`
- JPA debugger port: `portbase + 9`
- Felix shell service port for OSGi module management: `portbase + 66`

  When the `--portbase` option is specified, the output of this subcommand includes a complete list of used ports.

`--checkports`

Specifies whether to check for the availability of the administration, HTTP, JMS, JMX, and IIOP ports. The default value is `true`.

`--savemasterpassword`

Setting this option to `true` allows the master password to be written to the file system. If the master password is written to the file system, the instance can be started without the need to prompt for the password. If this option is `true`, the `--usemasterpassword` option is also true, regardless of the value that is specified on the command line. Because writing the master password to the file system is an insecure practice, the default is `false`.
The master-password file for an instance is saved in the node directory, not the domain directory. Therefore, this option is required only for the first instance that is created for each node in a domain.

`--masterpasswordlocation`

Only applies if the `--savemasterpassword` parameter is set to true. This parameter receives an absolute filepath that the master password will be saved to.
If this parameter is omitted, the default location will be used.

`--usemasterpassword`

Specifies whether the key store is encrypted with a master password that is built into the system or a user-defined master password.
If `false` (default), the keystore is encrypted with a well-known password that is built into the system. Encrypting the keystore with a password that is built into the system provides no additional security.
If `true`, the subcommand obtains the master password from the `AS_ADMIN_MASTERPASSWORD` entry in the password file or prompts for the master password. The password file is specified in the `--passwordfile` option of the `asadmin`utility.
If the `--savemasterpassword` option is `true`, this option is also true, regardless of the value that is specified on the command line.
The master password must be the same for all instances in a domain.

`--systemproperties`

Defines system properties for the instance. These properties override property definitions for port settings in the instance's configuration. Predefined port settings must be overridden if, for example, two clustered instances reside on the same host. In this situation, port settings for one instance must be overridden because both instances share the same configuration.
The following properties are available:

`ASADMIN_LISTENER_PORT`

This property specifies the port number of the HTTP port or HTTPS port through which the DAS connects to the instance to manage the instance. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTP requests. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`HTTP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used to listen for HTTPS requests. Valid value are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_LISTENER_PORT`

This property specifies the port number of the port that is used for IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_LISTENER_PORT`

This property specifies the port number of the port that is used for secure IIOP connections. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`IIOP_SSL_MUTUALAUTH_PORT`

This property specifies the port number of the port that is used for secure IIOP connections with client authentication. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JAVA_DEBUGGER_PORT`

This property specifies the port number of the port that is used for connections to the Java Platform Debugger Architecture (JPDA) (https://docs.oracle.com/en/java/javase/11/docs/specs/jpda/jpda.html) debugger. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMS_PROVIDER_PORT`

This property specifies the port number for the Java Message Service provider. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`JMX_SYSTEM_CONNECTOR_PORT`

This property specifies the port number on which the JMX connector listens. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`OSGI_SHELL_TELNET_PORT`

This property specifies the port number of the port that is used for connections to the Apache Felix Remote Shell (http://felix.apache.org/site/apache-felix-remote-shell.html). This shell uses the Felix shell service to interact with the OSGi module management subsystem. Valid values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges.

`--dataGridStartPort`

Sets Data Grid (Hazelcast) instance's starting port.

If set to `0` the Domain wide start port will be used instead.

The default value is `0`.

Operands

instance-name

The name of the instance that is being created.

The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Hyphen
  - Period
  - Underscore
- The name must be unique in the domain and must not be the name of another Payara Server instance, a cluster, a named configuration, or a node.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.

Examples

Example 1 Creating a Standalone Payara Server Instance

This example creates the standalone instance `il3` on the host where the command is run. The DAS is running on the same host. The instance references the only existing node.

```
asadmin> create-local-instance il3
Rendezvoused with DAS on localhost:4848.
Port Assignments for server instance il3:
JMX_SYSTEM_CONNECTOR_PORT=28686
JMS_PROVIDER_PORT=27676
HTTP_LISTENER_PORT=28080
ASADMIN_LISTENER_PORT=24848
JAVA_DEBUGGER_PORT=29009
IIOP_SSL_LISTENER_PORT=23820
IIOP_LISTENER_PORT=23700
OSGI_SHELL_TELNET_PORT=26666
HTTP_SSL_LISTENER_PORT=28181
IIOP_SSL_MUTUALAUTH_PORT=23920
Command create-local-instance executed successfully.
```

Example 2 Creating a Clustered Payara Server Instance on a Specific Node

This example creates the clustered instance `ymli2` on node `sj02`. The instance is a member of the cluster `ymlclust`.

The command is run on the host `sj02`, which is the host that the node `sj02` represents. The DAS is running on the host `sr04` and uses the default HTTP port for administration. Because no instances exist on the node, the host on which the DAS is running is provided through the `--host` option of the `asadmin` utility.

```
sj02# asadmin --host sr04 create-local-instance --cluster ymlclust --node sj02 ymli2
Rendezvoused with DAS on sr04:4848.
Port Assignments for server instance ymli2:
JMX_SYSTEM_CONNECTOR_PORT=28686
JMS_PROVIDER_PORT=27676
HTTP_LISTENER_PORT=28080
ASADMIN_LISTENER_PORT=24848
JAVA_DEBUGGER_PORT=29009
IIOP_SSL_LISTENER_PORT=23820
IIOP_LISTENER_PORT=23700
OSGI_SHELL_TELNET_PORT=26666
HTTP_SSL_LISTENER_PORT=28181
IIOP_SSL_MUTUALAUTH_PORT=23920
Command create-local-instance executed successfully.
```

Example 3 Creating a Standalone Payara Server Instance with Specific Data Grid Start Port

This example creates a Standalone Payara instance `instance2` in the domain `domain1` on the local host. Setting the Data Grid Start Port when an instance is created to `2900`.

```
asadmin> create-local-instance --dataGridStartPort 2900 --node localhost-domain1
instance2
Rendezvoused with DAS on localhost:4848.
```

```
Using DAS host localhost and port 4848 from existing das.properties for node
localhost-domain1. To use a different DAS, create a new node using create-node-ssh or
create-node-config. Create the instance with the new node and correct
host and port:
asadmin --host das_host --port das_port create-local-instance --node node_name
instance_name.
Port Assignments for server instance instance2:
OSGI_SHELL_TELNET_PORT=26667
JAVA_DEBUGGER_PORT=29010
JMS_PROVIDER_PORT=27677
HTTP_LISTENER_PORT=28081
IIOP_SSL_LISTENER_PORT=23821
ASADMIN_LISTENER_PORT=24849
IIOP_SSL_MUTUALAUTH_PORT=23921
JMX_SYSTEM_CONNECTOR_PORT=28687
HTTP_SSL_LISTENER_PORT=28182
IIOP_LISTENER_PORT=23701
Command create-local-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

create-managed-executor-service

Creates a managed executor service resource.

Synopsis

```
asadmin [asadmin-options] create-managed-executor-service [--help]
        [--enabled={false|true}]
        [--contextinfoenabled={false|true}]
        [--contextinfo={Classloader|JNDI|Security|WorkArea}]
        [--threadpriority threadpriority]
        [--longrunningtasks={false|true}]
        [--useforkjoinpool={false|true}]
        [--hungafterseconds hungafterseconds]
        [--corepoolsize corepoolsize]
        [--maximumpoolsize maximumpoolsize]
        [--keepaliveseconds keepaliveseconds]
        [--threadlifetimeseconds threadlifetimeseconds]
        [--taskqueuecapacity taskqueuecapacity]
        [--usevirtualthreads={false|true}]
        [--description description]
        [--property property]
        [--target target]
        jndi_name
```

Description

The `create-managed-executor-service` subcommand creates a managed executor service resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Determines whether the resource is enabled at runtime.

The default value is `true`.

`--contextinfoenabled`

Determines whether container contexts are propagated to threads. If set to `true`, the contexts specified in the `--contextinfo` option are propagated. If set to `false`, no contexts are propagated and the `--contextinfo` option is ignored.

The default value is `true`.

`--contextinfo`

Specifies individual container contexts to propagate to threads. Valid values are Classloader, JNDI, Security, and WorkArea. Values are specified in a comma-separated list and are case-insensitive.

All contexts are propagated by default.

`--threadpriority`

Specifies the priority to assign to created threads. The default value is 5.

`--longrunningtasks`

Specifies whether the resource should be used for long-running tasks. The default value is `false`. If set to `true`, long-running tasks are not reported as stuck.

`--hungafterseconds`

Specifies the number of seconds that a task can execute before it is considered unresponsive. The default value is 0, which means that tasks are never considered unresponsive.

`--corepoolsize`

Specifies the number of threads to keep in a thread pool, even if they are idle. The default value is 0. When a new task is submitted and the number of running threads is less than `corepoolsize`, a new thread is created to handle the request. When the value for `corepoolsize` is 0 (the default), new threads are never created unless the task queue is full or the resource is using direct queuing. Direct queuing occurs when `taskqueuecapacity` is 0, or when `taskqueuecapacity` is 2147483647 and `corepoolsize` is 0.

`--maximumpoolsize`

Specifies the maximum number of threads that a thread pool can contain. The default value is 2147483647, which means that the thread pool is essentially unbounded and can contain any number of threads.

`--keepaliveseconds`

Specifies the number of seconds that threads can remain idle when the number of threads is greater than `corepoolsize`.

The default value is 60.

`--threadlifetimeseconds`

Specifies the number of seconds that threads can remain in a thread pool before being purged, regardless of whether the number of threads is greater than `corepoolsize` or whether the threads are idle.

The default value is 0, which means that threads are never purged.

`--taskqueuecapacity`

Specifies the number of submitted tasks that can be stored in the task queue awaiting execution. The default value is 2147483647, which means that the task queue is essentially unbounded and can store any number of submitted tasks.

`--usevirtualthreads`

If enabled, virtual threads will be used instead of the default platform thread pool. They provide quick creation, minimal overhead, and fast thread switching, but are executed on limited "carrying threads". Use virtual threads for tasks which depend on external resources like databases, micro-services, etc. Do not use them for long calculation.

The default value is `false`.

`--description`

Descriptive details about the resource.

`--property`

Optional attribute name/value pairs for configuring the resource.

Payara Server does not define any additional properties for this resource. Moreover, this resource does not currently use any additional properties.

`--target`

Specifies the target for which you are creating the resource. Valid targets are:

`server`

Creates the resource for the default server instance. This is the default value.

`domain`

Creates the resource for the domain.

cluster_name

Creates the resource for every server instance in the specified cluster.

instance_name

Creates the resource for the specified server instance.

Operands

jndi_name

The JNDI name of this resource.

Examples

Example 1 Creating a Managed Executor Service Resource

This example creates a managed executor service resource named `concurrent/myExecutor`.

```
asadmin> create-managed-executor-service --description "Executor Service example"
--useforkjoinpool concurrent/myExecutor
Managed executor service concurrent/myExecutor created successfully.
Command create-managed-executor-service executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `delete-managed-executor-service`,
- `list-managed-executor-services`

create-managed-scheduled-executor-service

Creates a managed scheduled executor service resource.

Synopsis

```
asadmin [asadmin-options] create-managed-scheduled-executor-service [--help]
        [--enabled={false|true}]
        [--contextinfoenabled={false|true}]
        [--contextinfo={Classloader|JNDI|Security|WorkArea}]
        [--threadpriority threadpriority]
        [--longrunningtasks={false|true}]
        [--hungafterseconds hungafterseconds]
        [--corepoolsize corepoolsize]
        [--keepaliveseconds keepaliveseconds]
        [--threadlifetimeseconds threadlifetimeseconds]
        [--usevirtualthreads={false|true}]
        [--description description]
        [--property property]
        [--target target]
        jndi_name
```

Description

The `create-managed-scheduled-executor-service` subcommand creates a managed scheduled executor service resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Determines whether the resource is enabled at runtime.

The default value is `true`.

`--contextinfoenabled`

Determines whether container contexts are propagated to threads. If set to `true`, the contexts specified in the `--contextinfo` option are propagated. If set to `false`, no contexts are propagated and the `--contextinfo` option is ignored.

The default value is `true`.

`--contextinfo`

Specifies individual container contexts to propagate to threads. Valid values are Classloader, JNDI, Security, and WorkArea. Values are specified in a comma-separated list and are case-insensitive.

All contexts are propagated by default.

`--threadpriority`

Specifies the priority to assign to created threads. The default value is 5.

`--longrunningtasks`

Specifies whether the resource should be used for long-running tasks. The default value is `false`. If set to `true`, long-running tasks are not reported as stuck.

`--hungafterseconds`

Specifies the number of seconds that a task can execute before it is considered unresponsive. The default value is 0, which means that tasks are never considered unresponsive.

`--corepoolsize`

Specifies the number of threads to keep in a thread pool, even if they are idle. The default value is 0, which means that a thread is created when the first task is scheduled.

`--keepaliveseconds`

Specifies the number of seconds that threads can remain idle when the number of threads is greater than `corepoolsize`.

The default value is 60.

`--threadlifetimeseconds`

Specifies the number of seconds that threads can remain in a thread pool before being purged, regardless of whether the number of threads is greater than `corepoolsize` or whether the threads are idle.

The default value is 0, which means that threads are never purged.

`--usevirtualthreads`

If enabled, virtual threads will be used instead of the default platform thread pool. They provide quick creation, minimal overhead, and fast thread switching, but are executed on limited "carrying threads". Use virtual threads for tasks which depend on external resources like databases, micro-services, etc. Do not use them for long calculation.

The default value is `false`.

`--description`

Descriptive details about the resource.

`--property`

Optional attribute name/value pairs for configuring the resource. Payara Server does not define any additional properties for this resource. Moreover, this resource does not currently use any additional properties.

`--target`

Specifies the target for which you are creating the resource. Valid targets are:

`server`

Creates the resource for the default server instance. This is the default value.

`domain`

Creates the resource for the domain.

cluster_name

Creates the resource for every server instance in the specified cluster.

instance_name

Creates the resource for the specified server instance.

Operands

jndi_name

The JNDI name of this resource.

Examples

Example 1 Creating a Managed Scheduled Executor Service Resource

This example creates a managed scheduled executor service resource named `concurrent/myScheduledExecutor`.

```
asadmin> create-managed-scheduled-executor-service --description "Scheduled Executor
example" concurrent/myScheduledExecutor
Managed scheduled executor service concurrent/myScheduledExecutor created
successfully.
```

```
Command create-managed-scheduled-executor-service executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-managed-thread-factory

Creates a managed thread factory resource.

Synopsis

```
asadmin [asadmin-options] create-managed-thread-factory [--help]
        [--enabled={false|true}]
        [--contextinfoenabled={false|true}]
        [--contextinfo={Classloader|JNDI|Security|WorkArea}]
        [--threadpriority threadpriority]
        [--usevirtualthreads={false|true}]
        [--description description]
        [--property property]
        [--target target]
        jndi_name
```

Description

The `create-managed-thread-factory` subcommand creates a managed thread factory resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Determines whether the managed thread factory is enabled at runtime.

The default value is `true`.

`--contextinfoenabled`

Determines whether container contexts are propagated to threads. If set to `true`, the contexts specified in the `--contextinfo` option are propagated. If set to `false`, no contexts are propagated and the `--contextinfo` option is ignored.

The default value is `true`.

`--contextinfo`

Specifies individual container contexts to propagate to threads. Valid values are Classloader, JNDI, Security, and WorkArea. Values are specified in a comma-separated list and are case-insensitive.

All contexts are propagated by default.

`--threadpriority`

Specifies the priority to assign to created threads.

The default value is 5.

`--usevirtualthreads`

If enabled, virtual threads will be used instead of the default platform thread pool. They provide quick creation, minimal overhead, and fast thread switching, but are executed on limited "carrying threads". Use virtual threads for tasks which depend on external resources like databases, micro-services, etc. Do not use them for long calculation.

The default value is `false`.

`--description`

Descriptive details about the resource.

`--property`

Optional attribute name/value pairs for configuring the resource. Payara Server does not define any additional properties for this resource. Moreover, this resource does not currently use any additional properties.

`--target`

Specifies the target for which you are creating the resource. Valid targets are:

`server`

Creates the resource for the default server instance. This is the default value.

`domain`

Creates the resource for the domain.

cluster_name

Creates the resource for every server instance in the specified cluster.

instance_name

Creates the resource for the specified server instance.

Operands

jndi_name

The JNDI name of this resource.

Examples

Example 1 Creating a Managed Thread Factory Resource

This example creates a managed thread factory resource named `concurrent/myThreadFactory`.

```
asadmin> create-managed-thread-factory --description "Thread Factory example"
--threadpriority 1 concurrent/myThreadFactory
Managed thread factory concurrent/myThreadFactory created successfully.
Command create-managed-thread-factory executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-message-security-provider

Enables administrators to create a message security provider, which specifies how SOAP messages will be secured.

Synopsis

```
asadmin [asadmin-options] create-message-security-provider [--help]
[--target target]
--classname provider_class
[--layer message_layer] [--providertype provider_type]
[--requestauthsource request_auth_source ]
```

```
[--requestauthrecipient request_auth_recipient ]
[--responseauthsource response_auth_source ]
[--responseauthrecipient response_auth_recipient ]
[--isdefaultprovider] [--property name=value[:name=value]*]
provider_name
```

Description

The `create-message-security-provider` subcommand enables the administrator to create a message security provider for the security service which specifies how SOAP messages will be secured.

This command is supported in remote mode only.

Options

If an option has a short option name, then the short option precedes the long option name. Short options have one dash whereas long options have two dashes.

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which you are creating the message security provider. The following values are valid:

`server`

Creates the provider for the default server instance `server` and is the default value.

`domain`

Creates the provider for the domain.

cluster_name

Creates the provider for every server instance in the cluster.

instance_name

Creates the provider for a particular sever instance.

`--classname`

Defines the Java implementation class of the provider. Client authentication providers must implement the `com.sun.enterprise. security.jauth.ClientAuthModule` interface. Server-side providers must implement the `com.sun.enterprise.security jauth.ServerAuthModule` interface. A provider may implement both interfaces, but it must implement the interface corresponding to its provider type.

`--layer`

The message-layer entity used to define the value of the `auth-layer` attribute of `message-security-config` elements. The default is `HttpServlet`. Another option is `SOAP`.

`--providertype`

Establishes whether the provider is to be used as client authentication provider, server authentication provider, or both. Valid options for this property include `client`, `server`, or `client-server`.

`--requestauthsource`

The `auth-source` attribute defines a requirement for message-layer sender authentication (e.g. username password) or content authentication (e.g. digital signature) to be applied to request messages. Possible values are `sender` or `content`. When this argument is not specified, source authentication of the request is not required.

`--requestauthrecipient`

The `auth-recipient` attribute defines a requirement for message-layer authentication of the receiver of a message to its sender (e.g. by XML encryption). Possible values are `before-content` or `after-content`. The default value is `after-content`.

`--responseauthsource`

The `auth-source` attribute defines a requirement for message-layer sender authentication (e.g. username password) or content authentication (e.g. digital signature) to be applied to response messages. Possible values are `sender` or `content`. When this option is not specified, source authentication of the response is not required.

`--responseauthrecipient`

The `auth-recipient` attribute defines a requirement for message-layer authentication of the receiver of the response message to its sender (e.g. by XML encryption). Possible values are `before-content` or `after-content`. The default value is `after-content`.

`--isdefaultprovider`

The `default-provider` attribute is used to designate the provider as the default provider (at the layer) of the type or types identified by the `providertype` argument. There is no default associated with this option.

`--property`

Use this property to pass provider-specific property values to the provider when it is initialized. Properties passed in this way might include key aliases to be used by the provider to get keys from keystores, signing, canonicalization, encryption algorithms, etc.
The following properties may be set:

`security.config`

Specifies the location of the message security configuration file. To point to a configuration file in the domain-dir`/config` directory, use the system property `${com.sun.aas.instanceRoot}/config/`, for example: `${com.sun.aas.instanceRoot}/config/wss-server-config-1.0.xml`. The default is domain-dir`/config/ wss-serverconfig-1.0.xml`.

`debug`

If `true`, enables dumping of server provider debug messages to the server log. The default is `false`.

`dynamic.username. password`

If `true`, signals the provider runtime to collect the username and password from the `CallbackHandler` for each request. If `false`, the username and password for `wsse:UsernameToken`(s) is collected once, during module initialization. This property is only applicable for a `ClientAuthModule`. The default is `false`.

`encryption.key.alias`

Specifies the encryption key used by the provider. The key is identified by its keystore alias. The default value is `s1as`.

`signature.key.alias`

Specifies the signature key used by the provider. The key is identified by its keystore alias. The default value is `s1as`.

Operands

provider_name

The name of the provider used to reference the `provider-config` element.

Examples

Example 1 Creating a Message Security Provider

The following example shows how to create a message security provider for a client.

```
asadmin> create-message-security-provider
--classname com.sun.enterprise.security.jauth.ClientAuthModule
--providertype client mySecurityProvider
```

Exit Status

0

command executed successfully

1

error in executing the command

create-module-config

Adds the default configuration of a module to `domain.xml`.

Synopsis

```
asadmin [asadmin-options] create-module-config [--help]
[--dryrun={false|true}]
[--all={false|true}]
[--target target]
[service_name]
```

Description

The `create-module-config` subcommand adds the default configuration of a module to `domain.xml`.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--dryrun`

Displays the default configuration of a module but does not add it to `domain.xml`. The default value is `false`.

`--all`

Adds all default configurations of modules to `domain.xml` if they are not already in it. The default value is `false`.

`--target`

Specifies the target to which the default configuration is being added.
Possible values are as follows:

`server`

Adds the default configuration to the default server instance. This is the default value.

`domain`

Adds the default configuration to the default domain.

cluster-name

Adds the default configuration to every server instance in the specified cluster.

instance-name

Adds the default configuration to the specified instance.

Operands

service_name

The name of the module for which the default configuration is to be added.

Examples

Example 1 Adding a Default Configuration to domain.xml

This example adds the default configuration of the web container module to `domain1` in `server-config` (the default configuration). Use the `--dryrun` option to preview the configuration before it is added.

```
asadmin> create-module-config web-container
Command create-module-config executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-network-listener

Adds a new network listener socket.

Synopsis

```
asadmin [asadmin-options] create-network-listener [--help]
[--address address]
--listenerport listener-port
[--threadpool thread-pool]
--protocol protocol
[--transport transport]
[--enabled={true|false}]
[--jkenabled={false|true}]
[--target target]
```

```
listener-name
```

Description

The `create-network-listener` subcommand creates a network listener. This subcommand is supported in remote mode only.

If you edit the special network listener named `admin-listener`, you must restart the server for the changes to take effect. The Administration Console does not tell you that a restart is required in this case.

You can use the `create-http-listener` subcommand to create a network listener that uses the HTTP protocol without having to first create a protocol, transport, or HTTP configuration. This subcommand is a convenient shortcut, but it gives access to only a limited number of options.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--address`

The IP address or the hostname (resolvable by DNS).

`--listenerport`

The port number to create the listen socket on. Legal values are 1-65535. On UNIX, creating sockets that listen on ports 1-1024 requires superuser privileges. Configuring an SSL listen socket to listen on port 443 is standard.

`--threadpool`

The name of the thread pool for this listener. Specifying a thread pool is optional. The default is `http-thread-pool`.

`--protocol`

The name of the protocol for this listener.

`--transport`

The name of the transport for this listener. Specifying a transport is optional. The default is `tcp`.

`--enabled`

If set to `true`, the default, the listener is enabled at runtime.

`--jkenabled`

If set to `true`, `mod_jk` is enabled for this listener. The default is false.

`--target`

Creates the network listener only on the specified target. Valid values are as follows:

`server`

Creates the network listener on the default server instance. This is the default value.

configuration-name

Creates the network listener in the specified configuration.

cluster-name

Creates the network listener on all server instances in the specified cluster.

standalone-instance-name

Creates the network listener on the specified standalone server instance.

Operands

listener-name

The name of the network listener.

Examples

Example 1 Creating a Network Listener

The following command creates a network listener named `sampleListener` that is not enabled at runtime:

```
asadmin> create-network-listener --listenerport 7272 --protocol http-1
--enabled=false sampleListener
Command create-network-listener executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

create-node-config

Creates a node that is not enabled for remote communication.

Synopsis

```
asadmin [asadmin-options] create-node-config [--help]
[--nodehost node-host]
[--installdir as-install-parent] [--nodedir node-dir] node-name
```

Description

The `create-node-config` subcommand creates a node that is not enabled for remote communication. The `create-node-config` subcommand does not require the secure shell (SSH) to be configured to create the node.

A node represents a host on which the Payara Server software is installed. A node must exist for every host on which Payara Server instances reside.

To represent the host where the DAS is running, Payara Server provides the predefined node `localhost-domain`. The predefined node `localhost-domain` is not enabled for remote communication.

All administration of instances on a node that is not enabled for remote communication must be performed on the host that the node represents. The domain administration server (DAS) on a remote host cannot contact the node. To administer instances on a node that represents a host that is remote from the DAS, you must use the following subcommands:

- `create-local-instance`
- `delete-local-instance`
- `start-local-instance`

However, you may use `stop-local-instance` or `stop-instance` to stop the instances.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodehost`

The name of the host that the node represents. If this option is omitted, no host is specified for the node.

`--installdir`

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara5/`. If this option is omitted, no parent of the base installation directory of the Payara Server software is specified for the node.

`--nodedir`

The path to the directory that is to contain Payara Server instances that are created on the node. If a relative path is specified, the path is relative to the as-install directory. If this option is omitted, no directory for instances is specified for the node.

Operands

node-name

The name of the node.
The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Hyphen
  - Period
  - Underscore
- The name must be unique in the domain and must not be the name of another node, a cluster, a named configuration, or a Payara Server instance.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.

Examples

Example 1 Creating a Node That Is Not Enabled for Remote Communication

This example creates the node `sj03` for host `sj03.example.com`. The node is not enabled for remote communication.

```
asadmin> create-node-config --nodehost sj03.example.com sj03

Command create-node-config executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

create-node-docker

Creates a node that hosts server instances on a Docker containers.

Synopsis

```
asadmin [asadmin-options] create-node-ssh [--help]
[--nodehost node-host]
[--installdir as-install-parent]
[--nodedir node-dir]
[--dockerpasswordfile filepath]
[--dockerimage imageName]
```

```
[--dockerport port]
[--useTls={false|true}]
node-name
```

Description

The `create-node-docker` subcommand creates a server node hosted on a Docker container.

A node represents a host on which the Payara Server software is installed. A node must exist for every host on which Payara Server instances reside.

The domain administration server (DAS) contacts a Docker node's host through the Docker engine's REST API on its specific configured host and port. By default, the subcommand fails and the node is not created if the DAS cannot reach the configured Docker engine's process.

The setup of a Docker node is more involved that other types of nodes, so it is recommended reading about the requirements and conditions for this command to work properly in corresponding section in Payara Server's High Availability section.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodehost`

The name of the host where the Docker engine process is listening through its REST API. This option is mandatory, otherwise the command fails.

`--installdir`

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara/`. The default is the parent of the default base installation directory of the Payara Server software for the DAS.

When creating a Docker node this parameter is mostly irrelevant when using the official Payara Server Node images. Use this parameter to point to custom server installations in case of using different images.

`--nodedir`

The path to the directory that is to contain Payara Server instances that are created on the node. The default is `as-install/nodes`, where as-install is the base installation directory of the Payara Server software on the host.

If a relative path is specified, the path is relative to the `as-install` directory.

`--dockerPasswordFile`

This is the fully-qualified path of the password file that the Docker instance will use for authentication against the DAS.

Please note, that this path should be the path to the file on the **remote** machine where . This file should be a standard Payara Server password file as you would use with asadmin. This must be specified, as Docker instances require secure admin to be enabled to start.

`--dockerImage`

The Docker image to use for creating the container.

Defaults to `payara/server-node:main-7`.

`--dockerPort`

The port where the Docker engine's REST API endpoint is exposed.

Defaults to `2376`.

`--useTls`

Specifies whether the Docker engine's REST API endpoint is contacted through secure communication, as recommended in most environments. Defaults to `false`.

Operands

node-name

The name of the node.
The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Hyphen
  - Period
  - Underscore
- The name must be unique in the domain and must not be the name of another node, a cluster, a named configuration, or a Payara Server instance.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.

Examples

Example 1 Creating a Node

This example creates the node `docker-node-1` by contacting the Docker REST API which is hosted in `http://localhost:2376` (locally using the default port):

```
asadmin create-node-docker --nodehost localhost --dockerPasswordFile
/opt/passwordfile.txt --dockerport 2376 docker-node-1

Command create-node-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,

create-node-ssh

Creates a node that is enabled for communication over SSH.

Synopsis

```
asadmin [asadmin-options] create-node-ssh [--help]
--nodehost node-host
[--installdir as-install-parent] [--nodedir node-dir]
[--sshport ssh-port] [--sshuser ssh-user]
[--sshkeyfile ssh-keyfile]
[--force={false|true}]
[--install={false|true}] [--archive archive]
node-name
```

Description

The `create-node-ssh` subcommand creates a node that is enabled for communication over secure shell (SSH).

A node represents a host on which the Payara Server software is installed. A node must exist for every host on which Payara Server instances reside.

The domain administration server (DAS) contacts an SSH node's host through the SSH connector to

manage Payara Server instances that reside on the node. However, the DAS does not use the SSH connector to contact the host where the DAS is running because the DAS can run all `asadmin` subcommands locally.

By default, the subcommand fails and the node is not created if the DAS cannot contact the node's host through SSH. To force the node to be created in the DAS configuration even if the host cannot be contacted through SSH, set the `--force` option to `true`.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodehost`

The name of the host that the node represents. The name of the host must be specified. Otherwise, an error occurs.

`--installdir`

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara/`. The default is the parent of the default base installation directory of the Payara Server software for the DAS. This default is useful only if Payara Server is installed in the same location on all hosts.

`--nodedir`

The path to the directory that is to contain Payara Server instances that are created on the node. The default is `as-install/nodes`, where as-install is the base installation directory of the Payara Server software on the host. If a relative path is specified, the path is relative to the as-install directory.

`--sshport`

The port to use for SSH connections to this node's host. The default is 22. If the `--nodehost` option is set to `localhost-`domain, the `--sshport` option is ignored.

`--sshuser`

The user on this node's host that is to run the process for connecting to the host through SSH. The default is the user that is running the DAS process. To ensure that the DAS can read this user's SSH private key file, specify the user that is running the DAS process. If the `--nodehost` option is set to `localhost-domain`, the `--sshuser` option is ignored.

`--sshkeyfile`
