The absolute path to the SSH private key file for user that the `--sshuser` option specifies. This file is used for authentication to the `sshd` daemon on the node's host.

Payara Server also supports password authentication through the `AS_ADMIN_SSHPASSWORD` entry in the password file. The password file is specified in the `--paswordfile` option of the `asadmin` utility.

If the SSH private key file is protected by a passphrase, the password file must contain the `AS_ADMIN_SSHKEYPASSPHRASE` entry.
The path to the key file must be reachable by the DAS and the key file must be readable by the DAS.
The default is the a key file in the user's `.ssh` directory. If multiple key files are found, the subcommand uses the following order of preference:

1. `id_rsa`
2. `id_dsa`
3. `identity`

`--force`

Specifies whether the node is created in the DAS configuration even if validation of the node's parameters fails. To validate a node's parameters, the DAS must be able to contact the node's host through SSH. Possible values are as follows:

`false`

The node is not created if validation of the node's parameters fails (default).

`true`

The node is created even if validation of the node's parameters fails.

`--install`

Specifies whether the subcommand shall install the Payara Server software on the host that the node represents.
Possible values are as follows:

`false`

The subcommand shall not install the Payara Server software on the host (default).

`true`

The subcommand shall install the Payara Server software on the host.

`--archive`

The absolute path to the archive file of the Payara Server software that is to be installed. If this option is omitted and the `--install` is `true`, the subcommand creates a ZIP archive of the Payara Server software from the installation where this subcommand is run. The archive does not contain the `domains` directory or the `nodes` directory.

Operands

node-name

The name of the node.
The name must meet the following requirements:

- The name may contain only ASCII characters.
- The name must start with a letter, a number, or an underscore.
- The name may contain only the following characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Hyphen
  - Period
  - Underscore
- The name must be unique in the domain and must not be the name of another node, a cluster, a named configuration, or a Payara Server instance.
- The name must not be `domain`, `server`, or any other keyword that is reserved by Payara Server.

Examples

Example 1 Creating a Node

This example creates the node `adc` for the host `adc.example.com`. By default, the parent of the base installation directory of the Payara Server software is `/export/payara`.

```
asadmin> create-node-ssh
--nodehost adc.example.com
--installdir /export/payara adc

Command create-node-ssh executed successfully.
```

Example 2 Forcing the Creation of a Node

This example forces the creation of node `eg1` for the host `eghost.example.com`. The node is created despite the failure of the DAS to contact the host `eghost.example.com` to validate the node's parameters.

```
asadmin> create-node-ssh --force --nodehost eghost.example.com eg1
Warning: some parameters appear to be invalid.
Could not connect to host eghost.example.com using SSH.
There was a problem while connecting to eghost.example.com:22
eghost.example.com
Continuing with node creation due to use of --force.

Command create-node-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

create-password-alias

Creates a password alias.

Synopsis

```
asadmin [asadmin-options] create-password-alias [--help]
aliasname
```

Description

The `create-password-alias` subcommand creates an alias for a password. An alias is a token of the form `${ALIAS=aliasname}`. The password that corresponds to the alias name is stored in an encrypted form.

The `create-password-alias` subcommand can be run interactively or noninteractively.

- When run interactively, the subcommand prompts the user for the alias password and to confirm the alias password.
- When run noninteractively, the subcommand reads the alias password from a file that is passed through the `--passwordfile` option of the `asadmin` utility. The file must contain an entry of the form `{cprefix}ALIASPASSWORD`=alias-password, where alias-password is the alias password. The noninteractive form of this command is suitable for use in scripts.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

aliasname

Your choice of name for the password alias.

Examples

Example 1 Creating a Password Alias Interactively

This example creates the password alias `jmspassword-alias` interactively.

```
asadmin> create-password-alias jmspassword-alias
Enter the alias password>
Enter the alias password again>
Command create-password-alias executed successfully.
```

Example 2 Creating a Password Alias Noninteractively

This example uses the `--passwordfile` option of the `asadmin` utility to create the password alias `winuser` noninteractively.

```
$ asadmin --passwordfile aspwfile.txt create-password-alias winuser
Command create-password-alias executed successfully.
```

The file `aspwfile.txt` contains the following entry to specify the alias password:

```
AS_ADMIN_ALIASPASSWORD=sp@rky
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

create-protocol-filter

Adds a new protocol filter.

Synopsis

```
asadmin [asadmin-options] create-protocol-filter [--help]
--protocol protocol-name
--classname class-name
[--target server]
protocol-filter-name
```

Description

The `create-protocol-filter` subcommand creates a protocol filter for a protocol. This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

`--protocol`
: The name of the associated protocol.

`--classname`
: The fully qualified name of the Java class that implements the protocol filter.

`--target`
: Creates the protocol filter only on the specified target. Valid values are as follows:

  `server`
  : Creates the protocol filter on the default server instance. This is the default value.

  configuration-name
  : Creates the protocol filter in the specified configuration.

cluster-name

Creates the protocol filter on all server instances in the specified cluster.

standalone-instance-name

Creates the protocol filter on the specified standalone server instance.

Operands

protocol-filter-name

The name of the protocol filter.

Examples

Example 1 Creating a Protocol Filter

The following command creates a protocol filter named `http1-filter`:

```
asadmin> create-protocol-filter --protocol http1
--classname com.company22.MyProtocolFilter http1-filter
Command create-protocol-filter executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-protocol`,
- `delete-protocol-filter`,
- `list-protocol-filters`

create-protocol-finder

Adds a new protocol finder.

Synopsis

```
asadmin [asadmin-options] create-protocol-finder [--help]
--protocol protocol-name
--targetprotocol target-protocol-name
--classname class-name
[--target server]
```

```
protocol-finder-name
```

Description

The `create-protocol-finder` subcommand creates a protocol finder for a protocol. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--protocol`

The name of the associated protocol.

`--targetprotocol`

The name of the target protocol.

`--classname`

The fully qualified name of the Java class that implements the protocol finder.

`--target`

Creates the protocol finder only on the specified target. Valid values are as follows:

`server`

Creates the protocol finder on the default server instance. This is the default value.

configuration-name

Creates the protocol finder in the specified configuration.

cluster-name

Creates the protocol finder on all server instances in the specified cluster.

standalone-instance-name

Creates the protocol finder on the specified standalone server instance.

Operands

protocol-finder-name

The name of the protocol finder.

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `delete-protocol-finder`,
- `list-protocol-finders`

create-protocol

Adds a new protocol.

Synopsis

```
asadmin [asadmin-options] create-protocol [--help]
[--securityenabled={false|true}]
[--target target]
protocol-name
```

Description

The `create-protocol` subcommand creates a protocol. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--securityenabled`

If set to `true`, the protocol runs SSL. You can turn SSL2 or SSL3 ON or OFF and set ciphers using an `ssl` element. The security setting globally enables or disables SSL by making certificates available to the server instance. The default value is `false`.

`--target`

Creates the protocol only on the specified target. Valid values are as follows:

`server`

Creates the protocol on the default server instance. This is the default value.

configuration-name

Creates the protocol in the specified configuration.

cluster-name

Creates the protocol on all server instances in the specified cluster.

standalone-instance-name

Creates the protocol on the specified standalone server instance.

Operands

protocol-name

The name of the protocol.

Examples

Example 1 Creating a Protocol

The following command creates a protocol named `http-1` with security enabled:

```
asadmin> create-protocol --securityenabled=true http-1
Command create-protocol executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `delete-protocol`,
- `list-protocols`,
- `create-network-listener`

create-resource-adapter-config

Creates the configuration information for the connector module.

Synopsis

```
asadmin [asadmin-options] create-resource-adapter-config [--help]
[--threadpoolid threadpool]
[--objecttype object-type]
[--property (property-name=value)[:name=value]*]
```

```
raname
```

Description

The `create-resource-adapter-config` subcommand creates configuration information for the connector module. This subcommand can be run before deploying a resource adapter, so that the configuration information is available at the time of deployment. The resource adapter configuration can also be created after the resource adapter is deployed. In this case, the resource adapter is restarted with the new configuration. You must first create a thread pool, using the `create-threadpool` subcommand, and then identify that thread pool value as the ID in the `--threadpoolid` option.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--threadpoolid`

The thread pool ID from which the work manager gets the thread. This option takes only one thread pool ID.

`--objecttype`

The default is `user`.

`--property`

Keyword-value pairs that specify additional configuration properties of the resource adapter Java bean. The keyword-value pairs are separated by a colon (`:`). The properties are the names of setter methods of the class that is referenced by the `resourceadapter-class` element in the `ra.xml` file.

Operands

raname

Indicates the connector module name. It is the value of the `resource-adapter-name` in the `domain.xml` file.

Examples

Example 1 Creating a Resource Adapter Con figuration

This example creates a resource adapter configuration for `ra1`.

```
asadmin> create-resource-adapter-config --property foo=bar --threadpoolid
```

```
mycustomerthreadpool ra1
Command create-resource-adapter-config executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-threadpool`,
- `delete-resource-adapter-config`,
- `list-resource-adapter-configs`

create-resource-ref

Creates a reference to a resource.

Synopsis

```
asadmin [asadmin-options] create-resource-ref [--help]
[--target target]
[--enabled={false|true}] reference_name
```

Description

The `create-resource-ref` subcommand creates a reference from a cluster or an unclustered server instance to a previously created resource, for example, a JDBC resource created by using the `create-jdbc-resource` subcommand. This effectively results in the resource being made available in the JNDI tree of the instance or cluster.

The target instance or instances making up the cluster need not be running or available for this subcommand to succeed. If one or more instances are not available, they will receive the new resource the next time they start.

A `resource-ref` can only be created for bindable resources, such as a `jdbc-resource`, `connector-resource`, `admin-object-resource`, `mail-resource`, `custom-resource`, or `jndi-resource`.
A `jdbc-connection-pool` or a `connector-connection-pool` are not referred to directly by applications. Instead, they are referred to through a `jdbc-resource` or `connector-resource`, respectively.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which you are creating the resource reference. Valid targets are as follows:

`server`

Creates the resource reference for the default server instance. This is the default target.

cluster_name

Creates the resource reference for every server instance in the cluster.

instance_name

Creates the resource reference for the named unclustered server instance.

`--enabled`

Indicates whether the resource should be enabled. This value will take effect only if the resource is enabled at the global level. The default is `true`.

Operands

reference_name

The name or JNDI name of the resource.

Examples

Example 1 Creating a Reference to a JMS Destination Resource

This example creates a reference to the JMS destination resource `jms/Topic` on the cluster `Cluster1`.

```
asadmin> create-resource-ref --target Cluster1 jms/Topic
resource-ref jms/Topic created successfully.
Command create-resource-ref executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `delete-resource-ref`,
- `list-resource-refs`

create-service

configures the starting of a DAS or a Payara Server instance on an unattended boot

Synopsis

```
asadmin [asadmin-options] create-service [--help]
[--name service-name]
[--serviceproperties service-properties]
[--dry-run={false|true}] [--force={false|true}]
[--system-type system-type]
[--serviceuser service-user]
[--domaindir domain-dir]
[--nodedir node-dir] [--node node]
[domain-or-instance-name]
```

Description

The `create-service` subcommand configures the starting of a domain administration server (DAS) or a Payara Server instance on an unattended boot on Windows, Linux, and Oracle Solaris systems.

If no operand is specified and the domains directory contains only one domain, the subcommand configures the starting of the DAS for the default domain. If no operand is specified and the domains directory contains multiple domains, an error occurs.

If the operand specifies an instance, the `create-service` subcommand does not contact the domain administration server (DAS) to determine the node on which the instance resides.

To determine the node on which the instance resides, the subcommand searches the directory that contains the node directories. If multiple node directories exist, the node must be specified as an option of the subcommand.

The subcommand contains internal logic to determine whether the supplied operand is a DAS or an instance.

This subcommand is supported in local mode only.

Behavior of `create-service` on Windows Systems

On Windows systems, this subcommand must be run as the OS-level administrator user and requires the Microsoft .NET Framework (http://www.microsoft.com/net/), otherwise, the subcommand fails.

It creates a Windows service to represent the DAS or instance. The service is created in the disabled state. After this subcommand creates the service, you must use the Windows Services Manager or the Windows Services Wrapper to start, stop, uninstall, or install the service.

The subcommand creates the following Windows Services Wrapper files for the service in the `domain-dir\bin` directory or the `instance-dir\bin` directory:

- Configuration file: `service-nameService.xml`
- Executable file: `service-nameService.exe`

Behavior of `create-service` on Linux Systems

On Linux systems, the create-service subcommand first detects System-V or SystemD init systems.

On systems using System-V, it creates an initialization script `/etc/init.d/payara_domain-or-instance-name` and installs a link to this script in the `/etc/rc?.d` directories. After this subcommand creates the script, you must use this script to start, stop, or restart the domain or instance.

On systems using SystemD, the subcommand creates a configuration file `payara_domainname.service in /etc/systemd/system`. It is recommended to specify non-root user to run payara (parameter `--serviceuser`). It is possible to further configure the service via `--serviceproperties`.

On Linux systems, this subcommand must be run as the OS-level root user, because it writes to system directories.

Behavior of `create-service` on Oracle Solaris Systems

On Oracle Solaris systems, the `create-service` subcommand creates a Service Management Facility (SMF) service to represent the DAS or instance. The service is created in the disabled state. After this subcommand creates the service, you must use SMF commands to start, enable, disable, delete, or stop the service. For more information about SMF, see the following documentation for the Oracle Solaris operating system:

- Managing Services (Overview) in System Administration Guide: Basic Administration
- Managing Services (Tasks) in System Administration Guide: Basic Administration

On Oracle Solaris systems, this subcommand must be run as the OS-level user with superuser privileges. The configuration file for the DAS or instance must be stored in a directory to which the superuser has access and cannot be stored on a network file system. The service that is created is controlled by the OS-level user who owns the directory where the configuration of the DAS or instance resides.

On Oracle Solaris systems, the manifest file is created in the following directory by default:

```
/var/svc/manifest/application/GlassFish/domain-or-instance-name_domain-or-instance-root-dir
```

To run this subcommand, you must have `solaris.smf.*` authorization. For information about how to grant authorizations to users, see the `useradd` and `usermod` man pages.

To run these commands as non-root user, the system administrator must be contacted so that the relevant authorizations are granted. You must also ensure that the following conditions are met:

- Oracle Solaris 10 administration commands such as `svccfg`, `svcs`, and `auths` are available through the `PATH` statement, so that these commands can be executed. A simple test to do so is to run the command `which svccfg` in the shell.
- You must have write permission for the path `/var/svc/manifest/application/GlassFish`. Usually, the superuser has write permission to this path.

If you delete a service that you created by using the `create-service` subcommand, you must delete the directory that contains the manifest file and the entire contents of the directory. Otherwise, an attempt to re-create the service by using the `create-service` subcommand fails.

The Oracle Solaris command `svccfg` does not delete this directory.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

(Windows and Oracle Solaris systems only) The name of the service that you will use when administering the service through Oracle Solaris SMF commands or the service management features of the Windows operating system. The default is the name of the domain or instance that is specified as the operand of this subcommand.

`--serviceproperties`

Specifies a colon(:)-separated list of various properties that are specific to the service.

To customize the display name of the service in the Windows Service list, set the `DISPLAY_NAME` property to the required name.

For Oracle Solaris 10 systems, if you specify `net_privaddr`, the service's processes will be able to bind to the privileged ports (<1024) on the platform. You can bind to ports< `1024` only if the owner of the service is superuser, otherwise, this is not allowed.

On Linux systems using SystemD these properties are stored as Environment entries, accessible via Microprofile property in the applications.

`--dry-run`

`-n`

Previews your attempt to create a service. Indicates issues and the outcome that will occur if you run the command without using the `--dry-run` option. Nothing is actually configured. Default is false.

`--force`

Specifies whether the service is created even if validation of the service fails.

Possible values are as follows:

`true`

The service is created even if validation of the service fails.

`false`

The service is not created (default).

`--system-type`

If specified, system-type must be one of `systemd`, `systemv`, `solaris` or `windows`, which determine the type of init scripts to create.

If not specified, the command performs auto-detection of init system.

`--serviceuser`

(Linux systems only) The user that is to run the Payara Server software when the service is started. The default is the user that is running the subcommand. Specify this option if the Payara Server is to be run by a user other than the root user.

`--domaindir`

The absolute path of the directory on the disk that contains the configuration of the domain. If this option is specified, the operand must specify a domain.

`--nodedir`

Specifies the directory that contains the instance's node directory. The instance's files are stored in the instance's node directory.

The default is `as-install/nodes`. If this option is specified, the operand must specify an instance.

`--node`

Specifies the node on which the instance resides. This option may be omitted only if the directory that the `--nodedir` option specifies contains only one node directory. Otherwise, this option is required. If this option is specified, the operand must specify an instance.

Operands

domain-or-instance-name

The name of the domain or instance to configure. If no operand is specified, the default domain is used.

Examples

Example 1 Creating a Service on a Windows System

This example creates a service for the default domain on a system that is running Windows.

```
asadmin create-service
The Windows Service was created successfully.  It is ready to be started.  Here are
the details:
ID of the service: domain1
Display Name of the service:domain1 Payara Server
Server Directory: C:\payara7\glassfish\domains\domain1
Configuration file for Windows Services Wrapper:
C:\payara7\glassfish\domains\domain1\bin\domain1Service.xml
The service can be controlled using the Windows Services Manager or you can use the
Windows Services Wrapper instead:
Start Command:  C:\payara7\glassfish\domains\domain1\bin\domain1Service.exe  start
Stop Command:   C:\payara7\glassfish\domains\domain1\bin\domain1Service.exe  stop
Restart Command:  C:\payara7\glassfish\domains\domain1\bin\domain1Service.exe  restart
Uninstall Command:  C:\payara7\glassfish\domains\domain1\bin\domain1Service.exe
uninstall
Install Command:  C:\payara7\glassfish\domains\domain1\bin\domain1Service.exe  install
Status Command: C:\payara7\glassfish\domains\domain1\bin\domain1Service.exe status
You can also verify that the service is installed (or not) with sc query state= all
windows.services.uninstall.good=Found the Windows Service and successfully uninstalled
it.
For your convenience this message has also been saved to this file:
C:\payara7\glassfish\domains\domain1\PlatformServices.log
Command create-service executed successfully.
```

Example 2 Creating a Service on a Linux System using SystemD

This example creates a service for the default domain on a system that is running Linux and SystemD. It is necessary to inform SystemD about the new script by running systemctl daemon-reload. Then it is possible to start the service.

```
asadmin> create-service --service-user payaraadmin

The SystemD Service was created successfully. Here are the details:
Name of the service:domain1
Type of the service:Domain
Configuration location of the service:/etc/systemd/system/payara_domain1.service
User account that will run the service: payaraadmin
You have created the service but you need to start it yourself.  Here are the most
typical Linux commands of interest:

* systemctl daemon-reload
* systemctl start payara_domain1.service
* systemctl stop payara_domain1.service
* systemctl restart payara_domain1.service

For your convenience this message has also been saved to this file:
/opt/payara/glassfish/domains/domain1/PlatformServices.log
```

```
Command create-service executed successfully.
```

Example 3 Creating a Service on a Linux System using SystemV

This example creates a service for the default domain on a system that is running Linux and SystemV.

```
asadmin> create-service

Found the Linux Service and successfully uninstalled it.
The Service was created successfully. Here are the details:
Name of the service:domain1
Type of the service:Domain
Configuration location of the service:/etc/init.d/payara_domain1
User account that will run the service: root
You have created the service but you need to start it yourself.
Here are the most typical Linux commands of interest:

* /etc/init.d/payara_domain1 start
* /etc/init.d/payara_domain1 stop
* /etc/init.d/payara_domain1 restart

For your convenience this message has also been saved to this file:
/opt/payara/glassfish/domains/domain1/PlatformServices.log

Command create-service executed successfully.
```

Example 4 Creating a Service on an Oracle Solaris System

This example creates a service for the default domain on a system that is running Oracle Solaris.

```
asadmin> create-service

The Service was created successfully. Here are the details:
Name of the service:application/GlassFish/domain1
Type of the service:Domain
Configuration location of the service:/opt/payara/glassfish/domains
Manifest file location on the system:/var/svc/manifest/application
/GlassFish/domain1_opt_payara_glassfish_domains/Domain-service-smf.xml.
You have created the service but you need to start it yourself.
Here are the most typical Solaris commands of interest:
* /usr/bin/svcs -a | grep domain1 // status
* /usr/sbin/svcadm enable domain1 // start
* /usr/sbin/svcadm disable domain1 // stop
* /usr/sbin/svccfg delete domain1 // uninstall

Command create-service executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

create-ssl

Creates and configures the SSL element in the selected HTTP listener, IIOP listener, or IIOP service.

Synopsis

```
asadmin [asadmin-options] create-ssl [--help]
[--target target]
--type listener_or_service_type
--certname cert_name
[--ssl2enabled={false|true}] [--ssl2ciphers ss12ciphers]
[--ssl3enabled={true|false}] [--tlsenabled={true|false}]
[--ssl3tlsciphers ssl3tlsciphers]
[--tlsrollbackenabled={true|false}]
[--clientauthenabled={false|true}]
[listener_id]
```

Description

The `create-ssl` subcommand creates and configures the SSL element in the selected HTTP listener, IIOP listener, or IIOP service to enable secure communication on that listener/service.

This subcommand is supported in remote mode only.

Options

If an option has a short option name, then the short option precedes the long option name. Short options have one dash whereas long options have two dashes.

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which you are configuring the ssl element. The following values are valid:

`server`

Specifies the server in which the iiop-service or HTTP/IIOP listener is to be configured for SSL.

config

Specifies the configuration that contains the HTTP/IIOP listener or iiop-service for which SSL is to be configured.

cluster

Specifies the cluster in which the HTTP/IIOP listener or iiop-service is to be configured for SSL. All the server instances in the cluster will get the SSL configuration for the respective listener or iiop-service.

instance

Specifies the instance in which the HTTP/IIOP listener or iiop-service is to be configured for SSL.

`--type`

The type of service or listener for which the SSL is created. The type can be:

- `network-listener`
- `http-listener`
- `iiop-listener`
- `iiop-service`
- `jmx-connector`
  When the type is `iiop-service`, the `ssl-client-config` along with the embedded `ssl` element is created in `domain.xml`.

`--certname`

The nickname of the server certificate in the certificate database or the PKCS#11 token. The format of the name in the certificate is tokenname:nickname. For this property, the tokenname: is optional.

`--ssl2enabled`

Set this property to `true` to enable SSL2. The default value is `false`. If both SSL2 and SSL3 are enabled for a virtual server, the server tries SSL3 encryption first. In the event SSL3 encryption fails, the server then tries SSL2 encryption.

`--ssl2ciphers`

A comma-separated list of the SSL2 ciphers to be used. Ciphers not explicitly listed will be disabled for the target, even if those ciphers are available in the particular cipher suite you are using. If this option is not used, all supported ciphers are assumed to be enabled. Allowed values are:

- `rc4`
- `rc4export`
- `rc2`
- `rc2export`
- `idea`
- `des`
- `desede3`

`--ssl3enabled`

Set this property to `false` to disable SSL3. The default value is `true`. If both SSL2 and SSL3 are enabled for a virtual server, the server tries SSL3 encryption first. In the event SSL3 encryption fails, the server then tries SSL2 encryption.

`--tlsenabled`

Set this property to `false` to disable TLS. The default value is `true` It is good practice to enable TLS, which is a more secure version of SSL.

`--ssl3tlsciphers`

A comma-separated list of the SSL3 and/or TLS ciphers to be used. Ciphers not explicitly listed will be disabled for the target, even if those ciphers are available in the particular cipher suite you are using. If this option is not used, all supported ciphers are assumed to be enabled. Allowed values are:

- `SSL_RSA_WITH_RC4_128_MD5`
- `SSL_RSA_WITH_3DES_EDE_CBC_SHA`
- `SSL_RSA_WITH_DES_CBC_SHA`
- `SSL_RSA_EXPORT_WITH_RC4_40_MD5`
- `SSL_RSA_WITH_NULL_MD5`
- `SSL_RSA_WITH_RC4_128_SHA`
- `SSL_RSA_WITH_NULL_SHA`

`--tlsrollbackenabled`

Set to `true` (default) to enable TLS rollback. TLS rollback should be enabled for Microsoft

Internet Explorer 5.0 and 5.5. This option is only valid when `-tlsenabled=true`.

`--clientauthenabled`

Set to `true` if you want SSL3 client authentication performed on every request independent of ACL-based access control. Default value is `false`.

Operands

listener_id

The ID of the HTTP or IIOP listener for which the SSL element is to be created. The listener_id is not required if the `--type` is `iiop-service`.

Examples

Example 1 Creating an SSL element for an HTTP listener

The following example shows how to create an SSL element for an HTTP listener named `http-listener-1`.

```
asadmin> create-ssl
--type http-listener
--certname sampleCert http-listener-1
Command create-ssl executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `delete-ssl`

create-system-properties

Adds one or more system property elements that can be referenced elsewhere in the configuration.

Synopsis

```
asadmin [asadmin-options] create-system-properties [--help]
[--target target]
[name=value)[:name=value]*]
```

Description

The `create-system-properties` subcommand adds or updates system properties that can be referenced elsewhere on the server.

Payara Server provides hooks where tokens (system properties) can be specified. Because Payara Server does not have multiple server elements, you can specify a particular token at any level. When a domain supports multiple servers, the override potential can be exploited. When a domain is started or restarted, all `<system-property>` elements are resolved and available to the Java Virtual Machine by using the `System.setProperty()` call on each of them (with its name and value derived from the corresponding attributes of the element). This is analogous to sending the elements as `-D` parameters on the Java command line.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The target on which you are creating the system properties.

Operands

target

The valid targets for this subcommand are instance, cluster, configuration, domain, and server. Server is the default option. Valid values are:

`server`

Creates the properties on the default server instance. This is the default value.

`domain`

Creates the properties for all server instances in the default domain.

configuration_name

Creates the properties in the specified configuration.

cluster_name

Creates the properties on all server instances in the specified cluster.

instance_name

Creates the properties on a specified server instance.

name=value

The name value pairs of the system properties to add to the specified target. Multiple system properties must be separated by a : (colon). If a : (colon) appears in the name or value of a system property, it must be escaped with a \ (blackslash). If any system properties were previously defined, they are updated with the new values.

Examples

Example 1 Creating System Properties

This example creates a system property associated with an HTTP listener on a server instance named `myserver`.

```
asadmin> create-system-properties --target myserver http-listener-port=1088
Command create-system-properties executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-system-property`,
- `delete-system-property`,
- `list-system-properties`

create-system-property

Adds one or more system property elements that can be referenced elsewhere in the configuration.

Synopsis

```
asadmin [asadmin-options] create-system-property [--help]
[--target target]
[name=value]
```

Description

The `create-system-property` subcommand adds or updates a single system property that can be referenced elsewhere on the server.

Payara Server provides hooks where tokens (system properties) can be specified. Because Payara

Server does not have multiple server elements, you can specify a particular token at any level. When a domain supports multiple servers, the override potential can be exploited. When a domain is started or restarted, all `<system-property>` elements are resolved and available to the Java Virtual Machine by using the `System.setProperty()` call on each of them (with its name and value derived from the corresponding attributes of the element). This is analogous to sending the elements as `-D` parameters on the Java command line.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The target on which you are creating the system properties.

Operands

target

The valid targets for this subcommand are instance, cluster, configuration, domain, and server. Server is the default option. Valid values are:

`server`

Creates the property on the default server instance. This is the default value.

`domain`

Creates the property for all server instances in the default domain.

configuration_name

Creates the property in the specified configuration.

cluster_name

Creates the property on all server instances in the specified cluster.

instance_name

Creates the property on a specified server instance.

name=value

The name value pair of the system property to add to the specified target. If a system property was already defined, it is updated with the new value.

Examples

Example 1 Creating System Property

This example creates a system property associated with an HTTP listener on a server instance named `myserver`.

```
asadmin> create-system-property --target myserver http-listener-port=1088
Command create-system-property executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- `list-system-properties`

create-threadpool

Adds a thread pool.

Synopsis

```
asadmin [asadmin-options] create-threadpool [--help]
[--target target]
[--maxthreadpoolsize maxthreadpoolsize]
[--minthreadpoolsize minthreadpoolsize]
[--idletimeout idletimeout] [--maxqueuesize maxqueuesize]
threadpool-id
```

Description

The `create-threadpool` subcommand creates a thread pool with the specified name. You can specify maximum and minimum number of threads in the pool, the quantity of messages, and the idle timeout of a thread. The created thread pool can be used for servicing IIOP requests and for resource adapters to service work management requests. A thread pool can be used in multiple resource adapters.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are creating the thread pool.
Valid values are as follows:

`server`

Creates the thread pool for the default Payara Server instance `server` and is the default value

configuration-name

Creates the thread pool for the named configuration.

cluster-name

Creates the thread pool for every instance in the cluster.

instance-name

Creates the thread pool for a particular instance.

`--maxthreadpoolsize`

Specifies the maximum number of threads the pool can contain. Default is 5.

`--minthreadpoolsize`

Specifies the minimum number of threads in the pool. These are created when the thread pool is instantiated. Default is 2.

`--idletimeout`

Specifies the amount of time in seconds after which idle threads are removed from the pool. Default is 900.

`--maxqueuesize`

Specifies the maximum number of messages that can be queued until threads are available to process them for a network listener or IIOP listener. A value of -1 specifies no limit. Default is 4096.

Operands

threadpool-id

An ID for the work queue, for example, `threadpool-1`.

Examples

Example 1 Creating a Thread Pool

This command creates a new thread pool called `threadpool-l`.

```
asadmin> create-threadpool --maxthreadpoolsize 100
--minthreadpoolsize 20 --idletimeout 2 threadpool-1
Command create-threadpool executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `delete-threadpool`,
- `list-threadpools`

create-transport

Adds a new transport.

Synopsis

```
asadmin [asadmin-options] create-transport [--help]
[--acceptorthreads acceptor-threads]
[--bytebuffertype byte-buffer-type]
[--classname class-name]
[--displayconfiguration={false|true}]
[--enablesnoop={false|true}]
[--idlekeytimeoutseconds idle-key-timeout]
[--maxconnectionscount max-connections]
[--readtimeoutmillis read-timeout]
[--writetimeoutmillis write-timeout]
[--selectorpolltimeoutmillis selector-poll-timeout]
[--tcpnodelay={false|true}]
[--target target]
transport-name
```

Description

The `create-transport` subcommand creates a transport for a network listener. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--acceptorthreads`

The number of acceptor threads for the transport. The recommended value is the number of processors in the machine. The default value is `1`.

`--bytebuffertype`

The type of the buffer to be provided for input streams created by a network-listener. Allowed values are `HEAP` and `DIRECT`. The default value is `HEAP`.

`--classname`

The fully qualified name of the Java class that implements the transport. The default is `org.glassfish.grizzly.TCPSelectorHandler`.

`--displayconfiguration`

If `true`, flushes the internal network configuration to the server log. Useful for debugging, but reduces performance. The default is `false`.

`--enablesnoop`

If `true`, writes request/response information to the server log. Useful for debugging, but reduces performance. The default is `false`.

`--idlekeytimeoutseconds`

The idle key timeout. The default is `30` seconds.

`--maxconnectionscount`

The maximum number of connections for the network listener that references this transport. A value of `-1` specifies no limit. The default value is `4096`.

`--readtimeoutmillis`

The amount of time the server waits during the header and body parsing phase. The default is `30000` milliseconds, or 30 seconds.

`--writetimeoutmillis`

The amount of time the server waits before considering the remote client disconnected when writing the response. The default is `30000` milliseconds, or 30 seconds.

`--selectorpolltimeoutmillis`

The number of milliseconds a NIO Selector blocks waiting for events (user requests). The default value is `1000` milliseconds.

`--tcpnodelay`

If `true`, the default, enables `TCP_NODELAY` (also called Nagle's algorithm). The default is `false`.

`--target`

Creates the transport only on the specified target. Valid values are as follows:

`server`

Creates the transport on the default server instance. This is the default value.

configuration-name

Creates the transport in the specified configuration.

cluster-name

Creates the transport on all server instances in the specified cluster.

standalone-instance-name

Creates the transport on the specified standalone server instance.

Operands

transport-name

The name of the transport.

Examples

Example 1 Creating a Transport

The following command creates a transport named `http1-trans` that uses a non-default number of acceptor threads:

```
asadmin> create-transport --acceptorthreads 100 http1-trans
Command create-transport executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-network-listener`,
- `delete-transport`,
- `list-transports`

create-virtual-server

Creates the named virtual server.

Synopsis

```
asadmin [asadmin-options] create-virtual-server [--help]
--hosts hosts
[--networklisteners network-listeners]
[--defaultwebmodule default-web-module]
[--state={on|off}]
[--logfile log-file]
[--property (name=value)[:name=value]*]
[--target target]
virtual-server-id
```

Description

The `create-virtual-server` subcommand creates the named virtual server. Virtualization in the Payara Server allows multiple URL domains to be served by a single HTTP server process that is listening on multiple host addresses. If the application is available at two virtual servers, they still share the same physical resource pools.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--hosts`

A comma-separated (,) list of values allowed in the host request header to select the current virtual server. Each virtual server that is configured to the same connection group must have a unique host for that group.

`--networklisteners`

A comma-separated (,) list of network listener IDs. Required only for a virtual server that is not the default virtual server.

`--defaultwebmodule`

The standalone web module associated with this virtual server by default.

`--state`

Determines whether a virtual server is active (`on`) or inactive (`off` or disabled). Default is `on`. When inactive, the virtual server does not service requests.

`--logfile`

Name of the file where log entries for this virtual server are to be written. By default, this is the server log. The file and directory in which the access log is kept must be writable by the user account under which the server runs.

`--property`

Optional property name/value pairs for configuring the virtual server. The following properties are available:

`sso-max-inactive-seconds`

Specifies the number of seconds after which a user's single sign-on record becomes eligible for purging if no client activity is received. Since single sign-on applies across several applications on the same virtual server, access to any of the applications keeps the single sign-on record active. The default value is 300 seconds (5 minutes). Higher values provide longer single sign-on persistence for users, but at the expense of more memory use on the server.

`sso-reap-interval-seconds`

Specifies the number of seconds between purges of expired single sign-on records. The default value is 60.

`setCacheControl`

Specifies a comma-separated list of `Cache-Control` response directives. For a list of valid directives, see section 14.9 of the document at http://www.ietf.org/rfc/rfc2616.txt (`http://www.ietf.org/rfc/rfc2616.txt`).

`allowLinking`

If the value of this property is `true`, resources that are symbolic links will be served for all web applications deployed on this virtual server. Individual web applications may override this setting by using the property `allowLinking` under the `payara-web-app` element in the `payara-web.xml` file:

```
<payara-web-app>
<property name="allowLinking" value="[true|false]"/>
</payara-web-app>
```

sun-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

The default value is `true`.

`accessLogWriteInterval`

Indicates the number of seconds before the log will be written to the disk. The access log is written when the buffer is full or when the interval expires. If the value is 0 (zero), then the buffer is always written even if it is not full. This means that each time the server is accessed, the log message is stored directly to the file.

`accessLogBufferSize`

Specifies the size, in bytes, of the buffer where access log calls are stored.

`allowRemoteAddress`

This is a comma-separated list of regular expression patterns to which the remote client's IP address is compared. If this property is specified, the remote address must match for this request to be accepted. If this property is not specified, all requests will be accepted unless the remote address matches a `denyRemoteAddress` pattern. The default value for this property is null.

`denyRemoteAddress`

This is a comma-separated list of regular expression patterns to which the remote client's IP address is compared. If this property is specified, the remote address must not match for this request to be accepted. If this property is not specified, request acceptance is governed solely by the `allowRemoteAddress` property. The default value for this property is null.

`allowRemoteHost`

This is a comma-separated list of regular expression patterns to which the remote client's host name (as returned by `java.net.Socket.getInetAddress().getHostName()`) is compared. If this property is specified, the remote host name must match for this request to be accepted. If this property is not specified, all requests will be accepted unless the remote host name matches a denyRemoteHost pattern. The default value for this property is null.

`denyRemoteHost`

This is a comma-separated list of regular expression patterns to which the remote client's host name (as returned by `java.net.Socket.getInetAddress().getHostName()`) is compared. If this property is specified, the remote host name must not match for this request to be accepted. If this property is not specified, request acceptance is governed solely by the `allowRemoteHost` property. The default value for this property is null.

`authRealm`

Specifies the `name` attribute of an `auth-realm`, which overrides the server instance's default realm for standalone web applications deployed to this virtual server. A realm defined in a standalone web application's `web.xml` file overrides the virtual server's realm.

`securePagesWithPragma`

Set this property to `false` to ensure that for all web applications on this virtual server file downloads using SSL work properly in Internet Explorer.
You can set this property for a specific web application. For details, see payara-web-app in Payara Server Application Deployment section.

`contextXmlDefault`

Specifies the location, relative to domain-dir, of the `context.xml` file for this virtual server, if one is used. For more information about the `context.xml` file, see Using a context.xml File in the Payara Server Application Development section and The Context Container (`http://tomcat.apache.org/tomcat-5.5-doc/config/context.html`). Context parameters, environment entries, and resource definitions in `context.xml` are supported in the Payara Server.

`alternatedocroot_n`

Specifies an alternate document root (docroot), where n is a positive integer that allows specification of more than one. Alternate docroots allow web applications to serve requests for certain resources from outside their own docroot, based on whether those requests match one (or more) of the URI patterns of the web application's alternate docroots.
If a request matches an alternate docroot's URI pattern, it is mapped to the alternate docroot by appending the request URI (minus the web application's context root) to the alternate docroot's physical location (directory). If a request matches multiple URI patterns, the alternate docroot is determined according to the following precedence order:

- Exact match
- Longest path match
- Extension match
  For example, the following properties specify three alternate docroots. The URI pattern of the first alternate docroot uses an exact match, whereas the URI patterns of the second and third alternate docroots use extension and longest path prefix matches, respectively.

```
<property name="alternatedocroot_1"
   value="from=/my.jpg dir=/srv/images/jpg"/>
<property name="alternatedocroot_2"
   value="from=*.jpg dir=/srv/images/jpg"/>
<property name="alternatedocroot_3"
   value="from=/jpg/* dir=/src/images"/>
```

The `value` of each alternate docroot has two components: The first component, `from`, specifies the alternate docroot's URI pattern, and the second component, `dir`, specifies the alternate docroot's physical location (directory). Spaces are allowed in the `dir` component.
You can set this property for a specific web application. For details, see payara-web-app in Payara Server Application Deployment section.

`send-error_n`

Specifies custom error page mappings for the virtual server, which are inherited by all web applications deployed on the virtual server. A web application can override these custom error page mappings in its `web.xml` deployment descriptor. The value of each `send-error_n` property has three components, which may be specified in any order:
The first component, `code`, specifies the three-digit HTTP response status code for which the custom error page should be returned in the response.
The second component, `path`, specifies the absolute or relative file system path of the custom error page. A relative file system path is interpreted as relative to the `domain-dir/config` directory.
The third component, `reason`, is optional and specifies the text of the reason string (such as `Unauthorized` or `Forbidden`) to be returned.
For example:

```
<property name="send-error_1"
```

```
   value="code=401 path=/myhost/401.html reason=MY-401-REASON"/>
```

This example property definition causes the contents of `/myhost/401.html` to be returned with 401 responses, along with this response line:

```
HTTP/1.1 401 MY-401-REASON
```

`redirect_n`

Specifies that a request for an old URL is treated as a request for a new URL. These properties are inherited by all web applications deployed on the virtual server. The value of each `redirect_n` property has two components, which may be specified in any order:
The first component, `from`, specifies the prefix of the requested URI to match.
The second component, `url-prefix`, specifies the new URL prefix to return to the client. The from prefix is simply replaced by this URL prefix.
For example:

```
<property name="redirect_1"
value="from=/dummy url-prefix=http://etude"/>
```

`valve_n`

Specifies a fully qualified class name of a custom valve, where n is a positive integer that allows specification of more than one. The valve class must implement the `org.apache.catalina.Valve` interface from Tomcat or previous Payara Server releases, or the `org.glassfish.web.valve.GlassFishValve` interface from the current Payara Server release. For example:

```
<property name="valve_1"
   value="org.glassfish.extension.Valve"/>
```

You can set this property for a specific web application. For details, see payara-web-app in Payara Server Application Deployment section.

`listener_n`

Specifies a fully qualified class name of a custom Catalina listener, where n is a positive integer that allows specification of more than one. The listener class must implement the `org.apache.catalina.ContainerListener` or `org.apache.catalina.LifecycleListener` interface. For example:

```
<property name="listener_1"
   value="org.glassfish.extension.MyLifecycleListener"/>
```

You can set this property for a specific web application. For details, see payara-web-app in Payara Server Application Deployment section.

`errorReportValve`

Specifies a fully qualified class name of a custom valve that produces default error pages for applications on this virtual server. Specify an empty string to disable the default error page mechanism for this virtual server.

`cacheTTL`

Specifies the time to live (TTL), in milliseconds, for the virtual server cache used when serving files. Defaults to 5000.

`--target`

Creates the virtual server only on the specified target. Valid values are as follows:

`server`

Creates the virtual server on the default server instance. This is the default value.

configuration-name

Creates the virtual server in the specified configuration.

cluster-name

Creates the virtual server on all server instances in the specified cluster.

standalone-instance-name

Creates the virtual server on the specified standalone server instance.

Operands

virtual-server-id

Identifies the unique ID for the virtual server to be created. This ID cannot begin with a number.

Examples

Example 1 Creating a Virtual Server

The following command creates a virtual server named `sampleServer`:

```
asadmin> create-virtual-server --hosts pigeon,localhost
--property authRealm=ldap sampleServer
Command create-virtual-server executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

debug-asadmin

Variant of the `asadmin` utility for performing administrative tasks for Payara Server. This variant is useful for debugging local admin commands the launching of Payara Server. It suspends immediately waiting for a debug connection to port 9008.

Synopsis

```
debug-asadmin [--host host]
[--port port]
[--user admin-user]
[--passwordfile filename]
[--terse={true|false}]
[--secure={false|true}]
[--echo={true|false}]
[--interactive={true|false}]
[--detach={true|false}]
[--help]
[subcommand [options] [operands]]
```

Description

Use the `debug-asadmin` utility to debug local admin commands and the launching of the Payara Server. See the `asadmin` command for full documentation.

delete-admin-object

Removes the administered object with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] delete-admin-object [--help]
[--target target] jndi_name
```

Description

The `delete-admin-object` subcommand removes an administered object with the specified JNDI name.

This subcommand is supported in remote mote only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This is the name of the targets for which the administered object is to be deleted. Valid values are:

Resources are always created for a domain as a whole but are only active for targets for which a `<resource-ref>` has been created using the `--target` option when the resource was created. This means that deleting a resource only deletes the `<resource-ref>` element for the specified `--target`, and does not delete the resource from the domain as a whole unless `domain` is specified as the `--target` for the deletion.

`server`

Deletes the administered object for the default server instance `server` and is the default value.

configuration_name

Deletes the administered object for the specified configuration.

cluster_name

Deletes the administered object for the specified cluster.

instance_name

Deletes the administered object for a particular server instance.

Operands

jndi_name

JNDI name of the administered object to be deleted.

Examples

Example 1 Deleting an Administered Object

This example deletes the administered object named `jms/samplelqueue`.

```
asadmin> delete-admin-object jms/samplequeue
Command delete-admin-object executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-admin-object`,
- `list-admin-objects`

delete-application-ref

Removes a reference to an application.

Synopsis

```
asadmin [asadmin-options] delete-application-ref [--help]
[--target target]
[--cascade=false] reference_name
```

Description

The `delete-application-ref` subcommand removes a reference from a cluster or an unclustered server instance to an application. This effectively results in the application element being undeployed and no longer available on the targeted instance or cluster.

The target instance or instances making up the cluster need not be running or available for this subcommand to succeed. If one or more instances are not available, they will no longer load the application the next time they start.

Removal of the reference does not result in removal of the application from the domain. The bits are removed only by the `undeploy` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are removing the application reference. Valid values are

- `server`- Specifies the default server instance as the target. `server` is the name of the default server instance and is the default value.
- cluster_name - Specifies a certain cluster as the target.
- instance_name - Specifies a certain stand-alone server instance as the target.

`--cascade`

For a connector module, indicates whether the resources dependent on the module should also be recursively deleted. The default is `false`. The connector module can be either a stand-alone RAR file or a module within an EAR file.

Operands

reference_name

The name of the application or module, which can be a Java EE application module, Web module, EJB module, connector module or application client module.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (_), dash (`-`), and period (`.`) characters. To delete references to multiple versions, you can use an asterisk (`*`) as a wildcard character. For more information about module and application versions, see "Module and Application Versions" in Payara Server Application Deployment section.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-application-ref:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-application-ref:::example-1] **Example 1 Deleting an Application Reference**

The following example removes a reference to the Web module `MyWebApp` from the unclustered server instance `NewServer`.

```
asadmin> delete-application-ref --target NewServer MyWebApp
Command delete-application-ref executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`

delete-auth-realm

Removes the named authentication realm.

Synopsis

```
asadmin [asadmin-options] delete-auth-realm [--help]
[--target target]
auth_realm-name
```

Description

The `delete-auth-realm` subcommand removes the named authentication realm. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which you are deleting the authentication realm. Valid values are

`server`

Deletes the realm for the default server instance `server` and is the default value.

configuration_name

Deletes the realm for the named configuration.

cluster_name

Deletes the realm for every server instance in the cluster.

instance_name

Deletes the realm for a particular server instance.

Operands

auth_realm_name

Name of the realm to be deleted.

Examples

Example 1 Deleting an Authentication Realm

This example deletes the authentication realm `db`.

```
asadmin> delete-auth-realm db
Command delete-auth-realm executed successfully
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-auth-realm`,
- `list-auth-realms`

delete-cluster

deletes a Payara Server cluster

Synopsis

```
asadmin [asadmin-options] delete-cluster [--help]
cluster-name
```

Description

The `delete-cluster` subcommand deletes a Payara Server cluster. A cluster can be deleted only if the cluster contains no Payara Server instances. If a cluster that you are deleting contains any instances, stop and delete the instances before deleting the cluster.

If the cluster's named configuration was created automatically for the cluster and no other clusters or unclustered instances refer to the configuration, the configuration is deleted when the cluster is

deleted.A configuration that is created automatically for a cluster is named cluster-name`-config`, where cluster-name is the name of the cluster.

This command is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

cluster-name

The name of the cluster to delete.

Examples

Example 1 Deleting a Payara Server Cluster

This example deletes the Payara Server cluster `adccluster`.

```
asadmin> delete-cluster adccluster
Command delete-cluster executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

delete-config-property

Provides a way to delete a MicroProfile Configuration property in one of the built-in configuration sources.

Synopsis

```
asadmin [asadmin-options] delete-config-property [--help]
[--propertyName=<property.name>]
[--source={domain|config|server|application|module|cluster}]
[--sourceName=<source.name>]
[--moduleName=<module.name>]
[--target=<target[default:server]>]
```

Description

The `delete-config-property` deletes the record of a MicroProfile Configuration property in one of the built-in config sources.

The source is specified with `--source` and, where there is ambiguity, the `--sourceName` and `--moduleName` options can be used.

For example, where the source is `server`, the `--sourceName` can be used to specify the name of the server instance where the property is stored.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--propertyName`

The name of the configuration property to delete.

`--source`

The configuration source where the property is stored.

`--sourceName`

The name of the source when there may be ambiguity, for example a source of type `application` must specify the name of the application.

This property is required for sources of type: `config`, `server`, `application` or `module`

`--moduleName`

The name of the module when the source is of type `module`.

When this is specified, the `sourceName` parameter must be provided and must have the name of the application where the module is deployed.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Setting the configuration property value

This example deletes the `JMSBrokerURL` property from the configuration source named `myApplication`, belonging to the module `myModule`, and targeting the `myAppCluster` cluster.

```
asadmin delete-config-property --propertyName=JMSBrokerURL --source=module
--sourceName=myApplication --moduleName=myModule --target=myAppCluster
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-config-property`
- `get-config-property`

delete-config

Deletes an existing named configuration.

Synopsis

```
asadmin [asadmin-options] delete-config [--help]
configuration-name
```

Description

The `delete-config` subcommand deletes an existing named configuration from the configuration of the domain administration server (DAS). You can delete a configuration only if no Payara Server instances or clusters refer to the configuration. A standalone configuration is automatically deleted when the instance or cluster that refers to it is deleted. You cannot delete the `default-config` configuration that is copied to create standalone configurations.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

configuration-name

The name of the configuration that you are deleting.

Examples

Example 1 Deleting a Named Configuration

This example deletes the named configuration `pmdconfig`.

```
asadmin> delete-config pmdconfig

Command delete-config executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

delete-connector-connection-pool

Removes the specified connector connection pool.

Synopsis

```
asadmin [asadmin-options] delete-connector-connection-pool [--help]
[--cascade={false|true}] poolname
```

Description

The `delete-connector-connection-pool` subcommand removes the specified connector connection pool.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--cascade`

When set to true, all connector resources associated with the pool, and the pool itself, are deleted. When set to false, the deletion of pool fails if any resources are associated with the pool. The resource must be deleted explicitly or the option must be set to true. Default is false.

Operands

poolname

The name of the connection pool to be removed.

Examples

Example 1 Deleting a Connector Connection Pool

This example deletes the connector connection pool named `jms/qConnPool`.

```
asadmin> delete-connector-connection-pool
--cascade=false jms/qConnPool
Command delete-connector-connection-pool executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-connector-connection-pool`,
- `list-connector-connection-pools`,
- `ping-connection-pool`

delete-connector-resource

Removes the connector resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] delete-connector-resource [--help]
[--target target] jndi_name
```

Description

The `delete-connector-resource` subcommand removes the connector resource with the specified JNDI name.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target from which you want to remove the connector resource. Valid targets are:

Resources are always created for a domain as a whole but are only active for targets for which a `<resource-ref>` has been created using the `--target` option when the resource was created. This means that deleting a resource only deletes the `<resource-ref>` element for the specified `--target`, and does not delete the resource from the domain as a whole unless `domain` is specified as the `--target` for the deletion.

`server`

Deletes the connector resource from the default server instance. This is the default value.

`domain`

Deletes the connector resource from the domain.

cluster_name

Deletes the connector resource from every server instance in the cluster.

instance_name

Deletes the connector resource from a specified server instance.

Operands

jndi_name

The JNDI name of this connector resource.

Examples

Example 1 Deleting a Connector Resource

This example deletes a connector resource named `jms/qConnFactory`.

```
asadmin> delete-connector-resource jms/qConnFactory
Command delete-connector-resource executed successfully
```

Where `jms/qConnFactory` is the connector resource that is removed.

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-connector-resource`,
- `list-connector-resources`

delete-connector-security-map

Celetes a security map for the specified connector connection pool.

Synopsis

```
asadmin [asadmin-options] delete-connector-security-map [--help]
--poolname connector_connection_pool_name mapname
```

Description

The `delete-connector-security-map` subcommand deletes a security map for the specified connector connection pool.

For this subcommand to succeed, you must have first created a connector connection pool using the `create-connector-connection-pool` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

`--poolname`
: Specifies the name of the connector connection pool to which the security map that is to be deleted belongs.

Operands

mapname
: Name of the security map to be deleted.

Examples

Example 1 Deleting a Connector Security Map

This example deletes `securityMap1` for the existing connection pool named `connector-pool1`.

```
asadmin> delete-connector-security-map
```

```
--poolname connector-pool1 securityMap1
Command delete-connector-security-map executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-connector-security-map`,
- `list-connector-security-maps`,
- `update-connector-security-map`

delete-connector-work-security-map

Deletes a work security map for the specified resource adapter.

Synopsis

```
asadmin [asadmin-options] delete-connector-work-security-map [--help]
--raname raname
mapname
```

Description

The `delete-connector-work-security-map` subcommand deletes a security map associated with the specified resource adapter. For this subcommand to succeed, you must have first created and deployed the specified resource adapter.

The enterprise information system (EIS) is any system that holds the data of an organization. It can be a mainframe, a messaging system, a database system, or an application.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--raname`

Indicates the connector module name with which the work security map is associated.

Operands

mapname

The name of the work security map to be deleted.

Examples

Example 1 Deleting a Connector Work Security Map

This example deletes the work security map named `work_security_map_name` for the resource adapter named `ra_name`.

```
asadmin delete-connector-work-security-map
--raname ra_name work_security_map_name
Command delete-connector-work-security-map executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-connector-work-security-map`,
- `list-connector-work-security-maps`,
- `update-connector-work-security-map`

delete-context-service

Removes a context service resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] delete-context-service [--help]
[--target target]
context-service-name
```

Description

The `delete-context-service` subcommand removes a context service resource with the specified

JNDI name.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are deleting the resource. Valid targets are:

`server`

Deletes the resource from the default server instance. This is the default value.

`domain`

Deletes the resource from the domain.

cluster-name

Deletes the resource from every server instance in the specified cluster.

instance-name

Deletes the resource from the specified server instance.

Operands

context-service-name

The JNDI name of the resource to be deleted.

Examples

Example 1 Deleting a Context Service Resource

This example deletes the context service resource named `concurrent/myContextService`.

```
asadmin> delete-context-service concurrent/myContextService
Context service concurrent/myContextService deleted successfully.
Command delete-context-service executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-context-service`,
- `list-context-services`

delete-custom-resource

Removes a custom resource.

Synopsis

```
asadmin [asadmin-options] delete-custom-resource [--help]
[--target target] jndi-name
```

Description

The `delete-custom-resource` subcommand removes a custom resource.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the location of the custom resources that you are deleting. Valid targets are server, domain, cluster, and instance. The default is server.

Resources are always created for a domain as a whole but are only active for targets for which a `<resource-ref>` has been created using the `--target` option when the resource was created. This means that deleting a resource only deletes the `<resource-ref>` element for the specified `--target`, and does not delete the resource from the domain as a whole unless `domain` is specified as the `--target` for the deletion.

`server`

Deletes the resource for the default server instance. This is the default value.

`domain`

Deletes the resource for the domain.

cluster_name

Deletes the resource for every server instance in the cluster.

instance_name

Deletes the resource for a particular server instance.

Operands

jndi-name

The JNDI name of this resource.

Examples

Example 1 Deleting a Custom Resource

This example deletes a custom resource named `mycustomresource`.

```
asadmin> delete-custom-resource mycustomresource
Command delete-custom-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-custom-resource`,
- `list-custom-resources`

delete-deployment-group

Deletes a Payara Server deployment group.

Synopsis

```
asadmin [asadmin-options] create-deployment-group [--help]
name
```

Description

The `delete-deployment-group` subcommand deletes a Payara Server deployment group. If the deployment group contains instances on it, they will not be deleted when the group is deleted.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

name

The name of the deployment group to delete. If the name doesn't match any existing deployment groups the command will exit with an error.

Examples

Example 1 Deleting a Deployment Group

This example deletes a deployment group that is named `test-dgroup`:

```
asadmin delete-deployment-group test-dgroup
Command delete-deployment-group executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

delete-domain

Deletes a domain.

Synopsis

```
asadmin [asadmin-options] delete-domain [--help]
[--domaindir domaindir] domain-name
```

Description

The `delete-domain` subcommand deletes the specified domain. The domain must already exist and must be stopped.

This subcommand is supported in local mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

`--domaindir`
: The directory where the domain to be deleted is located. If specified, the path must be accessible in the file system. If not specified, the domain under the domain root directory, which defaults to as-install`/domains`, is deleted.

Operands

domain-name
: The unique name of the domain you want to delete.

Examples

Example 1 Deleting a Domain

This example deletes a domain named `mydomain4` from the default domains directory.

```
asadmin> delete-domain mydomain4
Domain mydomain4 deleted.
Command delete-domain executed successfully.
```

Example 2 deleting a Domain From an Alternate Location

This example deletes a domain named `sampleDomain` from the `/home/someuser/domains` directory.

```
asadmin> delete-domain --domaindir /home/someuser/domains sampleDomain
Domain sampleDomain deleted
Command delete-domain executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-domain`,
- `list-domains`,
- `start-domain`,
- `stop-domain`

delete-file-user

Removes the named file user.

Synopsis

```
asadmin [asadmin-options] delete-file-user [--help]
[--authrealmname auth_realm_name]
[--target target]
username
```

Description

The `delete-file-user` subcommand deletes the entry in the keyfile for the specified username.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--authrealmname`

The name of the authentication realm with which the user was created.

`--target`

This is the name of the target on which the command operates. The valid targets are:

`server`

Deletes the file user on the default server instance. This is the default value

`domain`

Deletes the file user in the domain.

cluster_name

Deletes the file user from every server instance in the cluster.

instance_name

Deletes the file user from a particular server instance.

Operands

username

This is the name of file user to be deleted.

Examples

Example 1 Deleting a User From a File Realm

The following example shows how to delete user named `sample_user` from a file realm.

```
asadmin> delete-file-user
sample_user
Command delete-file-user executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

delete-http-health-checker

delete-http-lb-config

delete-http-lb-ref

delete-http-lb

delete-http-listener

Removes a network listener.

Synopsis

```
asadmin [asadmin-options] delete-http-listener [--help]
[--target target]
listener-id
```

Description

The `delete-http-listener` subcommand removes the specified network listener.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the network listener only from the specified target. Valid values are as follows:

`server`

Deletes the network listener from the default server instance. This is the default value.

configuration-name

Deletes the network listener from the specified configuration.

cluster-name

Deletes the network listener from all server instances in the specified cluster.

standalone-instance-name

Deletes the network listener from the specified standalone server instance.

Operands

listener-id

The unique identifier for the network listener to be deleted.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-http-listener:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-http-listener:::example-1] **Example 1 Using the delete-http-listener subcommand**

The following command deletes the network listener named `sampleListener`:

```
asadmin> delete-http-listener sampleListener
Command delete-http-listener executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-http-listener`
- `list-http-listeners`,
- `restart-http-listeners`

delete-http-redirect

Removes an HTTP redirect.

Synopsis

```
delete-http-redirect [--help]
[--target target]
protocol-name
```

Description

The `delete-http-redirect` subcommand removes the specified HTTP redirect. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the HTTP redirect only from the specified target. Valid values are as follows:

`server`

Deletes the HTTP redirect from the default server instance. This is the default value.

configuration-name

Deletes the HTTP redirect from the specified configuration.

cluster-name

Deletes the HTTP redirect from all server instances in the specified cluster.

standalone-instance-name

Deletes the HTTP redirect from the specified standalone server instance.

Operands

protocol-name

The name of the associated protocol.

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-http-redirect:::examples]]

Example 1 Deleting a HTTP Redirect

The following command deletes the HTTP redirect named `http-redirect`:

```
asadmin> delete-http-redirect http-redirect
```

```
Command delete-http-redirect executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `create-http-redirect`

delete-http

Removes HTTP parameters from a protocol.

Synopsis

```
asadmin [asadmin-options] delete-http [--help]
[--target target]
protocol-name
```

Description

The `delete-http` subcommand removes the specified HTTP parameter set from a protocol. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the HTTP parameter set only from the specified target. Valid values are as follows:

`server`

Deletes the HTTP parameter set from the default server instance. This is the default value.

configuration-name

Deletes the HTTP parameter set from the specified configuration.

cluster-name

Deletes the HTTP parameter set from all server instances in the specified cluster.

standalone-instance-name

Deletes the HTTP parameter set from the specified standalone server instance.

Operands

protocol-name

The name of the protocol from which to delete the HTTP parameter set.

Examples

Example 1 Deleting an HTTP Parameter Set

The following command deletes the HTTP parameter set from a protocol named `http-1`:

```
asadmin> delete-http http-1
Command delete-http executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-http`

delete-iiop-listener

Removes an IIOP listener.

Synopsis

```
delete-iiop-listener [--help] [--target target] listener_id
```

Description

The `delete-iiop-listener` subcommand removes the specified IIOP listener. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are deleting the IIOP listener. Valid values are

`server`

Deletes the listener from the default server instance `server` and is the default value.

configuration_name

Deletes the listener from the named configuration.

cluster_name

Deletes the listener from every server instance in the cluster.

instance_name

Deletes the listener from a particular server instance.

Operands

listener_id

The unique identifier for the IIOP listener to be deleted.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-iiop-listener:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-iiop-listener:::example-1] **Example 1 Deleting an IIOP Listener**

The following command deletes the IIOP listener named `sample_iiop_listener`:

```
asadmin> delete-iiop-listener sample_iiop_listener
Command delete-iiop-listener executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-iiop-listener`
- `list-iiop-listeners`

delete-instance

delete-instance

Deletes a Payara Server instance.

Synopsis

```
asadmin [asadmin-options] delete-instance [--help]
instance-name
```

Description

The `delete-instance` subcommand deletes a Payara Server instance. This subcommand requires the secure shell (SSH) to be configured on the host where the domain administration server (DAS) is running and on the host that is represented by the node where the instance resides.

SSH is not required if the instance resides on a node of type `CONFIG` that represents the local host. A node of type `CONFIG` is not enabled for remote communication over SSH.

You may run this subcommand from any host that can contact the DAS.

The subcommand can delete any Payara Server instance, regardless of how the instance was created. For example, this subcommand can delete an instance that was created by using the `create-local-instance` subcommand.

The instance that is being deleted must not be running. Otherwise, an error occurs.

The subcommand deletes an instance by performing the following actions:

- Removing the instance from the configuration of the domain administration server (DAS)
- Deleting the instance's files from file system

If the instance that is being deleted is the only instance that is using the node directory, that directory is also removed.

If a standalone instance is deleted, the instance's standalone configuration is also deleted. A standalone instance refers to a configuration that is named instance-name`-config` to which no other clusters or unclustered instances refer.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

instance-name

The name of the instance to delete.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-instance:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-instance:::example-1] **Example 1 Deleting a Payara Server Instance**

This example deletes the Payara Server instance `pmdsainst`.

```
asadmin> delete-instance pmdsainst

Command delete-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

delete-jacc-provider

Enables administrators to delete JACC providers defined for a domain.

Synopsis

```
asadmin [asadmin-options] delete-jacc-provider [--help]
[--target target] jacc-provider-name
```

Description

The `delete-jacc-provider` subcommand enables administrators to delete JACC providers defined for a domain. JACC providers are defined as `jacc-provider` elements in the `security-service` element in the domain's `domain.xml` file. JACC providers can be created using the Payara Server Admin Console or the `create-jacc-provider` subcommand.

The default Payara Server installation includes two JACC providers, named `default` and `simple`. These default providers should not be deleted.

The JACC provider used byPayara Server for authorization is identified by the `jacc-provider` element of `security-service` in `domain.xml`. Therefore, if you delete the `jacc-provider` provider, make sure you change `jacc-provider` to the name of some other JACC provider that exists under `security-service`.

If you change the `jacc-provider` element to point to a different JACC provider, you must restart Payara Server.

This subcommand is supported in remote mode only.

Options

If an option has a short option name, then the short option precedes the long option name. Short options have one dash whereas long options have two dashes.

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are deleting the JACC provider. The following values are valid:

`server`

Deletes the JACC provider on the default server instance. This is the default value.

configuration_name

Deletes the JACC provider in the specified configuration.

cluster_name

Deletes the JACC provider on all server instances in the specified cluster.

instance_name

Deletes the JACC provider on a specified server instance.

Operands

jacc-provider-name

The name of the JACC provider to be deleted.

Examples

Example 1 Deleting a JACC provider

The following example shows how to delete a JACC provider named `testJACC` from the default domain.

```
asadmin> delete-jacc-provider testJACC

Command delete-jacc-provider executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

delete-javamail-resource

Removes a JavaMail session resource.

Synopsis

```
asadmin [asadmin-options] delete-javamail-resource [--help]
```

```
[--target target] jndi_name
```

Description

The `delete-javamail-resource` subcommand removes the specified JavaMail session resource. Ensure that you remove all references to this resource before running this subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target from which you are deleting the JavaMail session resource. Valid values are:

`server`

Deletes the resource from the default server instance. This is the default value.

`domain`

Deletes the resource from the domain.

cluster_name

Deletes the resource from every server instance in the cluster.

instance_name

Deletes the resource from a particular server instance.

Operands

jndi_name

The JNDI name of the JavaMail session resource to be deleted.

Examples

Example 1 Deleting a JavaMail Resource

This example deletes the JavaMail session resource named `mail/MyMailSession`.

```
asadmin> delete-javamail-resource mail/MyMailSession
Command delete-javamail-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-javamail-resource`,
- `list-javamail-resources`

delete-jdbc-connection-pool

Removes the specified JDBC connection pool.

Synopsis

```
asadmin [asadmin-options] delete-jdbc-connection-pool [--help]
[--cascade={false|true}]
jdbc_connection_pool_id
```

Description

The `delete-jdbc-connection-pool` subcommand deletes a JDBC connection pool. Before running this subcommand, all associations to the JDBC connection pool must be removed.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--cascade`

If the option is set to true, all the JDBC resources associated with the pool, apart from the pool itself, are deleted. When set to false, the deletion of pool fails if any resources are associated with the pool. Resources must be deleted explicitly or the option must be set to true. The default value is false.

Operands

jdbc_connection_pool_id

The name of the JDBC resource to be removed.

Examples

Example 1 Deleting a JDBC Connection Pool

This example deletes the `sample_derby_pool` JDBC connection pool.

```
asadmin> delete-jdbc-connection-pool --cascade=false sample_derby_pool
Command delete-jdbc-connection-pool executed correctly.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-jdbc-connection-pool`
- `list-jdbc-connection-pools`

delete-jdbc-resource

Removes a JDBC resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] delete-jdbc-resource [--help]
[--target target] jndi_name
```

Description

The `delete-jdbc-resource` subcommand removes a JDBC resource. Ensure that all associations to the JDBC resource are removed before running this subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target from which you are removing the JDBC resource. Valid targets are:

`server`

Removes the resource from the default server instance. This is the default value.

`domain`

Removes the resource from the domain.

cluster_name

Removes the resource from every server instance in the cluster.

instance_name

Removes the resource from a particular server instance.

Resources are always created for a domain as a whole but are only active for targets for which a `<resource-ref>` has been created using the `--target` option when the resource was created. This means that deleting a resource only deletes the `<resource-ref>` element for the specified `--target`, and does not delete the resource from the domain as a whole unless `domain` is specified as the `--target` for the deletion.

Operands

jndi_name

The JNDI name of this JDBC resource to be removed.

Examples

Example 1 Deleting a JDBC Resource

The following example deletes the JDBC resource named `jdbc/DerbyPool`.

```
asadmin> delete-jdbc-resource jdbc/DerbyPool
Command delete-jdbc-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-jdbc-resource`,
- `list-jdbc-resources`

delete-jms-host

Removes a JMS host.

Synopsis

```
asadmin [asadmin-options] delete-jms-host [--help]
[--target target]
jms_host_name
```

Description

The `delete-jms-host` subcommand removes the specified Java Message Service (JMS) host.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Deleting the default JMS host, named `default_JMS_host`, is not recommended.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the JMS host only from the specified target. Valid values are as follows:

`server`

Deletes the JMS host from the default server instance. This is the default value.

configuration-name

Deletes the JMS host from the specified configuration.

cluster-name

Deletes the JMS host from every server instance in the specified cluster.

instance-name

Deletes the JMS host from the specified server instance.

Operands

jms_host_name

The name of the host to be deleted.

Examples

Example 1 Deleting a JMS host

The following subcommand deletes the JMS host named `MyNewHost`.

```
asadmin> delete-jms-host MyNewHost
Command delete-jms-host executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-jms-host`,
- `jms-ping`,
- `list-jms-hosts`

delete-jms-resource

Removes a JMS resource.

Synopsis

```
asadmin [asadmin-options] delete-jms-resource [--help]
[--target target]
jndi_name
```

Description

The `delete-jms-resource` subcommand removes the specified Java Message Service (JMS) resource. Ensure that you remove all references to this resource before executing this subcommand.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the JMS resource only from the specified target. Valid values are as follows:

Resources are always created for a domain as a whole but are only active for targets for which a `<resource-ref>` has been created using the `--target` option when the resource was created. This means that deleting a resource only deletes the `<resource-ref>` element for the specified `--target`, and does not delete the resource from the domain as a whole unless `domain` is specified as the `--target` for the deletion.

`server`

Deletes the JMS resource from the default server instance. This is the default value.

`domain`

Deletes the JMS resource from the domain.

cluster-name

Deletes the JMS resource from every server instance in the specified cluster.

instance-name

Deletes the JMS resource from the specified server instance.

Operands

jndi_name

The JNDI name of the JMS resource to be deleted.

Examples

Example 1 Deleting a JMS destination resource

The following subcommand deletes the JMS destination resource named `jms/MyQueue`.

```
asadmin> delete-jms-resource jms/MyQueue
Administered object jms/MyQueue deleted.
Command delete-jms-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-jms-resource`,
- `list-jms-resources`

delete-jmsdest

Removes a JMS physical destination.

Synopsis

```
asadmin [asadmin-options] delete-jmsdest [--help]
--desttype type
[--target target]
dest_name
```

Description

The `delete-jmsdest` subcommand removes the specified Java Message Service (JMS) physical destination.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--desttype`

The type of the JMS destination. Valid values are `topic` and `queue`.

`--target`

Deletes the physical destination only from the specified target. Although the `delete-jmsdest` subcommand is related to resources, a physical destination is deleted using the JMS Service (JMS

Broker), which is part of the configuration. A JMS Broker is configured in the config section of `domain.xml`. Valid values are as follows:

`server`
: Deletes the physical destination from the default server instance. This is the default value.

configuration-name
: Deletes the physical destination from the specified configuration.

cluster-name
: Deletes the physical destination from every server instance in the specified cluster.

instance-name
: Creates the physical destination from the specified server instance.

Operands

dest_name
: The unique identifier of the JMS destination to be deleted.

Examples

Example 1 Deleting a physical destination

The following subcommand deletes the queue named `PhysicalQueue`.

```
asadmin> delete-jmsdest --desttype queue PhysicalQueue
Command delete-jmsdest executed successfully.
```

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `asadmin`
- `create-jmsdest`,
- `flush-jmsdest`,

delete-jndi-resource

Removes a JNDI resource.

Synopsis

```
asadmin [asadmin-options] delete-jndi-resource [--help]
[--target target] jndi_name
```

Description

The `delete-jndi-resource` subcommand removes the specified JNDI resource. You must remove all associations to the JNDI resource before running this subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Valid targets are described below.

Resources are always created for a domain as a whole but are only active for targets for which a `<resource-ref>` has been created using the `--target` option when the resource was created. This means that deleting a resource only deletes the `<resource-ref>` element for the specified `--target`, and does not delete the resource from the domain as a whole unless `domain` is specified as the `--target` for the deletion.

`server`

Deletes the resource from the default server instance. This is the default value

`domain`

Deletes the resource from the domain

cluster_name

Deletes the resource for every server instance in the cluster

instance_name

Deletes the resource from the specified server instance

Operands

jndi_name

The name of the JNDI resource to be removed.

Examples

Example 1 Deleting a JNDI Resource

This example removes an existing JNDI resource named `sample_jndi_resource`.

```
asadmin> delete-jndi-resource sample_jndi_resource
Command delete-jndi-resource executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-jndi-resource`,
- `list-jndi-resources`

delete-jvm-options

Removes one or more options for the Java application launcher.

Synopsis

```
asadmin [asadmin-options] delete-jvm-options [--help]
[--target target]
(jvm-option-name[=jvm-option-value]) [:jvm-option-name[=jvm-option-name]]*
```

Description

The `delete-jvm-options` subcommand removes one or more command-line options for the Java application launcher. These options are removed from the Java configuration `java-config` element of the `domain.xml` file. To see the Java application launcher options that can be deleted, use the `list-jvm-options` subcommand.

The deletion of some options requires a server restart for changes to become effective. Other options are set immediately in the environment of the domain administration server (DAS) and do not require a restart.

Whether a restart is required depends on the type of option.

- Restart is not required for Java system properties whose names do not start with `-Djava.` or `-Djavax.` (including the trailing period). For example, restart is not required for the following

Java system property:
`-Denvironment=Production`

- Restart is required for the following options:
  - Java system properties whose names start with `-Djava.` or `-Djavax.` (including the trailing period). For example:
    `-Djava.security.manager`
  - Startup parameters for the Java application launcher. For example:
    `-client`
    `-Xmx1024m`
    `-d64`

To restart the DAS, use the `restart-domain` command.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are removing Java application launcher options.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Operands

jvm-option-name

One or more options delimited by a colon (:). The format of the operand depends on the following:

- If the option has a name and a value, the format is option-name=value.

- If the option has only a name, the format is option-name. For example, `-Xmx2048m`.

If an option name or option value contains a colon, the backslash (`\`) must be used to escape the colon in the name or value. Other characters might also require an escape character. For more information about escape characters in subcommand options, see the `asadmin` man page.

Examples

Example 1 Deleting Java Application Launcher Options

This example removes multiple Java application launcher options.

```
asadmin> delete-jvm-options -Doption1=value1
"-Doption1=value1:-Doption2=value2"
Command delete-jvm-options executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

- `list-jvm-options`,
- `restart-domain`

For more information about the Java application launcher, see the reference page for the operating system that you are using:

- Oracle Solaris and Linux: java - the Java application launcher (http://java.sun.com/javase/7/docs/technotes/tools/solaris/java.html)
- Windows: java - the Java application launcher (http://java.sun.com/javase/7/docs/technotes/tools/windows/java.html)

delete-local-instance

Deletes a Payara Server instance on the machine where the subcommand is run/

Synopsis

```
asadmin [asadmin-options] delete-local-instance [--help]
```

```
[--nodedir node-dir] [--node node-name]
[instance-name]
```

Description

The `delete-local-instance` subcommand deletes a Payara Server instance on the machine where the subcommand is run. This subcommand does not require the secure shell (SSH) to be configured. You must run this command from the machine where the instance resides.

The subcommand can delete any Payara Server instance, regardless of how the instance was created. For example, this subcommand can delete an instance that was created by using the `create-instance` subcommand.

The instance that is being deleted must not be running. Otherwise, an error occurs.

The subcommand deletes an instance by performing the following actions:

- Removing the instance from the configuration of the domain administration server (DAS)
- Deleting the instance's files from file system

If the instance that is being deleted is the only instance that is using the node directory, that directory is also removed.

If a standalone instance is deleted, the instance's standalone configuration is also deleted. A standalone instance refers to a configuration that is named instance-name`-config` to which no other clusters or unclustered instances refer.

The `delete-local-instance` subcommand does not contact the DAS to determine the node on which the instance resides. To determine the node on which the instance resides, the subcommand searches the directory that contains the node directories. If multiple node directories exist, the node must be specified as an option of the subcommand.

If no operand is specified and only one instance resides on the specified node, the subcommand deletes the instance. If no operand is specified and multiple instances reside on the node, an error occurs.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodedir`

Specifies the directory that contains the instance's node directory. The instance's files are stored

in the instance's node directory. The default is as-install`/nodes`.

`--node`

Specifies the node on which the instance resides. This option may be omitted only if the directory that the `--nodedir` option specifies contains only one node directory. Otherwise, this option is required.

Operands

instance-name

The name of the instance to delete. This operand may be omitted if only one instance resides on the specified node. Otherwise, this operand is required.

Examples

Example 1 Deleting an Instance

This example deletes the instance `pmdsainst`.

```
asadmin> delete-local-instance pmdsainst

Command delete-local-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

delete-managed-executor-service

Removes a managed executor service resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] delete-managed-executor-service [--help]
[--target target]
managed_executor_service_name
```

Description

The `delete-managed-executor-service` subcommand removes a managed executor service resource with the specified JNDI name.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are deleting the resource. Valid targets are:

`server`

Deletes the resource from the default server instance. This is the default value.

`domain`

Deletes the resource from the domain.

cluster_name

Deletes the resource from every server instance in the specified cluster.

instance_name

Deletes the resource from the specified server instance.

Operands

managed_executor_service_name

The JNDI name of the resource to be deleted.

Examples

Example 1 Deleting a Managed Executor Service Resource

This example deletes the managed executor service resource named `concurrent/myExecutor`.

```
asadmin> delete-managed-executor-service concurrent/Executor1
```

```
Managed executor service concurrent/Executor1 deleted successfully.
Command delete-managed-executor-service executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-managed-executor-service`,
- `list-managed-executor-services`

delete-managed-scheduled-executor-service

Removes a managed scheduled executor service resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] delete-managed-scheduled-executor-service [--help]
[--target target]
managed_scheduled_executor_service_name
```

Description

The `delete-managed-scheduled-executor-service` subcommand removes a managed scheduled executor service resource with the specified JNDI name.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are deleting the resource. Valid targets are:

`server`

Deletes the resource from the default server instance. This is the default value.

`domain`

Deletes the resource from the domain.

cluster_name

Deletes the resource from every server instance in the specified cluster.

instance_name

Deletes the resource from the specified server instance.

Operands

managed_scheduled_executor_service_name

The JNDI name of the resource to be deleted.

Examples

Example 1 Deleting a Managed Scheduled Executor Service Resource

This example deletes the managed scheduled executor service resource named `concurrent/myScheduledExecutor`.

```
asadmin> delete-managed-scheduled-executor-service concurrent/ScheduledExecutor1
Managed scheduled executor service concurrent/ScheduledExecutor1 deleted successfully.
Command delete-managed-scheduled-executor-service executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-managed-scheduled-executor-service`,
- `list-managed-scheduled-executor-services`

delete-managed-thread-factory

Removes a managed thread factory resource with the specified JNDI name.

Synopsis

```
asadmin [asadmin-options] delete-managed-thread-factory [--help]
[--target target]
```

```
managed_thread_factory_name
```

Description

The `delete-managed-thread-factory` subcommand removes a managed thread factory resource with the specified JNDI name.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are deleting the resource. Valid targets are:

`server`

Deletes the resource from the default server instance. This is the default value.

`domain`

Deletes the resource from the domain.

cluster_name

Deletes the resource from every server instance in the specified cluster.

instance_name

Deletes the resource from the specified server instance.

Operands

managed_thread_factory_name

The JNDI name of the resource to be deleted.

Examples

Example 1 Deleting a Managed Thread Factory Resource

This example deletes the managed thread factory resource named `concurrent/myThreadFactory`.

```
asadmin> delete-managed-thread-factory concurrent/Factory1
Managed thread factory concurrent/Factory1 deleted successfully.
Command delete-managed-thread-factory executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-managed-thread-factory`,
- `list-managed-thread-factories`

delete-message-security-provider

Enables administrators to delete a message security provider.

Synopsis

```
asadmin [asadmin-options] delete-message-security-provider [--help]
[--target target]
--layer message_layer
provider_name
```

Description

The `delete-message-security-provider` subcommand enables administrators to delete a message security provider.

In terms of what happens when this subcommand is run, the `provider-config` sub-element for the given message layer (`message-security-config` element of `domain.xml` is deleted. The `domain.xml` file specifies parameters and properties to the Payara Server). The options specified in the list below apply to attributes within the `message-security-config` and `provider-config` sub-elements of the `domain.xml` file.

If the message-layer (`message-security-config` attribute) does not exist, it is created, and then the `provider-config` is created under it.

This command is supported in remote mode only.

Options

If an option has a short option name, then the short option precedes the long option name. Short options have one dash whereas long options have two dashes.

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are deleting the message security provider. Valid values are

`server`

Deletes the message security provider from the default server instance `server` and is the default value

`domain`

Deletes the message security provider from the domain.

cluster_name

Deletes the message security provider from every server instance in the cluster.

instance_name

Deletes the message security provider from a particular sever instance.

`--layer`

The message-layer from which the provider has to be deleted. The default value is `HttpServlet`.

Operands

provider_name

The name of the provider used to reference the `provider-config` element.

Examples

Example 1 Deleting a message security provider

The following example shows how to delete a message security provider for a client.

```
asadmin> delete-message-security-provider
--layer SOAP mySecurityProvider
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,

- `create-message-security-provider`,
- `list-message-security-providers`

delete-module-config

Removes the configuration of a module from `domain.xml`.

Synopsis

```
asadmin [asadmin-options] delete-module-config [--help]
[--target target]
service_name
```

Description

The `delete-module-config` subcommand removes the configuration of a module from `domain.xml` and causes the module to use the default configuration included in the module.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the link:Technical Documentation/Payara Server Documentation/Command Reference/asadmin.adoc#asadmin-1m[`asadmin`] help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which the configuration is to be deleted.
Possible values are as follows:

`server`

Deletes the configuration from the default server instance. This is the default value.

`domain`

Deletes the configuration from the default domain.

cluster-name

Deletes the configuration from every server instance in the specified cluster.

instance-name

Deletes the configuration from the specified instance.

Operands

service_name

The name of the module for which configuration is to be removed.

Examples

Example 1 Deleting a Default Configuration From domain.xml

This example deletes the configuration of the web container module from `domain1` in `server-config` (the default configuration).

```
asadmin> delete-module-config web-container
Command delete-module-config executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-module-config`,

delete-network-listener

Removes a network listener.

Synopsis

```
asadmin [asadmin-options] delete-network-listener [--help]
[--target target]
listener-name
```

Description

The `delete-network-listener` subcommand removes the specified network listener. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the network listener only from the specified target. Valid values are as follows:

`server`

Deletes the network listener from the default server instance. This is the default value.

configuration-name

Deletes the network listener from the specified configuration.

cluster-name

Deletes the network listener from all server instances in the specified cluster.

standalone-instance-name

Deletes the network listener from the specified standalone server instance.

Operands

listener-name

The name of the network listener to be deleted.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-network-listener:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-network-listener:::example-1] **Example 1 Deleting a Network Listener**

The following command deletes the network listener named `sampleListener`:

```
asadmin> delete-network-listener sampleListener
Command delete-network-listener executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-network-listener`,

- `set-network-listener-configuration`,
- `list-network-listeners`

delete-node-config

Deletes a node that is not enabled for remote communication.

Synopsis

```
asadmin [asadmin-options] delete-node-config [--help]
node-name
```

Description

The `delete-node-config` subcommand deletes a node that is not enabled for remote communication from the domain. This subcommand does not require the secure shell (SSH) to be configured.

This subcommand can delete only a node that is not enabled for remote communication. The subcommand for deleting other types of nodes depends on the type of the node:

- A node that is enabled for remote communication over SSH must be deleted by using the `delete-node-ssh` subcommand.

To determine whether a node is enabled for remote communication, use the `list-nodes` subcommand.

No Payara Server instances must reside on the node that is being deleted. Otherwise, the subcommand fails. Before running this subcommand, delete any instances that reside on the node by using, for example, the `delete-instance` subcommand or the `delete-local-instance` subcommand.

The predefined node `localhost-` pdomain cannot be deleted.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

node-name

The name of the node to delete. The node must not be enabled for communication over SSH. Otherwise, an error occurs.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-node-config:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-node-config:::example-1] **Example 1 Deleting a Node That Is Not Enabled for Remote Communication**

This example deletes the node `sj03`, which is not enabled for remote communication.

```
asadmin> delete-node-config sj03

Command delete-node-config executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

- `update-node-ssh`

delete-node-docker

Deletes a Docker node

Synopsis

```
asadmin [asadmin-options] delete-node-docker [--help]
node-name
```

Description

The `delete-node-docker` subcommand deletes a Docker node. The command will assume that the node's configuration to be able to reach the container are still valid and will de-register the node configuration from the DAS and will automatically remove the container that corresponds to the deleted node.

If the settings of the Docker node are not valid or if the Docker engine is not reachable through its REST API endpoint, an error will occur and the command will fail.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

node-name

The name of the node to delete.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-node-docker:::example-1]]

Example 1 Deleting a Docker Node

This example deletes the node `docker-node-1`:

```
asadmin> delete-node-docker docker-node-1
Command delete-node-docker executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,

- `create-node-docker`,
- `delete-instance`,
- `delete-local-instance`,
- `list-nodes`,
- `update-node-docker`

delete-node-ssh

Deletes a node that is enabled for communication over SSH.

Synopsis

```
asadmin [asadmin-options] delete-node-ssh [--help]
[--uninstall={false|true}] [--force={false|true}]
node-name
```

Description

The `delete-node-ssh` subcommand deletes a node that is enabled for communication over secure shell (SSH) from the domain. This subcommand does not require SSH to be configured.

This subcommand can delete only a node that is enabled for communication over SSH. The subcommand for deleting other types of nodes depends on the type of the node:

- A node that is not enabled for remote communication must be deleted by using the `delete-node-config` subcommand.

To determine whether a node is enabled for communication over SSH, use the `list-nodes` subcommand.

No Payara Server instances must reside on the node that is being deleted. Otherwise, the subcommand fails. Before running this subcommand, delete any instances that reside on the node by using, for example, the `delete-instance` subcommand or the `delete-local-instance` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--uninstall`

Specifies whether the Payara Server software is uninstalled from host that the node represents. Possible values are as follows:

`false`

The Payara Server software is not uninstalled from the host (default).

`true`

The Payara Server software is uninstalled from the host. By default, if any node except the predefined node `localhost-` domain resides on any host from which Payara Server software is being uninstalled, the subcommand fails. To uninstall the Payara Server software from a host on which user-defined nodes reside, set the `--force` option to `true`. If the `--force` option is `true`, the subcommand removes the entire content of the parent of the base installation directory.

`--force`

If `--uninstall` is true, specifies whether the subcommand uninstalls the Payara Server software from a host even if a user-defined node resides on the host. Possible values are as follows:

`false`

If a user-defined node resides on a host, the software is not uninstalled and the subcommand fails (default).
If the `--force` option is `false`, the subcommand removes only the Payara Server software files. Other content if the parent of the base installation directory, such as configuration files, are not removed.

`true`

The subcommand uninstalls the Payara Server software from the host even if a user-defined node resides on the host.
If the `--force` option is `true`, the subcommand removes the entire content of the parent of the base installation directory.

Operands

node-name

The name of the node to delete. The node must be enabled for communication over SSH. Otherwise, an error occurs.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-node-ssh:::example-1]]

Example 1 Deleting a Node That Is Enabled for Communication Over SSH

This example deletes the node `eg1`, which is enabled for communication over SSH.

```
asadmin> delete-node-ssh eg1
```

```
Command delete-node-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

delete-password-alias

Deletes a password alias.

Synopsis

```
asadmin [asadmin-options] delete-password-alias [--help]
aliasname
```

Description

This subcommand deletes a password alias.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

aliasname

This is the name of the substitute password as it appears in `domain.xml`.

Examples

Example 1 Deleting a Password Alias

```
asadmin>delete-password-alias
jmspassword-alias
```

Command delete-password-alias executed successfully

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-password-alias`,
- `list-password-aliases`,
- `update-password-alias`

delete-protocol-filter

Removes a protocol filter.

Synopsis

```
asadmin [asadmin-options] delete-protocol-filter [--help]
--protocol protocol-name
[--target server]
protocol-filter-name
```

Description

The `delete-protocol-filter` subcommand removes the specified protocol filter. This subcommand

is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--protocol-name`

The name of the associated protocol.

`--target`

Deletes the protocol filter only from the specified target. Valid values are as follows:

`server`

Deletes the protocol filter from the default server instance. This is the default value.

configuration-name

Deletes the protocol filter from the specified configuration.

cluster-name

Deletes the protocol filter from all server instances in the specified cluster.

standalone-instance-name

Deletes the protocol filter from the specified standalone server instance.

Operands

protocol-filter-name

The name of the protocol filter to be deleted.

Examples

Example 1 Deleting a Protocol Filter

The following command deletes the protocol filter named `http1-filter`:

```
asadmin> delete-protocol-filter --protocol http1 http1-filter
Command delete-protocol-filter executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-protocol-filter`,
- `list-protocol-filters`

delete-protocol-finder

Removes a protocol finder.

Synopsis

```
asadmin [asadmin-options] delete-protocol-finder [--help]
--protocol protocol-name
[--target server]
protocol-finder-name
```

Description

The `delete-protocol-finder` subcommand removes the specified protocol finder. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--protocol-name`

The name of the associated protocol.

`--target`

Deletes the protocol finder only from the specified target. Valid values are as follows:

`server`

Deletes the protocol finder from the default server instance. This is the default value.

configuration-name

Deletes the protocol finder from the specified configuration.

cluster-name

Deletes the protocol finder from all server instances in the specified cluster.

standalone-instance-name

Deletes the protocol finder from the specified standalone server instance.

Operands

protocol-finder-name

The name of the protocol finder to be deleted.

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-protocol-finder`,
- `list-protocol-finders`

delete-protocol

Removes a protocol.

Synopsis

```
asadmin [asadmin-options] delete-protocol [--help]
[--target target]
protocol-name
```

Description

The `delete-protocol` subcommand removes the specified protocol. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the protocol only from the specified target. Valid values are as follows:

`server`

Deletes the protocol from the default server instance. This is the default value.

configuration-name

Deletes the protocol from the specified configuration.

cluster-name

Deletes the protocol from all server instances in the specified cluster.

standalone-instance-name

Deletes the protocol from the specified standalone server instance.

Operands

protocol-name

The name of the protocol to be deleted.

Examples

Example 1 Deleting a Protocol

The following command deletes the protocol named `http-1`:

```
asadmin> delete-protocol http-1
Command delete-protocol executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-protocol`,
- `list-protocols`

delete-resource-adapter-config

Deletes the resource adapter configuration.

Synopsis

```
asadmin [asadmin-options] delete-resource-adapter-config [--help]
```

```
raname
```

Description

The `delete-resource-adapter-config` subcommand deletes the configuration information for the connector module.

This command is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

raname

Specifies the connector module name.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-resource-adapter-config:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-resource-adapter-config:::example-1] **Example 1 Deleting a Resource Adapter Configuration**

This example deletes the configuration information for `ra1`.

```
asadmin> delete-resource-adapter-config ra1
Command delete-resource-adapter-config executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-resource-adapter-config`,
- `list-resource-adapter-configs`

delete-resource-ref

Removes a reference to a resource.

Synopsis

```
asadmin [asadmin-options] delete-resource-ref [--help]
[--target target] reference_name
```

Description

The `delete-resource-ref` subcommand removes from a cluster or an unclustered server instance a reference to a resource (for example, a JDBC resource). This effectively results in the removal of the resource from the JNDI tree of the targeted instance or cluster.

The target instance or instances making up the cluster need not be running or available for this subcommand to succeed. If one or more instances are not available, they will no longer load the resource in the JNDI tree the next time they start.

Removal of the reference does not result in removal of the resource from the domain. The resource is removed only by the `delete` subcommand for that resource (for example, `delete-jdbc-resource`).

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target from which you are removing the resource reference. Valid values are

`server`

Removes the resource reference from the default server instance `server` and is the default value.

cluster_name

Removes the resource reference from every server instance in the cluster.

instance_name

Removes the resource reference from the named unclustered server instance.

Operands

reference_name

The name or JNDI name of the resource.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-resource-ref:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-delete-resource-ref:::example-1] **Example 1 Removing a Reference to a Resource**

This example removes a reference to the JMS destination resource `jms/Topic` on the cluster `cluster1`.

```
asadmin> delete-resource-ref --target cluster1 jms/Topic
resource-ref jms/Topic deleted successfully.
Command delete-resource-ref executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

delete-service

Deletes the init scripts created by the `create-service` subcommand.

Synopsis

```
asadmin _delete-service [--help]
[--name service-name]
[--system-type system-type]
[--nodedir node-dir] [--node node]
[domain-or-instance-name]
```

Description

The _delete-service subcommand deletes init scripts created by the `create-script` subcommand.

If no operand is specified and the domains directory contains only one domain, the subcommand deletes the script starting the DAS for the default domain. If no operand is specified and the domains directory contains multiple domains, an error occurs.

The subcommand contains internal logic to smartly determine whether the supplied operand is a DAS or an instance.

This subcommand is supported in local mode only.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

(Windows and Oracle Solaris systems only) The name of the service that you will use when administering the service through Oracle Solaris SMF commands or the service management features of the Windows operating system.

The default is the name of the domain or instance that is specified as the operand of this subcommand.

`--system-type`

If specified, system-type must be one of `systemd`, `systemv`, `solaris` or `windows`, which determine the type of init scripts to create.

If not specified, the command performs auto-detection of init system.

`--domaindir`

The absolute path of the directory on the disk that contains the configuration of the domain. If this option is specified, the operand must specify a domain.

`--nodedir`

Specifies the directory that contains the instance's node directory. The instance's files are stored in the instance's node directory. The default is `as-install/nodes`. If this option is specified, the operand must specify an instance.

`--node`

Specifies the node on which the instance resides. This option may be omitted only if the directory that the `--nodedir` option specifies contains only one node directory.

Otherwise, this option is required. If this option is specified, the operand must specify an instance.

Operands

domain-or-instance-name

The name of the domain or instance to configure. If no operand is specified, the default domain is used.

Examples

Example Deleting a Service on a Linux System using SystemD init

This example deletes a service for the default domain on a system that is running Linux and SystemD.

It is necessary to inform SystemD about deleting the script by running systemctl daemon-reload.

```
asadmin _delete-service
Command _delete-service executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-service`

delete-ssl

Deletes the SSL element in the selected HTTP listener, IIOP listener, or IIOP service.

Synopsis

```
asadmin [asadmin-options] delete-ssl [--help]
[--target target]
--type listener_or_service_type
listener_id
```

Description

The `delete-ssl` subcommand deletes the SSL element in the selected HTTP listener, IIOP listener, or IIOP service.

The listener_id is not required if the `--type` is `iiop-service`.

This subcommand is supported in remote mode only.

Options

If an option has a short option name, then the short option precedes the long option name. Short options have one dash whereas long options have two dashes.

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which you are configuring the ssl element. The following values are valid:

`server`

Specifies the server in which the iiop-service or HTTP/IIOP listener is to be unconfigured for SSL.

config

Specifies the configuration that contains the HTTP/IIOP listener or iiop-service for which SSL is to be unconfigured.

cluster

Specifies the cluster in which the HTTP/IIOP listener or iiop-service is to be unconfigured for SSL. All the server instances in the cluster will get SSL unconfigured for the respective listener or iiop-service.

instance

Specifies the instance in which the HTTP/IIOP listener or iiop-service is to be unconfigured for SSL.

`--type`

The type of service or listener for which the SSL is deleted. The type must be one of the following types:

- `http-listener`
- `iiop-listener`
- `iiop-service`

Operands

listener_id

The ID of the listener from which the SSL element is to be deleted.
The listener_id operand is not required if the `--type` is `iiop-service`.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-delete-ssl:::example-1]]

Example 1 Deleting an SSL element from an HTTP listener

The following example shows how to delete an SSL element from an HTTP listener named `http-listener-1`.

```
asadmin> delete-ssl
--type http-listener http-listener-1
Command delete-ssl executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-ssl`

delete-system-property

Removes a system property of the domain, configuration, cluster, or server instance, one at a time.

Synopsis

```
asadmin [asadmin-options] delete-system-property [--help]
[--target target_name ]
[property_name]
```

Description

The `delete-system-property` subcommand deletes a system property of a domain, configuration, cluster, or server instance. Make sure that the system property is not referenced elsewhere in the configuration before deleting it.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are deleting the system properties. The valid targets for this subcommand are instance, cluster, configuration, domain, and server. Server is the default option.

Operands

property_name

The name of the system property to remove.

Examples

Example 1 Deleting a System Property

This example deletes the system property named `http-listener-port`.

```
asadmin> delete-system-property http-listener-port
Command delete-system-property executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-system-properties`,
- `list-system-properties`

delete-threadpool

Removes a thread pool.

Synopsis

```
asadmin [asadmin-options] delete-threadpool [--help]
[--target target] threadpool-id
```

Description

Removes the thread pool with the specified ID. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target from which you are removing the thread pool.
Valid values are as follows:

`server`

Deletes the thread pool for the default Payara Server instance `server` and is the default value.

configuration-name

Deletes the thread pool for the named configuration.

cluster-name

Deletes the thread pool for every instance in the cluster.

instance-name

Deletes the thread pool for a particular instance.

Operands

threadpool-id

An ID for the work queue, for example, `thread-pool1`, `threadpool-2`, and so forth.

Examples

Example 1 Deleting a Thread Pool

This example deletes `threadpool-1`.

```
asadmin> delete-threadpool threadpool-1
Command delete-threadpool executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-threadpool`,
- `list-threadpools`

delete-transport

Removes a transport.

Synopsis

```
asadmin [asadmin-options] delete-transport [--help]
[--target target]
transport-name
```

Description

The `delete-transport` subcommand removes the specified transport. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the transport only from the specified target. Valid values are as follows:

`server`

Deletes the transport from the default server instance. This is the default value.

configuration-name

Deletes the transport from the specified configuration.

cluster-name

Deletes the transport from all server instances in the specified cluster.

standalone-instance-name

Deletes the transport from the specified standalone server instance.

Operands

transport-name

The name of the transport to be deleted.

Examples

Example 1 Deleting a Transport

The following command deletes the transport named `http1-trans`:

```
asadmin> delete-transport http1-trans
Command delete-transport executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-transport`,
- `list-transports`

delete-virtual-server

Removes a virtual server.

Synopsis

```
asadmin [asadmin-options] delete-virtual-server [--help]
[--target target] virtual-server-id
```

Description

The `delete-virtual-server` subcommand removes the virtual server with the specified virtual server ID. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Deletes the virtual server only from the specified target. Valid values are as follows:

`server`

Deletes the virtual server from the default server instance. This is the default value.

configuration-name

Deletes the virtual server from the specified configuration.

cluster-name

Deletes the virtual server from all server instances in the specified cluster.

standalone-instance-name

Deletes the virtual server from the specified standalone server instance.

Operands

virtual-server-id

The unique identifier for the virtual server to be deleted.

Examples

Example 1 Deleting a Virtual Server

The following command deletes the virtual server named `sample_vs1`:

```
asadmin> delete-virtual-server sample_vs1
Command delete-virtual-server executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-virtual-server`,
- `list-virtual-servers`

deploy-remote-archive

Deploys the specified component from a remote location.

Synopsis

```
asadmin [asadmin-options] deploy-remote-archive [--help]
[--force={false|true}]
[--virtualservers virtual_servers]
[--contextroot context_root]
[--precompilejsp={false|true}]
[--verify={false|true}]
[--name component_name]
[--upload={true|false}]
[--retrieve local_dirpath]
[--dbvendorname dbvendorname]
[--deploymentplan deployment_plan]
[--altdd alternate_deploymentdescriptor]
[--runtimealtdd runtime_alternate_deploymentdescriptor]
[--deploymentorder deployment_order]
[--enabled={true|false}]
[--generatermistubs={false|true}]
[--availabilityenabled={false|true}]
[--asyncreplication={true|false}]
[--lbenabled={true|false}]
[--keepstate={false|true}]
[--libraries jar_file[,jar_file]*]
[--target target]
[--type pkg-type]
[--properties(name=value)[:name=value]*]
[--skipdsfailure]
[--additionalRepositories (repo1,repo2,...,repoN)]
[url|(groupId,artefactId,versionNumber)]
```

Description

The `deploy-remote-archive` subcommand deploys applications to the server and works in exactly the same as the `deploy` subcommand, but instead of accepting a local file path as its operand this command deploys an artifact that is available on a remote location via:

- A public URL where the artifact is hosted.
- A set of Maven GAV coordinates where the artifact is hosted.

This subcommand is supported in remote mode only.

Although the command can accept a set Maven GAV coordinates, it does not actually make use of Maven, and so artefacts will not be saved into your local Maven repository.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--force`

If set to `true`, redeploys the component even if the specified component has already been deployed or already exists. Default is `false`.

`--virtualservers`

One or more virtual server IDs. Multiple IDs are separated by commas.

`--contextroot`

Valid only if the archive is a web module. It is ignored for other archive types; it will be the value specified by default-context-path in web.xml, if specified; defaults to filename without extension.

`--precompilejsp`

By default this option does not allow the JSP to be precompiled during deployment. Instead, JSPs are compiled during runtime. Default is `false`.

`--verify`

If set to true and the required verifier packages are installed from the Update Tool, the syntax and semantics of the deployment descriptor is verified. Default is `false`.

`--name`

Name of the deployable component.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. For more information about module and application versions, see "Module and Application Versions" in Payara Server Application Deployment section.

`--upload`

Specifies whether the subcommand uploads the file to the DAS. In most situations, this option can be omitted.
Valid values are as follows:

`false`

The subcommand does not upload the file and attempts to access the file through the specified file name. If the DAS cannot access the file, the subcommand fails.
For example, the DAS might be running as a different user than the administration user and does not have read access to the file. In this situation, the subcommand fails if the `--upload` option is `false`.

`true`

The subcommand uploads the file to the DAS over the network connection.
The default value depends on whether the DAS is on the host where the subcommand is run or is on a remote host.

- If the DAS is on the host where the subcommand is run, the default is `false`.
- If the DAS is on a remote host, the default is `true`.
  If a directory filepath is specified, this option is ignored.

`--retrieve`

Retrieves the client stub JAR file from the server machine to the local directory.

`--dbvendorname`

Specifies the name of the database vendor for which tables are created. Supported values include `db2`, `mssql`, `h2`, `mysql`, `oracle`, `derby`, `javadb`, `postgresql`, and `sybase`. These values are case-insensitive. If not specified, the value of the `database-vendor-name` attribute in `glassfish-ejb-jar.xml` is used. If the connection cannot be established, or if the value is not valid, SQL-92 compliance is presumed.

`--deploymentplan`

Deploys the deployment plan, which is a JAR file that contains Payara Server descriptors. Specify this option when deploying a pure EAR file. A pure EAR file is an EAR without Payara Server descriptors.

`--altdd`

Deploys the application using a Jakarta EE standard deployment descriptor that resides outside of the application archive. Specify an absolute path or a relative path to the alternate deployment descriptor file. The alternate deployment descriptor overrides the top-level deployment descriptor packaged in the archive. For example, for an EAR, the `--altdd` option overrides `application.xml`. For a standalone module, the `--altdd` option overrides the top-level module descriptor such as `web.xml`.

`--runtimealtdd`

Deploys the application using a Payara Server runtime deployment descriptor that resides outside of the application archive. Specify an absolute path or a relative path to the alternate deployment descriptor file. The alternate deployment descriptor overrides the top-level deployment descriptor packaged in the archive. For example, for an EAR, the `--runtimealtdd` option overrides `payara-application.xml`. For a standalone module, the `--runtimealtdd` option overrides the top-level module descriptor such as `glassfish-web.xml` (deprecated) or `payara-web.xml`. Applies to Payara Server deployment descriptors only (`glassfish-.xml/payara-.xml`); the name of the alternate deployment descriptor file must begin with `glassfish-` (or `payara-` in specific cases). Does not apply to `sun-*.xml` deployment descriptors, which are deprecated.

`--deploymentorder`

Specifies the deployment order of the application. This is useful if the application has dependencies and must be loaded in a certain order at server startup. The deployment order is specified as an integer. The default value is 100. Applications with lower numbers are loaded before applications with higher numbers. For example, an application with a deployment order

of 102 is loaded before an application with a deployment order of 110. If a deployment order is not specified, the default value of 100 is assigned. If two applications have the same deployment order, the first application to be deployed is the first application to be loaded at server startup.
The deployment order is typically specified when the application is first deployed but can also be specified or changed after initial deployment using the `set` subcommand. You can view the deployment order of an application using the `get` subcommand.

`--enabled`

Allows users to access the application. If set to `false`, users will not be able to access the application. This option enables the application on the specified target instance or cluster. If you deploy to the target `domain`, this option is ignored, since deploying to the domain doesn't deploy to a specific instance or cluster. The default is `true`.

`--generatermistubs`

If set to `true`, static RMI-IIOP stubs are generated and put into the `client.jar`. If set to `false`, the stubs are not generated. Default is `false`.

`--availabilityenabled`

This option controls whether high-availability is enabled for web sessions and for stateful session bean (SFSB) checkpointing and potentially passivation. If set to false (default) all web session saving and SFSB checkpointing is disabled for the specified application, web application, or EJB module. If set to true, the specified application or module is enabled for high-availability. Set this option to true only if high availability is configured and enabled at higher levels, such as the server and container levels.

`--asyncreplication`

This option controls whether web session and SFSB states for which high availability is enabled are first buffered and then replicated using a separate asynchronous thread. If set to `true` (default), performance is improved but availability is reduced. If the instance where states are buffered but not yet replicated fails, the states are lost. If set to `false`, performance is reduced but availability is guaranteed. States are not buffered but immediately transmitted to other instances in the cluster.

`--lbenabled`

This option controls whether the deployed application is available for load balancing. The default is true.

`--keepstate`

This option controls whether web sessions, SFSB instances, and persistently created EJB timers are retained between re-deployments.
The default is false. This option is supported only on the default server instance, named `server`. It is not supported and ignored for any other target.
Some changes to an application between re-deployments prevent this feature from working properly. For example, do not change the set of instance variables in the SFSB bean class.
For web applications, this feature is applicable only if in the `payara-web.xml` file the `persistence-type` attribute of the `session-manager` element is `file`.
For stateful session bean instances, the persistence type without high availability is set in the server (the `sfsb-persistence-type` attribute) and must be set to `file`, which is the default and

recommended value.
If any active web session, SFSB instance, or EJB timer fails to be preserved or restored, none of these will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.
To preserve active state data, Payara Server serializes the data and saves it in memory. To restore the data, the class loader of the newly redeployed application deserializes the data that was previously saved.

`--libraries`

A comma-separated list of library JAR files. Specify the library JAR files by their relative or absolute paths. Specify relative paths relative to domain-dir`/lib/applibs`. The libraries are made available to the application in the order specified.

`--target`

Specifies the target to which you are deploying. Valid values are:

`server`

Deploys the component to the default server instance `server` and is the default value.

`domain`

Deploys the component to the domain. If `domain` is the target for an initial deployment, the application is deployed to the domain, but no server instances or clusters reference the application. If `domain` is the target for a redeployment (the `--force` option is set to true), and dynamic reconfiguration is enabled for the clusters or server instances that reference the application, the referencing clusters or server instances automatically get the new version of the application. If redeploying, and dynamic configuration is disabled, the referencing clusters or server instances do not get the new version of the application until the clustered or standalone server instances are restarted.

cluster_name

Deploys the component to every server instance in the cluster.

instance_name

Deploys the component to a particular stand-alone sever instance.

`--type`

The packaging archive type of the component that is being deployed. Possible values are as follows:

`car`

The component is packaged as a CAR file.

`ear`

The component is packaged as an EAR file.

`ejb`

The component is an EJB packaged as a JAR file.

`osgi`

The component is packaged as an OSGi bundle.

`rar`

The component is packaged as a RAR file.

`war`

The component is packaged as a WAR file.

`--properties` **or** `--property`

Optional keyword-value pairs that specify additional properties for the deployment. The available properties are determined by the implementation of the component that is being deployed or redeployed. The `--properties` option and the `--property` option are equivalent. You can use either option regardless of the number of properties that you specify.
You can specify the following properties for a deployment:

`jar-signing-alias`

Specifies the alias for the security certificate with which the application client container JAR file is signed. Java Web Start will not run code that requires elevated permissions unless it resides in a JAR file signed with a certificate that the user's system trusts. For your convenience, Payara Server signs the JAR file automatically using the certificate with this alias from the domain's keystore. Java Web Start then asks the user whether to trust the code and displays the Payara Server certificate information. To sign this JAR file with a different certificate, add the certificate to the domain keystore, then use this property. For example, you can use a certificate from a trusted authority, which avoids the Java Web Start prompt, or from your own company, which users know they can trust. Default is `s1as`, the alias for the self-signed certificate created for every domain.

`java-web-start-enabled`

Specifies whether Java Web Start access is permitted for an application client module. Default is true.

`compatibility`

Specifies the Payara Server release with which to be backward compatible in terms of JAR visibility requirements for applications. The only allowed value is `v2`, which refers to Payara Enterprise Server version 2 or Sun Java System Application Server version 9.1 or 9.1.1. Beginning in Java EE 6, the Java EE platform specification imposed stricter requirements than Java EE 5 did on which JAR files can be visible to various modules within an EAR file. In particular, application clients must not have access to EJB JAR files or other JAR files in the EAR file unless references use the standard Java SE mechanisms (extensions, for example) or the Jakarta EE library-directory mechanism. Setting this property to `v2` removes these restrictions.

`keepSessions={false|true}`

Superseded by the `--keepstate` option.
If the `--force` option is set to `true`, this property can by used to specify whether active sessions of the application that is being redeployed are preserved and then restored when the redeployment is complete. Applies to HTTP sessions in a web container. Default is

`false`.

`false`

Active sessions of the application are not preserved and restored (default).

`true`

Active sessions of the application are preserved and restored.
If any active session of the application fails to be preserved or restored, none of the sessions will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.
To preserve active sessions, Payara Server serializes the sessions and saves them in memory. To restore the sessions, the class loader of the newly redeployed application deserializes any sessions that were previously saved.

`preserveAppScopedResources`

If set to `true`, preserves any application-scoped resources and restores them during redeployment. Default is `false`.

```
Other available properties are determined by the implementation of the component
that is being redeployed. +
For components packaged as OSGi bundles (`--type=osgi`), the `deploy` subcommand
accepts properties arguments to wrap a WAR file as a WAB (Web Application Bundle)
at the time of deployment. The subcommand looks for a key named `UriScheme` and,
if present, uses the key as a URL stream handler to decorate the input stream.
Other properties are used in the decoration process. For example, the Payara
Server OSGi web container registers a URL stream handler named `webbundle`, which
is used to wrap a plain WAR file as a WAB. For more information about usage, see
the example in this help page.
```

`--skipdsfailure`

This option will skip over a data source failure. This means an application can be deployed with a data source set up, but the database need not be running at the time.

Without this option the deployment would fail if a data source is defined and the database is not available at deployment time.

```
asadmin deploy --skipdsfailure /home/mark/clusterjsp-1.1.war
```

`--additionalRepositories`

This option is used to instruct the command additional Maven2 remote repositories on top of Maven Central that the command can use to look for the artifact when a set of GAV coordinates are used in the operand. The value this option takes is a comma-separated string of all remote repositories URLs, like this:

```
https://nexus.payara.fish/payara-artifacts,https://google.co.uk
```

If an application artifact matching the GAV coordinates exists on multiple repositories, the first artifact found will be deployed. The order that the repositories are searched is the order that you specify them in.
For example, if this option's value is *repo1,repo2*, the order that the repositories would be searched is: *Maven Central → repo1 → repo2*.

Operands

url|(groupId,artifactId,versionNumber)

This operand supports 2 type of values:

- The URL where the archive that contains the application that is being deployed is located. This URL must correspond to publicly available HTTP(S) resources.
- A set of Maven GAV coordinates (`groupId`, `artifactId`, `versionNumber`) where the application artifact can be located in a remote Maven repository. The three coordinates are specified in a comma-separated string.

By default, the command will look for a matching artifact in Maven Central. Additional Maven repositories can be configured using the `--additionalRepositories` option

Examples

Example 1 Deploying an Application hosted on a public HTTP(S) location

This example deploys the enterprise application packaged in the `clusterjsp-1.1.war` file to the default server instance `server`, which is hosted in the remote location pointed by the `https://nexus.payara.fish/repository/payara-artifacts/fish/payara/testing/clusterjsp/1.1/clusterjsp-1.1.war` URL:

```
asadmin deploy-remote-archive --name clusterjsp
https://nexus.payara.fish/repository/payara-
artifacts/fish/payara/testing/clusterjsp/1.1/clusterjsp-1.1.war

Application deployed successfully with name clusterjsp.
Command deploy-remote-archive executed successfully
```

Example 2 Deploying a Web Application Using GAV coordinates

This example deploys the web application in the `clusterjsp-1.1.war` file to the default server instance `server`. This application can be located in the `fish.payara.testing:clusterjsp:1.1` GAV coordinates:

```
asadmin deploy-remote-archive --name clusterjsp fish.payara.testing,clusterjsp,1.1

Application deployed successfully with name clusterjsp.
Command deploy-remote-archive executed successfully
```

Example 3 Deploying a Web Application Using GAV coordinates using an additional remote repository

This example deploys the web application in the `clusterjsp-1.1.war` file to the default server instance `server` like the previous one, but configures the command to search for the Maven artifact on the remote repository `https://nexus.payara.fish/repository/payara-artifacts`:

```
asadmin deploy-remote-archive --name clusterjsp --additionalRepositories
https://nexus.payara.fish/repository/payara-artifacts
fish.payara.testing,clusterjsp,1.1

Application deployed successfully with name clusterjsp.
Command deploy-remote-archive executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

```

Description

The `deploy` subcommand deploys applications to the server. Applications can be enterprise applications, web applications, Enterprise JavaBeans (EJB) modules, connector modules, and application client modules. If the component is already deployed or already exists, it is forcibly redeployed if the `--force` option is set to `true` (default is `false`).

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--force`

If set to `true`, redeploys the component even if the specified component has already been deployed or already exists. Default is `false`.

`--virtualservers`

One or more virtual server IDs. Multiple IDs are separated by commas.

`--contextroot`

Valid only if the archive is a web module. It is ignored for other archive types; it will be the value specified by default-context-path in web.xml, if specified; defaults to filename without extension.

`--precompilejsp`

By default this option does not allow the JSP to be precompiled during deployment. Instead, JSPs are compiled during runtime. Default is `false`.

`--verify`

If set to true and the required verifier packages are installed from the Update Tool, the syntax and semantics of the deployment descriptor is verified. Default is `false`.

`--name`

Name of the deployable component.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. For more information about module and application versions, see "Module and Application Versions" in Payara Server Application Deployment section.

`--upload`

Specifies whether the subcommand uploads the file to the DAS. In most situations, this option can be omitted.
Valid values are as follows:

`false`

The subcommand does not upload the file and attempts to access the file through the specified file name. If the DAS cannot access the file, the subcommand fails.
For example, the DAS might be running as a different user than the administration user and does not have read access to the file. In this situation, the subcommand fails if the `--upload` option is `false`.

`true`

The subcommand uploads the file to the DAS over the network connection.
The default value depends on whether the DAS is on the host where the subcommand is run or is on a remote host.

- If the DAS is on the host where the subcommand is run, the default is `false`.
- If the DAS is on a remote host, the default is `true`.
  If a directory filepath is specified, this option is ignored.

`--retrieve`

Retrieves the client stub JAR file from the server machine to the local directory.

`--dbvendorname`

Specifies the name of the database vendor for which tables are created. Supported values include `db2`, `mssql`, `h2`, `mysql`, `oracle`, `derby`, `javadb`, `postgresql`, and `sybase`. These values are case-insensitive. If not specified, the value of the `database-vendor-name` attribute in `glassfish-ejb-jar.xml` is used. If the connection cannot be established, or if the value is not valid, SQL-92 compliance is presumed.

`--deploymentplan`

Deploys the deployment plan, which is a JAR file that contains Payara Server descriptors. Specify this option when deploying a pure EAR file. A pure EAR file is an EAR without Payara Server descriptors.

`--altdd`

Deploys the application using a Jakarta EE standard deployment descriptor that resides outside of the application archive. Specify an absolute path or a relative path to the alternate deployment descriptor file. The alternate deployment descriptor overrides the top-level

deployment descriptor packaged in the archive. For example, for an EAR, the `--altdd` option overrides `application.xml`. For a standalone module, the `--altdd` option overrides the top-level module descriptor such as `web.xml`.

`--runtimealtdd`

Deploys the application using a Payara Server runtime deployment descriptor that resides outside of the application archive. Specify an absolute path or a relative path to the alternate deployment descriptor file. The alternate deployment descriptor overrides the top-level deployment descriptor packaged in the archive. For example, for an EAR, the `--runtimealtdd` option overrides `payara-application.xml`. For a standalone module, the `--runtimealtdd` option overrides the top-level module descriptor such as `glassfish-web.xml` (deprecated) or `payara-web.xml`. Applies to Payara Server deployment descriptors only (`glassfish-.xml/payara-.xml`); the name of the alternate deployment descriptor file must begin with `glassfish-` (or `payara-` in specific cases). Does not apply to `sun-*.xml` deployment descriptors, which are deprecated.

`--deploymentorder`

Specifies the deployment order of the application. This is useful if the application has dependencies and must be loaded in a certain order at server startup. The deployment order is specified as an integer. The default value is 100. Applications with lower numbers are loaded before applications with higher numbers. For example, an application with a deployment order of 102 is loaded before an application with a deployment order of 110. If a deployment order is not specified, the default value of 100 is assigned. If two applications have the same deployment order, the first application to be deployed is the first application to be loaded at server startup.
The deployment order is typically specified when the application is first deployed but can also be specified or changed after initial deployment using the `set` subcommand. You can view the deployment order of an application using the `get` subcommand.

`--enabled`

Allows users to access the application. If set to `false`, users will not be able to access the application. This option enables the application on the specified target instance or cluster. If you deploy to the target `domain`, this option is ignored, since deploying to the domain doesn't deploy to a specific instance or cluster. The default is `true`.

`--generatermistubs`

If set to `true`, static RMI-IIOP stubs are generated and put into the `client.jar`. If set to `false`, the stubs are not generated. Default is `false`.

`--availabilityenabled`

This option controls whether high-availability is enabled for web sessions and for stateful session bean (SFSB) checkpointing and potentially passivation. If set to false (default) all web session saving and SFSB checkpointing is disabled for the specified application, web application, or EJB module. If set to true, the specified application or module is enabled for high-availability. Set this option to true only if high availability is configured and enabled at higher levels, such as the server and container levels.

`--asyncreplication`

This option controls whether web session and SFSB states for which high availability is enabled are first buffered and then replicated using a separate asynchronous thread. If set to `true`

(default), performance is improved but availability is reduced. If the instance where states are buffered but not yet replicated fails, the states are lost. If set to `false`, performance is reduced but availability is guaranteed. States are not buffered but immediately transmitted to other instances in the cluster.

`--lbenabled`

This option controls whether the deployed application is available for load balancing. The default is true.

`--keepstate`

This option controls whether web sessions, SFSB instances, and persistently created EJB timers are retained between redeployments.
The default is false. This option is supported only on the default server instance, named `server`. It is not supported and ignored for any other target.
Some changes to an application between redeployments prevent this feature from working properly. For example, do not change the set of instance variables in the SFSB bean class.
For web applications, this feature is applicable only if in the `payara-web.xml` file the `persistence-type` attribute of the `session-manager` element is `file`.
For stateful session bean instances, the persistence type without high availability is set in the server (the `sfsb-persistence-type` attribute) and must be set to `file`, which is the default and recommended value.
If any active web session, SFSB instance, or EJB timer fails to be preserved or restored, none of these will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.
To preserve active state data, Payara Server serializes the data and saves it in memory. To restore the data, the class loader of the newly redeployed application deserializes the data that was previously saved.

`--libraries`

A comma-separated list of library JAR files. Specify the library JAR files by their relative or absolute paths. Specify relative paths relative to domain-dir`/lib/applibs`. The libraries are made available to the application in the order specified.

`--target`

Specifies the target to which you are deploying. Valid values are:

`server`

Deploys the component to the default server instance `server` and is the default value.

`domain`

Deploys the component to the domain. If `domain` is the target for an initial deployment, the application is deployed to the domain, but no server instances or clusters reference the application. If `domain` is the target for a redeployment (the `--force` option is set to true), and dynamic reconfiguration is enabled for the clusters or server instances that reference the application, the referencing clusters or server instances automatically get the new version of the application. If redeploying, and dynamic configuration is disabled, the referencing clusters or server instances do not get the new version of the application until the clustered or standalone server instances are restarted.

cluster_name

Deploys the component to every server instance in the cluster.

instance_name

Deploys the component to a particular stand-alone sever instance.

`--type`

The packaging archive type of the component that is being deployed. Possible values are as follows:

`car`

The component is packaged as a CAR file.

`ear`

The component is packaged as an EAR file.

`ejb`

The component is an EJB packaged as a JAR file.

`osgi`

The component is packaged as an OSGi bundle.

`rar`

The component is packaged as a RAR file.

`war`

The component is packaged as a WAR file.

`--properties` **or** `--property`

Optional keyword-value pairs that specify additional properties for the deployment. The available properties are determined by the implementation of the component that is being deployed or redeployed. The `--properties` option and the `--property` option are equivalent. You can use either option regardless of the number of properties that you specify.
You can specify the following properties for a deployment:

`jar-signing-alias`

Specifies the alias for the security certificate with which the application client container JAR file is signed. Java Web Start will not run code that requires elevated permissions unless it resides in a JAR file signed with a certificate that the user's system trusts. For your convenience, Payara Server signs the JAR file automatically using the certificate with this alias from the domain's keystore. Java Web Start then asks the user whether to trust the code and displays the Payara Server certificate information. To sign this JAR file with a different certificate, add the certificate to the domain keystore, then use this property. For example, you can use a certificate from a trusted authority, which avoids the Java Web Start prompt, or from your own company, which users know they can trust. Default is `s1as`, the alias for the self-signed certificate created for every domain.

`java-web-start-enabled`

Specifies whether Java Web Start access is permitted for an application client module. Default is true.

`compatibility`

Specifies the Payara Server release with which to be backward compatible in terms of JAR visibility requirements for applications. The only allowed value is `v2`, which refers to Payara Enterprise Server version 2 or Sun Java System Application Server version 9.1 or 9.1.1. Beginning in Java EE 6, the Java EE platform specification imposed stricter requirements than Java EE 5 did on which JAR files can be visible to various modules within an EAR file. In particular, application clients must not have access to EJB JAR files or other JAR files in the EAR file unless references use the standard Java SE mechanisms (extensions, for example) or the Jakarta EE library-directory mechanism. Setting this property to `v2` removes these restrictions.

`keepSessions={false|true}`

Superseded by the `--keepstate` option.
If the `--force` option is set to `true`, this property specifies whether active sessions of the application being redeployed are preserved and restored after redeployment. Applies to HTTP sessions in a web container. Default is `false`.

`false`

Active sessions of the application are not preserved and restored (default).

`true`

Active sessions of the application are preserved and restored.
If any active session of the application fails to be preserved or restored, none of the sessions will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.
To preserve active sessions, Payara Server serializes the sessions and saves them in memory. To restore the sessions, the class loader of the newly redeployed application deserializes any sessions that were previously saved.

`preserveAppScopedResources`

If set to `true`, preserves any application-scoped resources and restores them during redeployment. Default is `false`.

`allowFacesCdiInitialisation={false|true}`

If set to true, enables scanning for Jakarta Faces content in the application, and if detected, forcing an attempt to initialise CDI and Weld even if bean discovery is set to "none". Default is false.

Other available properties are determined by the implementation of the component that is being redeployed.
For components packaged as OSGi bundles (`--type=osgi`), the `deploy` subcommand accepts properties arguments to wrap a WAR file as a WAB (Web Application Bundle) at the time of deployment. The subcommand looks for a key named `UriScheme` and, if present, uses the key as a URL stream handler to decorate the input stream. Other properties are used in the decoration

process. For example, the Payara Server OSGi web container registers a URL stream handler named `webbundle`, which is used to wrap a plain WAR file as a WAB. For more information about usage, see the example in this help page.

`--skipdsfailure`

This option will skip over a data source failure. This means an application can be deployed with a data source set up, but the database need not be running at the time.

Without this option the deployment would fail if a data source is defined and the database is not available at deployment time.

```
asadmin deploy --skipdsfailure /home/mark/clusterjsp-1.1.war
```

Operands

file_archive|filepath

The path to the archive that contains the application that is being deployed. This path can be a relative path or an absolute path. The archive can be in either of the following formats:

- An archive file, for example, `/export/JEE_apps/hello.war`.
  If the `--upload` option is set to `true`, this is the path to the deployable file on the local client machine. If the `--upload` option is set to `false`, this is the path to the file on the server machine.
- A directory that contains the exploded format of the deployable archive. This is the path to the directory on the server machine. If you specify a directory, the `--upload` option is ignored.

Examples

Example 1 Deploying an Enterprise Application

This example deploys the enterprise application packaged in the `Cart.ear` file to the default server instance `server`. You can use the `--target` option to deploy to a different server instance or to a cluster.

```
asadmin> deploy Cart.ear
Application deployed successfully with name Cart.
Command deploy executed successfully
```

Example 2 Deploying a Web Application With the Default Context Root

This example deploys the web application in the `hello.war` file to the default server instance `server`. You can use the `--target` option to deploy to a different server instance or to a cluster.

```
asadmin> deploy hello.war
Application deployed successfully with name hello.
Command deploy executed successfully
```

Example 3 Forcibly Deploying a Web Application With a Specific Context Root

This example forcibly deploys the web application in the `hello.war` file. The context root of the deployed web application is `greetings`. If the application has already been deployed, it is redeployed.

```
asadmin> deploy --force=true --contextroot greetings hello.war
Application deployed successfully with name hello.
Command deploy executed successfully
```

Example 4 Deploying a Connector Module

This example deploys a connector module that is packaged in a RAR file.

This example uses the `--target` option. The target in this example is an existing standalone server instance that does not belong to a cluster.

```
asadmin> deploy --target myinstance jdbcra.rar
Application deployed successfully with name jdbcra.
Command deploy executed successfully
```

Example 5 Specifying the Deployment Order for an Application

This example specifies the deployment order for two applications. The `cart` application is loaded before the `horse` application at server startup.

Some lines of output are omitted from this example for readability.

```
asadmin> deploy --deploymentorder 102 --name cart cart.war
...
asadmin> deploy --deploymentorder 110 --name horse horse.war
...
```

Example 6 Deploying an Application Using an Alternate Jakarta EE 8 Deployment Descriptor File

This example deploys an application using a Jakarta EE standard deployment descriptor file that resides outside the application archive.

```
asadmin> deploy --altdd path_to_alternate_descriptor cart.ear
Application deployed successfully with name cart.
Command deploy executed successfully
```

Example 7 Deploying an Application Using an Alternate Payara Server Deployment Descriptor File

This example deploys an application using a Payara Server runtime deployment descriptor file that resides outside the application archive.

```
asadmin> deploy --runtimealtdd path_to_alternate_runtime_descriptor horse.ear
Application deployed successfully with name horse.
Command deploy executed successfully
```

Example 8 Wrapping a WAR File as a WAB

This example wraps a plain WAR file as a WAB when an OSGi bundle is deployed, and is specific to components packaged as OSGi bundles.

The backslash (\) character is used to escape characters in the command. For more information about escape characters in options for the `asadmin` utility, see the `asadmin` help page.

```
asadmin deploy --type osgi \
--properties "UriScheme=webbundle:Bundle-SymbolicName=bar:\
Import-Package=javax.servlet;javax.servlet.http;
%20version\\=3.0;resolution\\:
=mandatory:Web-ContextPath=/foo" \
/tmp/test_sample1.war
Application deployed successfully with name sample1.
Command deploy executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

disable-asadmin-recorder

Disables the Asadmin recorder.

Synopsis

```
asadmin [asadmin-options] disable-asadmin-recorder [--help]
```

Description

The `disable-asadmin-recorder` subcommand deactivates the Asadmin Recorder feature, ceasing the capture and logging of asadmin commands executed through the Admin Console.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Disabling asadmin Recorder

This example deactivates the Asadmin Recorder feature.

```
asadmin disable-asadmin-recorder

Command disable-asadmin-recorder executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `enable-asadmin-recorder`

disable-http-lb-application

disable-http-lb-server

disable-monitoring

Disables monitoring for the server or for specific monitorable module.

Synopsis

```
asadmin [asadmin-options] disable-monitoring [--help]
[--modules module-name][:module-name]*
```

Description

The `disable-monitoring` subcommand is used to turn off monitoring for Payara Server or for particular modules during runtime. Changes are dynamic, that is, server restart is not required.

Running the `disable-monitoring` subcommand without the `--module` option disables the monitoring service by setting the `monitoring-enabled` attribute of the `monitoring-service` element to `false`. The individual modules retain their monitoring levels, but no monitoring data is generated because the entire monitoring service is disabled.

This subcommand used with the `--modules` option disables monitoring for a module by setting the monitoring level to OFF. The status of the monitoring service is not affected. For a list of monitorable modules, see the `--modules` option in this help page.

An alternative method for disabling monitoring is to use the `set` subcommand. In this case, the server must be restarted for changes to take effect.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--modules`

Disables the specified module or modules by setting the monitoring level to OFF. Multiple modules are separated by : (colon). Monitorable modules include `connector-connection-pool`, `connector-service`, `ejb-container`, `http-service`, `jdbc-connection-pool`, `jersey`, `jpa`, `jms-service`, `jvm`, `security`, `thread-pool`, `transaction-service`, `web-container`, and `web-services-container`. Additional modules can be listed by using the `get` subcommand.

Operands

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-disable-monitoring:::example-1]]

Example 1 Disabling the Monitoring Service for Payara Server

This example disables monitoring for Payara Server in general by setting the `enable-monitoring` flag

to `false` (default is `true`).

```
asadmin> disable-monitoring
Command disable-monitoring executed successfully
```

[[Technical Documentation-Payara Server Documentation-Command Reference-disable-monitoring:::example-2]]

Example 2 Disabling Monitoring for the Web and EJB Containers

This example disables monitoring for specific containers. Their monitoring levels will be set to OFF.

```
asadmin> disable-monitoring --modules web-container:ejb-container
Command disable-monitoring executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

disable-phone-home

Disables the phone home services.

Synopsis

```
asadmin> disable-phone-home
```

Description

The phone home data is presently used to gather usage statistics about the corresponding distribution, such as how long users typically run instances, and what versions they use. The phone

home service is enabled by default when starting a Payara Server and can be disabled by using this command. Make sure to restart Payara Server for the changes to take effect.

Examples

Example 1 Disable Phone Home Service

```
asadmin>  disable-phone-home
Phone Home Service is disabled

Command disable-phone-home executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

disable-secure-admin-internal-user

Instructs the Payara Server DAS and instances to not use the specified admin user to authenticate with each other and to authorize admin operations.

Synopsis

```
asadmin [asadmin-options] disable-secure-admin-internal-user [--help]
admin-username
```

Description

The `disable-secure-admin-internal-user` subcommand disables secure admin from using the username (instead of SSL certificates) to authenticate the DAS and instances with each other and to authorize admin operations.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

admin-username

The admin username that Payara Server should not use to authenticate the DAS and instances with each other and to authorize admin operations.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-disable-secure-admin-internal-user:::example-1]]

Example 1 Disabling a username for secure admin

The following example disables secure admin from using username tester to authenticate the DAS and instances with each other and to authorize admin operations.

```
asadmin> disable-secure-admin-internal-user tester

Command disable-secure-admin-internal-user executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `enable-secure-admin-internal-user`

disable-secure-admin-principal

Disables the certificate for authorizing access in secure administration.

Synopsis

```
asadmin [asadmin-options] disable-secure-admin-principal [--help]
--alias aliasname | DN
```

Description

The `disable-secure-admin-principal` subcommand disables the certificate as being valid for authorizing access as part of secure administration.

You must specify either the `--alias` option, or the DN.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--alias`

The alias name of the certificate in the truststore. Payara Server looks up the certificate in the truststore using that alias and, if found, disables the corresponding DN as being valid for secure administration. Because alias-name must be an alias associated with a certificate currently in the truststore, you may find it most useful for self-signed certificates.

Operands

DN

The distinguished name of the certificate, specified as a comma-separated list in quotes. For example, `"CN=system.amer.oracle.com,OU=GlassFish,O=Oracle Corporation,L=Santa Clara,ST=California,C=US"`.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-disable-secure-admin-principal:::example-1]]

Example 1 Disables trust of a DN for secure administration

The following example shows how to disable trust of a DN for authorizing access in secure administration.

```
asadmin> disable-secure-admin-principal
"CN=system.amer.oracle.com,OU=GlassFish,
O=Oracle Corporation,L=Santa Clara,ST=California,C=US"

Command disable-secure-admin-principal executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

disable-secure-admin

Disables secure admin if it is already enabled.

Synopsis

```
asadmin [asadmin-options] disable-secure-admin [--help]
```

Description

The `disable-secure-admin` subcommand disables secure admin if it is already enabled.

You must restart any running servers in the domain after you enable or disable secure admin. It is simpler to enable or disable secure admin with only the DAS running, then restart the DAS, and then start any other instances.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-disable-secure-admin:::example-1]]

Example 1 Disabling `secure admin` for a domain

The following example shows how to disable `secure admin` for a domain.

```
asadmin> disable-secure-admin
server-config
default-config
```

```
Command disable-secure-admin executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `enable-secure-admin`

disable

Disables the component.

Synopsis

```
asadmin [asadmin-options] disable [--help]
[--target target_name] component_name
```

Description

The `disable` subcommand immediately disables the specified deployed component. If the component has not been deployed, an error message is returned.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are disabling the component. Valid values are:

`server`

Disables the component on the default server instance `server` and is the default value.

domain_name

Disables the component on the named domain.

cluster_name

Disables the component on every server instance in the cluster.

instance_name

Disables the component on a particular clustered or stand-alone server instance.

Operands

component_name

name of the component to be disabled.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (_), dash (-), and period (.) characters. To disable multiple versions, you can use an asterisk (*) as a wildcard character. For more information about module and application versions, see "Module and Application Versions" in Payara Server Application Deployment section.

Examples

Example 1 Disabling a Component

This example disables the deployed component `sampleApp`.

```
asadmin> disable sampleApp
Command disable executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

enable-asadmin-recorder

Enables the asadmin recorder.

Synopsis

```
asadmin [asadmin-options] enable-asadmin-recorder [--help]
```

Description

The `enable-asadmin-recorder` subcommand activates the Asadmin Recorder feature, allowing for the capture and logging of all asadmin commands executed through the Admin Console.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Enabling asadmin Recorder

This example activates the Asadmin Recorder feature.

```
asadmin enable-asadmin-recorder

Command enable-asadmin-recorder executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `disable-asadmin-recorder`

enable-http-lb-application

enable-http-lb-server

enable-monitoring

Enables monitoring for the server or for specific monitorable modules.

Synopsis

```
asadmin [asadmin-options] enable-monitoring [--help]
[--target target]
[--mbean={false|true}]
[--dtrace={true|false}]
[--modules modules[=level][:module[=level]]*
[--pid pid]
[--options options]]
```

Description

The `enable-monitoring` subcommand is used to turn on monitoring for Payara Server or for particular modules during runtime. Changes are dynamic, that is, server restart is not required.

By default, the monitoring service is enabled, that is, the `monitoring-enabled` attribute of the `monitoring-service` element is `true`. However, the default monitoring level for individual modules is `OFF`. This subcommand used with the `--modules` option can enable monitoring for a given module by setting the monitoring level to HIGH or LOW. If level is not specified when running the subcommand, the level defaults to HIGH.

The specific meanings of HIGH or LOW are determined by the individual containers. For a list of monitorable modules, see the `--modules` option in this help page.

An alternative method for enabling monitoring is to use the `set` subcommand. In this case, the server must be restarted for changes to take effect.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target on which to enabling monitoring. Valid values are as follows:

`server`

Enables monitoring for the default server instance `server` and is the default value.

configuration-name

Enables monitoring for the named configuration.

cluster-name

Enables monitoring for every server instance in the cluster.

instance-name

Enables monitoring for a particular server instance.

`--mbean`

Enables Mbean monitoring. Default value is false.

`--dtrace`

Only usable if the DTrace Monitoring module is present. Enables Oracle Solaris DTrace monitoring. Default value is false.

`--modules`

Enables specified module or modules by indicating monitoring level. Valid levels are OFF, HIGH, LOW. If level is not specified, the default setting is HIGH. Multiple modules are separated by : (colon). Monitorable modules include `connector-connection-pool`, `connector-service`, `ejb-container`, `http-service`, `jdbc-connection-pool`, `jersey`, `jpa`, `jms-service`, `jvm`, `security`, `thread-pool`, `transaction-service`, `web-container`, and `web-services-container`. Additional modules can be listed by using the `get` subcommand.

`--pid`

Specifies the Payara Server JVM process identifier (PID). When monitoring is enabled, the `btrace-agent` is attached, based on the specified PID. Need to specify only in exceptional cases when the system cannot determine the PID. In this situation, the subcommand prompts for the PID of the corresponding Payara Server process.

`--options`

Sets the following `btrace-agent` options:

`debug`

Enables debugging for BTrace. Default value is false.

Examples

Example 1 Enabling the Monitoring Service for Payara Server

This example enables monitoring for Payara Server in general shell setting the `enable-monitoring` flag to `true` (default is `true`)shell

```
asadmin> enable-monitoring
Command enable-monitoring executed successfully
```

Example 2 Enabling Monitoring for the Web and EJB Containers

This example enables monitoring for specific containers by setting their monitoring levels.

```
asadmin> enable-monitoring --modules web-container=LOW:ejb-container=HIGH
Command enable-monitoring executed successfully
```

Example 3 Turning on Debugging for Monitoring

This example turns on debugging.

```
asadmin> enable-monitoring --options debug=true
Command enable-monitoring executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

enable-phone-home

Enables the phone home services.

Synopsis

```
asadmin> enable-phone-home
```

Description

The phone home data is presently used to gather usage statistics about the corresponding distribution, such as how long users typically run instances, and what versions they use. The phone home service is enabled by default when starting a Payara Server.

Examples

Example 1 Enable Phone Home Service

```
asadmin>  enable-phone-home
Phone Home Service is enabled

Command enable-phone-home executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `disable-phone-home`,
- `list-phone-home`

enable-secure-admin-internal-user

Instructs the Payara Server DAS and instances to use the specified admin user and the password associated with the password alias to authenticate with each other and to authorize admin operations.

Synopsis

```
asadmin [asadmin-options] enable-secure-admin-internal-user [--help]
[--passwordalias pwdaliasname]
admin-username
```

Description

The `enable-secure-admin-internal-user` subcommand instructs all servers in the domain to authenticate to each other, and to authorize admin operations submitted to each other, using an existing admin username and password rather than SSL certificates. This generally means that you must:

1. Create a valid admin user.

   ```
   asadmin> create-file-user --authrealmname admin-realm --groups
   asadmin newAdminUsername
   ```

2. Create a password alias for the just-created password.

```
asadmin> create-password-alias passwordAliasName
```

3. Use that username and password for inter-process authentication and admin authorization.

```
asadmin> enable-secure-admin-internal-user
--passwordalias passwordAliasName
newAdminUsername
```

If Payara Server finds at least one secure admin internal user, then if secure admin is enabled Payara Server processes will not use SSL authentication and authorization with each other and will instead use username password pairs.

If secure admin is enabled, all Payara Server processes continue to use SSL encryption to secure the content of the admin messages, regardless of how they authenticate to each other.

Most users who use this subcommand will need to set up only one secure admin internal user. As a general practice, you should not use the same username and password pair for internal admin communication and for admin user login.

If you set up more than one secure admin internal user, you should not make any assumptions about which username and password pair Payara Server will choose to use for any given admin request.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--passwordalias`

The password alias for the user that Payara Server should use for internally authenticating and authorizing the DAS to instances and the instances to the DAS.

Operands

admin-username

The admin username that Payara Server should use for internally authenticating and authorizing the DAS to instances and the instances to the DAS.

Examples

Example 1 Specifying a username and password for secure admin

The following example allows secure admin to use a username and password alias for authentication and authorization between the DAS and instances, instead of certificates.

```
asadmin> enable-secure-admin-internal-user
--passwordalias passwordAliasName
newAdminUsername
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `disable-secure-admin-internal-user`,
- `enable-secure-admin`

enable-secure-admin-principal

Instructs Payara Server, when secure admin is enabled, to accept admin requests from clients identified by the specified SSL certificate.

Synopsis

```
asadmin [asadmin-options] enable-secure-admin-principal [--help]
--alias aliasname | DN
```

Description

The `enable-secure-admin-principal` subcommand instructs Payara Server to accept admin requests when accompanied by an SSL certificate with the specified distinguished name (DN). If you use the "`--alias` aliasname" form, then Payara Server looks in its truststore for a certificate with the specified alias and uses the DN associated with that certificate. Otherwise, Payara Server records the value you specify as the DN.

You must specify either the `--alias` option, or the DN.

You can run `enable-secure-admin-principal` multiple times so that Payara Server accepts admin requests from a client sending a certificate with any of the DNs you specify.

When you run `enable-secure-admin`, Payara Server automatically records the DNs for the admin alias and the instance alias, whether you specify those values or use the defaults. You do not need to run `enable-secure-admin-principal` yourself for those certificates. Other than these certificates, you must run `enable-secure-admin-principal` for any other DN that Payara Server should authorize to send admin requests. This includes DNs corresponding to trusted certificates (those with a certificate chain to a trusted authority.)

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--alias`

The alias name of the certificate in the trust store. Payara Server looks up certificate in the trust store using that alias and, if found, stores the corresponding DN as being valid for secure administration. Because alias-name must be an alias associated with a certificate currently in the trust store, you may find it most useful for self-signed certificates.

Operands

DN

The distinguished name of the certificate, specified as a comma-separated list in quotes. For example, `"CN=system.amer.oracle.com,OU=GlassFish,O=Oracle Corporation,L=Santa Clara,ST=California,C=US"`.

Examples

Example 1 Trusting a DN for secure administration

The following example shows how to specify a DN for authorizing access in secure administration.

```
asadmin> enable-secure-admin-principal
"CN=system.amer.oracle.com,OU=GlassFish,
O=Oracle Corporation,L=Santa Clara,ST=California,C=US"

Command enable-secure-admin-principal executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `disable-secure-admin-principal`,
- `enable-secure-admin`

enable-secure-admin

Enables secure admin (if it is not already enabled), optionally changing the alias used for DAS-to-instance admin messages or the alias used for instance-to-DAS admin messages.

Synopsis

```
asadmin [asadmin-options] enable-secure-admin [--help]
[--adminalias=alias]
[--instancealias=alias]
```

Description

The `enable-secure-admin` subcommand causes the DAS and the instances in the domain to use SSL certificates for encrypting the messages they send to each other. This subcommand also allows the DAS to accept administration messages from remote admin clients such as the asadmin utility and IDEs.

You must restart any running servers in the domain after you enable or disable secure admin. It is simpler to enable or disable secure admin with only the DAS running, then restart the DAS, and then start any other instances.

By default, when secure admin is enabled the DAS and the instances use these SSL certificates to authenticate to each other as security "principals" and to authorize admin access. The `--asadminalias` value indicates to the DAS which SSL certificate it should use to identify itself to the instances. The `--instancealias` value determines for instances which SSL certificate they should use to identify themselves to the DAS.

The `enable-secure-admin` subcommand fails if any administrative user in the domain has a blank password.

Alternatively, you can use the `enable-secure-admin-internal-user` subcommand to cause the servers to identify themselves using a secure admin user name and password.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the link:Technical Documentation/Payara Server Documentation/Command Reference/asadmin#asadmin-1m[`asadmin`] help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--adminalias`

The alias that refers to the SSL/TLS certificate on the DAS. This alias is used by the DAS to identify itself to instances. The default value is `s1as`.

`--instancealias`

The alias that refers to the SSL/TLS certificate on the instances. This alias is used by the instances to identify themselves to the DAS. The default value is `glassfish-instance`.

Examples

Example 1 Enabling `secure admin` for a domain

The following example shows how to enable `secure admin` for a domain using an admin alias `adtest` and an instance alias `intest`

```
asadmin> enable-secure-admin --adminalias adtest --instancealias intest
server-config
default-config

Command enable-secure-admin executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `disable-secure-admin`,
- `enable-secure-admin-principal`,
- `enable-secure-admin-internal-user`

enable

Enables the component.

Synopsis

```
asadmin [asadmin-options] enable [--help]
[--target target_name] component_name
```

Description

The `enable` subcommand enables the specified deployed component. If the component is already enabled, then it is re-enabled. If it has not been deployed, then an error message is returned.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are enabling the component. Valid values are:

`server`

Enables the default server instance `server` and is the default value.

domain_name

Enables the named domain.

cluster_name

Enables every server instance in the cluster.

instance_name

Enables a particular clustered or stand-alone server instance.

Operands

component_name

name of the component to be enabled.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. For more information about module and application versions, see "Module and Application Versions" in Payara Server Application Deployment section.
At most one version of a module or application can be enabled on a server instance. All other versions are disabled. Enabling one version automatically disables all others.

Examples

Example 1 Enabling a Component

This example enables the disabled component, `sampleApp`.

```
asadmin> enable sampleApp
Command enable executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `deploy`,
- `disable`,
- `undeploy`
- Payara Server Application Deployment section

export-http-lb-config

export-sync-bundle

Exports the configuration data of a cluster or standalone instance to an archive file.

Synopsis

```
asadmin [asadmin-options] export-sync-bundle [--help]
--target target
[--retrieve={false|true}]
[file-name]
```

Description

The `export-sync-bundle` subcommand exports the configuration data of a cluster or standalone instance to an archive file. The archive file can then be used with the `import-sync-bundle` subcommand to restore the configuration data.

Importing an instance's configuration data transfers the data to a host for an instance without the need for the instance to be able to communicate with the domain administration server (DAS). Importing an instance's configuration data is typically required for the following reasons:

- To reestablish the instance after an upgrade
- To synchronize the instance manually with the DAS when the instance cannot contact the DAS

The subcommand creates an archive that contains the following files and directories in the current domain directory:

- All the files in the following directories:
  - `config`
  - `docroot`

- The entire contents of the following directories and their subdirectories:
  - `applications`
  - `config/`target, where target is the cluster or standalone instance for which configuration data is being exported
  - `generated`
  - `lib`

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The cluster or standalone instance for which to export configuration data. The `--target` option is required. This option must not specify a clustered Payara Server instance. If this option specifies a clustered instance, an error occurs. To export configuration data for a clustered instance, specify the name of the cluster of which the instance is a member, not the instance.

`--retrieve`

Specifies whether the archive file is downloaded from the DAS host to the host where the subcommand is run.
Possible values are as follows:

`true`

The archive file is downloaded to the host where the subcommand is run.

`false`

The archive file is not downloaded and remains on the DAS host (default).

Operands

file-name

The file name and location of the archive file to which to export the data.
The default depends on the setting of the `--retrieve` option:

- If `--retrieve` is `false`, the default is `sync/`target-sync-bundle.zip` in the current domain directory.
- If `--retrieve` is `true`, the default is target`-sync-bundle.zip` in the current working directory.
  target is the cluster or standalone instance that the `--target` option specifies.
  If a relative path is specified, the directory to which the path is appended depends on the setting of the `--retrieve` option:

- If `--retrieve` is `false`, the path is appended to the `config` subdirectory of the current domain directory.
- If `--retrieve` is `true`, the path is appended to the current working directory.
  If an existing directory is specified without a filename, the file name of the archive file is target`-sync-bundle.zip`, where target is the cluster or standalone instance that the `--target` option specifies.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-export-sync-bundle:::example-1]]

Example 1 Exporting the Configuration Data of a Cluster

This example exports the configuration data of the cluster `pmdcluster`.

```
asadmin> export-sync-bundle --target=pmdcluster
Sync bundle: /export/payara7/glassfish/domains/domain1/sync/
pmdcluster-sync-bundle.zip

Command export-sync-bundle executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `import-sync-bundle`

export

Marks a variable name for automatic export to the environment of subsequent commands in multimode.

Synopsis

```
asadmin [asadmin-options] export [--help]
[variable-name=value [variable-name=value]*]
```

Description

In multimode, the `export` subcommand marks an environment variable for automatic export to the

environment of subsequent commands. All subsequent commands use the variable name value as specified unless you exit multimode, or use the `unset` subcommand to unset the variable. If only the variable name is specified, the current value of that variable name is displayed.

If the `export` subcommand is used without any arguments, a list of all the exported variables and their values is displayed. Exported shell environment variables set prior to invoking the `asadmin` utility are imported automatically and set as exported variables within `asadmin`. Environment variables that are not exported cannot be read by the `asadmin` utility.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

variable-name=value

Variable name and value for automatic export to the environment to be used by subsequent commands.

Examples

Example 1 Listing the Environment Variables That Are Set

This example lists the environment variables that have been set.

```
asadmin> export
Command export executed successfully
```

Example 2 Setting an Environment Variable

This example sets the `AS_ADMIN_HOST` environment variable to `bluestar`.

```
asadmin> export AS_ADMIN_HOST=bluestar
Command export executed successfully
```

Example 3 Setting Multiple Environment Variables

This example sets a number of environment variables for the multimode environment.

```
asadmin> export AS_ADMIN_HOST=bluestar AS_ADMIN_PORT=8000
AS_ADMIN_USER=admin AS_ADMIN_PREFIX=server1.jms-service
```

```
ceX=server1.jms-service
Command export executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `multimode`,
- `unset`

flush-connection-pool

Reintializes all connections established in the specified connection pool.

Synopsis

```
asadmin [asadmin-options] flush-connection-pool [--help]
[--appname application [--modulename module]
pool_name
```

Description

The `flush-connection-pool` subcommand resets a JDBC connection pool or a connector connection pool to its initial state. Any existing live connections are destroyed, which means that the transactions associated with these connections are lost. The subcommand then recreates the initial connections for the pool, and restores the pool to its steady pool size.

This subcommand is supported in remote mode only.

Application Scoped Resources

The `flush-connection-pool` subcommand can target resources that are scoped to a specific application or module, as defined in the `glassfish-resources.xml` or `payara-resources.xml` for the Payara Server domain.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

- To reference the `jndi-name` for an application scoped resource, perform the lookup using the `java:app` prefix.

- To reference the `jndi-name` for a module scoped resource, perform the lookup using the `java:module` prefix.

The `jndi-name` for application-scoped-resources or module-scoped-resources are specified using the format `java:app/`jdbc/myDataSource` or `java:module/`jdbc/myModuleLevelDataSource`. This naming scope is defined in the Jakarta EE Specification (`https://jakarta.ee/specifications/`).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--appname`

Name of the application in which the application scoped resource is defined.

`--modulename`

Name of the module in which the module scoped resource is defined.

Operands

pool_name

Name of the connection pool to be reinitialized.

Flushing a Connection Pool

This example reinitializes the JDBC connection pool named `__TimerPool`.

```
asadmin> flush-connection-pool __TimerPool
Command flush-connection-pool executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `list-connector-connection-pools`,
- `list-jdbc-connection-pools`

flush-jmsdest

Purges messages in a JMS destination.

Synopsis

```
asadmin [asadmin-options] flush-jmsdest [--help]
--desttype {topic|queue}
[--target target]
destname
```

Description

The `flush-jmsdest` subcommand purges the messages from a physical destination in the server's Java Message Service (JMS) configuration.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--desttype`

This option indicates the type of physical destination from which you want to purge messages. The supported destination types are `topic` and `queue`.

`--target`

Purges messages from the physical destination only for the specified target. Valid values are as follows:

`server`

Purges messages from the physical destination for the default server instance. This is the default value.

configuration-name

Purges messages from the physical destination in the specified configuration.

cluster-name

Purges messages from the physical destination for every server instance in the specified cluster.

instance-name

Purges messages from the physical destination for the specified server instance.

Operands

dest_name

The unique identifier of the JMS destination to be purged.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-flush-jmsdest:::example-1]]

Example 1 Purging messages from a physical destination

The following subcommand purges messages from the queue named `PhysicalQueue`.

```
asadmin> flush-jmsdest --desttype queue PhysicalQueue
Command flush-jmsdest executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `list-jmsdest`

freeze-transaction-service

Freezes the transaction subsystem.

Synopsis

```
asadmin [asadmin-options] freeze-transaction-service [--help]
[--target target]
```

Description

The `freeze-transaction-service` subcommand freezes the transaction subsystem, preventing the transaction manager from starting, completing, or changing the state of all in-flight transactions. Invoke this command before rolling back any in-flight transactions. Invoking this subcommand on

an already frozen transaction subsystem has no effect. Restarting the server unfreezes the transaction subsystem. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are freezing the transaction service. Valid values are:

`server`

Freezes the transaction service for the default server instance `server` and is the default value.

configuration_name

Freezes the transaction service for all server instances that use the named configuration.

cluster_name

Freezes the transaction service for every server instance in the cluster.

instance_name

Freezes the transaction service for a particular server instance.

Examples

Example 1 Using freeze-transaction-service

```
% asadmin freeze-transaction-service
Command freeze-transaction-service executed successfully
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- Transactions" in Jakarta EE Specification

generate-bash-autocomplete

Creates an Asadmin CLI autocompletion script for bash.

Synopsis

```
asadmin generate-bash-autocomplete [--help]
[--force=false]
[--localcommands=false]
[file]
```

Description

The created file will be located in the server's host and not the client. If they are on different hosts, then the file will be needed to copied from the server to the client.

You can add the resulting file to your bash path by adding source `path/to/outputfile` to your .bashrc settings or copy the file into the `/etc/bash_completion.d` directory.

This means that you can run asadmin commands by typing asadmin in a terminal, and you can use double-tab to autocomplete a command, similar to other bash commands.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--force`

Whether to overwrite a script file if one already exists. The default value is `false`.

`--file`

The path for the resulting file. The default value is `as-install/bin/bash_autocomplete`.

`--localCommands`

This option will include local asadmin commands.

The default value is `false`.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-generate-bash-autocomplete:::example-1]]

Example 1 Creating an asadmin autocompletion script for bash.

This example shows a script that is generated if no file is specified.

```
asadmin generate-bash-autocomplete
Written bash autocomplete file to /export/payara7/glassfish/bin/bash_autocomplete
Command generate-bash-autocomplete executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

generate-csr

Generates a new CSR (certificate signing request).

Synopsis

```
asadmin generate-csr [--help]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[alias]
```

Description

This command can generate a certificate signing request (CSR) for an instance or listener's self-signed certificate, placing the resultant CSR file in the `as-install/glassfish/tls` directory, using the alias name as the generated file name for the CSR.

The command overwrite a CSR with the same name already present in the directory.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are generating the CSR. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

Operands

alias

The alias name to use when generating the CSR for the corresponding self-signed certificate.

Examples

Example 1 Generate a new CSR for the certificate with the `test-cert` alias

```
asadmin generate-csr --listener http-listener-2 --target instance-1 test_cert
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

generate-encryption-key

Generates an encryption key for Data Grid secure communication.

Synopsis

```
asadmin [asadmin-options] generate-encryption-key
[--help]
[--dontCheckIfRunning={true|false}]
[--domaindir domaindir]
[domain-name]
```

Description

This command can be used to generate an encryption key used by Payara Server to perform encryption and decryption of the data stored within the Data Grid.

For more information on the Data Grid mechanism, see Data Grid Encryption.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--dontCheckIfRunning`

Determines whether to check if the targeted domain is running or not.

The default value is `false`.

`--domaindir`

The path to the directory containing the target domain. The default domain directory is `as-install/domains`.

Operands

domain-name

The name of the domain to target. The default is `domain1`.

Examples

Example 1 Generates an encryption key.

This example generates an encryption key used by Payara Server to perform encryption and decryption of the data stored within the data grid.

```
asadmin> generate-encryption-key
Enter the current master password>
Command generate-encryption-key executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- `get-hazelcast-configuration`

generate-jvm-report

Shows the JVM machine statistics for a given target instance.

Synopsis

```
generate-jvm-report [--help] [--type=jvm-statistic-type] [--target target]
```

Description

The `generate-jvm-report` subcommand creates a report that shows the threads (dump of stack trace), classes, memory, or loggers for a given target instance, including the domain administration server (DAS). If a type is not specified, a summary report is generated. This subcommand only provides statistics for the Payara Server instance processes. This subcommand provides an alternative to sending Ctrl+Break or `kill -3` signals to Payara Server processes to obtain a stack trace for processes that are hanging.

The information in the report is obtained from managed beans (MBeans) and MXBeans that are provided in the Java Platform, Standard Edition (Java SE) or JDK software with which Payara Server is being used.

If Payara Server is running in the Java Runtime Environment (JRE) software from JDK release 6 or Java SE 6, additional information is provided. For example:

- System load on the available processors
- Object monitors that are currently held or requested by a thread
- Lock objects that a thread is holding, for example, `ReentrantLock` objects and `ReentrantReadWriteLock` objects

If the JRE software cannot provide this information, the report contains the text `NOT_AVAILABLE`.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which you are showing JVM machine statistics.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--type`

The type of report that is to be generated. Default is `summary`.

`summary`

Displays summary information about the threads, classes, and memory (default).

`memory`

Provides information about heap and non-heap memory consumption, memory pools, and garbage collection statistics for a given target instance.

`class`

Provides information about the class loader for a given target instance.

`thread`

Provides information about threads running and the thread dump (stack trace) for a given target instance.

`log`

Provides information about the loggers that are registered in the Virtual Machine for the Java platform (Java Virtual Machine or JVM machine).[Foot1]

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-generate-jvm-report:::example-1]]

Example 1 Obtaining Summary Information for the JVM Machine

This example shows a partial listing of a report that is generated if no type is specified. This same report is generated if the `summary` type is specified.

```
asadmin> generate-jvm-report
Operating System Information:
Name of the Operating System: SunOS
Binary Architecture name of the Operating System: sparc, Version: 5.10
Number of processors available on the Operating System: 32
System load on the available processors for the last minute: 7.921875.
(Sum of running and queued runnable entities per minute)
General Java Runtime Environment Information for the VM: 64097@sr1-usca-22
...
```

```
sun.desktop = gnome
sun.io.unicode.encoding = UnicodeBig
sun.java.launcher = SUN_STANDARD
sun.jnu.encoding = ISO646-US
sun.management.compiler = HotSpot Client Compiler
sun.os.patch.level = unknown
user.dir = /home/thisuser/GlassFish/glassfishv3/glassfish/domains/mydomain4/config
user.home = /home/thisuser
user.language = en
user.name = thisuser
user.timezone = US/Pacific
Command generate-jvm-report executed successfully
```

[[Technical Documentation-Payara Server Documentation-Command Reference-generate-jvm-report:::example-2]]

Example 2 Obtaining Information for a Particular JVM Machine Type

This example generates a report that shows information on the class loader.

```
asadmin> generate-jvm-report --type=class
Class loading and unloading in the Java Virtual Machine:
Number of classes currently loaded in the Java Virtual Machine: 3,781
Number of classes loaded in the Java Virtual Machine since the startup: 3,868
Number of classes unloaded from the Java Virtual Machine: 87
Just-in-time (JIT) compilation information in the Java Virtual Machine:
Java Virtual Machine compilation monitoring allowed: true
Name of the Just-in-time (JIT) compiler: HotSpot Client Compiler
Total time spent in compilation: 0 Hours 0 Minutes 4 Seconds
Command generate-jvm-report executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-jvm-options`,
- `delete-jvm-options`,
- `list-jvm-options`

[[Technical Documentation-Payara Server Documentation-Command Reference-generate-jvm-report:::footnote-1]#Technical Documentation-Payara Server Documentation-Command Reference-generate-jvm-report:::footnote-1] Footnote 1: The terms "Java Virtual Machine" and "JVM" mean a Virtual Machine for the Java platform.

generate-self-signed-certificate

Generates a new self-signed certificate in the specified server configuration.

Synopsis

```
asadmin generate-self-signed-certificate [--help]
[--reload={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[--distinguishedName=name]
[--alternativeNames=<"ALT1;ALT2;ALT3">]
[alias]
```

Description

This command can generate a self-signed certificate for an instance, placing the resultant key pair in the target instance or listener's keystore and truststores.

If the instance or listener is configured to use the default keystore and truststore, the command will instead synchronize the instance with the DAS (under the assumption the certificate has been added to the default key and trust store of the DAS), since any certificates added to the instance stores would be lost upon next synchronisation.

This command will not overwrite an entry already present in the keystore with the same alias. In this scenario no certificate is generated and the command exits.
In the case however where there is not an entry with the same alias in the key store but there is in the trust store, a certificate will be generated and the entry in the trust store will be overwritten.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are generating the certificate. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--reload`

Whether the HTTP listeners should be reloaded. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

`--distinguishedName`

`--dn`

The distinguished name (DN) to use when generating the certificate.

`--alternativeNames`

`--altnames`

The semicolon (`;`) separated list of additional Subject Alternative Names to add to the generated certificate.

Operands

alias

The alias name to use when generating the certificate and storing it in the keystore and truststores.

Examples

Example 1 Generate a new self-signed certificate under the `test-cert` alias

```
asadmin generate-self-signed-certificate --dn "CN=test.payara.fish,IP=192.168.1.1"
--listener http-listener-2 --alternativenames
"test2.payara.fish;DNS:test3.payara.fish,IP:127.0.0.1,EMAIL:anon@payara.fish" --target
Instance1 test_cert
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `renew-self-signed-certificates`,
- `add-to-keystore`,
- `add-to-truststore`

get-active-module-config

Displays the current active configuration of a service or instance.

Synopsis

```
asadmin [asadmin-options] get-active-module-config [--help]
[--target target]
[--all={false|true}]
[service_name]
```

Description

The `get-active-module-config` subcommand displays the current active configuration of a service or instance.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which you want to view the current active configuration of a specific service or an entire instance.
Possible values are as follows:

`server`

Displays the current active configuration for the default server instance. This is the default value.

`domain`

Displays the current active configuration for the default domain.

cluster-name

Displays the current active configuration for every server instance in the specified cluster.

instance-name

Displays the current active configuration for the specified instance.

`--all`

Displays all current active configurations.
The default value is `false`.

Operands

service_name

The name of the module for which you want to display the current active configuration.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-get-active-module-config:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-get-active-module-config:::example-1] **Example 1 Displaying the Current Active Configuration**

This example displays the current active configuration for the JMS service in `server-config` (the default configuration).

```
asadmin> get-active-module-config jms-service
At location: domain/configs/config[server-config]
<jms-service default-jms-host="default_JMS_host" type="EMBEDDED"
  <jms-host port="7676" host="localhost" name="default_JMS_host"/>
</jms-service>
Command get-active-module-config executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `create-module-config`,
- `delete-module-config`

get-admin-audit-configuration

Retrieves the current settings of the Admin Audit Service.

Synopsis

```
asadmin [asadmin-options] get-admin-audit-configuration [--help]
[--target=server]
```

Description

The `get-admin-audit-configuration` subcommand is used to list the configuration settings of the auditing service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the server instance or cluster for which to display the current admin audit configuration.

Examples

Example

```
asadmin> get-admin-audit-configuration

Enabled  Audit Level
```

```
false    MODIFIERS
Name     Notifier Enabled
LOG      false

Command get-admin-audit-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-admin-audit-configuration`,
- `enable-asadmin-recorder`,
- `disable-asadmin-recorder`,
- `asadmin-recorder-enabled`

get-asadmin-recorder-configuration

Returns the current configuration of the Asadmin Recorder service.

Synopsis

```
asadmin [asadmin-options] get-asadmin-recorder-configuration [--help]
```

Description

The `get-asadmin-recorder-configuration` command is used to retrieve the current configuration settings of the Asadmin Recorder feature in Payara Server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1

Returns the current configuration of the asadmin recorder.

```
asadmin> get-asadmin-recorder-configuration
Enabled  Filter Commands  Output Location                 Filtered Commands
Prepend Enabled  Prepended Options
true     true             /home/user/asadmin-commands.txt
version,_(.*),list(.*),get(.*),(.*)-list-services,uptime,enable-asadmin-
recorder,disable-asadmin-recorder,set-asadmin-recorder-configuration,asadmin-recorder-
enabledfalse
Command get-asadmin-recorder-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-asadmin-recorder-configuration`,
- `enable-asadmin-recorder`,
- `disable-asadmin-recorder`,
- `asadmin-recorder-enabled`,

get-aws-config-source-configuration

Gets the configuration for the AWS Secrets configuration source.

Synopsis

```
asadmin [asadmin-options] get-aws-config-source-configuration [--help]
[--target=server]
```

Description

The `get-aws-config-source-configuration` retrieves the current configuration for the AWS Config Source.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the configuration of the AWS secrets

This example retrieves the AWS Secrets Cloud Config Source.

```
asadmin get-aws-config-source-configuration

Enabled  Region Name  Secret Name
true     eu-west-2    payara/test/key
```

Exit Status

get-azure-config-source-configuration

Gets the configuration settings of an Azure Secrets configuration source.

Synopsis

```
asadmin [asadmin-options] get-azure-config-source-configuration [--help] [--
target=server]
```

Description

The `get-azure-config-source-configuration` retrieves the current configuration for the Azure Config Source.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the configuration of the Azure secrets

This example retrieves the Azure Secrets Cloud Config Source.

```
asadmin> get-azure-config-source-configuration

Enabled Tenant ID Client ID Key VaultName Private Key Path Thumbprint
true 22b3bb26-e046-42df-9c96-65dbd72c1c81 22b3bb26-e046-42df-9c96-65dbd72c1c81 demo-
secret-key-vault path/to/privatekey.pem 84E05C1D98BCE3A5421D225B140B36E86A3D5534
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

get-cdieventbus-notifier-configuration

Retrieves the settings of the Event Bus notifier

Synopsis

```
asadmin [asadmin-options] get-eventbus-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the Event Bus notifier in Payara Server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the CDI Event Bus notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

Examples

Example 1 Retrieve the settings for the CDI Event Bus notifier in the DAS

```
asadmin get-cdieventbus-notifier-configuration

Enabled  Filter   Loopback
false    WARNING  false
Command get-cdieventbus-notifier-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `set-cdieventbus-notifier-configuration`

get-client-stubs

get-client-stubs

Retrieves the application JAR files needed to launch the application client.

Synopsis

```
asadmin [asadmin-options] get-client-stubs [--help]
--appname application_name
local_directory_path
```

Description

The `get-client-stubs` subcommand copies the required JAR files for an `AppClient` standalone module or each `AppClient` module in an application from the server machine to the local directory. Each client's generated JAR file is retrieved, along with any required supporting JAR files . The client JAR file name is of the form app-name`Client.jar`. Before executing the `get-client-stubs` subcommand, you must deploy the application or module. The generated client JAR file is useful for running the application using the `appclient` utility. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--appname`

The name of the application or stand-alone client module.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. For more information about module and application versions, see "Module and Application Versions" in Payara Server Application Deployment section.

Operands

local_directory_path

The path to the local directory where the client stub JAR file should be stored.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-get-client-stubs:::example-1]]

Example 1 Using get-client-stubs

```
asadmin> get-client-stubs --appname myapplication /sample/example
Command get-client-stubs executed successfully
```

Exit Status

0

command executed successfully

1

error in executing the command

get-config-dir

Gets the settings of the Directory configuration settings.

Synopsis

```
asadmin [asadmin-options] get-config-dir [--help] [--target=<target[default:server]>]
```

Description

The `get-config-dir` gets the value of the directory to be used for the directory config source.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

`--target`
: Specifies the target where the configuration source resides.
Valid values are as follows:

  `server`
  : Specifies the DAS (default).

  instance-name
  : Specifies a Payara Server instance.

  cluster-name
  : Specifies a cluster.

  configuration-name
  : Specifies a named configuration.

Example

Example 1 Getting the Config Directory.

This example gets the directory to be used for the directory config source.

```
asadmin get-config-dir --target=myAppCluster
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-config-dir`

get-config-ordinal

Returns the ordinal value for the given configuration source type.

Synopsis

```
asadmin [asadmin-options] get-config-ordinal [--help] [--target=server]
[--source={domain|config|server|application|module|cluster}]
```

Description

The `get-config-ordinal` returns ordinal value for the given ConfigSource type.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--source`

The ConfigSource to get the ordinal for.

Must be one of: `domain`, `config`, `server`, `application`, `module`, `cluster`

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the ordinal value

This example gets the ordinal value for the source 'cluster'.

```
asadmin> get-config-ordinal --source=cluster
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-config-ordinal`

get-config-property

Provides a way to get the value of a MicroProfile configuration property stored in a specific configuration source.

Synopsis

```
asadmin [asadmin-options] get-config-property [--help]
[--propertyName=<property.name>]
[--source={domain|config|server|application|module|cluster}]
[--sourceName=<source.name>]
[--moduleName=<module.name>]
[--target=<target[default:server]>]
```

Description

The `get-config-property` gets the value for the given Eclipse MicroProfile configuration property name in one of the built-in configuration sources.

The source is specified with `--source` and, where there is ambiguity, the `--sourceName` and `--moduleName` options can be used.

For example, where the source is `server`, the `--sourceName` can be used to specify the name of the server where the property is to be stored.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--propertyName`

The name of the configuration property to get.

`--source`

The configuration source where the property is stored.

`--sourceName`

The name of the source when there may be ambiguity, for example a source of type `application` must specify the name of the application.

This property is required for sources of type: `config`, `server`, `application` or `module`

`--moduleName`

The name of the module when the source is of type `module`. When this is specified, the `sourceName` parameter must be provided and must have the name of the application where the module is deployed.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the configuration property value

This example gets the `JMSBrokerURL` property value within the configuration source named `myApplication`, belonging to the module `myModule`, and targeting the `myAppCluster` cluster.

```
asadmin get-config-property --propertyName=JMSBrokerURL --source=module
--sourceName=myApplication --moduleName=myModule --target=myAppCluster
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

get-datadog-notifier-configuration

Retrieves the settings of the DataDog notifier.

Synopsis

```
asadmin [asadmin-options] get-datadog-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the DataDog notifier in Payara Server.

This command is available as long as the DataDog notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the DataDog notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the DataDog notifier in the DAS

```
asadmin get-datadog-notifier-configuration

Enabled  Filter   Key
true     WARNING  af510f122026bc9107f7c5f4f049e597
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

get-discord-notifier-configuration

Retrieves the settings of the Discord notifier.

Synopsis

```
asadmin [asadmin-options] get-discord-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the Discord notifier in Payara Server.

This command is available as long as the Discord notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the Discord notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the Discord notifier in the DAS

```
asadmin get-discord-notifier-configuration

Enabled  Filter   Webhook ID  Webhook Token
true     WARNING  xxx         yyy
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,

get-dynamodb-config-source-configuration

Gets the configuration for the DynamoDB configuration source.

Synopsis

```
asadmin [asadmin-options] get-dynamodb-config-source-configuration [--help]
[--target=server]
```

Description

The `get-dynamodb-config-source-configuration` retrieves the current configuration for the DynamoDB Config Source.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the configuration of the DynamoDB secrets

This example retrieves the current configuration for the DynamoDB Config Source.

```
asadmin get-dynamodb-config-source-configuration
Enabled  Region Name  Table Name  Key Column Name  Value Column Name  Limit
true     eu-west-2    Books       ISBN             Title              10
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-dynamodb-config-source-configuration`

get-ejb-invoker-configuration

Retrieves the `ejb-invoker` application settings.

Synopsis

```
asadmin [asadmin-options] set-ejb-invoker-configuration [--help]
[--target] target
```

Description

Returns the current configuration options for the `ejb-invoker` application on the targeted configuration.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which retrieve the EJB invoker endpoint's configuration. Valid values are as follows:

`server`

Retrieves the configuration for the EJB invoker endpoint configured for the default server instance `server` and is the default value.

cluster-name

Retrieves the configuration for the EJB invoker endpoint configured for every server instance in the cluster.

deployment-group-name

Retrieves the configuration for the EJB invoker endpoint configured for every server instance in the deployment group.

instance-name

Retrieves the configuration for the EJB invoker endpoint configured for a particular server instance.

Examples

The following command returns the current configuration options from the deployment group `test-dg`:

```
asadmin> get-ejb-invoker-configuration --target test-dg
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-ejb-invoker-configuration`

get-email-notifier-configuration

Retrieves the settings of the Email notifier

Synopsis

```
asadmin [asadmin-options] get-email-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the Email notifier in Payara Server.

This command is available as long as the Email notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the Email notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the Email notifier in the DAS

```
asadmin get-email-notifier-configuration

Enabled  JNDI Name                  Recipient
true     mail/sampleSession         notifications@example.com
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `set-email-notifier-configuration`

get-environment-warning-configuration

Retrieves the current settings of the Environment Warning feature in the Admin Console

Synopsis

```
asadmin [asadmin-options] get-environment-warning-configuration [--help]
```

Description

The `get-environment-warning-configuration` subcommand gets the current environment warning configuration.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example

```
asadmin> get-environment-warning-configuration
Enabled  Message                         Background Colour  Text Colour
true     Caution, this is on production  #ff00ff            #00ff00
Command get-environment-warning-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-environment-warning-configuration`

get-eventbus-notifier-configuration

Retrieves the settings of the Event Bus notifier

Synopsis

```
asadmin [asadmin-options] get-eventbus-notifier-configuration [--help]
```

```
[--target target]
```

Description

This command can be used to retrieves the current settings of the Event Bus notifier in Payara Server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the Event Bus notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

Examples

Example 1 Retrieve the settings for the Event Bus notifier in the DAS

```
asadmin get-eventbus-notifier-configuration

Enabled  Filter   Topic Name
false    WARNING  payara.notification.event

Command get-eventbus-notifier-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `set-eventbus-notifier-configuration`

get-fault-tolerance-configuration

Retrieves the configuration settings of the MicroProfile Fault Tolerance service.

Synopsis

```
asadmin [asadmin-options] get-fault-tolerance-configuration [--help]
[--target=server-config]
```

Description

The `get-fault-tolerance-configuration` returns the current configuration options for the MicroProfile Fault Tolerance service on the specified target.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target of this command.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting MicroProfile Fault Tolerance configuration

This example gets the current configuration of the Fault Tolerance service.

```
asadmin get-fault-tolerance-configuration --target=instance1
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-fault-tolerance-configuration`

get-gcp-config-source-configuration

Gets the configuration for the GCP configuration source.

Synopsis

```
asadmin [asadmin-options] get-gcp-config-source-configuration [--help]
[--target=server]
```

Description

The `get-gcp-config-source-configuration` retrieves the current configuration for the GCP Config source.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the configuration of the GCP secrets

This example retrieves the current configuration for the GCP Config Source.

```
asadmin> get-gcp-config-source-configuration

Enabled  Project Name  JSON Key File
true     payara-test   payara-test-8a8aa4fbb520.json
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-gcp-config-source-configuration`

get-hashicorp-config-source-configuration

Gets the configuration for the HashiCorp configuration source.

Synopsis

```
asadmin [asadmin-options] get-hashicorp-config-source-configuration [--help]
[--target=server]
```

Description

The `get-hashicorp-config-source-configuration` retrieves the current configuration for the HashiCorp Config Source.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the configuration of the HashiCorp secrets

This example retrieves the current configuration for the HashiCorp Config Source.

```
asadmin get-hashicorp-config-source-configuration

Enabled  API Version  Secrets Engine Path  Secrets Path  Vault Address
true     2            secret               my-secret     https://127.0.0.1:8200
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-hashicorp-config-source-configuration`

get-hazelcast-configuration

Retrieves the current Data Grid (Hazelcast) configuration.

Synopsis

```
asadmin [asadmin-options] get-hazelcast-configuration
[--help]
[--target target]
[--checkEncrypted={true|false}]
```

Description

This command can be used to retrieve the current Data Grid (Hazelcast) configuration settings.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are executing this operation. Valid values are:

`server`

Applies to the default server instance. This is the default value.

instance_name

Applies to a specified server instance.

`--checkEncrypted`

This option helps check if encryption of data stored in the Domain Data Grid store is enabled or disabled.

Examples

Example 1 Retrieves the current Hazelcast configuration.

```
asadmin> get-hazelcast-configuration
Property Name                   PropertyValue           Scope
Configuration File              hazelcast-config.xml    Domain
Interfaces                                              Domain
Auto Increment Port             false                   Domain
Start Port                      5902                    Domain
Cluster Name                    development             Domain
License Key                                             Domain
Host Aware Partitioning         true                    Domain

get-health

Provides information on the cluster health.

Synopsis

```
asadmin [asadmin-options] get-health [--help]
cluster_name
```

Description

The `get-health` subcommand gets information about the health of the cluster. Note that if the group management service (GMS) is not enabled, the basic information about whether the server instances in this cluster are running or not running is not returned. For each server instance, one of the following states is reported: `not started`, `started`, `stopped`, `rejoined`, or `failed`. This subcommand is available in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

cluster_name

The name of the cluster for which you want the health information. This subcommand prompts you for the cluster name if you don't specify it.

Examples

Example 1 Checking the health of server instances in a cluster

```
asadmin> get-health cluster1
instance1 started since Wed Sep 29 16:32:46 EDT 2010
instance2 started since Wed Sep 29 16:32:45 EDT 2010
Command get-health executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

get-healthcheck-configuration

Lists the current Healthcheck service settings.

Synopsis

```
asadmin [asadmin-options] get-healthcheck-configuration
[--help]
[--target target]
```

Description

Lists the current configuration for the health check service, configured checkers and enabled notifiers.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--target`
: This option helps specify the target on which you are retrieving the Healthcheck service settings. Valid values are:

  `server`
  : Applies to the default server instance. This is the default value.

  cluster_name
  : Applies to every server instance in the cluster.

  instance_name
  : Applies to a specified server instance.

Examples

Example 1 Retrieves configuration in the DAS

A sample output is as follows:

```
asadmin get-healthcheck-configuration

Health Check Service Configuration is enabled?: true
Historical Tracing Enabled?: true
Historical Tracing Store Size: 20

Name                   Notifier Enabled
log-notifier           true
jms-notifier           false
cdieventbus-notifier   false
eventbus-notifier      false

Below are the list of configuration details of each checker listed by its name.

Name  Enabled  Time  Unit     Add to MicroProfile Health  Critical Threshold  Warning
Threshold  Good Threshold
CPUC  true     5     MINUTES  true                        80                  50
0
HEAP  true     5     MINUTES  false                       80                  50
0

Name   Enabled  Time  Unit     Add to MicroProfile Health  Threshold Time  Threshold
Unit
STUCK  true     5     MINUTES  false                       5               MINUTES

Name  Enabled  Time  Unit     Add to MicroProfile Health
MPM   true     5     MINUTES  false

Monitored Metric Name  Description
base_thread_max_count Displays the peak live thread count since the Java virtual
machine started or peak was reset. This includes daemon and non-daemon threads.
base_gc_total_total    Displays the total number of collections that have occurred.
This attribute lists -1 if the collection count is undefined for this collector.

Command get-healthcheck-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

get-jdbc-config-source-configuration

Gets the settings of the JDBC configuration source.

Synopsis

```
asadmin [asadmin-options] get-jdbc-config-source-configuration [--help] [--
target=server]
```

Description

The `get-jdbc-config-source-configuration` retrieves the current configuration for the JDBC Config Source

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

Example

Example 1 Retrieving the JDBC Config Source configurations.

This example gets the configuration of the JDBC config source.

```
asadmin get-jdbc-config-source-configuration
JNDI Name  Table Name  Key-Column Name  Value-Column Name
jndi-name  Books       ISBN             Title
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

get-jms-notifier-configuration

Retrieves the settings of the JMS notifier

Synopsis

```
asadmin [asadmin-options] get-log-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the JMS notifier in Payara Server Full Profile.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the JMS notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the JMS notifier in the DAS

```
asadmin get-jms-notifier-configuration

Enabled  Filter   Context Factory Class  Connection Factory Name  Queue Name  URL
Username  Password
true     WARNING  com.sun.enterprise.naming.SerialInitContextFactory
jms/__defaultConnectionFactory  notifierQueue  localhost:7676  myusername  mypassword
Command get-jms-notifier-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- asadmin,
- set-jms-notifier-configuration

get-jmx-monitoring-configuration

Retrieves the JMX monitoring service general settings.

Synopsis

```
asadmin [asadmin-options] get-jmx-monitoring-configuration
[--help]
[--target target]
[--pretty={false|true}]
```

Description

This command can be used to view the current configuration of the JMX monitoring service.

Options

asadmin-options

Options for the asadmin utility. For information about these options, see the asadmin help page.

--help

-?

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the JMX monitoring service configuration. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`pretty`

Default to `false`. Whether to displays boolean configuration values options as a **tick** or a **cross**

Examples

Example 1 Get current JMX monitoring service configuration

```
asadmin get-jmx-monitoring-configuration
JMX Monitoring Enabled  JMX Log Frequency  JMX Log Frequency Unit
true                    5                  MINUTES

Name                   Notifier Enabled
slack-notifier         false
snmp-notifier          false
teams-notifier         false
datadog-notifier       false
jms-notifier           false
newrelic-notifier      false
log-notifier           true
cdieventbus-notifier   false
eventbus-notifier      false
email-notifier         false
discord-notifier       false

Object Name             Attribute              Description
java.lang:type=Memory   HeapMemoryUsage.used
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

get-ldap-config-source-configuration

Gets the settings of the LDAP configuration source.

Synopsis

```
asadmin [asadmin-options] get-ldap-config-source-configuration [--help] [--
target=server]
```

Description

The `get-ldap-config-source-configuration` gets the current configuration settings for the LDAP configuration source.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--target`
: Specifies the target where the configuration source resides.
Valid values are as follows:

  `server`
  : Specifies the DAS (default).

  instance-name
  : Specifies a Payara Server instance.

  cluster-name
  : Specifies a cluster.

Example

Example 1 Getting the LDAP configuration

This example retrieves the current configuration for the LDAP Config Source.

```
asadmin get-ldap-config-source-configuration
Enabled     Url                              Auth Type       Start TLS Enabled
BindDN                                  BindDN Password     Search Base     Search
Filter       Search Scope        Connection Timeout      Read Timeout
true        ldap://ldap.forumsys.com:389    simple          false
cn=read-only-admin,dc=example,dc=com    password
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

get-log-notifier-configuration

Retrieves the settings of the Log notifier

Synopsis

```
asadmin [asadmin-options] get-log-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the log notifier in Payara Server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the log notifier. Valid values are:

`server`
: Applies to the default server instance. This is the default value.

cluster_name
: Applies to every server instance in the cluster.

instance_name
: Applies to a specified server instance.

Examples

Example 1 Retrieve the settings for the log notifier in the DAS

```
asadmin> get-log-notifier-configuration

Enabled  Filter   Use Separate Log File
true     WARNING  false
Command get-log-notifier-configuration executed successfully.
```

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `set-log-notifier-configuration`,

get-metrics-configuration

Gets the configuration settings of the MicroProfile Metrics service.

Synopsis

```
asadmin [asadmin-options] get-metrics-configuration [--help]
[--target <instance-name>]
```

Description

The `get-metrics-configuration` returns the current configuration options for the metrics service on the targeted configuration.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for its respective configuration.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting the configuration of the metrics service

This example get the metrics service configuration of the `dg1` deployment group

```
asadmin get-metrics-configuration --target dg1
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-metrics-configuration`

get-microprofile-healthcheck-configuration

Retrieves the configuration settings of the MicroProfile HealthCheck service.

Synopsis

```
asadmin [asadmin-options] get-microprofile-healthcheck-configuration [--help]
[--target=server-config]
```

Description

The `get-microprofile-healthcheck-configuration` returns the current configuration options for the MicroProfile Health Check service on the specified target.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target of this command.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Getting MicroProfile Health Check configuration

This example gets the current configuration of the Health Check service.

```
asadmin get-microprofile-healthcheck-configuration --target=instance1

Enabled  EndPoint  VirtualServers  Security Enabled  Roles
true     health                    false             microprofile
```

```
Command get-microprofile-healthcheck-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-microprofile-healthcheck-configuration`

get-monitoring-level

Retrieves the level configuration of a monitoring service's server module.

Synopsis

```
asadmin [asadmin-options] get-monitoring-level
[--help]
[--module module]
[--target target]
```

Description

This command can be used to get monitoring level of a module.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the level configuration of a monitored module. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--module`

The name of the module. If omitted, the command will return the configuration of all registered modules.

Examples

Example 1 Get the monitoring level set for the JVM Module

```
asadmin get-monitoring-level --module=jvm --target=server

Module  Monitoring Level
jvm     HIGH
Command get-monitoring-level executed successfully.
```

Example 2 Get the monitoring level set for all modules

```
asadmin get-monitoring-level --target=server

Module                       Monitoring Level
cloud                        OFF
cloud-elasticity             OFF
cloud-orchestrator           OFF

- `set-monitoring-level`

get-monitoring-service-configuration

Retrieves the monitoring service general settings.

Synopsis

```
asadmin [asadmin-options] get-monitoring-service-configuration
[--help]
[--target target]
```

Description

This command can be used to view the current configuration of the monitoring service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the monitoring service configuration. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

Examples

Example 1 Get current monitoring service configuration

```
asadmin get-monitoring-service-configuration
Monitoring Enabled  AMX Enabled  MBeans Enabled  DTrace Enabled
true                true         true            false

Command get-monitoring-service-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- Monitoring Basics,

get-newrelic-notifier-configuration

Retrieves the settings of the New Relic notifier.

Synopsis

```
asadmin [asadmin-options] get-newrelic-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the New Relic notifier in Payara Server.

This command is available as long as the New Relic notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the New Relic notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the New Relic notifier in the DAS

```
asadmin get-newrelic-notifier-configuration

Enabled  Filter  Key                                Account Id
true     WARNING   b5815wdxj6lF_tmMBljQa5y1603JTiLh  1658989
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `set-newrelic-notifier-configuration`

get-notification-configuration

Retrieves the notification service general settings.

Synopsis

```
asadmin [asadmin-options] get-notification-configuration
[--help]
[--target target]
```

Description

This command can be used to view the current configuration of the notification service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the notification service configuration. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

Examples

Example 1 Get current notification service configuration

```
asadmin get-notification-configuration

Notifier Name         Enabled  Notifier Enabled  Filter Level
slack-notifier        true     false             WARNING
snmp-notifier         true     false             WARNING

get-openapi-configuration

Gets the current settings of the MicroProfile OpenAPI service.

Synopsis

```
asadmin [asadmin-options] get-openapi-configuration [--help]
  [--target=<target>]
```

Description

This command get the current settings of the MicroProfile OpenAPI service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target of this command.
Valid values are as follows:

`server`
: Specifies the DAS (default).

instance-name
: Specifies a Payara Server instance.

cluster-name
: Specifies a cluster.

configuration-name
: Specifies a named configuration.

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `asadmin`
- `set-openapi-configuration`

get-requesttracing-configuration

Retrieves the Request Tracing service's configuration.

Synopsis

```
asadmin [asadmin-options] get-requesttracing-configuration [--help]
```

Description

This command can be used to list the configuration settings of the Request Tracing.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

Examples

Example 1 Retrieve Request Tracing Service Configuration

```
asadmin> get-requesttracing-configuration
```

Will give an output similar to the following:

```
Request Tracing Service Enabled?: true
Request Tracing Service Sample Rate: 1.0
Request Tracing Service Adaptive Sampling Enabled?: false
Request Tracing Service Application Only?: true
Request Tracing Service Threshold Value: 30
Request Tracing Service Threshold Unit: SECONDS
Request Tracing Service Sample Rate First?: true
Request Tracing Service Reservoir Sampling Enabled?: false
Request Tracing Service Trace Store Size: 20
Request Tracing Service Historic Trace Store Enabled?: false
Below are the configuration details of each notifier listed by its name.

Notifier Name         Notifier Enabled
jms-notifier          false
log-notifier          true
cdieventbus-notifier  false
eventbus-notifier     false
Command get-requesttracing-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- asadmin,

- list-requesttraces

get-rest-monitoring-configuration

Retrieves the REST monitoring service general settings.

Synopsis

```
asadmin [asadmin-options] get-rest-monitoring-configuration
```

```
[--help]
[--target target]
```

Description

This command can be used to view the current configuration of the JMX monitoring service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the REST monitoring service configuration. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

Examples

Example 1 Get current REST monitoring service configuration

```
asadmin get-rest-monitoring-configuration
Rest Monitoring Enabled  Rest Monitoring Application Name  Context Root      Security
Enabled
false                    __restmonitoring                 /rest-monitoring  false
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- Monitoring Basics,
- `set-rest-monitoring-configuration`

get-slack-notifier-configuration

Retrieves the settings of the Slack notifier.

Synopsis

```
asadmin [asadmin-options] get-slack-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the Slack notifier in Payara Server.

This command is available as long as the Slack notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the Slack notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the Slack notifier in the DAS

```
asadmin get-slack-notifier-configuration

Enabled  Filter   Token 1    Token 2    Token 3
true     WARNING  T43CHENUC  B441EFQB1  Jas8P3jCZ4wK8Y2m88dCxGkn
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `set-slack-notifier-configuration`

get-snmp-notifier-configuration

Retrieves the settings of the SNMP notifier

Synopsis

```
asadmin [asadmin-options] get-snmp-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the SNMP notifier in Payara Server.

This command is available as long as the SNMP notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the SNMP notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the SNMP notifier in the DAS

```
asadmin > get-snmp-notifier-configuration

Enabled  Filter   Community  OID                Version  Host       SNMP Port
true     WARNING  example    .1.3.6.1.2.1.1.8   v2c      127.0.0.1  162
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `set-snmp-notifier-configuration`

get-teams-notifier-configuration

Retrieves the settings of the MS Teams notifier.

Synopsis

```
asadmin [asadmin-options] get-teams-notifier-configuration [--help]
[--target target]
```

Description

This command can be used to retrieves the current settings of the MS Teams notifier in Payara Server.

This command is available as long as the MS Teams notifier's core module is installed in the server.

> This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are retrieving the settings of the MS Teams notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to on a specified server instance.

Examples

Example 1 Retrieve the settings for the MS Teams notifier in the DAS

```
asadmin get-teams-notifier-configuration

Enabled  Filter   Webhook URL
true     WARNING  https://outlook.office.com/webhook/xyz
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `set-teams-notifier-configuration`

get-toml-config-source-configuration

Gets the settings of the TOML configuration source.

Synopsis

```
asadmin [asadmin-options] get-toml-config-source-configuration [--help] [--
target=server]
```

Description

The `get-toml-config-source-configuration` retrieves the current configuration for the TOML Config Source

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

Example

Example 1 Retrieving the toml Config Source configurations.

This example gets the configuration of the toml config source.

```
asadmin get-toml-config-source-configuration
Enabled  Path                               Depth
true     /Users/payara/workspace/test.TOML  5
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `set-toml-config-source-configuration`

get

Gets the values of configurable or monitorable attributes.

Synopsis

```
asadmin [asadmin-options] get [--help]
[--monitor={true|false}]
[--aggregatedataonly={true|false}]
(dotted-attribute--name)+
```

Description

The `get` subcommand uses dotted names to get the names and values of configurable or monitorable attributes for Payara Server elements.

You can use the `list` subcommand to display the dotted names that represent individual server components and subsystems. For example, a dotted name might be `server.applications.web-module`. Attributes from the monitoring hierarchy are read-only, but configuration attributes can be modified using the `set` subcommand. For more detailed information on dotted names, see the `dotted-names` help page.

Characters that have special meaning to the shell or command interpreter, such as * (asterisk), should be quoted or escaped as appropriate to the shell, for example, by enclosing the argument in quotes. In multimode, quotes are needed only for arguments that include spaces, quotes, or backslash.

The following list shows common usage of the `get` subcommand with the * (asterisk):

`get or get *.`

Gets all values on all dotted name prefixes.

`get domain*` or `get domain*.*`

Gets all values on the dotted names that begin with `domain`.

`get config..`

Gets all values on the dotted names that match `config.*`.

`get domain.j2ee-applications..ejb-module..*`

Gets all values on all EJB modules of all applications.

`get web-modules..*`

Gets all values on all web modules whether in an application or standalone.

`get ...`

Gets all values on all dotted names that have four parts.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--monitor`

`-m`

Defaults to `false`. If set to false, the configurable attribute values are returned. If set to `true`, the monitorable attribute values are returned.

`--aggregatedataonly`

`-c`

Aggregates monitoring data for all Payara Server instances in a cluster. The default value is `false`.

Operands

dotted-attribute-name

Identifies the attribute name in the dotted notation. At least one dotted name attribute is required. The dotted notation is the syntax used to access attributes of configurable entities.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-get:::example-1]]

Example 1 Getting the Attributes of a Configurable Element

This example gets the attributes of `listener.http-listener-1`.

```
asadmin> get server.http-service.http-listener.http-listener-1.*
server.http-service.http-listener.http-listener-1.acceptor-threads = 1
server.http-service.http-listener.http-listener-1.address = 0.0.0.0
```

```
server.http-service.http-listener.http-listener-1.blocking-enabled = false
server.http-service.http-listener.http-listener-1.default-virtual-server = server
server.http-service.http-listener.http-listener-1.enabled = true
server.http-service.http-listener.http-listener-1.external-port =
server.http-service.http-listener.http-listener-1.family = inet
server.http-service.http-listener.http-listener-1.id = http-listener-1
server.http-service.http-listener.http-listener-1.port = 8080
server.http-service.http-listener.http-listener-1.redirect-port =
server.http-service.http-listener.http-listener-1.security-enabled = false
server.http-service.http-listener.http-listener-1.server-name =
Command get executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-get:::example-2]]

Example 2 Getting Monitorable Objects

This example gets the configuration attributes for setting the monitoring level and shows whether they are enabled (LOW or HIGH) or disabled (OFF). The `jvm` component is enabled for monitoring.

```
asadmin> get server.monitoring-service.module-monitoring-levels.*
server.monitoring-service.module-monitoring-levels.connector-connection-pool=OFF
server.monitoring-service.module-monitoring-levels.connector-service=OFF
server.monitoring-service.module-monitoring-levels.d-trace=OFF
server.monitoring-service.module-monitoring-levels.ejb-container=OFF
server.monitoring-service.module-monitoring-levels.http-service=OFF
server.monitoring-service.module-monitoring-levels.jdbc-connection-pool=OFF
server.monitoring-service.module-monitoring-levels.jms-service=OFF
server.monitoring-service.module-monitoring-levels.jvm=HIGH
server.monitoring-service.module-monitoring-levels.orb=OFF
server.monitoring-service.module-monitoring-levels.thread-pool=OFF
server.monitoring-service.module-monitoring-levels.transaction-service=OFF
server.monitoring-service.module-monitoring-levels.web-container=OFF
Command get executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-get:::example-3]]

Example 3 Getting Attributes and Values for a Monitorable Object

This example gets all attributes and values of the `jvm` monitorable object.

```
asadmin> get --monitor server.jvm.*
server.jvm.HeapSize_Current = 45490176
server.jvm.HeapSize_Description = Describes JvmHeapSize
server.jvm.HeapSize_HighWaterMark = 45490176
server.jvm.HeapSize_LastSampleTime = 1063217002433
server.jvm.HeapSize_LowWaterMark = 0
server.jvm.HeapSize_LowerBound = 0
server.jvm.HeapSize_Name = JvmHeapSize
server.jvm.HeapSize_StartTime = 1063238840055
```

```
server.jvm.HeapSize_Unit = bytes
server.jvm.HeapSize_UpperBound = 531628032
server.jvm.UpTime_Count = 1063238840100
server.jvm.UpTime_Description = Describes JvmUpTime
server.jvm.UpTime_LastSampleTime = 1-63238840070
server.jvm.UpTime_Name = JvmUpTime
server.jvm.UpTime_StartTime = 1063217002430
server.jvm.UpTime_Unit = milliseconds
Command get executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

import-sync-bundle

Imports the configuration data of a clustered instance or standalone instance from an archive file.

Synopsis

```
asadmin [asadmin-options] import-sync-bundle [--help]
--instance instance-name
[--nodedir node-dir] [--node node-name]
file-name
```

Description

The `import-sync-bundle` subcommand imports the configuration data of a clustered instance or standalone instance from an archive file that was created by the `export-sync-bundle` subcommand.

You must run this subcommand on the host where the instance resides. To contact the domain administration server (DAS), this subcommand requires the name of the host where the DAS is running. If a non-default port is used for administration, this subcommand also requires the port number. You must provide this information through the `--host` option and the `--port` option of the `asadmin` utility.

Importing an instance's configuration data transfers the data to a host for an instance without the need for the instance to be able to communicate with the DAS. Importing an instance's configuration data is typically required for the following reasons:

- To reestablish the instance after an upgrade
- To synchronize the instance manually with the domain administration server (DAS) when the instance cannot contact the DAS

The subcommand imports an instance's configuration data by performing the following operations:

- Creating or updating the instance's files and directories
- Attempting to register the instance with the DAS

If the attempt to register the instance with the DAS fails, the subcommand does not fail. Instead, the subcommand displays a warning that the attempt failed. The warning contains the command to run to register the instance with the DAS.

The `import-sync-bundle` subcommand does not contact the DAS to determine the node on which the instance resides. If the node is not specified as an option of the subcommand, the subcommand determines the node from the DAS configuration in the archive file.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--instance`

The instance for which configuration data is being imported. The instance must already exist in the DAS configuration. The archive file from which the data is being imported must contain data for the specified instance.

`--nodedir`

The directory that contains the instance's node directory. The instance's files are stored in the instance's node directory. The default is as-install`/nodes`.

`--node`

The node on which the instance resides. If this option is omitted, the subcommand determines the node from the DAS configuration in the archive file.

Operands

file-name

The name of the file, including the path, that contains the archive file to import. This operand is

required.

Examples

Example 1 Importing Configuration Data for a Clustered Instance

This example imports the configuration for the clustered instance `ymli2` on the node `sj02` from the archive file `/export/payara7/glassfish/domains/domain1/sync/ymlcluster-sync-bundle.zip`.

The command is run on the host `sj02`, which is the host that the node `sj02` represents. The DAS is running on the host `sr04` and uses the default HTTP port for administration.

```
sj02# asadmin --host sr04 import-sync-bundle --node sj02 --instance ymli2
/export/payara7/glassfish/domains/domain1/sync/ymlcluster-sync-bundle.zip
Command import-sync-bundle executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `export-sync-bundle`

install-node-ssh

Installs Payara Server software on specified SSH-enabled hosts.

Synopsis

```
asadmin [asadmin-options] install-node-ssh [--help]
[--archive archive]
[--create={false|true}] [--save[={false|true}]
[--installdir as-install-parent]
[--sshport ssh-port] [--sshuser ssh-user]
[--sshkeyfile ssh-keyfile]
[--force={false|true}]
host-list
```

Description

The `install-node-ssh` subcommand installs Payara Server software on the hosts that are specified as the operand of the subcommand. This subcommand requires secure shell (SSH) to be configured

on the host where the subcommand is run and on each host where the Payara Server software is being installed.

This subcommand is equivalent to the `install-node` subcommand.

If necessary, the subcommand creates a ZIP archive of the Payara Server software from the installation where this subcommand is run. The archive does not contain the `domains` directory or the `nodes` directory. These directories are synchronized from the domain administration server (DAS) when instances on nodes that represent the hosts are created and started. The subcommand does not delete the archive after installing the Payara Server software from the archive on the specified hosts.

If multiple hosts are specified, the configuration of the following items is the same on all hosts:

- Base installation directory
- SSH port
- SSH user
- SSH key file

If the SSH key file does not exist on a host where the Payara Server software is to be installed, the subcommand runs interactively and prompts for a password. To enable the subcommand to run noninteractively, the following conditions must be met:

- The `--interactive` option of the `asadmin` utility must be `false`.
- The `--passwordfile` option of the `asadmin` utility must specify a password file.
- The password file must contain the `AS_ADMIN_SSHPASSWORD` entry.

The subcommand does not modify the configuration of the DAS.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--archive`

The absolute path to the archive file of the Payara Server software that is to be installed. If no archive file is specified, the subcommand creates an archive from the installation of Payara Server software from which the subcommand is run. This archive is created in the home directory of the user that is running the command.

`--create`

Specifies whether the subcommand should create an archive file of the Payara Server software to install.

`false`

No archive file is created. The subcommand installs the software from the existing archive file that the `--archive` option specifies (default).

`true`

The subcommand creates an archive file from the installation of Payara Server software from which the subcommand is run.

`--save`

Specifies whether the archive file from which the software is installed is saved after installation.

`false`

The archive file is not saved. The subcommand deletes the file after installing the software (default).

`true`

The archive file is saved.

`--installdir`

The absolute path to the parent of the base installation directory where the Payara Server software is to be installed on each host, for example, `/export/payara7/`. If the directory does not exist, the subcommand creates the directory.
The user that is running this subcommand must have write access to the specified directory. Otherwise, an error occurs.
To overwrite an existing an installation of the Payara Server software, set the `--force` option to `true`. If the directory already contains an installation and the `--force` option is `false`, an error occurs.
The default is the parent of the base installation directory of the Payara Server software on the host where this subcommand is run.

`--sshport`

The port to use for SSH connections to the host where the Payara Server software is to be installed. The default is 22.

`--sshuser`

The user on the host where the Payara Server software is to be installed that is to run the process for connecting through SSH to the host. The default is the user that is running this subcommand. To ensure that the DAS can read this user's SSH private key file, specify the user that is running the DAS process.

`--sshkeyfile`

The absolute path to the SSH private key file for user that the `--sshuser` option specifies. This file is used for authentication to the `sshd` daemon on the host.
The user that is running this subcommand must be able to reach the path to the key file and

read the key file.
The default is a key file in the user's `.ssh` directory. If multiple key files are found, the subcommand uses the following order of preference:

1. `id_rsa`
2. `id_dsa`
3. `identity`

`--force`

Specifies whether the subcommand overwrites an existing installation of the Payara Server software in the directory that the `--installdir` option specifies. Possible values are as follows:

`false`

The existing installation is not overwritten (default).

`true`

The existing installation is overwritten.

Operands

host-list

A space-separated list of the names of the hosts where the Payara Server software is to be installed.

Examples

Example 1 Installing Payara Server Software at the Default Location

This example installs Payara Server software on the hosts `sj03.example.com` and `sj04.example.com` at the default location.

```
asadmin> install-node-ssh sj03.example.com sj04.example.com
Created installation zip /home/gfuser/glassfish2339538623689073993.zip
Successfully connected to gfuser@sj03.example.com using keyfile /home/gfuser

install-node

Installs Payara Server software on specified SSH-enabled hosts

Synopsis

```
asadmin [asadmin-options] install-node [--help]
[--archive archive]
[--create={false|true}] [--save[={false|true}]
[--installdir as-install-parent]
[--sshport ssh-port] [--sshuser ssh-user]
[--sshkeyfile ssh-keyfile]
[--force={false|true}]
host-list
```

Description

The `install-node` subcommand installs Payara Server software on the hosts that are specified as the operand of the subcommand. This subcommand requires secure shell (SSH) to be configured on the host where the subcommand is run and on each host where the Payara Server software is being installed.

This subcommand is equivalent to the `install-node-ssh` subcommand.

If necessary, the subcommand creates a ZIP archive of the Payara Server software from the installation where this subcommand is run. The archive does not contain the `domains` directory or the`nodes` directory. These directories are synchronized from the domain administration server (DAS) when instances on nodes that represent the hosts are created and started. The subcommand does not delete the archive after installing the Payara Server software from the archive on the specified hosts.

If multiple hosts are specified, the configuration of the following items is the same on all hosts:

- Base installation directory
- SSH port
- SSH user
- SSH key file

If the SSH key file does not exist on a host where the Payara Server software is to be installed, the subcommand runs interactively and prompts for a password. To enable the subcommand to run non-interactively, the following conditions must be met:

- The `--interactive` option of the `asadmin` utility must be `false`.
- The `--passwordfile` option of the `asadmin` utility must specify a password file.
- The password file must contain the `AS_ADMIN_SSHPASSWORD` entry.

The subcommand does not modify the configuration of the DAS.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--archive`

The absolute path to the archive file of the Payara Server software that is to be installed. If no archive file is specified, the subcommand creates an archive from the installation of Payara Server software from which the subcommand is run. This archive is created in the home directory of the user that is running the command.

`--create`

Specifies whether the subcommand should create an archive file of the Payara Server software to install.

`false`

No archive file is created. The subcommand installs the software from the existing archive file that the `--archive` option specifies (default).

`true`

The subcommand creates an archive file from the installation of Payara Server software from which the subcommand is run.

`--save`

Specifies whether the archive file from which the software is installed is saved after installation.

`false`

The archive file is not saved. The subcommand deletes the file after installing the software (default).

`true`

The archive file is saved.

`--installdir`

The absolute path to the parent of the base installation directory where the Payara Server software is to be installed on each host, for example, `/export/payara7/`. If the directory does not exist, the subcommand creates the directory.
The user that is running this subcommand must have write access to the specified directory. Otherwise, an error occurs.
To overwrite an existing an installation of the Payara Server software, set the `--force` option to `true`. If the directory already contains an installation and the `--force` option is `false`, an error occurs.
The default is the parent of the base installation directory of the Payara Server software on the host where this subcommand is run.

`--sshport`

The port to use for SSH connections to the host where the Payara Server software is to be installed. The default is 22.

`--sshuser`

The user on the host where the Payara Server software is to be installed that is to run the process for connecting through SSH to the host. The default is the user that is running this subcommand. To ensure that the DAS can read this user's SSH private key file, specify the user that is running the DAS process.

`--sshkeyfile`

The absolute path to the SSH private key file for user that the `--sshuser` option specifies. This file is used for authentication to the `sshd` daemon on the host.
The user that is running this subcommand must be able to reach the path to the key file and read the key file.
The default is a key file in the user's `.ssh` directory. If multiple key files are found, the subcommand uses the following order of preference:

1. `id_rsa`
2. `id_dsa`
3. `identity`

`--force`

Specifies whether the subcommand overwrites an existing installation of the Payara Server software in the directory that the `--installdir` option specifies. Possible values are as follows:

`false`

The existing installation is not overwritten (default).

`true`

The existing installation is overwritten.

Operands

host-list

A space-separated list of the names of the hosts where the Payara Server software is to be installed.

Examples

Example 1 Installing Payara Server Software at the Default Location

This example installs Payara Server software on the hosts `sj03.example.com` and `sj04.example.com` at the default location.

```
asadmin> install-node sj03.example.com sj04.example.com
Created installation zip /home/gfuser/glassfish2339538623689073993.zip
Successfully connected to gfuser@sj03.example.com using keyfile /home/gfuser

jms-ping

Checks if the JMS service is up and running.

Synopsis

```
asadmin [asadmin-options] jms-ping [--help]
[-- target target]
```

Description

The `jms-ping` subcommand checks if the Java Message Service (JMS) service (also known as the JMS provider) is up and running. When you start the Payara Server, the JMS service starts by default.

The `jms-ping` subcommand pings only the default JMS host within the JMS service. It displays an error message when it is unable to ping a built-in JMS service.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which the operation is to be performed. Valid values are as follows:

`server`

Pings the JMS service for the default server instance. This is the default value

configuration-name

Pings the JMS service for all clusters using the specified configuration.

cluster-name

Pings the JMS service for the specified cluster.

instance-name

Pings the JMS service for the specified server instance.

Examples

Example 1 Verifying that the JMS service is running

The following subcommand checks to see if the JMS service is running on the default server.

```
asadmin> jms-ping
JMS-ping command executed successfully
Connector resoure test_jms_adapter created.
Command jms-ping executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

list-admin-objects

Gets all the administered objects.

Synopsis

```
asadmin [asadmin-options] list-admin-objects [--help]
[target]
```

Description

The `list-admin-objects` subcommand lists all the administered objects.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

The target for which administered objects are to be listed. Valid values are as follows:

`server`

Lists the administered objects on the default server instance. This is the default value.

configuration-name

Lists the administered objects in the specified configuration.

cluster-name

Lists the administered objects on all server instances in the specified cluster.

instance-name

Lists the administered objects on a specified server instance.

Examples

Example 1 Listing Administered Objects

This example lists all the administered objects.

```
asadmin> list-admin-objects
jms/samplequeue
jms/anotherqueue
Command list-admin-objects executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-admin-object`,
- `delete-admin-object`

list-application-refs

Lists the existing application references.

Synopsis

```
asadmin [asadmin-options] list-application-refs [--help]
```

```
[--long={false|true}] [target]
```

Description

The `list-application-refs` subcommand lists all application references in a cluster or an unclustered server instance. This effectively lists all the modules deployed on the specified target (for example, J2EE applications, Web modules, and enterprise bean modules).

If multiple versions of a module or application are deployed, this subcommand lists all versions. To list which version is enabled, set the `--long` option to `true`. For more information about module and application versions, see Module and Application Versions in Payara Server Application Deployment Guide.

The target instance or instances making up the cluster need not be running or available for this subcommand to succeed.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

If `true`, displays whether each module or application listed is enabled. The default is `false`.

Operands

target

The target for which you are listing the application references. Valid values are

- `server`- Specifies the default server instance as the target. `server` is the name of the default server instance and is the default value.
- cluster_name- Specifies a certain cluster as the target.
- instance_name- Specifies a certain server instance as the target.

Examples

Example 1 Listing Application References

The following example lists the application references for the unclustered server instance `NewServer`.

```
asadmin> list-application-refs NewServer
ClientSessionMDBApp
```

```
MEjbApp
__ejb_container_timer_app
Command list-application-refs executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-application-ref`,
- `delete-application-ref`

list-applications

Lists deployed applications.

Synopsis

```
asadmin [asadmin-options] list-applications [--help]
[--long={false|true}] [--resources] [--subcomponents]
[--type type] [target]
```

Description

The `list-applications` subcommand lists deployed Jakarta EE applications and the type of each application that is listed.

If the `--type` option is not specified, all applications are listed. If the type option is specified, you must specify a type. The possible types are listed in the Options section of this help page.

If multiple versions of a module or application are deployed, this subcommand lists all versions. To list which version is enabled, set the `--long` option to `true`. For more information about module and application versions, see Module and Application Versions in Payara Server Application Deployment Guide.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

If `true`, displays whether each module or application listed is enabled. The default is `false`.

`--resources`

Lists the application-scoped resources for each application. If the `--subcomponents` option is also used, lists the application-scoped resources for each component within the application.

`--subcomponents`

Lists the subcomponents of each application. The subcomponents listed depend on the application type. For example, for a Jakarta EE application (EAR file), modules are listed. For a web application, servlets and JSP pages are listed. For an EJB module, EJB subcomponents are listed.

`--type`

Specifies the type of the applications that are to be listed. The options are as follows:

- `application`
- `appclient`
- `connector`
- `ejb`
- `web`
- `webservice`

  If no type is specified, all applications are listed.

Operands

`--target`

This is the name of the target upon which the subcommand operates. The valid values are as follows:

`server`

Lists the applications for the default server instance `server` and is the default value.

`domain`

Lists the applications for the domain.

cluster_name

Lists the applications for the cluster.

instance_name

Lists the applications for a particular stand-alone server instance.

Examples

Example 1 Listing the Web Applications

```
asadmin> list-applications --type web
hellojsp <web>
Command list-applications executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-sub-components`,
- `show-component-status`

list-auth-realms

Lists the authentication realms.

Synopsis

```
asadmin [asadmin-options] list-auth-realms [--help]
[target]
```

Description

The `list-auth-realms` subcommand lists the authentication realms. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

The name of the target for which you want to list the authentication realms.

`server`

Lists the realms for the default server instance `server` and is the default value.

configuration_name

Lists the realms for the named configuration.

cluster_name

Lists the realms for every server instance in the cluster.

instance_name

Lists the realms for a particular server instance.

Examples

Example 1 Listing authentication realms

```
asadmin> list-auth-realms
file
ldap
certificate
db
Command list-auth-realms executed successfully
```

Where file, ldap, certificate, and db are the available authentication realms.

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-auth-realm`,
- `delete-auth-realm`

list-backups

Lists all backups.

Synopsis

```
asadmin [asadmin-options] list-backups [--help]
[--long[={false|true}]]
[--domaindir domain-root-dir]
[--backupdir backup-directory]
[--backupconfig backup-config-name]
[domain-name]
```

Description

The `list-backups` subcommand displays information about domain backups.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Displays detailed information about each backup.
The default value is `false`.

`--domaindir`

Specifies the domain root directory, the parent directory of the domain upon which the command will operate.
The default value is `as-install/domains`.

`--backupdir`

Specifies the directory under which backup files are stored.
The default value is `as-install/domains/domain-dir/backups`. If the domain is not in the default location, the location is `domain-dir/backups`.

`--backupconfig`

Restricts the listing of backup files in the backup directory to those for the specified domain backup configuration.

Operands

domain-name

Specifies the domain for which backups are listed.
This operand is optional if only one domain exists in the Payara Server installation.

Examples

Example 1 Listing Domain Backups

This example provides detailed information about backups in the default domain.

```
asadmin> list-backups --long
Description               : domain1 backup created on 2023_12_01 by user adminuser
GlassFish Version         : Payara Server main-7 #badassfish
Backup User               : adminuser
Backup Date               : Wed Dec 01 09:22:45 PST 2023
Domain Name               : domain1
Backup Type               : full
Backup Config Name        :
Backup Filename (origin)  :
/payara/glassfish/domains/domain1/backups/domain1_2023_12_01_v00001.zip
Domain Directory          : /payara/glassfish/domains/domain1

Description               : domain1 backup created on 2023_12_16 by user adminuser
GlassFish Version         : Payara Server main-7 #badassfish
Backup User               : adminuser
Backup Date               : Thu Dec 16 09:23:48 PST 2023
Domain Name               : domain1
Backup Type               : full
Backup Config Name        :
Backup Filename (origin)  :
/payara/glassfish/domains/domain1/backups/domain1_2023_12_16_v00001.zip
Domain Directory          : /payara/glassfish/domains/domain1

Command list-backups executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `backup-domain`,
- `restore-domain`

list-batch-job-executions

Lists batch job executions and execution details.

Synopsis

```
asadmin [asadmin-options] list-batch-job-executions [--help]
[--target target]
[--executionid execution-id]
[--long={false|true}]
[--output output]
[--header={false|true}]
[instance_ID]
```

Description

The `list-batch-job-executions` subcommand lists batch job executions and execution details.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which to list batch job executions and execution details. Valid values are as follows:

`server`

Lists executions for the default server instance `server` and is the default value.

cluster-name

Lists executions for every server instance in the cluster.

instance-name

Lists executions for a particular server instance.

`--executionid`

`-x`

Specifies the execution ID of a specific batch job execution.

`--long`

`-l`

Displays detailed information about batch job executions. The default value is `false`.

`--output`

`-o`

Displays specific details about batch job executions. Use a comma-separated list to specify the details to display and their order. The values are case-insensitive. A subset of all possible

headings is displayed by default.
Possible values are as follows:

`jobname`

Displays the name of the job.

`executionid`

Displays the ID assigned to the execution of the batch job. A new execution is created the first time a job is started and every time the existing execution is restarted.

`starttime`

Displays the start time of the execution.

`endtime`

Displays the finish time of the execution.

`batchstatus`

Displays the status of the execution as set by the batch runtime.

`exitstatus`

Displays the status of the execution as set by the Job XML for the job or by the batch application. By default, the exit status and the batch status are the same unless the exit status is explicitly overridden.

`jobparameters`

Displays the properties passed to the batch runtime for the batch job execution, listed as name/value pairs.

`stepcount`

Displays the number of steps in the batch job execution.

`--header`

`-h`

Specifies whether column headings are displayed when the `--long` option is used. The default value is `true`. To suppress the headings, set the `--header` option to `false`.

Operands

instance_id

The ID of the job instance for which to list execution details.

Examples

Example 1 Listing Batch Job Executions

This example lists batch job executions for the default server instance and displays specific details.

```
asadmin> list-batch-job-executions -o=jobname,executionid,batchstatus,exitstatus
JOBNAME  EXECUTIONID  BATCHSTATUS  EXITSTATUS
```

```
payroll  9            COMPLETED    COMPLETED
bonus    6            FAILED       FAILED
Command list-batch-job-executions executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-batch-jobs`,
- `list-batch-job-steps`,
- `list-batch-runtime-configuration`,
- `set-batch-runtime-configuration`

list-batch-job-steps

Lists steps for a specific batch job execution.

Synopsis

```
asadmin [asadmin-options] list-batch-job-steps [--help]
[--long={false|true}]
[--target target]
[--output output]
[--header={false|true}]
execution_id
```

Description

The `list-batch-job-steps` subcommand lists steps for a specific batch job execution.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which to list batch job steps. Valid values are as follows:

`server`

Lists steps for the default server instance `server` and is the default value.

cluster-name

Lists steps for every server instance in the cluster.

instance-name

Lists steps for a particular server instance.

`--long`

`-l`

Displays detailed information about batch job steps. The default value is `false`.

`--output`

`-o`

Displays specific details about batch job steps. Use a comma-separated list to specify the details to display and their order. The values are case-insensitive. A subset of all possible headings is displayed by default.
Possible values are as follows:

`stepname`

Displays the name of the step.

`stepid`

Displays the step ID.

`starttime`

Displays the start time of the step.

`endtime`

Displays the finish time of the step.

`batchstatus`

Displays the status of the step as set by the batch runtime.

`exitstatus`

Displays the status of the step as set by the Job XML for the job or by the batch application. By default, the exit status and the batch status are the same unless the exit status is explicitly overridden.

`stepmetrics`

Displays metrics for the step.

`value`

Displays a value for each step metric. The value represents the number of items read, written,

committed, and so on.

`--header`

`-h`

Specifies whether column headings are displayed when the `--long` option is used. The default value is `true`. To suppress the headings, set the `--header` option to `false`.

Operands

execution_id

The ID of the execution for which to list batch job steps and details.

Examples

Example 1 Listing Batch Job Steps

This example lists batch job steps and specific step details for a job execution with the execution ID of `7`. The target is the default server instance.

Some lines of output are omitted from this example for readability.

```
asadmin> list-batch-job-steps o=stepname,stepid,batchstatus,stepmetrics 7
STEPNAME   STEPID   BATCHSTATUS   STEPMETRICS
prepare    7        COMPLETED     METRICNAME          VALUE
                                  READ_COUNT          8
                                  WRITE_COUNT         8
                                  PROCESS_SKIP_COUNT  0
process    8        COMPLETED     METRICNAME          VALUE
                                  READ_COUNT          8
                                  WRITE_COUNT         8
                                  PROCESS_SKIP_COUNT  0
...
Command list-batch-job-steps executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-batch-jobs`,
- `list-batch-job-executions`,
- `list-batch-runtime-configuration`,

- `set-batch-runtime-configuration`

list-batch-jobs

Lists batch jobs details.

Synopsis

```
asadmin [asadmin-options] list-batch-jobs [--help]
[--target target]
[--long={false|true}]
[--output output]
[--limit] limit
[--offset] offset
[--header={false|true}]
[job_name]
```

Description

The `list-batch-jobs` subcommand lists batch jobs and job details.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--target`
: Specifies the target for which to list batch jobs and job details. Valid values are as follows:

  `server`
  : Lists batch jobs for the default server instance `server` and is the default value.

  cluster-name
  : Lists batch jobs for every server instance in the cluster.

  instance-name
  : Lists batch jobs for a particular server instance.

`--long`

`-l`
: Displays detailed information about batch jobs. The default value is `false`.

`--limit`
: Sets the number of rows of batch jobs to display

`--offset`

Sets the number of rows of batch jobs to skip

`--output`

`-o`

Displays specific details about batch jobs. Use a comma-separated list to specify the details to display and their order. The values are case-insensitive. The `jobname` and `instancecount` column headings are displayed by default.
Possible values are as follows:

`jobname`

Displays the name of the job.

`appname`

Displays the name of the application.

`instancecount`

Displays the number of job instances.

`instanceid`

Displays the ID assigned to the job instance.

`executionid`

Displays the ID assigned to the execution of the batch job. A new execution is created the first time a job is started and every time the existing execution is restarted.

`batchstatus`

Displays the status of the job as set by the batch runtime.

`starttime`

Displays the start time of the job.

`endtime`

Displays the finish time of the job.

`exitstatus`

Displays the status of the job as set by the Job XML for the job or by the batch application. By default, the exit status and the batch status are the same unless the exit status is explicitly overridden.

`--header`

`-h`

Specifies whether column headings are displayed when the `--long` option is used. The default value is `true`. To suppress the headings, set the `--header` option to `false`.

Operands

job_name

The name of the job for which to list details.

Examples

Example 1 Listing Batch Jobs

This example lists batch jobs for the default server instance.

```
asadmin> list-batch-jobs
JOBNAME  INSTANCECOUNT
payroll  9
bonus    6
Command list-batch-jobs executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-batch-job-executions`,
- `list-batch-job-steps`,
- `list-batch-runtime-configuration`,
- `set-batch-runtime-configuration`

list-batch-runtime-configuration

Displays the configuration of the batch runtime.

Synopsis

```
asadmin [asadmin-options] list-batch-runtime-configuration [--help]
[--target target]
[--output output]
[--header={false|true}]
```

Description

The `list-batch-runtime-configuration` subcommand displays the configuration of the batch runtime. Batch runtime configuration data is stored in the `config` element in `domain.xml`.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which to list the batch runtime configuration. Valid values are as follows:

`server`

Lists the batch runtime configuration for the default server instance `server` and is the default value.

cluster-name

Lists the batch runtime configuration for every server instance in the cluster.

instance-name

Lists the batch runtime configuration for a particular server instance.

`--output`

`-o`

Displays specific details about the batch runtime configuration. Use a comma-separated list to specify the details to display and their order. The values are case-insensitive. The `datasourcelookupname` and `executorservicelookupname` column headings are displayed by default. Possible values are as follows:

`datasourcelookupname`

The JNDI lookup name of the data source used to store job information. By default, the batch runtime uses the default data source `jdbc/__TimerPool`.

`executorservicelookupname`

The JNDI lookup name of the managed executor service used to provide threads to jobs. By default, the batch runtime uses the default managed executor service `concurrent/__defaultManagedExecutorService`.

`--header`

`-h`

Specifies whether column headings are displayed when the `--long` option is used. The default value is `true`. To suppress the headings, set the `--header` option to `false`.

Examples

Example 1 Listing Batch Runtime Configuration

The following example lists the configuration of the batch runtime for the default server instance.

```
asadmin> list-batch-runtime-configuration
DATASOURCELOOKUPNAME     EXECUTORSERVICELOOKUPNAME
jdbc/_default            concurrent/__defaultManagedExecutorService
Command list-batch-runtime-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `set-batch-runtime-configuration`,
- `list-batch-jobs`,
- `list-batch-job-executions`,

list-cache-keys

Lists all keys in a Hazelcast cache.

Synopsis

```
asadmin [asadmin-options] list-cache-keys
[--help]
[--target target]
[--name name]
```

Description

This command can be used to list all keys in a Hazelcast (Data Grid) cache.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are executing this operation. Valid values are:

`server`

Applies to the default server instance. This is the default value.

instance_name

Applies to a specified server instance.

`--name`

Name of the cache to query.

If omitted, this command will be executed for all available caches in the corresponding target.

Examples

Example 1 Lists all keys in all available caches.

```
asadmin> list-cache-keys
{
Cache payara-instance-map
{5d0928cf-fd3d-404f-a6c6-985293f0295f,
c7d90acc-43a3-492d-8c9c-8cd9b950fb37,
5e984e01-0c6a-4b34-b608-56b79285c36b,
9ba96a9f-d7ff-4c79-acef-8dd8091f40a6,
Cache payara.instance.store
{5d0928cf-fd3d-404f-a6c6-985293f0295f,
5e984e01-0c6a-4b34-b608-56b79285c36b,
Cache payara.micro.applications.store
{__admingui,
}

Command list-cache-keys executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `generate-encryption-key`

list-caches

Lists all configured Hazelcast distributed caches.

Synopsis

```
asadmin [asadmin-options] list-caches
[--help]
[--target target]
```

Description

This command can be used to list the Hazelcast distributed caches configured in the corresponding target.

For each cache entry, a minimal amount of information is printed out.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--target`
: This option helps specify the target on which you are executing this operation. Valid values are:

  `server`
  : Applies to the default server instance. This is the default value.

  instance_name
  : Applies to a specified server instance.

Examples

Example 1 Lists the Hazelcast distributed caches in the domain.

```
asadmin> list-caches
{
HZMap payara-instance-map hz:impl:mapService 4 entries
HZMap payara.instance.store hz:impl:mapService 2 entries
HZMap payara.micro.applications.store hz:impl:mapService 1 entries
}

Command list-caches executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

list-clusters

Lists existing clusters in a domain.

Synopsis

```
asadmin [asadmin-options] list-clusters [--help]
[target]
```

Description

The `list-clusters` subcommand lists existing clusters in a domain. The list can be filtered by cluster, instance, node, or configuration. For each cluster that is listed, the subcommand indicates whether the cluster is running.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Filters the list of clusters by specifying the target for which the clusters are to be listed. Valid values are as follows:

`domain`

Lists all clusters in the domain (default).

cluster-name

Lists only the specified cluster.

instance-name

Lists the cluster of which the specified instance is a member.

node-name

Lists the clusters that contain an instance that resides on the specified node. For example, if instance `pmdi1` in cluster `pmdc` and instance `ymli1` in cluster `ymlc` reside on node `n1`, `pmdc` and `ymlc` are listed.

configuration-name

Lists all clusters that contain instances whose configuration is defined by the named configuration.

Examples

Example 1 Listing All Clusters in a Domain

This example lists all clusters in the current domain.

```
asadmin> list-clusters
pmdclust not running
ymlclust not running

Command list-clusters executed successfully.
```

Example 2 Displaying the Status of a Cluster

This example displays status of the cluster `ymlclust`, which is not running.

```
asadmin> list-clusters ymlclust
ymlclust not running

Command list-clusters executed successfully.
```

Example 3 Listing All Clusters That Are Associated With a Node

This example lists the clusters that contain an instance that resides on the node `sj02`.

```
asadmin> list-clusters sj02
ymlclust not running

Command list-clusters executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

list-commands

Lists available commands.

Synopsis

```
asadmin [asadmin-options] list-commands [--help]
[--localonly={false|true}] [--remoteonly={false|true}]

pattern-list
```

Description

The `list-commands` subcommand lists the `asadmin` subcommands.

By default, the `list-commands` subcommand displays a list of local subcommands followed by a list of remote subcommands. You can specify that only remote subcommands or only local subcommands are listed and that only subcommands whose names contain a specified text string are listed.

This subcommand is supported in local mode and remote mode.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--localonly`

If this option is set to true, only local commands are listed. Default is false.
If this option is set to true, the `--remoteonly` option must be set to false. Otherwise, an error occurs.

`--remoteonly`

If this option is set to true, only remote commands are listed. Default is false.
If this option is set to true, the `--localonly` option must be set to false. Otherwise, an error occurs.

Operands

pattern-list

A space-separated list of text strings on which to filter the list of subcommands. Only the subcommands that contain any one of the specified text strings is listed.

Examples

Example 1 Listing the Local Subcommands

This example lists only the local subcommands.

```
asadmin> list-commands --localonly=true
********** Local Commands **********
change-admin-password
change-master-password
create-domain
create-service
delete-domain
export
help
```

```
list-commands
list-domains
login
monitor
multimode
restart-domain
start-database
start-domain
stop-database
stop-domain
unset
verify-domain-xml
version
Command list-commands executed successfully.
```

Example 2 Filtering the Subcommands That Are Listed

This example lists only the subcomands whose names contain the text `configure` or `set`.

```
asadmin> list-commands configure set
********** Local Commands **********
setup-ssh
unset

********** Remote Commands **********
configure-jms-cluster                   set-log-levels
configure-lb-weight                     set-web-context-param
configure-ldap-for-admin                set-web-env-entry
set                                     unset-web-context-param
set-log-attributes                      unset-web-env-entry

Command list-commands executed successfully.
```

Example 3 Listing All Subcommands

This example first displays a list of the local subcommands, followed by a partial list of the remote subcommands.

```
asadmin> list-commands
********** Local Commands **********
change-admin-password
change-master-password
create-domain
create-service
delete-domain
export
help
list-commands
list-domains
```

```
login
monitor
multimode
restart-domain
start-database
start-domain
stop-database
stop-domain
unset
verify-domain-xml
version
********** Remote Commands **********
__locations                             enable
add-resources                           enable-monitoring
configure-ldap-for-admin                flush-jmsdest
create-admin-object                     freeze-transaction-service
                                        generate-jvm-report
create-auth-realm                       get
create-connector-connection-pool        get-client-stubs
create-connector-resource               get-host-and-port
create-connector-security-map           jms-ping
create-connector-work-security-map      list
create-custom-resource                  list-admin-objects
create-file-user                        list-app-refs
create-http                             list-applications
create-http-listener
create-iiop-listener                    list-auth-realms
create-javamail-resource
create-jdbc-connection-pool             list-connector-connection-pools
create-jdbc-resource                    list-connector-resources
create-jms-host                         list-connector-security-maps
create-jms-resource                     list-connector-work-security-maps
create-jmsdest                          list-containers
create-jndi-resource                    list-custom-resources
create-jvm-options                      list-file-groups
                                        list-file-users
create-message-security-provider        list-http-listeners
create-network-listener                 list-iiop-listeners
create-password-alias                   list-javamail-resources
                                        list-jdbc-connection-pools
create-protocol                         list-jdbc-resources
create-resource-adapter-config          list-jms-hosts
create-resource-ref                     list-jms-resources
create-ssl                              list-jmsdest
create-system-properties                list-jndi-entries
create-threadpool                       list-jndi-resources
create-transport                        list-jvm-options
create-virtual-server
delete-admin-object                     list-logger-levels
                                        list-message-security-providers
```

```
...
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `list-containers`,
- `list-modules`

list-configs

list-configs

Lists named configurations.

Synopsis

```
asadmin [asadmin-options] list-configs [--help]
[target]
```

Description

The `list-configs` subcommand lists named configurations in the configuration of the domain administration server (DAS). The list can be filtered by cluster, instance, or named configuration.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Filters the list of configurations. Valid values are as follows:

`domain`

Lists all named configurations in the current domain.

cluster-name

Lists the named configuration that defines the configuration of instances in the specified cluster.

instance-name

Lists the named configuration that defines the configuration of the specified instance.

configuration-name

Lists the specified named configuration. Use this option to determine whether a named configuration exits.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-configs:::example-1]]

Example 1 Listing All Named Configurations in a Domain

This example lists all named configurations in the current domain.

```
asadmin> list-configs
server-config
default-config
pmdclust-config
pmdsharedconfig
pmdcpinst-config
ymlclust-config
il1-config
il2-config

Command list-configs executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `copy-config`,
- `delete-config`

- `configuration`

list-connector-connection-pools

Lists the existing connector connection pools.

Synopsis

```
asadmin [asadmin-options] list-connector-connection-pools [--help]
```

Description

The `list-connector-connection-pools` subcommand list connector connection pools that have been created.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-connector-connection-pools:::example-1]]

Example 1 Listing the Connector Connection Pools

This example lists the existing connector connection pools.

```
asadmin> list-connector-connection-pools
jms/qConnPool
Command list-connector-connection-pools executed successfully
```

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `asadmin`,
- `create-connector-connection-pool`,
- `delete-connector-connection-pool`,
- `ping-connection-pool`

list-connector-resources

Lists all connector resources.

Synopsis

```
asadmin [asadmin-options] list-connector-resources [--help]
[target]
```

Description

The `list-connector-resources` subcommand lists all connector resources.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

Operands

target
: The target for which the connector resources are to be listed. Valid values are as follows:

  `server`
  : Lists the connector resources on the default server instance. This is the default value.

  `domain`
  : Lists the connector resources for the domain.

  cluster-name
  : Lists the connector resources on all server instances in the specified cluster.

  instance-name
  : Lists the connector resources on a specified server instance.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-connector-resources:::example-1]]

Example 1 Listing Connector Resources

This example lists all existing connector resources.

```
asadmin> list-connector-resources
jms/qConnFactory
Command list-connector-resources executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-connector-resource`,
- `delete-connector-resource`

list-connector-security-maps

Lists the security maps belonging to the specified connector connection pool.

Synopsis

```
asadmin [asadmin-options] list-connector-security-maps [--help]
[--securitymap securitymap]
[--verbose={false|true}]
pool-name
```

Description

The `list-connector-security-maps` subcommand lists the security maps belonging to the specified connector connection pool.

For this subcommand to succeed, you must have first created a connector connection pool using the `create-connector-connection-pool` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--securitymap`

Specifies the name of the security map contained within the connector connection pool from which the identity and principals should be listed. With this option, `--verbose` is redundant.

`--verbose`

If set to `true`, returns a list including the identity, principals, and security name. The default is `false`.

Operands

pool-name

Name of the connector connection pool for which you want to list security maps.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-connector-security-maps:::example-1]]

Example 1 Listing the Connector Security Maps

This example lists the existing connector security maps for the pool named `connector-Pool1`.

```
asadmin> list-connector-security-maps connector-Pool1
securityMap1
Command list-connector-security-maps executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-connector-security-map`,
- `delete-connector-security-map`,

- `update-connector-security-map`

list-connector-work-security-maps

Lists the work security maps belonging to the specified resource adapter.

Synopsis

```
asadmin [asadmin-options] list-connector-work-security-maps [--help]
[--securitymap securitymap]
resource_adapter_name
```

Description

The `list-connector-work-security-maps` subcommand lists the work security maps belonging to the specified resource adapter.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--securitymap`

Specifies the name of the security map contained within the resource adapter from which the identity and principals should be listed.

Operands

resource_adapter_name

The name of the resource adapter for which you want to list security maps.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-connector-work-security-maps:::example-1]]

Example 1 Listing Connector Work Security Maps

This example lists the current connector work security maps for the resource adapter named `my_resource_adapter`.

```
asadmin> list-connector-work-security-maps my_resource_adapter
workSecurityMap1: EIS principal=eis-principal-2, mapped principal=server-principal-2
```

```
workSecurityMap1: EIS principal=eis-principal-1, mapped principal=server-principal-1
workSecurityMap2: EIS principal=eis-principal-2, mapped principal=server-principal-2
workSecurityMap2: EIS principal=eis-principal-1, mapped principal=server-principal-1
Command list-connector-work-security-maps executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-connector-work-security-map`,
- `delete-connector-work-security-map`,
- `update-connector-work-security-map`

list-containers

Lists application containers.

Synopsis

```
asadmin [asadmin-options] list-containers [--help]
```

Description

The `list-containers` subcommand displays a list of application containers.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-containers:::example-1]]

Example 1 Listing the Application Containers

This example lists the current application containers.

```
asadmin> list-containers
List all known application containers

faulttolerance
metrics
appclient
jpa
jpa
osgi
connector
grizzly
health
jwtauth
ejb
openapi
webservices
security
payara-resources_ear
payara-resources
resources_ear
resources
web
ear
cdi
cdi
config

Command list-containers executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- asadmin,
- list-commands,
- list-modules

list-context-services

Lists context service resources.

Synopsis

```
asadmin [asadmin-options] list-context-services [--help]
[target]
```

Description

The `list-context-services` subcommand lists context service resources.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

Operands

target
: Specifies the target for which context service resources are to be listed. Valid targets are:

  `server`
  : Lists the resources on the default server instance. This is the default value.

  `domain`
  : Lists the resources for the domain.

  cluster-name
  : Lists the resources on all server instances in the specified cluster.

  instance-name
  : Lists the resources on a specified server instance.

Examples

Example 1 Listing Context Service Resources

This example lists context service resources on the default server instance.

```
asadmin> list-context-services
concurrent/__defaultContextService
```

```
concurrent/myContextService1
concurrent/myContextService2
Command list-context-services executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-context-service`,
- `delete-context-service`

list-custom-resources

Gets all custom resources.

Synopsis

```
asadmin [asadmin-options] list-custom-resources [--help]
[target]
```

Description

The `list-custom-resources` subcommand lists the custom resources.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

This operand specifies the location of the custom resources. Valid targets are:

`server`
: Lists the resources on the default server instance. This is the default value

`domain`
: Lists the resources in the domain.

cluster_name
: Lists the resources for every server instance in the cluster.

instance_name
: Lists the resources for a particular server instance.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-custom-resources:::example-1]]

Example 1 Listing Custom Resources

This example lists the current custom resources.

```
asadmin> list-custom-resources
sample_custom_resource01
sample_custom_resource02
Command list-custom-resources executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-list-custom-resources:::example-2]]

Example 2 Using the list-custom-resources command with a target

The following example displays the usage of this command.

```
asadmin> list-custom-resources --user admin --passwordfile
passwords.txt --host plum --port 4848 target6

sample_custom_resource03
sample_custom_resource04
Command list-custom-resources executed successfully.
```

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `asadmin`,
- `create-custom-resource`,
- `delete-custom-resource`

list-deployment-groups

List all deployment groups registered in an existing server domain.

Synopsis

```
asadmin [asadmin-options] list-deployment-groups [--help]
```

Description

The `list-deployment-groups` subcommand lists all existing deployment groups registered in the server domain.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

Examples

Example 1 Listing Deployment Groups

This example lists existing deployment groups created in the domain:

```
asadmin list-deployment-groups
List of Deployment Groups:
        test-dgroup1
        test-dgroup2

Command list-deployment-groups executed successfully.
```

Exit Status

0
: command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-deployment-group`,
- `delete-deployment-group`,
- `start-deployment-group`,
- `stop-deployment-group`,
- `restart-deployment-group`

list-domains

Lists the domains in the specified directory.

Synopsis

```
asadmin [asadmin-options] list-domains [--help]
[--domaindir domaindir]
[--long={false|true}]
[--header={false|true}]
```

Description

The `list-domains` subcommand lists the domains in the specified domains directory. If the domains directory is not specified, the domains in the default directory are listed. If there is more that one domains directory, the `--domaindir` option must be specified. The status of each domain is included.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--domaindir`

The directory where the domains are to be listed. If specified, the path must be accessible in the files stem. If not specified, the domains in the domain root directory are listed. The default location of the domain root directory is `as-install/domains`.

`--long`

`-l`

Displays detailed information about the administration servers in the listed domains, including host names and port numbers. The default value is `false`.

`--header`

`-h`

Specifies whether a header is displayed when the `--long` option is used. The default value is `true`. To suppress the header, set the `--header` option to `false`.

Examples

Example 1 Listing Domains

This example lists the domains in the default directory.

```
asadmin> list-domains
Name: domain1 Status: Running
Name: domain2 Status: Not running
Name: domain4 Status: Running, restart required to apply configuration changes
Command list-domains executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-domain`,
- `delete-domain`,
- `start-domain`,
- `stop-domain`

list-file-groups

Lists file groups.

Synopsis

```
asadmin [asadmin-options] list-file-groups [--help]
[--name username] [--authrealmname auth_realm_name]
```

```
[--target target]
```

Description

The `list-file-groups` subcommand lists the file users and groups supported by the file realm authentication. This subcommand lists available groups in the file user. If the `--name` option is not specified, all groups are listed.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

Identifies the name of the file user for whom the groups will be listed.

`--authrealmname`

The name of the authentication realm for which to list available groups.

`--target`

This option specifies which configurations you can list. Valid targets are:

`server`

Lists the file groups in the current server. This is the default value.

cluster_name

Lists the file groups in a cluster.

instance_name

Lists the file groups for a particular instance.

Examples

Example 1 Listing Groups in all File Realms

This example list all file realm groups defined for the server.

```
asadmin> list-file-groups
staff
manager
Command list-file-groups executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-file-user`,
- `delete-file-user`,
- `list-file-users`,
- `update-file-user`

list-file-users

Lists the file users.

Synopsis

```
asadmin [asadmin-options] list-file-users [--help]
[--authrealmname auth_realm_name] [target]
```

Description

The `list-file-users` subcommand displays a list of file users supported by file realm authentication.

Options

`--help`
`-?`

Displays the help text for the subcommand.

`--authrealmname`

Lists only the users in the specified authentication realm.

Operands

target

Specifies the target for which you want to list file users. The following values are valid:

`server`

Lists the file users on the default server instance. This is the default value.

configuration_name

Lists the file users in the specified configuration.

cluster_name

Lists the file users on all server instances in the specified cluster.

instance_name

Lists the file users on a specified server instance.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-file-users:::example-1]]

Example 1 Listing Users in a Specific File Realm

The following example lists the users in the file realm named `sample_file_realm`.

```
asadmin> list-file-users --authrealmname sample_file_realm
sample_user05
sample_user08
sample_user12
Command list-file-users executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-file-user`,
- `delete-file-user`,
- `list-file-groups`,
- `update-file-user`

list-hazelcast-cluster-members

List the current members of the Data Grid visible to the domain.

Synopsis

```
asadmin [asadmin-options] list-hazelcast-cluster-members
```

```
[--help]
[--type type]
```

Description

This command can be used to list the current members of the Data Grid in a formatted table.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--type`

Specifies the type of cluster members to list, which will be either `server` or `micro`. The default value is `both`.

Examples

Example 1 List the current members of the Data Grid visible to the domain

```
asadmin> list-hazelcast-cluster-members --type server
Instance Name  Instance Group  Instance Type  Host Name     HTTP Ports  HTTPS Ports
Admin Port  Hazelcast Port  Lite Member  Deployed Applications  Last Heartbeat
instance1      MicroShoal      INSTANCE       /172.18.64.1  28080       28181
24848       2900            false                              2024-03-26 01:23:23
server         MicroShoal      DAS            /172.18.64.1  8080        8181
4848        4900            false        __admingui              2024-03-26 01:23:20
Command list-hazelcast-cluster-members executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- Domain Data Grid,
- `list-hazelcast-members`,
- `restart-hazelcast`,

- `list-cache-keys`,
- `list-caches`,
- `clear-cache`,

- `get-hazelcast-configuration`,
- `generate-encryption-key`

list-hazelcast-members

List the Data Grid (Hazelcast) current members.

Synopsis

```
asadmin [asadmin-options] list-hazelcast-members
[--help]
[--target target]
```

Description

This command can be used to list all Data Grid members (including the DAS, server instances, Payara Micro instances, other nodes) that correspond to the selected target.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are executing this operation. Valid values are:

`server`

Applies to the default `server` instance. This is the default value.

instance_name

Applies to a specified server instance.

Examples

Example 1 List current Data Grid members

```
asadmin> list-hazelcast-members
{ instance1-MicroShoal-/172.18.64.1:2900 server-MicroShoal-/172.18.64.1:4900-this }
```

```
Command list-hazelcast-members executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

list-healthcheck-services

Lists the names of all available Healthcheck services.

Synopsis

```
asadmin [asadmin-options] list-healthcheck-services
[--help]
```

Description

Prints a detailed list of all available Healthcheck services (as in, individual services that generate healthcheck events based on performance metrics) in the current server installation.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 List current Healthcheck services

```
asadmin list-healthcheck-services

Available Health Check Services:
Name                    Description
healthcheck-mpmetrics   Provides a way to monitor and log the values of metrics
exposed by MicroProfile Metrics
healthcheck-cpu         Provides ratio on cpu usage time with severity according to
defined threshold values
healthcheck-gc          Provides ratio on garbage collection count with severity
according to defined threshold values
healthcheck-heap        Provides ratio on used heap memory with severity according to
defined threshold values
healthcheck-threads     Lists hogging threads with their id when given thresholds
exceed
healthcheck-machinemem  Provides ratio on used machine memory with severity according
to defined threshold values
healthcheck-cpool       Provides ratio on connection usage for a given pool name with
severity according to defined threshold values
healthcheck-stuck       Provides thread name, id and stack trace for requests which
reach over defined threshold values
healthcheck-mp          Checks that all instances are responding to Microprofile
Healthcheck requests with an UP response

Command list-healthcheck-services executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

list-http-lb-configs

list-http-lbs

list-http-listeners

Lists the existing network listeners.

Synopsis

```
asadmin [asadmin-options] list-http-listeners [--help]
[target]
```

Description

The `list-http-listeners` subcommand lists the existing network listeners.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

Operands

target
: Restricts the listing to network listeners for a specified target. Valid values are as follows:

  `server`
  : Lists the netowork listeners for the default server instance. This is the default value.

  configuration-name
  : Lists the network listeners for the specified configuration.

  cluster-name
  : Lists the network listeners for all server instances in the specified cluster.

  instance-name
  : Lists the network listeners for the specified server instance.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-http-listeners:::example-1]]

Example 1 Listing Network Listeners

The following command lists all the network listeners for the server instance:

```
asadmin> list-http-listeners
http-listener-1
http-listener-2
admin-listener
Command list-http-listeners executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-http-listener`,
- `delete-http-listener`,
- `restart-http-listeners`

list-iiop-listeners

Lists the existing IIOP listeners.

Synopsis

```
asadmin [asadmin-options] list-iiop-listeners [--help]
[target]
```

Description

The `list-iiop-listeners` subcommand lists the existing IIOP listeners.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

This operand specifies the target for which the IIOP listeners are to be listed. Valid values are:

`server`

Lists the listeners in the default server instance `server` and is the default value.

configuration_name

Lists the listeners in the specified configuration.

cluster_name

Lists the listeners in the specified cluster.

instance_name

Lists the listeners in a particular server instance.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-iiop-listeners:::example-1]]

Example 1 Using the list-iiop-listeners subcommand

The following command lists all the IIOP listeners for the server instance:

```
asadmin> list-iiop-listeners
orb-listener-1
SSL
SSL_MUTUALAUTH
sample_iiop_listener
Command list-iiop-listeners executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-iiop-listener`,
- `delete-iiop-listener`

list-instances

Lists Payara Server instances in a domain.

Synopsis

```
asadmin [asadmin-options] list-instances [--help]
[--timeoutmsec timeout]
[--long={false|true} | --nostatus={false|true}]
[--standaloneonly={false|true} | target]
```

Description

The `list-instances` subcommand lists Payara Server instances in a domain. The list can be filtered by cluster, instance, node, or configuration.

The subcommand displays every Payara Server instance in the specified target, regardless of how each instance was created. For example, this subcommand lists instances that were created by using the `create-instance` subcommand and by using the `create-local-instance` subcommand.

By default, the subcommand indicates whether each instance that is listed is running. Options of this subcommand control the information that is displayed for each instance.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--timeoutmsec`

The time limit in milliseconds for determining the status of instances. The default is 2,000, which is equivalent to 2 seconds.

`--long`

`-l`

Specifies whether detailed information is displayed for each instance that is listed.
The `--long` option and `--nostatus` option are mutually exclusive. If both options are specified in the same command, an error occurs.
Valid values are as follows:

`true`

The following details are displayed for each instance that is listed:

- The name of the instance

- The name of the host where the instance's node resides
- The HTTP port on which the instance listens for administration requests
- The process identifier (PID) of the instance process or -1 if the instance is not running
- The name of the cluster of which the instance is a member, if any
- The state of the instance, which is `running` or `not running`
  When an instance is listed, some configuration changes in the domain administration server (DAS) for the instance might not have been applied to the instance itself. In this situation, the commands that are required to apply the changes are listed adjacent to the state of the instance. The maximum number of commands that are listed for an instance is 10.

`false`

Only the name of the instance and an indication of whether the instance is running are displayed (default). The length of time that the instance has been running is not displayed.

`--nostatus`

Specifies whether information about whether instances are running is suppressed.
The `--long` option and `--nostatus` option are mutually exclusive. If both options are specified in the same command, an error occurs.
Valid values are as follows:

`true`

Information about whether instances are running is suppressed. Only the name of each instance is displayed.

`false`

Information about whether instances are running is displayed (default).

`--standaloneonly`

Specifies whether only standalone instances are listed.
The `--standaloneonly` option and the target operand and are mutually exclusive. If both the `--standaloneonly` option and the target operand are specified in the same command, an error occurs.
Valid values are as follows:

`true`

Only standalone instances are listed.

`false`

All instances in the specified target are listed (default).

Operands

target

Filters the list of Payara Server instances by specifying the target for which instances are listed.
The target operand and the `--standaloneonly` option are mutually exclusive. If both the target operand and the `--standaloneonly` option are specified in the same command, an error occurs.

Valid values are as follows:

`domain`
: Lists all instances in the domain (default).

cluster-name
: Lists the instances that are members of the specified cluster.

instance-name
: Lists only the specified instance.

node-name
: Lists the instances that reside on the specified node.

configuration-name
: Lists all instances whose configuration is defined by the specified named configuration.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-instances:::example-1]]

Example 1 Listing Basic Information About All Payara Server Instances in a Domain

This example lists the name and status of all Payara Server instances in the current domain.

```
asadmin> list-instances
pmd-i-sj02 running
yml-i-sj02 running
pmd-i-sj01 running
yml-i-sj01 running
pmdsa1 not running

Command list-instances executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-list-instances:::example-2]]

Example 2 Listing Detailed Information About All Payara Server Instances in a Domain

This example lists detailed information about all Payara Server instances in the current domain.

```
asadmin> list-instances --long=true
NAME        HOST       PORT   PID    CLUSTER     STATE
pmd-i-sj01  sj01       24848  31310  pmdcluster   running
yml-i-sj01  sj01       24849  25355  ymlcluster   running
pmdsa1      localhost  24848  -1     ---          not running
pmd-i-sj02  sj02       24848  22498  pmdcluster   running
yml-i-sj02  sj02       24849  20476  ymlcluster   running
```

```
ymlsa1      localhost  24849  -1     ---          not running
Command list-instances executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-list-instances:::example-3]]

Example 3 Displaying the Status of an Instance

This example displays status of the instance `pmd-i-sj01`, which is running.

```
asadmin> list-instances pmd-i-sj01
pmd-i-sj01 running
Command list-instances executed successfully.
```

[[Technical Documentation-Payara Server Documentation-Command Reference-list-instances:::example-4]]

Example 4 Listing Only Standalone Instances in a Domain

This example lists only the standalone instances in the current domain.

```
asadmin> list-instances --standaloneonly=true
pmdsa1 not running
Command list-instances executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

- `asadmin`,
- `create-instance`,
- `create-local-instance`

list-jacc-providers

Enables administrators to list JACC providers defined for a domain.

Synopsis

```
asadmin [asadmin-options] list-jacc-providers [--help]
```

```
[target]
```

Description

The `list-jacc-providers` subcommand enables administrators to list the JACC providers defined for a domain. JACC providers are defined as `jacc-provider` elements in the `security-service` element in the domain's `domain.xml` file. JACC providers can be created using the Payara Server Admin Console or the `create-jacc-provider` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Specifies the target for which you want to list JACC providers. The following values are valid:

`server`

Lists the JACC providers on the default server instance. This is the default value.

configuration_name

Lists the JACC providers in the specified configuration.

cluster_name

Lists the JACC providers on all server instances in the specified cluster.

instance_name

Lists the JACC providers on a specified server instance.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-jacc-providers:::example-1]#Technical Documentation-Payara Server Documentation-Command Reference-list-jacc-providers:::example-1] **Example 1 Listing JACC providers**

The following example shows how to list JACC providers for the default domain.

```
asadmin> list-jacc-providers
default
simple
testJACC
```

```
Command list-jacc-providers executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jacc-provider`,
- `delete-jacc-provider`

list-javamail-resources

Lists the existing JavaMail session resources.

Synopsis

```
asadmin [asadmin-options] list-javamail-resources [--help] [target]
```

Description

The `list-javamail-resources` subcommand lists the existing JavaMail session resources.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

This operand specifies the target for which the JavaMail session resources are to be listed. Valid values are:

`server`

Lists the resources for the default server instance. This is the default value.

`domain`

Lists the resources for the domain.

cluster_name

Lists the resources for the specified cluster.

instance_name

Lists the resources for a particular server instance.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-javamail-resources:::example-1]]

Example 1 Listing JavaMail Resources

This example lists the JavaMail session resources for the server instance.

```
asadmin> list-javamail-resources
mail/MyMailSession
Command list-javamail-resources executed successfuly.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-javamail-resource`,
- `delete-javamail-resource`

list-jdbc-connection-pools

Lists all JDBC connection pools.

Synopsis

```
asadmin [asadmin-options] list-jdbc-connection-pools [--help]
```

Description

The `list-jdbc-connection-pools` subcommand lists the current JDBC connection pools.

This subcommand is supported in the remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

[[Technical Documentation-Payara Server Documentation-Command Reference-list-jdbc-connection-pools:::example-1]]

Example 1 Listing the JDBC Connection Pools

This example lists the existing JDBC connection pools.

```
asadmin> list-jdbc-connection-pools
sample_derby_pool
__TimerPool
Command list-jdbc-connection-pools executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jdbc-connection-pool`,
- `delete-jdbc-connection-pool`

list-jdbc-resources

Lists all JDBC resources.

Synopsis

```
asadmin [asadmin-options] list-jdbc-resources [--help]
[target target]
```

Description

The `list-jdbc-resources` subcommand displays a list of the existing JDBC resources.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

`--target`

This operand specifies which JDBC resources you can list. Usage of this operand is optional. Valid values are:

`server`

Lists the JDBC resources in the current server and is the default.

`domain`

Lists the JDBC resources in the current domain.

cluster_name

Lists the JDBC resources in a cluster.

instance_name

Lists the JDBC resources for a particular instance.

Examples

Example 1 Listing the JDBC Resources

This example lists the current JDBC resources.

```
asadmin> list-jdbc-resources
jdbc/DerbyPool
Command list-jdbc-resources executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jdbc-resource`,
- `delete-jdbc-resource`

list-jms-hosts

Lists the existing JMS hosts.

Synopsis

```
asadmin [asadmin-options] list-jms-hosts [--help]
[--target target]
```

Description

The `list-jms-hosts` subcommand lists the existing Java Message Service (JMS) hosts for the JMS service.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Restricts the listing to JMS hosts for a specified target. Valid values are as follows:

`server`

Lists the JMS hosts for the default server instance. This is the default value.

configuration-name

Lists the JMS hosts for the specified configuration.

cluster-name

Lists the JMS hosts for all server instances in the specified cluster.

instance-name

Lists the JMS hosts for the specified server instance.

Examples

Example 1 Listing all JMS hosts

The following subcommand lists the JMS hosts for the JMS service.

```
asadmin> list-jms-hosts server-config
default_JMS_host
MyNewHost
Command list-jms-hosts executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jms-host`,
- `delete-jms-host`,
- `jms-ping`

list-jms-resources

Lists the JMS resources.

Synopsis

```
asadmin [asadmin-options] list-jms-resources [--help]
[--restype type]
[target]
```

Description

The `list-jms-resources` subcommand lists the existing Java Message Service (JMS) resources (destination and connection factory resources).

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--restype`

The JMS resource type can be `jakarta.jms.Topic`, `jakarta.jms.Queue`, `jakarta.jms.ConnectionFactory`, `jakarta.jms.TopicConnectionFactory`, or `jakarta.jms.QueueConnectionFactory`.

Operands

target

Restricts the listing to resources for a specified target. Valid values are as follows:

`server`

Lists the resources for the default server instance. This is the default value.

`domain`

Lists the resources for the domain.

cluster-name

Lists the resources for every server instance in the specified cluster.

instance-name

Lists the resources for the specified server instance.

Examples

Example 1 Listing all JMS resources

The following subcommand lists all JMS resources.

```
asadmin> list-jms-resources
jms/Queue
jms/ConnectionFactory
jms/DurableConnectionFactory
jms/Topic
Command list-jms-resources executed successfully.
```

Example 2 Listing JMS resources of a specified type

The following subcommand lists all `jakarta.jms.ConnectionFactory` resources.

```
asadmin> list-jms-resources --restype jakarta.jms.ConnectionFactory
jms/ConnectionFactory
jms/DurableConnectionFactory
Command list-jms-resources executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jms-resource`,
- `delete-jms-resource`

list-jmsdest

Lists the existing JMS physical destinations.

Synopsis

```
asadmin [asadmin-options] list-jmsdest [--help]
[--desttype type]
[target]
```

Description

The `list-jmsdest` subcommand lists the Java Message Service (JMS) physical destinations.

This subcommand is supported in remote mode only. Remote `asadmin` subcommands require a running domain administration server (DAS).

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--desttype`

The type of JMS destination to be listed. Valid values are `topic` and `queue`.

Operands

target

Restricts the listing to physical destinations for a specified target. Valid values are as follows:

`server`

Lists the physical destinations for the default server instance. This is the default value.

configuration-name

Lists the physical destinations in the specified configuration.

cluster-name

Lists the physical destinations for every server instance in the specified cluster.

instance-name

Lists the physical destinations for the specified server instance.

Examples

Example 1 Listing all physical destinations

The following subcommand lists all the physical destinations.

```
asadmin> list-jmsdest
PhysicalQueue
PhysicalTopic
Command list-jmsdest executed successfully.
```

Example 2 Listing all physical destinations of a specified type

The following subcommand lists all physical topics.

```
asadmin> list-jmsdest --desttype topic
PhysicalTopic
Command list-jmsdest executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jmsdest`,

- `delete-jmsdest`,
- `flush-jmsdest`

list-jndi-entries

Browses and queries the JNDI tree.

Synopsis

```
asadmin [asadmin-options] list-jndi-entries [--help]
[--context context_name]
[target]
```

Description

Use this subcommand to browse and query the JNDI tree.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--context`
: The name of the JNDI context or subcontext. If context is not specified, all entries in the naming service are returned. If context (such as `ejb`) is specified, all those entries are returned.

Operands

target
: This operand specifies the JNDI tree to browse.
Possible values are as follows:

  `server`
  : Browses the JNDI tree for the default Payara Server instance (default). The default instance is the domain administration server (DAS).

  `domain`
  : Browses the JNDI tree for the current domain.

  cluster-name
  : Browses the JNDI tree for the specified cluster.

instance-name

Browses the JNDI tree for the specified Payara Server instance.

Examples

Example 1 Browsing the JNDI Tree

This example browses the JNDI tree for the default Payara Server instance.

```
asadmin> list-jndi-entries
java:global: com.sun.enterprise.naming.impl.TransientContext
jdbc: com.sun.enterprise.naming.impl.TransientContext
ejb: com.sun.enterprise.naming.impl.TransientContext
com.sun.enterprise.container.common.spi.util.InjectionManager:
com.sun.enterprise.container.common.impl.util.InjectionManagerImpl

Command list-jndi-entries executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-jndi-resource`,
- `delete-jndi-resource`,
- `list-jndi-resources`

list-jndi-resources

Lists all existing JNDI resources.

Synopsis

```
list-jndi-resources [--help] [target]
```

Description

The `list-jndi-resources` subcommand identifies all existing JNDI resources.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

The target for which the JNDI resources are to be listed. Valid values are as follows:

`server`

Lists the JNDI resources on the default server instance. This is the default value.

configuration-name

Lists the JNDI resources for the specified configuration.

cluster-name

Lists the JNDI resources on all server instances in the specified cluster.

instance-name

Lists the JNDI resources on a specified server instance.

Examples

Example 1 Listing JNDI Resources

This example lists the JNDI resources on the default server instance.

```
asadmin> list-jndi-resources
jndi_resource1
jndi_resource2
jndi_resource3
Command list-jndi-resources executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,

- `create-jndi-resource`,
- `delete-jndi-resource`

list-jobs

Lists information about subcommands that were started using `asadmin --detach` or that contain progress information.

Synopsis

```
asadmin [asadmin-options] list-jobs [--help]
[job_id]
```

Description

The `list-jobs` subcommand lists information about subcommands that were started using the `asadmin` utility option `--detach` or that contain progress information. The `--detach` option detaches long-running subcommands and executes them in the background in detach mode.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

job_id

The ID of the job for which you want to list information.

Examples

Example 1 Checking Job Status

This example provides information about subcommands that were started using `asadmin --detach` or that contain progress information.

```
asadmin> list-jobs
JOB ID     COMMAND           STATE       EXIT CODE TIME OF COMPLETION
1          create-cluster    COMPLETED   SUCCESS   2013-02-15 16:16:16 PST
2          deploy            COMPLETED   FAILURE   2013-02-15 18:26:30 PST
Command list-jobs executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `attach`,
- `configure-managed-jobs`

list-jvm-options

Lists options for the Java application launcher.

Synopsis

```
asadmin [asadmin-options] list-jvm-options [--help]
[--target target]
```

Description

The `list-jvm-options` subcommand displays a list of command-line options that are passed to the Java application launcher when Payara Server is started.

The options are managed by using the JVM Options page of the Administration Console or by using the `create-jvm-options` and `delete-jvm-options` subcommands.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which you are listing Java application launcher options.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Examples

Example 1 Listing the Java Application Launcher Options

This example lists the options that are used by the Java application launcher.

```
asadmin> list-jvm-options
-Djava.security.auth.login.config=${com.sun.aas.instanceRoot}/config/login.conf
-XX: LogVMOutput
-XX: UnlockDiagnosticVMOptions
-Dcom.sun.enterprise.config.config_environment_factory_class=
com.sun.enterprise.config.serverbeans.AppserverConfigEnvironmentFactory
-Djavax.net.ssl.keyStore=${com.sun.aas.instanceRoot}/config/keystore.jks
-XX:NewRatio=2
-DANTLR_USE_DIRECT_CLASS_LOADING=true
-Djava.security.policy=${com.sun.aas.instanceRoot}/config/server.policy
-Djdbc.drivers=org.apache.derby.jdbc.ClientDriver
-Djavax.net.ssl.trustStore=${com.sun.aas.instanceRoot}/config/cacerts.jks
-client

- Windows: java - the Java application launcher (http://docs.oracle.com/javase/6/docs/technotes/tools/windows/java.html)

list-keystore-entries

Displays entries in the specified domain keystore

Synopsis

```
asadmin list-keystore-entries [--help]
[--verbose={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[alias]
```

Description

This command displays either all or a specific store entry from the target instance or listener's key store.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are listing its keystore entries. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--verbose`

Whether to print the full entry details. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

Operands

alias

The alias name of the entry to list. If not provided then all entries in the keystore are listed.

Examples

Example 1 List all entries in the `production` domain's keystore

```
asadmin list-keystore-entries --domainName production
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `renew-self-signed-certificates`,
- `add-to-keystore`,
- `add-to-truststore`

list-libraries

Lists library JAR files on Payara Server.

Synopsis

```
asadmin [asadmin-options] list-libraries [--help]
[--type={common|ext|app}]
```

Description

The `list-libraries` subcommand lists library archive files on Payara Server.

The `--type` option specifies the library type and the Payara Server directory for which libraries are to be listed.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--type`

Specifies the library type and the Payara Server directory for which libraries are listed. Valid values are as follows:

`common`

Lists the library files for the Common class loader directory, `domain-dir/lib`. This is the default.

`ext`

Lists the library files for the Java optional package directory, `domain-dir/lib/ext`.

`app`

Lists the library files for the application-specific class loader directory, `domain-dir/lib/applibs`.
For more information about these directories, see Class Loaders in the Payara Server Application section.

Examples

Example 1 Listing Libraries

This example lists the libraries in the application-specific class loader directory on the default server instance.

```
asadmin> list-libraries --type app
mylib.jar
xlib.jar
ylib.jar
zlib.jar
Command list-libraries executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `add-library`,
- `remove-library`,

list-log-attributes

Lists all logging attributes defined for a specified target in a domain.

Synopsis

```
asadmin [asadmin-options] list-log-attributes [--help]
[target]
```

Description

The `list-log-attributes` subcommand lists all logging attributes currently defined for the specified Payara Server domain or target within a domain. The values listed correspond to the values in the `logging.properties` file for the domain.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Valid values are:

- `server` - The default server instance. This is the default value.
- configuration_name - The name of a specific configuration.
- cluster_name - The name of a target cluster.
- instance_name - The name of a target server instance.

Examples

Example 1 Listing the Logger Attributes for a Domain

This example lists all loggers attributes for the default domain.

```
asadmin> list-log-attributes
com.sun.enterprise.server.logging.GFFileHandler.alarms <false>
com.sun.enterprise.server.logging.GFFileHandler.file \
<${com.sun.aas.instanceRoot}/logs/server.log>
com.sun.enterprise.server.logging.GFFileHandler.flushFrequency ①
com.sun.enterprise.server.logging.GFFileHandler.formatter \
<com.sun.enterprise.server.logging.UniformLogFormatter>
com.sun.enterprise.server.logging.GFFileHandler.logtoConsole <false>
com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles ⑳
com.sun.enterprise.server.logging.GFFileHandler.retainErrorsStasticsForHours ⑳
com.sun.enterprise.server.logging.GFFileHandler.rotationLimitInBytes
com.sun.enterprise.server.logging.GFFileHandler.rotationTimelimitInMinutes ⑳
com.sun.enterprise.server.logging.SyslogHandler.useSystemLogging <false>
handlers <java.util.logging.ConsoleHandler>
java.util.logging.ConsoleHandler.formatter \
<com.sun.enterprise.server.logging.UniformLogFormatter>
java.util.logging.FileHandler.count ①
java.util.logging.FileHandler.formatter <java.util.logging.XMLFormatter>
java.util.logging.FileHandler.limit
java.util.logging.FileHandler.pattern <%h/java%u.log>
log4j.logger.org.hibernate.validator.util.Version <warn>

Command list-log-attributes executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

list-log-levels

Lists the loggers and their log levels.

Synopsis

```
asadmin [asadmin-options] list-log-levels [--help]
[--target target]
```

Description

The `list-log-levels` subcommand lists the current Payara Server loggers and their log levels. This subcommand reports on all the loggers that are listed in the `logging.properties` file. In some cases, loggers that have not been created by the respective containers will appear in the list.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The server, cluster or server instance for which log levels will be listed.

Operands

target

Valid values are:

- server_name - Default target is `server`. If no target is specified then log levels are listed for the server.
- cluster_name - The name of a target cluster.
- instance_name - The name of a target server instance.

Examples

Example 1 Listing the Log Levels

This example lists the existing loggers and indicates how their log levels are set.

list-loggers

Lists existing loggers.

Synopsis

```
asadmin [asadmin-options] list-loggers [--help]
```

Description

The `list-loggers` subcommand lists the existing Payara Server loggers. Internal loggers are not listed. The `list-loggers` subcommand lists the logger name, subsystem, and description.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Listing the Loggers

This example lists the logger name, subsystem, and description for each logger. Some lines of output are omitted from this example for readability.

```
asadmin> list-loggers
Logger Name                              Subsystem         Logger Description
...
jakarta.enterprise.monitoring              Monitoring        Monitoring Logger
jakarta.enterprise.system.core.ee          AS-CORE           Java EE Core Kernel
jakarta.enterprise.system.jmx              JMX               JMX System Logger
jakarta.enterprise.system.tools.admin      ADMIN             Administration Services
...
Command list-loggers executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-log-levels`,
- `set-log-file-format`

list-managed-executor-services

Lists managed executor service resources.

Synopsis

```
asadmin [asadmin-options] list-managed-executor-services [--help]
[target]
```

Description

The `list-managed-executor-services` subcommand lists managed executor service resources.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Specifies the target for which managed executor service resources are to be listed. Valid targets are:

`server`

Lists the resources on the default server instance. This is the default value.

`domain`

Lists the resources for the domain.

cluster-name

Lists the resources on all server instances in the specified cluster.

instance-name

Lists the resources on a specified server instance.

Examples

Example 1 Listing Managed Executor Service Resources

This example lists managed executor service resources on the default server instance.

```
asadmin> list-managed-executor-services
concurrent/__defaultManagedExecutorService
concurrent/Executor1
concurrent/Executor2
Command list-managed-executor-services executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-managed-executor-service`,
- `delete-managed-executor-service`

list-managed-scheduled-executor-services

Lists managed scheduled executor service resources.

Synopsis

```
asadmin [asadmin-options] list-managed-scheduled-executor-services [--help]
[target]
```

Description

The `list-managed-scheduled-executor-services` subcommand lists managed scheduled executor service resources.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Specifies the target for which managed scheduled executor service resources are to be listed. Valid targets are:

`server`

Lists the resources on the default server instance. This is the default value.

`domain`

Lists the resources for the domain.

cluster-name

Lists the resources on all server instances in the specified cluster.

instance-name

Lists the resources on a specified server instance.

Examples

Example 1 Listing Managed Scheduled Executor Service Resources

This example lists managed scheduled executor service resources on the default server instance.

```
asadmin> list-managed-scheduled-executor-services
concurrent/__defaultManagedExecutorService
concurrent/ScheduledExecutor1
concurrent/ScheduledExecutor2
Command list-managed-scheduled-executor-services executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-managed-scheduled-executor-service`,
- `delete-managed-scheduled-executor-service`

list-managed-thread-factories

Lists managed thread factory resources.

Synopsis

```
asadmin [asadmin-options] list-managed-thread-factories [--help]
[target]
```

Description

The `list-managed-thread-factories` subcommand lists managed thread factory resources.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Specifies the target for which managed thread factory resources are to be listed. Valid targets are:

`server`

Lists the resources on the default server instance. This is the default value.

`domain`

Lists the resources for the domain.

cluster-name

Lists the resources on all server instances in the specified cluster.

instance-name

Lists the resources on a specified server instance.

Examples

Example 1 Listing Managed Thread Factory Resources

This example lists managed thread factory resources on the default server instance.

```
asadmin> list-managed-thread-factories
concurrent/__defaultManagedThreadFactory
concurrent/Factory1
concurrent/Factory2
Command list-managed-thread-factories executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-managed-thread-factory`,
- `delete-managed-thread-factory`

list-message-security-providers

Lists all security message providers for the given message layer.

Synopsis

```
asadmin [asadmin-options] list-message-security-providers [--help]
--layer message_layer
[target]
```

Description

The `list-message-security-providers` subcommand enables administrators to list all security message providers (`provider-config` sub-elements) for the given message layer (`message-security-config` element of `domain.xml`).

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--layer`

The message-layer for which the provider has to be listed. The default value is `HttpServlet`.

Operands

target

Restricts the listing to message security providers for a specific target. Valid values include:

`server`

Lists providers for the default server instance `server` and is the default value.

`domain`

Lists providers for the domain.

cluster

Lists providers for the server instances in the cluster.

instance

Lists providers for a particular server instance.

Examples

Example 1 Listing message security providers

The following example shows how to list message security providers for a message layer.

```
asadmin> list-message-security-providers
--layer SOAP
XWS_ClientProvider
ClientProvider
XWS_ServerProvider
ServerProvider
Command list-message-security-providers executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-message-security-provider`,
- `delete-message-security-provider`

list-modules

Lists Payara Server modules.

Synopsis

```
asadmin [asadmin-options] list-modules [--help]
```

Description

The `list-modules` subcommand displays a list of modules that are accessible to the Payara Server module subsystem. The version of each module is shown.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Listing Payara Server Modules

This example provides a partial listing of modules that are accessible to the Payara Server module subsystem

```
asadmin> list-modules

list-network-listeners

Lists the existing network listeners.

Synopsis

```
asadmin [asadmin-options] list-network-listeners [--help]
[target]
```

Description

The `list-network-listeners` subcommand lists the existing network listeners.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Restricts the listing to network listeners for a specified target. Valid values are as follows:

`server`

Lists the network listeners for the default server instance. This is the default value.

configuration-name

Lists the network listeners for the specified configuration.

cluster-name

Lists the network listeners for all server instances in the specified cluster.

instance-name

Lists the network listeners for the specified server instance.

Examples

Example 1 Listing Network Listeners

The following command lists all the network listeners for the server instance:

```
asadmin> list-network-listeners
admin-listener
http-listener-1
https-listener-2
Command list-network-listeners executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

list-nodes-config

Lists all Payara Server nodes that do not support remote communication in a domain.

Synopsis

```
asadmin [asadmin-options] list-nodes-config [--help]
[--long={false|true}]
```

Description

The `list-nodes-config` subcommand lists all Payara Server nodes that do not support remote communication in a domain.

To list all nodes in a domain regardless of the type of the node, run the `list-nodes` subcommand.

By default, the subcommand displays the following information for each node that is listed:

- The name of the node
- The type of the node, which is `CONFIG`
- The name of the host that the node represents

The `--long` option of the subcommand specifies whether the nodes are listed in long format. In long format, the following additional information about each node is displayed:

- The path to the parent of the base installation directory of Payara Server on the host that the node represents
- A comma-separated list of the names of the Payara Server instances that reside on the node

If the `--terse` option of the `asadmin` utility is `true` and the `--long` option of the subcommand is `false`, the subcommand lists only the name of each node.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Specifies whether the nodes are listed in long format.
Possible values are as follows:

`true`

The nodes are listed in long format.

`false`

The nodes are listed in short format (default).

Examples

Example 1 Listing Payara Server Nodes

This example displays the name, type, and host for all Payara Server nodes that do not support remote communication in the domain `domain1`.

```
asadmin> list-nodes-config
localhost-domain1  CONFIG  localhost
devnode  CONFIG  localhost
Command list-nodes-config executed successfully.
```

Example 2 Listing Only the Names of Payara Server Nodes

This example uses the `--terse` option of the `asadmin` utility to list only the names of the Payara Server nodes that do not support remote communication in the domain `domain1`.

```
asadmin> list-nodes-config --terse=true
localhost-domain1
devnode
```

Example 3 Listing Payara Server Nodes in Long Format

This example lists the Payara Server nodes that do not support remote communication in the domain `domain1`in long format.

```
asadmin> list-nodes-config --long=true
NODE NAME           TYPE     NODE HOST   INSTALL DIRECTORY    REFERENCED BY
localhost-domain1   CONFIG   localhost   /export/payara7
devnode             CONFIG   localhost   /export/payara7   pmdsa1
Command list-nodes-config executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

- `list-nodes-ssh`

list-nodes-ssh

lists all Payara Server nodes that support communication over SSH in a domain.

Synopsis

```
asadmin [asadmin-options] list-nodes-ssh [--help]
[--long={false|true}]
```

Description

The `list-nodes-ssh` subcommand lists all Payara Server nodes that support communication over secure shell (SSH) in a domain.

To list all nodes in a domain regardless of the type of the node, run the `list-nodes` subcommand.

By default, the subcommand displays the following information for each node that is listed:

- The name of the node
- The type of the node, which is `SSH`
- The name of the host that the node represents

The `--long` option of the subcommand specifies whether the nodes are listed in long format. In long format, the following additional information about each node is displayed:

- The path to the parent of the base installation directory of Payara Server on the host that the node represents
- A comma-separated list of the names of the Payara Server instances that reside on the node

If the `--terse` option of the `asadmin` utility is `true` and the `--long` option of the subcommand is `false`, the subcommand lists only the name of each node.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Specifies whether the nodes are listed in long format.
Possible values are as follows:

`true`

The nodes are listed in long format.

`false`

The nodes are listed in short format (default).

Examples

Example 1 Listing Payara Server Nodes

This example displays the name, type, and host for all Payara Server nodes that support communication over SSH in a domain.

```
asadmin> list-nodes-ssh
sj02  SSH  sj02.example.com
sj01  SSH  sj01.example.com
Command list-nodes-ssh executed successfully.
```

Example 2 Listing Only the Names of Payara Server Nodes

This example uses the `--terse` option of the `asadmin` utility to list only the names of the Payara Server nodes that support communication over SSH in a domain.

```
asadmin> list-nodes-ssh --terse=true
sj02
sj01
```

Example 3 Listing Payara Server Nodes in Long Format

This example lists the Payara Server nodes that support communication over SSH in a domain in long format.

```
asadmin> list-nodes-ssh --long=true
NODE NAME   TYPE   NODE HOST          INSTALL DIRECTORY    REFERENCED BY
sj02        SSH    sj02.example.com   /export/payara7   pmd-i-sj02, yml-i-sj02
sj01        SSH    sj01.example.com   /export/payara7   pmd-i-sj01, yml-i-sj01
Command list-nodes-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

list-nodes

Lists all Payara Server nodes in a domain.

Synopsis

```
asadmin [asadmin-options] list-nodes [--help]
[--long={false|true}]
```

Description

The `list-nodes` subcommand lists all Payara Server nodes in a domain.

By default, the subcommand displays the following information for each node that is listed:

- The name of the node
- The type of the node, which is one of the following types:::

  `CONFIG`

  The node does not support remote communication.

`SSH`

The node supports communication over secure shell (SSH).

- The name of the host that the node represents

The `--long` option of the subcommand specifies whether the nodes are listed in long format. In long format, the following additional information about each node is displayed:

- The path to the parent of the base installation directory of Payara Server on the host that the node represents
- A comma-separated list of the names of the Payara Server instances that reside on the node

If the `--terse` option of the `asadmin` utility is `true` and the `--long` option of the subcommand is `false`, the subcommand lists only the name of each node.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Specifies whether the nodes are listed in long format.
Possible values are as follows:

`true`

The nodes are listed in long format.

`false`

The nodes are listed in short format (default).

Examples

Example 1 Listing Payara Server Nodes

This example displays the name, type, and host for all Payara Server nodes in the domain `domain1`.

```
asadmin> list-nodes
localhost-domain1  CONFIG  localhost
sj02  SSH  sj02.example.com
sj01  SSH  sj01.example.com
devnode  CONFIG  localhost
```

```
Command list-nodes executed successfully.
```

Example 2 Listing Only the Names of Payara Server Nodes

This example uses the `--terse` option of the `asadmin` utility to list only the names of the Payara Server nodes in the domain `domain1`.

```
asadmin> list-nodes --terse=true
localhost-domain1
sj02
sj01
devnode
```

Example 3 Listing Payara Server Nodes in Long Format

This example lists the Payara Server nodes in the domain `domain1` in long format.

```
asadmin> list-nodes --long=true
NODE NAME           TYPE     NODE HOST          INSTALL DIRECTORY     REFERENCED BY
localhost-domain1   CONFIG   localhost          /export/payara7
sj02                SSH      sj02.example.com   /export/payara7    pmd-i2, yml-i2
sj01                SSH      sj01.example.com   /export/payara7    pmd-i1, yml-i1
devnode             CONFIG   localhost          /export/payara7    pmdsa1
Command list-nodes executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

list-notifiers

List all available notifiers to the server.

Synopsis

```
asadmin [asadmin-options] list-notifiers
[--help]
[--target target]
```

Description

This command can be used to list all available notifiers.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 List current notifiers

```
asadmin>  list-notifiers
Available Notifier Services:
        cdieventbus-notifier
        eventbus-notifier
        log-notifier
        jms-notifier

Command list-notifiers executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `notification-configure`

list-password-aliases

Lists all password aliases.

Synopsis

```
asadmin [asadmin-options] list-password-aliases [--help]
```

Description

This subcommand lists all of the password aliases.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Listing all password aliases

```
asadmin> list-password-aliases
jmspassword-alias
Command list-password-aliases executed successfully
```

Exit Status

0

command executed successfully

1

error in executing the command

list-persistence-types

Lists registered persistence types for HTTP sessions and SFSB instances.

Synopsis

```
asadmin [asadmin-options] list-persistence-types [--help]
--type={web|ejb}
```

Description

The `list-persistence-types` subcommand lists registered persistence types for HTTP sessions and stateful session bean (SFSB) instances. The built-in persistence types are `memory`, `file`, and `hazelcast`. The `memory` type does not apply to SFSB instances.

Other persistence types can be added using the `StrategyBuilder` class.

To set the persistence type for HTTP sessions, use the `set` subcommand to set the `persistence-type` attribute. For example:

```
asadmin> set c1-config.availability-service.web-container-availability.persistence-
type=file
```

To set the persistence type for SFSB instances without availability enabled, use the `set` subcommand to set the `sfsb-persistence-type` attribute. For example:

```
asadmin> set c1-config.availability-service.ejb-container-availability.sfsb-
persistence-type=file
```

To set the persistence type for SFSB instances with availability enabled, use the `set` subcommand to set the `sfsb-ha-persistence-type` attribute. For example:

```
asadmin> set
c1-config.availability-service.ejb-container-availability.sfsb-ha-persistence-
type=hazelcast
```

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--type`

Specifies the type of sessions for which persistence types are listed. Allowed values are as follows:

- `web` — Lists persistence types for HTTP sessions.
- `ejb` — Lists persistence types for SFSB instances.

Examples

Example 1 Listing Persistence Types for HTTP Sessions

This example lists persistence types for HTTP sessions.

```
asadmin> list-persistence-types --type=web
memory
file
hazelcast
Command list-persistence-types executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

list-phone-home

List the current status of the Phone Home service.

Synopsis

```
asadmin> list-phone-home
```

Description

The phone home data is presently used to gather usage statistics about the corresponding distribution, such as how long users typically run instances, and what versions they use. This command shows whether the phone home service is enabled or disabled.

Examples

Example 1 List Phone Home Service

```
asadmin>  list-phone-home
Phone Home Service is enabled

Command list-phone-home executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `disable-phone-home`,
- `enable-phone-home`

list-protocol-filters

Lists the existing protocol filters.

Synopsis

```
asadmin [asadmin-options] list-protocol-filters [--help]
[--target server]
protocol-name
```

Description

The `list-protocol-filters` subcommand lists the existing protocol filters. This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

target

Restricts the listing to protocol filters for a specified target. Valid values are as follows:

`server`

Lists the protocol filters for the default server instance. This is the default value.

configuration-name

Lists the protocol filters for the specified configuration.

cluster-name

Lists the protocol filters for all server instances in the specified cluster.

instance-name

Lists the protocol filters for the specified server instance.

Operands

protocol-name

The name of the protocol for which to list protocol filters.

Examples

Example 1 Listing Protocol Filters

The following command lists all the protocol filters for the server instance:

```
asadmin> list-protocol-filters http1
http1-filter
https1-filter
Command list-protocol-filters executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-protocol-filter`,
- `delete-protocol-filter`

list-protocol-finders

Lists the existing protocol finders.

Synopsis

```
asadmin [asadmin-options] list-protocol-finders [--help]
[--target server]
protocol-name
```

Description

The `list-protocol-finders` subcommand lists the existing protocol finders.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

target

Restricts the listing to protocol finders for a specified target. Valid values are as follows:

`server`

Lists the protocol finders for the default server instance. This is the default value.

configuration-name

Lists the protocol finders for the specified configuration.

cluster-name

Lists the protocol finders for all server instances in the specified cluster.

instance-name

Lists the protocol finders for the specified server instance.

Operands

protocol-name

The name of the protocol for which to list protocol finders.

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-protocol-finder`,
- `delete-protocol-finder`

list-protocols

Lists the existing protocols.

Synopsis

```
asadmin [asadmin-options] list-protocols [--help]
[target]
```

Description

The `list-protocols` subcommand lists the existing protocols.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

Operands

target
: Restricts the listing to protocols for a specified target. Valid values are as follows:

  `server`
  : Lists the protocols for the default server instance. This is the default value.

  configuration-name
  : Lists the protocols for the specified configuration.

  cluster-name
  : Lists the protocols for all server instances in the specified cluster.

  instance-name
  : Lists the protocols for the specified server instance.

Examples

Example 1 Listing Protocols

The following command lists all the protocols for the server instance:

```
asadmin> list-protocols
admin-listener
http-1
http-listener-1
http-listener-2
Command list-protocols executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-protocol`,
- `delete-protocol`

list-requesttraces

Retrieves a list of request tracing service traces.

Synopsis

```
asadmin [asadmin-options] list-requesttraces [--help]
[--first] value
[--historicTraces={true|false}]
```

Description

This command can be used to list a number of previous request trace messages from either the current or historic trace stores of the Request Tracing Service.

The request tracing messages are in JSON format, so can be parsed by log parsing tools as if it were in the following format:

```
{
   "traceSpans":[
      {
```

```
         "operationName":"processContainerRequest",
         "spanContext":{
            "spanId":"61fa3c1c-9f62-43fe-8e55-faba2ce77f92",
            "traceId":"13bdc5c0-7827-4106-ad32-0242fb75a732"
         },
         "startTime":"2018-03-15T12:36:07.391Z[Europe/London]",
         "endTime":"2018-03-15T12:36:07.560Z[Europe/London]",
         "traceDuration":"169000000",
         "spanTags":[
            {
               "Server":"server"
            },
            {
               "Domain":"domain1"
            }
         ]
      },
      {
         "operationName":"authenticateJaspic",
         "spanContext":{
            "spanId":"fb929e4d-1477-4841-a088-0d07888608a6",
            "traceId":"13bdc5c0-7827-4106-ad32-0242fb75a732"
         },
         "startTime":"2018-03-15T12:36:07.391Z[Europe/London]",
         "endTime":"2018-03-15T12:36:07.392Z[Europe/London]",
         "traceDuration":"1000000",
         "spanTags":[
            {
               "Context":""
            },
            {
               "AppContext":"__asadmin "
            },
            {
               "AuthResult":"true"
            },
            {
               "Principal":"admin"
            }
         ]
      },
      {
         "operationName":"processServletRequest",
         "spanContext":{
            "spanId":"94cc4722-0990-4230-aa34-f0e0f629b1d8",

hi=treeForm:tree:nodes:hazelcast]"
            },
            {
               "QueryString":"bare=true"
            },
            {
               "Method":"GET"
            },
            {
               "URL":"http://localhost:4848/cluster/cluster/clusters.jsf"
            },
            {
               "accept":"[*/*]"
            },
            {
               "host":"[localhost:4848]"
            },
            {
               "connection":"[keep-alive]"
            },
            {
               "Class":"jakarta.faces.webapp.FacesServlet"
            },
            {
               "accept-encoding":"[gzip, deflate]"
            },
            {
               "user-agent":"[Mozilla/5.0 (X11; Linux x86_64; rv:52.0) Gecko/20100101
Firefox/52.0]"
            }
         ],
         "references":[
            {
               "spanContext":{
                  "spanId":"61fa3c1c-9f62-43fe-8e55-faba2ce77f92",
                  "traceId":"13bdc5c0-7827-4106-ad32-0242fb75a732"
               },
               "relationshipType":"ChildOf"
            }
         ]
      }
   ]
```

```
}
```

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--first`

Defaults to `false`. A limit for the number of Request Tracing messages to return in the output.

`--historicTraces`

Defaults to `true`. Whether to get the traces from the historic trace store or not.

Examples

Example 1 Retrieve Non-historic traces

```
asadmin> list-requesttraces --historictraces false
```

Will give an output similar to the following:

```
Occurring Time            Elapsed Time  Traced Message
2018-03-15T12:36:07.391Z  169           {"traceSpans":[

list-resource-adapter-configs

Lists the names of the current resource adapter configurations.

Synopsis

```
asadmin [asadmin-options] list-resource-adapter-configs [--help]
[--raname raname] [--verbose {false|true}]
```

Description

This command lists the configuration information in the `domain.xml` for the connector module. It lists an entry called `resource-adapter-config` in the `domain.xml` file. If the `--raname` option is specified, only the resource adapter configurations for the specified connector module are listed.

This command is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--raname`

Specifies the connector module name.

`--verbose`

Lists the properties that are configured. Default value is false.

Examples

Example 1 Listing the Resource Adapter Configurations

This example lists the current resource adapter configurations.

```
asadmin> list-resource-adapter-configs
ra1
ra2
Command list-resource-adapter-configs executed successfully
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-resource-adapter-config`,
- `delete-resource-adapter-config`

list-resource-refs

Lists existing resource references.

Synopsis

```
asadmin [asadmin-options] list-resource-refs [--help]
[target]
```

Description

The `list-resource-refs` subcommand lists all resource references in a cluster or an unclustered server instance. This effectively lists all the resources (for example, JDBC resources) available in the JNDI tree of the specified target.

The target instance or instances in the cluster need not be running or available for this subcommand to succeed.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

The target for which you are listing the resource references. Valid targets are as follows:

`server`

Lists the resource references for the default server instance and is the default target.

cluster_name

Lists the resource references for every server instance in the cluster.

instance_name

Lists the resource references for the named unclustered server instance.

Examples

Example 1 Listing Resource References for a Cluster

This example lists resource references for the cluster `cluster1`.

```
asadmin> list-resource-refs cluster1
jms/Topic
Command list-resource-refs executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-resource-ref`,
- `delete-resource-ref`

list-rest-endpoints

Lists all the rest endpoints of a deployed web application

Synopsis

```
asadmin [asadmin-options] list-rest-endpoints [--help]
[--componentname=componentname]
[appname]
```

Description

Lists all the rest endpoints of a deployed web application.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--componentname`

Name of the REST endpoint component to list.

Operands

`appname`

Name of the deployed application to list all of their rest endpoints.

Examples

Example 1 Listing all the rest endpoints for a deployed application

This example lists all the rest endpoints for the application `sse-producer`.

```
asadmin list-rest-endpoints sse-producer
GET     /sse-producer/rest/application.wadl
GET     /sse-producer/rest/sse/register
Command list-rest-endpoints executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

list-secure-admin-internal-users

Lists the user names that the Payara Server DAS and instances use to authenticate with each other and to authorize admin operations.

Synopsis

```
asadmin [asadmin-options] list-secure-admin-internal-users [--help]
[--long={false|true}]
[--output output]
[--header={false|true}]
[name]
```

Description

The `list-secure-admin-internal-users` subcommand lists the user names that the Payara Server DAS and instances use to authenticate with each other and to authorize admin operations.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Displays detailed information about each internal user. The default value is `false`.

`--output`

`-o`

Displays specific details about each internal user. Use a comma-separated list to specify the details you want to display and their order. The values are case-insensitive.
Possible values are as follows:

`username`

Displays the user name for the internal user.

`password-alias`

Displays the password alias for the internal user.

`--header`

`-h`

Specifies whether column headings are displayed when the `--long` option is used. The default value is `true`. To suppress the headings, set the `--header` option to `false`.

Operands

name

The user name for the internal user for which you want to display details.

Examples

Example 1 Listing the User Name for Secure Admin

This example lists the user names that the Payara Server DAS and instances use to authenticate with each other and to authorize admin operations.

```
asadmin> list-secure-admin-internal-users

Command list-secure-admin-internal-users executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `enable-secure-admin`,
- `enable-secure-admin-internal-user`

list-secure-admin-principals

Lists the certificates for which Payara Server accepts admin requests from clients.

Synopsis

```
asadmin [asadmin-options] list-secure-admin-principals [--help]
[--long={false|true}]
[--output output]
[--header={false|true}]
[name]
```

Description

The `list-secure-admin-principals` subcommand lists the certificates for which Payara Server accepts admin requests from clients.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Displays detailed information about the certificates for which Payara Server accepts admin requests from clients. The default value is `false`.

`--output`

`-o`

Displays specific details about the certificates for which Payara Server accepts admin requests from clients. Use a comma-separated list to specify the details you want to display and their order. The values are case-insensitive.
Possible values are as follows:

`DN`

Displays the distinguished name (DN) of each certificate.

`--header`

`-h`

Specifies whether column headings are displayed when the `--long` option is used. The default value is `true`. To suppress the headings, set the `--header` option to `false`.

Operands

name

The distinguished name of the certificate, specified as a comma-separated list in quotes. For example: `"CN=system.amer.oracle.com,OU=GlassFish,O=Oracle Corporation,L=Santa Clara,ST=California,C=US"`.

Examples

Example 1 Listing the Certificates

This example lists the certificates for which Payara Server accepts admin requests from clients.

```
asadmin> list-secure-admin-principals
CN=localhost,OU=Payara,O==Payara Foundation,L=Great Malvern,ST=Worcestershire,C=UK
```

```
CN=localhost-instance,OU=Payara,O=Payara Foundation,L=Great
Malvern,ST=Worcestershire,C=UK
Command list-secure-admin-principals executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `enable-secure-admin`,
- `enable-secure-admin-principal`

list-sub-components

Lists EJB or servlet components in a deployed module or module of a deployed application.

Synopsis

```
asadmin [asadmin-options] list-sub-components [--help]
[--type type]
[--appname appname] [--resources]
modulename
```

Description

The `list-sub-components` subcommand lists EJB or servlet components in a deployed module or in a module of a deployed application. If a module is not specified, all modules are listed. The `--appname` option functions only when the specified module is stand-alone. To display a specific module in an application, you must specify the module name with the `--appname` option.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--type`

Specifies the type of component to be listed. The options are `ejbs` and `servlets`. If nothing is specified, then all of the components are listed.

`--appname`

Identifies the name of the application. This option is required when the desired output is the subcomponents of an embedded module of a deployed application.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. For more information about module and application versions, see Module and Application Versions in Payara Server Application Deployment section.

`--resources`

Lists the application-scoped resources for each subcomponent.

Operands

modulename

Specifies the name of the module containing the subcomponent.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. For more information about module and application versions, see Module and Application Versions in Payara Server Application Deployment section.

Examples

Example 1 Listing Subcomponents

This example lists the subcomponents of the `MEjbApp` application within the `mejb.jar` module.

```
asadmin> list-sub-components --appname MEjbApp mejb.jar
MEJBBean <StatelessSessionBean>
Command list-sub-components executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

list-supported-cipher-suites

Enables administrators to list the cipher suites that are supported and available to a specified Payara Server target.

Synopsis

```
asadmin [asadmin-options] list-supported-cipher-suites [--help]
[--target target]
```

Description

The `list-supported-cipher-suites` subcommand enables administrators to list the cipher suites that are supported and available to a specified Payara Server target. The cipher suites that may be available in addition to the default SSL/TLS providers that are bundled with Payara Server packages will vary depending on the third-party provider.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--target`
: Specifies the target for which you want to list cipher suites. The following values are valid:

  `server`
  : Lists the cipher suites for the default server instance. This is the default value.

  configuration_name
  : Lists the cipher suites for the specified configuration.

  cluster_name
  : Lists the cipher suites for all server instances in the specified cluster.

  instance_name
  : Lists the cipher suites for a specified server instance.

Examples

Example 1 Listing cipher suites

The following example shows how to list cipher suites for the default domain.

```
asadmin> list-supported-cipher-suites
SSL_RSA_WITH_RC4_128_MD5
SSL_RSA_WITH_RC4_128_SHA
TLS_RSA_WITH_AES_128_CBC_SHA
TLS_DHE_RSA_WITH_AES_128_CBC_SHA
TLS_DHE_DSS_WITH_AES_128_CBC_SHA
SSL_RSA_WITH_3DES_EDE_CBC_SHA
SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA
SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA
SSL_RSA_WITH_DES_CBC_SHA
SSL_DHE_RSA_WITH_DES_CBC_SHA
SSL_DHE_DSS_WITH_DES_CBC_SHA
SSL_RSA_EXPORT_WITH_RC4_40_MD5
SSL_RSA_EXPORT_WITH_DES40_CBC_SHA
SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA
SSL_DHE_DSS_EXPORT_WITH_DES40_CBC_SHA
SSL_RSA_WITH_NULL_MD5
SSL_RSA_WITH_NULL_SHA
SSL_DH_anon_WITH_RC4_128_MD5
TLS_DH_anon_WITH_AES_128_CBC_SHA
SSL_DH_anon_WITH_3DES_EDE_CBC_SHA
SSL_DH_anon_WITH_DES_CBC_SHA
SSL_DH_anon_EXPORT_WITH_RC4_40_MD5
SSL_DH_anon_EXPORT_WITH_DES40_CBC_SHA

Command list-supported-cipher-suites executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

list-system-properties

Lists the system properties of the domain, configuration, cluster, or server instance.

Synopsis

```
asadmin [asadmin-options] list-system-properties [--help]
[target]
```

Description

Shared or clustered server instances will often need to override attributes defined in their referenced configuration. Any configuration attribute in a server instance can be overridden through a system property of the corresponding name. This list-system-properties subcommand lists the system properties of a domain, configuration, cluster, or server instance.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

This restricts the listing to system properties for a specific target. Valid values are:

domain

Lists the system properties defined for the domain.

configuration_name

Lists the system properties for the named configuration as well as those the cluster inherits from the domain.

cluster_name

Lists the system properties defined for the named cluster as well as those the cluster. inherits from its configuration and the domain.

instance_name

Lists the system properties defined for the named server instance as well as those the server inherits from its cluster (if the instance is clustered), its configuration, and the domain.

Examples

Example 1 Listing System Properties

This example lists the system properties on `localhost`.

```
asadmin> list-system-properties
http-listener-port=1088
Command list-system-properties executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-system-properties`,
- `delete-system-property`

list-threadpools

Lists all the thread pools.

Synopsis

```
asadmin [asadmin-options] list-threadpools [--help]
target
```

Description

The `list-threadpools` subcommand lists the Payara Server thread pools.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

This operand specifies the target for which you are listing thread pools. This operand is required.

Valid values are as follows:

`server`
: Lists the thread pools for the default Payara Server instance `server`.

configuration-name
: Lists the thread pools for the named configuration.

cluster-name
: Lists the thread pools for every instance in the cluster.

instance-name
: Lists the thread pools for a particular instance.

Examples

Example 1 Listing Thread Pools

This example lists the current thread pools for the default instance `server`.

```
asadmin> list-threadpools server
admin-thread-pool
http-thread-pool
thread-pool-1
Command list-threadpools executed successfully.
```

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `asadmin`,
- `create-threadpool`,
- `delete-threadpool`

list-timers

Lists all persistent timers owned by server instance(s).

Synopsis

```
asadmin [asadmin-options] list-timers [--help]
```

```
[target]
```

Description

The `list-timers` subcommand lists the persistent timers owned by a specific server instance or a cluster of server instances.

This command is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

The target is either a standalone server instance or a cluster. If the target is the stand-alone instance, then the number of timers owned by the instance is listed. If the target is a cluster, then the number of timers owned by each instance in the cluster is listed. The default target is `server`, the default server instance.

Examples

Example 1 Listing Current Timers in a Server Instance

This example lists persistent timers in a particular standalone server instance. There is one currently active timer set.

```
asadmin> list-timers server
1

The list-timers command was executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

list-transports

Lists the existing transports.

Synopsis

```
asadmin [asadmin-options] list-transports [--help]
[target]
```

Description

The `list-transports` subcommand lists the existing transports.

This subcommand is supported in remote mode only.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

Operands

target
: Restricts the listing to transports for a specified target. Valid values are as follows:

  `server`
  : Lists the transports for the default server instance. This is the default value.

  configuration-name
  : Lists the transports for the specified configuration.

  cluster-name
  : Lists the transports for all server instances in the specified cluster.

  instance-name
  : Lists the transports for the specified server instance.

Examples

Example 1 Listing Transports

The following command lists all the transports for the server instance:

```
asadmin> list-transports
http1-trans
tcp
Command list-transports executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

list-truststore-entries

Displays entries in the specified domain trust store

Synopsis

```
asadmin list-truststore-entries [--help]
[--verbose={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[alias]
```

Description

This command displays either all or a specific store entry from the target instance or listener's trust store.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are listing its truststore entries. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--verbose`

Whether to print the full entry details. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

Operands

alias

The alias name of the entry to list. If not provided then all entries in the truststore are listed.

Examples

Example 1 List all entries in the `production` domain's truststore

```
asadmin list-keystore-entries --domainName production
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- SSL Certificate Management,
- `generate-csr`,
- `renew-self-signed-certificates`,
- `add-to-keystore`,
- `add-to-truststore`

list-virtual-servers

Lists the existing virtual servers.

Synopsis

```
asadmin [asadmin-options] list-virtual-servers [--help]
[target]
```

Description

The `list-virtual-servers` subcommand lists the existing virtual servers.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

target

Restricts the listing to virtual servers for a specified target. Valid values are as follows:

`server`

Lists the virtual servers for the default server instance. This is the default value.

configuration-name

Lists the virtual servers for the specified configuration.

cluster-name

Lists the virtual servers for all server instances in the specified cluster.

instance-name

Lists the virtual servers for the specified server instance.

Examples

Example 1 Listing Virtual Servers

The following command lists all the virtual servers for the server instance:

```
asadmin> list-virtual-servers
server
__asadmin
Command list-virtual-servers executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- link:Technical Documentation/Payara Server Documentation/Command Reference/asadmin#asadmin-1m[`asadmin`,role=unresolved],
- link:Technical Documentation/Payara Server Documentation/Command Reference/create-virtual-server#create-virtual-server[`create-virtual-server`,role=unresolved],
- link:Technical Documentation/Payara Server Documentation/Command Reference/delete-virtual-server#delete-virtual-server[`delete-virtual-server`,role=unresolved]

list-web-context-param

Lists servlet context-initialization parameters of a deployed web application or module.

Synopsis

```
asadmin [asadmin-options] list-web-context-param [--help]
[--name=context-param-name] application-name[/module]
```

Description

The `list-web-context-param` subcommand lists the servlet context-initialization parameters of one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

The application must already be deployed. Otherwise, an error occurs.

The `list-web-context-param` subcommand lists only parameters that have previously been set by using the `set-web-context-param` subcommand. The subcommand does not list parameters that are set only in the application's deployment descriptor.

For each parameter, the following information is displayed:

- The name of the parameter
- The value to which the parameter is set
- The value of the `--ignoreDescriptorItem` option of the `set-web-context-param` subcommand that was specified when the parameter was set
- The description of the parameter or `null` if no description was specified when the parameter was set

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

The name of the servlet context-initialization parameter that is to be listed. If this option is omitted, all parameters of the application that have previously been set are listed.

Operands

application-name

The name of the application. This name can be obtained from the Administration Console or by using the `list-applications` subcommand.
The application must already be deployed. Otherwise, an error occurs.

module

The relative path to the module within the application's enterprise archive (EAR) file. The path to the module is specified in the `module` element of the application's `application.xml` file.
module is required only if the servlet context-initialization parameter applies to a web module of a Jakarta EE application. If specified, module must follow application-name, separated by a slash (/).
For example, the `application.xml` file for the `myApp` application might specify the following web module:

```
<module>
    <web>
        <web-uri>myWebModule.war</web-uri>
    </web>
</module>
```

The module would be specified as the operand of this command as `myApp/myWebModule.war`.

Examples

Example 1 Listing Servlet Context-Initialization Parameters for a Web Application

This example lists all servlet context-initialization parameters of the web application `basic-ezcomp` that have been set by using the `set-web-context-param` subcommand. Because no description was specified when the `javax.faces.PROJECT_STAGE` parameter was set, `null` is displayed instead of a description for this parameter.

```
asadmin> list-web-context-param basic-ezcomp
javax.faces.STATE_SAVING_METHOD = client ignoreDescriptorItem=false
//The location where the application's state is preserved
javax.faces.PROJECT_STAGE = null ignoreDescriptorItem=true //null
Command list-web-context-param executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `list-applications`,
- `set-web-context-param`,
- `unset-web-context-param`

list-web-env-entry

Lists environment entries for a deployed web application or module.

Synopsis

```
asadmin [asadmin-options] list-web-env-entry [--help]
[--name=env-entry-name] application-name[/module]
```

Description

The `list-web-env-entry` subcommand lists the environment entries for one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

The application must already be deployed. Otherwise, an error occurs.

The `list-web-env-entry` subcommand lists only entries that have previously been set by using the `set-web-env-entry` subcommand. The subcommand does not list environment entries that are set only in the application's deployment descriptor.

For each entry, the following information is displayed:

- The name of the entry
- The Java type of the entry
- The value to which the entry is set
- The value of the `--ignoreDescriptorItem` option of the `set-web-env-entry` subcommand that was specified when the entry was set
- The description of the entry or `null` if no description was specified when the entry was set

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

The name of the environment entry that is to be listed. The name is a JNDI name relative to the `java:comp/env` context. The name must be unique within a deployment component. If this option is omitted, all environment entries that have previously been set for the application are listed.

Operands

application-name

The name of the application. This name can be obtained from the Administration Console or by using the `list-applications` subcommand.
The application must already be deployed. Otherwise, an error occurs.

module

The relative path to the module within the application's enterprise archive (EAR) file. The path to the module is specified in the `module` element of the application's `application.xml` file.
module is required only if the environment entry applies to a web module of a Jakarta EE application. If specified, module must follow application-name, separated by a slash (/).
For example, the `application.xml` file for the `myApp` application might specify the following web module:

```
<module>
    <web>
        <web-uri>myWebModule.war</web-uri>
    </web>
</module>
```

```
The module would be specified as the operand of this command as
`myApp/myWebModule.war`.
```

Examples

Example 1 Listing Environment Entries for a Web Application

This example lists all environment entries that have been set for the web application `hello` by using the `set-web-env-entry` subcommand. Because no description was specified when the `Hello Port` environment entry was set, `null` is displayed instead of a description for this entry.

```
asadmin> list-web-env-entry hello
Hello User (java.lang.String) = techscribe ignoreDescriptorItem=false
 //User authentication for Hello appplication
Hello Port (java.lang.Integer) = null ignoreDescriptorItem=true //null

Command list-web-env-entry executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `list-applications`,
- `set-web-env-entry`,
- `unset-web-env-entry`

list

Lists configurable or monitorable elements.

Synopsis

```
asadmin [asadmin-options] list [--help]
[--monitor={false|true}]
[dotted-parent-attribute-name]
```

Description

The `list` subcommand lists configurable and monitorable attributes of Payara Server.

The output of the `list` subcommand is a list of the dotted names that represent individual server components and subsystems. For example, `server.applications.web-module`. After you know the particular component or subsystem, you can then use the `get` subcommand to access any attributes, and the `set` subcommand to modify configurable attributes.

The following rules apply to dotted names in a `list` subcommand:

Characters that have special meaning to the shell or command interpreter, such as * (asterisk), should be quoted or escaped as appropriate to the shell, for example, by enclosing the argument in quotes. In multimode, quotes are needed only for arguments that include spaces, quotes, or backslash.

- Any `list` subcommand that has a dotted name that is not followed by a wildcard (*) lists the current node's immediate children. For example, the following command lists all immediate children belonging to the server node:

  ```
  asadmin> list server
  ```

- Any `list` subcommand that has a dotted name followed by a wildcard(*) lists a hierarchical tree of child nodes from the current node. For example, the following command lists all child nodes of applications and their subsequent child nodes, and so on:

  ```
  asadmin> list server.applications.*
  ```

- Any `list` subcommand that has a dotted name preceded or followed by a wildcard **() of the**

form *dotted name or dottedname lists all nodes and their child nodes that match the regular expression created by the provided matching pattern.

For detailed information about dotted names, see the `dotted-names` help page.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--monitor`

`-m`

Defaults to false. If set to false, the configurable attribute values are returned. If set to true, the monitorable attribute values are returned.

Operands

dotted-parent-element-name

Configurable or monitorable element name

Examples

Example 1 Listing Dotted Names of Configurable Elements

This example lists the elements that can be configured.

```
asadmin> list *
applications
configs
configs.config.server-config
configs.config.server-config.admin-service
configs.config.server-config.admin-service.das-config
configs.config.server-config.admin-service.jmx-connector.system
configs.config.server-config.admin-service.property.adminConsoleContextRoot
configs.config.server-config.admin-service.property.adminConsoleDownloadLocation
configs.config.server-config.admin-service.property.ipsRoot
configs.config.server-config.ejb-container
configs.config.server-config.ejb-container.ejb-timer-service
configs.config.server-config.http-service
configs.config.server-config.http-service.access-log
configs.config.server-config.http-service.virtual-server.__asadmin
configs.config.server-config.http-service.virtual-server.server
configs.config.server-config.iiop-service
configs.config.server-config.iiop-service.iiop-listener.SSL
configs.config.server-config.iiop-service.iiop-listener.SSL.ssl
configs.config.server-config.iiop-service.iiop-listener.SSL_MUTUALAUTH
```

```
configs.config.server-config.iiop-service.iiop-listener.SSL_MUTUALAUTH.ssl
configs.config.server-config.iiop-service.iiop-listener.orb-listener-1
configs.config.server-config.iiop-service.orb
configs.config.server-config.java-config
configs.config.server-config.jms-service
configs.config.server-config.jms-service.jms-host.default_JMS_host
...
property.administrative.domain.name
resources
resources.jdbc-connection-pool.DerbyPool
resources.jdbc-connection-pool.DerbyPool.property.DatabaseName

servers.server.server
servers.server.server.resource-ref.jdbc/__TimerPool
servers.server.server.resource-ref.jdbc/__default
system-applications
Command list executed successfully.
```

Example 2 Listing Attributes of a Configurable Element

This example lists the attributes of the web container.

```
asadmin> list configs.config.server-config.web-container
configs.config.server-config.web-container
configs.config.server-config.web-container.session-config
Command list executed successfully.
```

Example 3 Listing Dotted Names of Monitorable Objects

This example lists the names of the monitorable objects that are enabled for monitoring.

```
asadmin> list --monitor *
server.jvm
server.jvm.class-loading-system
server.jvm.compilation-system
server.jvm.garbage-collectors
server.jvm.garbage-collectors.Copy
server.jvm.garbage-collectors.MarkSweepCompact
server.jvm.memory
```

```
server.jvm.operating-system
server.jvm.runtime
server.network
server.network.admin-listener
server.network.admin-listener.connections
server.network.admin-listener.file-cache
server.network.admin-listener.keep-alive
server.network.admin-listener.thread-pool
server.network.http-listener-1
server.network.http-listener-1.connections
server.network.http-listener-1.file-cache
server.network.http-listener-1.keep-alive
server.network.http-listener-1.thread-pool
server.transaction-service
Command list executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get`,
- `set`,
- `dotted-names`

login

Logs you into a domain.

Synopsis

```
asadmin [asadmin-options] login [--help]
```

Description

The purpose of the `login` subcommand is to ease domain administration by letting you log into a particular domain. If Payara Server domains are created on various machines (locally), you can run the `asadmin` utility from any of these machines and manage domains located elsewhere (remotely). This is especially useful when a particular machine is chosen as an administration client that manages multiple domains and servers.

The `login` subcommand prompts you for the administrator user name and password. After

successful login, the `.asadminpass` file is created in your home directory. (This is the same file that is modified when you run the `create-domain` subcommand with the `--savelogin` option.) The literal host name is stored, and no resolution with the DNS is attempted. If a domain is being administered from other machines, it is sufficient to run the `login` subcommand once. You do not need to specify the `asadmin` utility options `--user` and `--passwordfile` when you run additional remote subcommands on that domain. After you have logged into a domain, you still need to provide the host and port for any subsequent remote subcommands unless you chose the default values for `--host` (localhost) and `--port` (4848) options.

Subsequent use of same subcommand with the same parameters will result in overwriting the contents of the `.asadminpass` file for the given administration host and port. You can decide to overwrite the file or to reject such a login.

Login information is saved permanently and can be used across multiple domain restarts.

There is no `logout` subcommand. If you want to log in to another domain, run the `login` subcommand and specify new values for the `asadmin` utility options `--host` and `--port`.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Logging Into a Domain on a Remote Machine

This example logs into a domain located on another machine. Options are specified before the `login` subcommand.

```
asadmin --host foo --port 8282 login
Please enter the admin user name>admin
Please enter the admin password>

Trying to authenticate for administration of server at host [foo]
and port [8282] ...
Login information relevant to admin user name [admin] for host [foo]
and admin port [8282] stored at [/.asadminpass] successfully.
Make sure that this file remains protected. Information stored in this
file will be used by asadmin commands to manage associated domain.
```

Example 2 Logging Into a Domain on the Default Port of Localhost

This example logs into a domain on `mylhost` on the default port. Options are specified before the `login` subcommand.

```
asadmin --host myhost login
Please enter the admin user name>admin
Please enter the admin password>
Trying to authenticate for administration of server
at host [myhost] and port [4848] ...
An entry for login exists for host [myhost] and port [4848], probably
from an earlier login operation.
Do you want to overwrite this entry (y/n)?y
Login information relevant to admin user name [admin] for host [myhost]
and admin port [4848] stored at [/home/joe/.asadminpass] successfully.
Make sure that this file remains protected. Information stored in this
file will be used by asadmin commands to manage associated domain.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

migrate-timers

Moves EJB timers when a clustered instance was stopped or has crashed.

Synopsis

```
asadmin [asadmin-options] migrate-timers [--help]
[--target target_server_name]
server_name
```

Description

The `migrate-timers` subcommand moves EJB timers to a specified server when a server instance stops or crashes, if automatic timer migration is not enabled in the cluster configuration.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This is the target server instance. If this option is not specified, then DAS will find a server instance or multiple server instances. A migration notification will be sent to the selected server instances.

Operands

server_name

This is the server instance on which the timers are currently located. This server instance should not be running during the migration process.

Examples

Example 1 Migrating Timers

This example shows how to migrate timers from the server named `instance1` to a server named `instance2`.

```
asadmin> migrate-timers --target instance2 instance1
This command was successfully executed.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `list-timers`

monitor

Displays monitoring data for commonly used components and services.

Synopsis

```
asadmin [asadmin-options] monitor [--help]
--type type
[--interval interval]
[--filter filter]
instance-name
```

Description

The `monitor` subcommand displays statistics for commonly monitored Payara Server components and services. The `--type` option must be used to specify the object for which statistics are to be displayed.Data is displayed continuously in a tabular form, or the data can be displayed at a particular time interval by using the `--interval` option.

Before a given component or service can be monitored, monitoring must be enabled (set to HIGH or LOW) for the component or service by using the Administration Console, the enable-monitoring subcommand, or the set subcommand.

The monitor subcommand has options for filtering the results and capturing the output in a Comma Separated Values (CSV) file. The output appears in a table format. To view the legend of the table header, type `h`.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--type`

The component or service to monitor. This option is required. No default value is defined.

`httplistener`

For this type, the attribute `server.monitoring-service.module-monitoring-levels.http-service` must be set to LOW or HIGH.

Displays the following statistics for the HTTP listener service

`ec`

The total number errors in the processing of HTTP requests.

`mt`

The longest response time (in milliseconds) for the processing of a single HTTP request.

`pt`

The total amount of time (in milliseconds) that the HTTP listener service has spent in processing HTTP requests.

`rc`

The total number of requests that the HTTP listener service has processed.

`jvm`

For this type, the attribute `server.server-config.monitoring-service.module-monitoring-levels.jvm` must be set to LOW or HIGH.

Displays the following statistics for the Virtual Machine for the Java platform (Java Virtual Machine or JVM machine)

`UpTime`

The number of milliseconds that the JVM machine has been running since it was last started.

`min`

The initial amount of memory (in bytes) that the JVM machine requests from the operating system for memory management during startup.

`max`

The maximum amount of memory that can be used for memory management.

`low`

Retained for compatibility with other releases.

`high`

Retained for compatibility with other releases.

`count`

The amount of memory (in bytes) that is guaranteed to be available for use by the JVM machine.

`webmodule`

For this type, the attribute `server.server-config.monitoring-service.module-monitoring-levels.web-container` must be set to LOW or HIGH.

Displays the following statistics for all deployed web modules

`asc`

The number of currently active sessions.

`ast`

The total number of sessions that are currently active or have been active previously.

`rst`

The total number of rejected sessions.

`st`

The total number of sessions that have been created.

`ajlc`

The number of currently active JavaServer Pages (JSP) technology pages that are loaded.

`mjlc`

The maximum number of JSP technology pages that were active at any time simultaneously.

`tjlc`

Total number of JSP technology pages that have been loaded.

`aslc`

The number of currently active Java servlets that are loaded.

`mslc`

The maximum number of Java servlets that were active at any time simultaneously.

`tslc`

The total number of Java servlets that have been loaded.

`--interval`

The interval in seconds before capturing monitoring attributes. The interval must be greater than 0. The monitoring attributes are displayed on `stdout` until you type Control-C or `q`. The default value is 30.

`--filter`

Do not specify this option. This option is retained for compatibility with earlier releases. If you specify this option, a syntax error does not occur. Instead, the subcommand runs successfully and displays a warning message that the option is ignored.

Operands

instance-name

The server instance for which to view monitoring data. The default value is `server`.

Examples

Example 1 Displaying Monitoring Statistics by Interval

This example displays monitoring data for the JVM machine every 2000 seconds.

```
asadmin> monitor --type=jvm --interval 2000 server

JVM Monitoring
UpTime(ms)                Heap and NonHeap Memory(bytes)
current                   min         max         low         high        count
957843                    29523968    188284928   0           0           60370944

Command monitor executed successfully.
```

Example 2 Filtering the Monitoring Data

This example uses the filter option to show `http-listener-1` statistics.

```
asadmin> monitor --type httplistener --filter http-listener-1 server

HTTP Listener Monitoring: http-listener-1
br   bs   c200 c2xx c302 c304 c3xx c400 c401 c403 c404 c4xx c503 c5xx coc  co
ctc  ctb  ec   moc  mst  mt   mtm  mst  pt   rc
0    0    0    0    0    3    3    0    0    0    0    0    0    0    0    0
2    0    0    1    20   20   2    2    6    3
```

To see the legend for the table headings, type `h`.

```

monitoring

Reviewing the runtime state of components and services deployed in Payara Server.

Description

Monitoring is the process of reviewing the statistics of a system to improve performance or solve problems. By monitoring the state of various components and services deployed in Payara Server, performance bottlenecks can be identified, failures can be anticipated, and runtime standards can be established and observed. Data gathered by monitoring can also be useful in performance tuning and capacity planning.

The Payara Server monitoring service is enabled by default, that is, the `monitoring-enabled` attribute of the `monitoring-service` element is set to true. Once the monitoring service is enabled, a deployed module can then be enabled for monitoring by setting its monitoring level to `HIGH` or `LOW` (default is `OFF`).

Monitoring can be configured dynamically by using the Administration Console or the `enable-monitoring`/`disable-monitoring` and `set-monitoring-service-configuration` subcommands. The `set` subcommand can also be used with dotted names to enable or disable monitoring. However, a server restart is required for changes made by using the `set` subcommand to take effect.

Monitoring data can be viewed by using the Administration Console or by using the subcommands of the `asadmin` utility.

- The `monitor` subcommand displays monitoring data for a given type, similar to the UNIX `top` command. The data is presented at given intervals.
- The `list` and `get` subcommands display comprehensive data. Both use dotted names to specify monitorable objects.

Alternate tools for monitoring Payara Server components and services include JConsole and the REST interface.

The Monitoring Scripting Client or DTrace Monitoring can be used to start the available monitoring probes. Using these tools is helpful in identifying performance issues during runtime.

Monitoring Scripting Client or DTrace Monitoring are only usable if their modules are present.

multimode

Allows multiple subcommands to be run while preserving environment settings and remaining in the asadmin utility.

Synopsis

```
asadmin [asadmin-options] multimode [--help]
[--file filename]
[--printprompt={true|false}] [--encoding encode]
```

Description

The `multimode` subcommand processes `asadmin` subcommands sequentially in a single session. The command-line interface prompts for a subcommand, runs that subcommand, displays the results of that subcommand, and then prompts for the next subcommand. All the `asadmin` options set in multimode apply to subsequent commands until the multimode session is exited. You exit `multimode` by typing `exit`, `quit`, or Ctrl-D.

You can use the `export` subcommand to set your environment, or use the `unset` subcommand to remove environment variables from the multimode environment.

You can also provide subcommands by passing a previously prepared list of subcommands from a file or standard input (pipe). When you use a file, you can include comment lines in the file by entering the hash symbol (`#`) as the first character of the line.

You can invoke `multimode` from within a multimode session. When you exit the second multimode environment, you return to your original multimode environment.

All the remote `asadmin` utility options can be supplied when invoking the `multimode` subcommand. The settings will apply as defaults for all subcommands that are run within the multimode session. For a list of the `asadmin` utility options, see the `asadmin` help page.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--file`

`-f`

Reads the subcommands in the specified file.

`--printprompt`

Controls printing of the `asadmin` prompt. By default, this option is set to the same value as the `--interactive` `asadmin` utility option. Normally you will not need to specify this option. Default is true.

`--encoding`

Specifies the character set for the file to be decoded. By default, the system character set is used.

Examples

Example 1 Starting a Multimode Session

This example starts a multimode session where: `%` is the system prompt.

```
% asadmin multimode
asadmin>
```

You can also start a multimode session by typing `asadmin` without options or subcommands at the system prompt.

Example 2 Running Multiple Commands From a File

This example runs a sequence of subcommands from the `commands_file.txt` file.

```
% asadmin multimode --file commands_file.txt
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

notification-configure

Configures the notification service.

Synopsis

```
asadmin [asadmin-options] notification-configure
```

```
[--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
```

Description

This command can be used to configure the behaviour of the log notifier in Payara Server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the notification service. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the notification service

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Examples

Example 1 Enables the notification service

```
asadmin> notification-configure --enabled=true --dynamic=true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

osgi-shell

Provides interactive access to the Apache Felix Gogo remote shell for the execution of OSGi shell commands.

Synopsis

```
asadmin [asadmin-options] osgi-shell [--help]
[--file file]
[--printprompt={false|true}]
[--encoding encoding]
```

Description

The `osgi-shell` subcommand provides interactive access to the Apache Felix Gogo remote shell for the execution of OSGi shell commands. The remote shell is provided with Payara Server and used to administer and inspect the OSGi runtime.

OSGi shell commands are executed on the server and results are printed on the client. Because the shell is interactive, no operands are accepted. Scripting is supported, which means that multiple commands can be executed in sequence from a text file.

A related subcommand is the `osgi` subcommand, which passes a single command to the remote shell for execution. Results are returned by the `asadmin` utility. For more information about the `osgi` subcommand, see the `osgi` help page.

This subcommand is supported in local mode only. Unlike other local subcommands, however, the domain administration server (DAS) and the server instance whose shell is being accessed must be running.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--file`

`-f`

Reads the commands in the specified file.

`--printprompt`

Controls printing of the shell prompt. The default value is `true`, which means the shell prompt is displayed.

`--encoding`

Specifies the character set for the file to be decoded. By default, the system character set is used.

Examples

Example 1 Listing Apache Felix Gogo Remote Shell Commands

This example lists Apache Felix Gogo remote shell commands.

Some lines of output are omitted from this example for readability.

```
asadmin> osgi-shell
Use "exit" to exit and "help" for online help.
gogo$ help
felix:bundlelevel
felix:cd
felix:frameworklevel
felix:headers
felix:help
felix:inspect
felix:install
felix:lb
felix:log
felix:ls
...
gogo:cat
gogo:each
gogo:echo
gogo:format
gogo:getopt
gogo:gosh
gogo:grep
...
gogo$
```

Example 2 Running a Remote Shell Command

This example runs the Felix Remote Shell Command `lb` without any arguments to list all installed OSGi bundles.

Some lines of output are omitted from this example for readability.

```
asadmin> osgi-shell
Use "exit" to exit and "help" for online help.
gogo$ lb
START LEVEL 2
ID|State      |Level|Name
 0|Active     |    0|System Bundle
 1|Active     |    1|Metro Web Services API OSGi Bundle
 2|Active     |    1|jakarta.annotation API
 3|Active     |    1|jaxb-api
...
gogo$
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- `osgi`

osgi

Delegates the command line to the Apache Felix Gogo remote shell for the execution of OSGi shell commands.

Synopsis

```
asadmin [asadmin-options] osgi [--help]
[--session session]
[--session-id session-id]
[--instance instance]
[command_line]
```

Description

The `osgi` subcommand delegates the command line to the Apache Felix Gogo remote shell for the execution of OSGi shell commands. Commands are executed by the remote shell and results are returned by the `asadmin` utility. The remote shell is provided with Payara Server and used to

administer and inspect the OSGi runtime.

Multiple command-line sessions can be created. Use the `--session` and `--session-id` options to run commands in a specific command-line session. If no session is specified, a new session is created to run commands and closed when execution completes.

A related subcommand is the `osgi-shell` subcommand, which enables you to run multiple commands from a file or run commands interactively. For more information about the `osgi-shell` subcommand, see the `osgi-shell` help page.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the `osgi` subcommand.

`--session`

Performs command-line session operations. Valid values are:

`new`

Creates a new session and returns a session ID.

`stop`

Stops the session with the specified session ID.

`list`

Lists all active sessions.

`execute`

Runs a command in the session with the specified session ID.

`--session-id`

Specifies the session ID for command-line session operations.

`--instance`

Specifies the server instance to which the command is being delegated.
The default is the domain administration server (DAS). The DAS must be running to run a command on another instance.

Operands

command_line

The complete command-line syntax as provided for commands in the Apache Felix Gogo remote shell.

Examples

Example 1 Listing Apache Felix Gogo Remote Shell Commands

This example lists the Apache Felix Gogo remote shell commands that can be used with the `osgi` subcommand.

Some lines of output are omitted from this example for readability.

```
asadmin> osgi help
felix:bundlelevel
felix:cd
felix:frameworklevel
felix:headers
felix:help
felix:inspect
felix:install
felix:lb
felix:log
felix:ls
felix:refresh
felix:resolve
...
gogo:cat
gogo:each
gogo:echo
gogo:format
gogo:getopt
gogo:gosh
gogo:grep
...
Command osgi executed successfully.
```

Example 2 Running a Remote Shell Command

This example runs the Felix Remote Shell Command `lb` without any arguments to list all installed OSGi bundles.

Some lines of output are omitted from this example for readability.

```
asadmin> osgi lb
START LEVEL 2
ID|State      |Level|Name
 0|Active     |    0|System Bundle
 1|Active     |    1|Metro Web Services API OSGi Bundle
 2|Active     |    1|jakarta.annotation API
 3|Active     |    1|jaxb-api
...
Command osgi executed successfully.
```

Example 3 Running Commands That Create and Target a Specific Command-Line Session

This example runs commands that create and target a specific command-line session.

Some lines of output are omitted from this example for readability.

```
asadmin> osgi --session new
9537e570-0def-4f2e-9c19-bc8f51a8082f
...
asadmin> osgi --session list
9537e570-0def-4f2e-9c19-bc8f51a8082f
...
asadmin> osgi --session execute --session-id 9537e570-0def-4f2e-9c19-bc8f51a8082f lb

START LEVEL 2
ID|State      |Level|Name
 0|Active     |    0|System Bundle
 1|Active     |    1|Metro Web Services API OSGi Bundle
 2|Active     |    1|jakarta.annotation API
 3|Active     |    1|jaxb-api
...
asadmin> osgi --session stop --session-id 9537e570-0def-4f2e-9c19-bc8f51a8082f

Command osgi executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- asadmin,
- osgi-shell

package-appclient

Packs the application client container libraries and jar files.

Synopsis

```
package-appclient
```

Description

Use the `package-appclient` command to pack the application client container libraries and jar files into an `appclient.jar` file, which is created in the `as-install/lib` directory on the machine on which Payara Server is installed. The `appclient.jar` file provides an application client container package targeted at remote hosts that do not contain a server installation.

After copying the `appclient.jar` file to a remote location, unjar or unzip it to get a set of libraries and jar files in the `appclient` directory under the current directory.

After unjarring on the client machine, modify `appclient/glassfish/config/asenv.conf` (`asenv.bat` for Windows) as follows:

- set `AS_WEBSERVICES_LIB` to path-to-appclient`/appclient/lib`
- set `AS_IMQ_LIB` to path-to-appclient`/appclient/mq/lib`
- set `AS_INSTALL` to path-to-appclient`/appclient`
- set `AS_JAVA` to your JDK 7 or JRE 7 home directory
- set `AS_ACC_CONFIG` to path-to-appclient`/appclient/glassfish/domains/domain1/config/sun-acc.xml`

Modify `appclient/glassfish/domains/domain1/config/sun-acc.xml` as follows:

- Ensure the `DOCTYPE` file references path-to-appclient`/appclient/glassfish/lib/dtds`
- Ensure that `target-server` address attribute references the server machine.
- Ensure that `target-server` port attribute references the ORB port on the remote machine.
- Ensure that `log-service` references a log file; if the user wants to put log messages to a log file.

To use the newly installed application client container, you must do the following:

- Obtain the application client files for your target application, including the generated yourAppClient.jar file.
- Execute the `appclient` utility: `appclient -`client yourAppClient.jar

Attributes

See `attributes` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Unstable

See Also

- `appclient`

ping-connection-pool

Tests if a connection pool is usable.

Synopsis

```
asadmin [asadmin-options] ping-connection-pool [--help]
pool_name
[--appname application [--modulename module]
```

Description

The `ping-connection-pool` subcommand tests if an existing JDBC or connector connection pool is usable . For example, if you create a new JDBC connection pool for an application that is expected to be deployed later, the JDBC pool is tested with this subcommand before deploying the application.

Before testing availability of a connection pool, you must create the connection pool with authentication and ensure that the server or database is started.

This subcommand is supported in remote mode only.

Application Scoped Resources

The `ping-connection-pool` subcommand can target resources that are scoped to a specific application or module, as defined in the `glassfish-resources.xml` or `payara-resources.xml` for the Payara Server domain.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

- To reference the `jndi-name` for an application scoped resource, perform the lookup using the `java:app` prefix.
- To reference the `jndi-name` for a module scoped resource, perform the lookup using the `java:module` prefix.

The `jndi-name` for application-scoped-resources or module-scoped-resources are specified using the format `java:app/`jdbc/myDataSource or `java:module/`jdbc/myModuleLevelDataSource`.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--appname`

Name of the application in which the application scoped resource is defined.

`--modulename`

Name of the module in which the module scoped resource is defined.

Operands

pool_name

Name of the connection pool to be reinitialized.

Examples

Example 1 Contacting a Connection Pool

This example tests to see if the connection pool named `DerbyPool` is usable.

```
asadmin> ping-connection-pool DerbyPool
Command ping-connection-pool executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-connector-connection-pool`,
- `create-jdbc-connection-pool`,
- `delete-connector-connection-pool`,
- `delete-jdbc-connection-pool`,
- `list-connector-connection-pools`,
- `list-jdbc-connection-pools`

ping-node-ssh

Tests if a node that is enabled for communication over SSH is usable.

Synopsis

```
asadmin [asadmin-options] ping-node-ssh [--help]
[--validate={false|true}] node-name
```

Description

The `ping-node-ssh` subcommand tests if a node that is enabled for communication over secure shell (SSH) is usable. This subcommand requires secure shell (SSH) to be configured on the machine where the domain administration server (DAS) is running and on the machine where the node

resides. You may run this command from any machine that can contact the DAS.

If the node is usable, the subcommand displays a confirmation that the subcommand could connect to the node through SSH. This confirmation includes the name of the host that the node represents.

Optionally, the subcommand can also validate the node to determine if the `asadmin` utility can run on the host that the node represents. To validate a node, the subcommand runs the `version` subcommand. If the node is valid, the subcommand displays the version that the `version` subcommand returns.

The node that is specified as the operand of this subcommand must be enabled for communication over SSH. If the node is not enabled for communication over SSH, an error occurs. To determine whether a node is enabled for communication over SSH, use the `list-nodes` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--validate`

Specifies whether the subcommand validates the node.
Possible values are as follows:

`true`

The node is validated.

`false`

The node is not validated (default).

Operands

node-name

The name of the node to test. The node must be enabled for communication over SSH. Otherwise, an error occurs.

Examples

Example 1 Testing if an SSH-Enabled Node Is Usable

This example tests if the SSH-enabled node `sj03-node` is usable.

```
asadmin> ping-node-ssh sj03-node
Successfully made SSH connection to node sj03-node (sj03.example.com)
```

```
Command ping-node-ssh executed successfully.
```

Example 2 Validating an SSH-Enabled Node

This example validates the SSH-enabled node `adc-node`.

```
asadmin> ping-node-ssh --validate=true adc-node
Successfully made SSH connection to node adcnode (adc.example.com)
GlassFish version found at /export/payara:
Using locally retrieved version string from version class.
Version = Payara Server main-7 #badassfish (build 00)
Command version executed successfully.
Command ping-node-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `delete-node-ssh`,
- `list-nodes`,
- `setup-ssh`,
- `update-node-ssh`,
- `version`

print-certificate

Prints legible and detailed information of one or multiple SSL certificate and key entries.

Synopsis

```
asadmin [asadmin-options] print-certificate [--help]
[--certificatealias certificatealias]
[--providerclass providerclass]
[file]
```

Description

The `print-certificate` subcommand is useful to print legible and detailed information of one or multiple SSL certificate and key entries.

Since the output generated by the standard keytool utility is not standardized (especially distinguished names since they usually they use RFC 1779), it is recommended to use this command instead.

See Printing Certificate Data for more information.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--certificatealias`

If the file is a keystore, this is an alias used to access the certificate.

`--providerclass`

The name of a custom `java.security.Provider` implementation class to be preferred in this command execution

Operands

file

File containing the certificate

Examples

Example 1 Printing a DER certificate with one entry

This example prints a DER certificate with one entry.

```
asadmin print-certificate ./certificate.der

Found Certificate:
Subject:    UID=LDAP-
Test,EMAILADDRESS=nobody@nowhere.space,CN=PrintCertificateCommandTest,OU=Test Test\,
Test,O=Payara Foundation,L=Pilsen,C=CZ
Validity:   Thu Aug 01 02:00:00 CEST 2019 - Fri Aug 02 02:00:00 CEST 2019
S/N:        1
Version:    3
Issuer:     UID=LDAP-

```

```
Public Key: RSA, 2048 bits
Sign. Alg.: SHA256withRSA (OID: 1.2.840.113549.1.1.11)
Command print-certificate executed successfully.
```

Example 2 Printing a specific certificate using a P12 format keystore

This example prints a specific certificate using a P12 format keystore.

```
asadmin> print-certificate --certificatealias s1as ./keystore.p12

Keystore Password>
Found Certificate:
Subject:    CN=localhost,OU=Payara,O=Payara Foundation,L=Great
Malvern,ST=Worcestershire,C=UK
Validity:   Tue Aug 06 14:06:14 CEST 2019 - Fri Aug 03 14:06:14 CEST 2029
S/N:        886895448
Version:    3
Issuer:     CN=localhost,OU=Payara,O=Payara Foundation,L=Great
Malvern,ST=Worcestershire,C=UK
Public Key: RSA, 2048 bits
Sign. Alg.: SHA256withRSA (OID: 1.2.840.113549.1.1.11)
Command print-certificate executed successfully.
```

Example 3 Plugging an alternative provider

This example plugins a different `java.security.Provider` implementation to get different outputs when running the `print-certificate` command. In this example, we use the **BouncyCastle** library, which leads to one significant difference: A highlighted, uppercase signature's algorithm name.

```
#Copy the library to the asadmin lib directory first
cp .../bcprov-jdk15on-1.62.jar .../payara7/glassfish/lib/asadmin/

purge-jbatch-repository

Purges the current Jakarta Batch repository.

Synopsis

```
asadmin [asadmin-options] purge-jbatch-repository [--help]
[app-tag]
```

Description

The `purge-jbatch-repository` subcommand will purge the current Jakarta Batch repository of all jobs scheduled for the referenced application's tag.

The command will remove all current jobs created by the referenced application whether these jobs are running or not.

If you are having trouble finding the application's tag for your application, you can get it programmatically on a Java EE application by using the following code:

```
import com.ibm.jbatch.container.servicesmanager.ServicesManager;
import com.ibm.jbatch.container.servicesmanager.ServicesManagerImpl;
import com.ibm.jbatch.container.services.IPersistenceManagerService;
...

JobOperator jobOperator = getJobOperator();
Long executionId = jobOperator.start("job-name", new Properties());

ServicesManager manager = ServicesManagerImpl.getInstance();
IPersistenceManagerService ps = manager.getPersistenceManagerService();
String applicationTag = ps.getJobCurrentTag(jobid);
```

If using Maven, you'll have to add a dependency to IBM's **JBatch Container Runtime** to your

project to access the classes referenced above:

```
<dependency>
    <groupId>com.ibm.jbatch</groupId>
    <artifactId>com.ibm.jbatch.container</artifactId>
    <version>2.1.1</version>
    <scope>provided</scope>
</dependency>
```

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

app-tag

The application tag whose Jakarta Batch jobs will be purged from the repository.

The application's tag is structured like this:

```
<Configuration Identifier>:<Application Name>__/<Application Name>
```

Where **Configuration Identifier** is the identifier of the configuration associated to the instance or cluster where the application is deployed and **Application Name** is the name of the deployed application.

See the description of the command on how to acquire the application's tag in a programmatic manner.

Examples

To remove all current jobs for an application named *jbatch-test* deployed on the DAS (`server-config`) then run the following command:

```
asadmin> purge-jbatch-repository "server-config:jbatch-test__/jbatch-test"
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

recover-transactions

Manually recovers pending transactions.

Synopsis

```
asadmin [asadmin-options] recover-transactions [--help]
[--transactionlogdir transaction_log_dir]
[--target target_server_name] server_name
```

Description

The `recover-transactions` subcommand manually recovers pending transactions.

For an installation of multiple server instances, you can run the `recover-transactions` subcommand from a surviving server instance to recover transactions after a server failure. To use this subcommand in this way, the following conditions must be met:

- Delegated transaction recovery is disabled.
- Transaction logs are stored on a shared file system or in a database that is accessible to all server instances.

For a stand-alone server, do not use this subcommand to recover transactions after a server failure. For a stand-alone server, the `recover-transactions` subcommand can recover transactions only when a resource fails, but the server is still running. If a stand-alone server fails, only the full startup recovery process can recover transactions that were pending when the server failed.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--transactionlogdir`

The location of the transaction logs for a server for which transaction recovery is requested. This option applies only if transaction logs are stored on a shared file system.

`--target`

The target server that performs the recovery for the server that is specified by the server_name operand. The target server should be running.

Operands

server_name

For a stand-alone server, the value of this operand is typically `server`. Transactions are recovered only if a resource fails, but the server is still running.
For an installation of multiple server instances, the value of this operand is the name of the server for which the recovery is required. The in-flight transactions on this server will be recovered. If this server is running, recovery is performed by the same server. In this situation, the `--transactionlogdir` and `--target` options should be omitted. If the server is not running, the `--target` option is required, and the `--transactionlogdir` option is also required if transaction logs are stored on a shared file system.

Examples

Example 1 Recovering transactions on a running server

```
% asadmin recover-transactions server1
Transaction recovered.
```

Example 2 Recovering transactions for a server that is not running

```
% asadmin recover-transactions --transactionlogdir /logs/tx --target server1 server2
Transaction recovered.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,

- `rollback-transaction`,
- `unfreeze-transaction-service`
- Administering Transactions" in Payara Server General Administration section,
- Transactions

redeploy

Redeploys the specified component.

Synopsis

```
asadmin [asadmin-options] redeploy [--help]
--name component_name
[--upload={true|false}]
[--retrieve local_dirpath]
[--dbvendorname dbvendorname]
[--deploymentplan deployment_plan]
[--altdd alternate_deploymentdescriptor]
[--runtimealtdd runtime_alternate_deploymentdescriptor]
[--deploymentorder deployment_order]
[--enabled={true|false}]
[--generatermistubs={false|true}]
[--contextroot context_root]
[--precompilejsp={true|false}]
[--verify={false|true}]
[--virtualservers virtual_servers]
[--availabilityenabled={false|true}]
[--asyncreplication={true|false}]
[--lbenabled={true|false}]
[--keepstate={false|true}]
[--libraries jar_file[,jar_file]*]
[--target target]
[--type pkg-type]
[--properties(name=value)[:name=value]*]
[--warlibs={false|true}]
[file_archive|filepath]
```

Description

The `redeploy` subcommand redeploys an enterprise application, web application, module based on the Enterprise JavaBeans (EJB) specification (EJB module), connector module, or application client module that is already deployed or already exists. The `redeploy` subcommand preserves the settings and other options with which the application was originally deployed. The application must already be deployed. Otherwise, an error occurs.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--virtualservers`

One or more virtual server IDs. Multiple IDs are separated by commas.

`--contextroot`

Valid only if the archive is a web module. It is ignored for other archive types; it will be the value specified by default-context-path in web.xml, if specified; defaults to filename without extension.

`--precompilejsp`

By default this option does not allow the JSP to be precompiled during deployment. Instead, JSPs are compiled during runtime. Default is `false`.

`--verify`

If set to true and the required verifier packages are installed from the Update Tool, the syntax and semantics of the deployment descriptor is verified. Default is `false`.

`--name`

Name of the deployable component.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. For more information about module and application versions, see Module and Application Versions in Payara Server Application Deployment section.

`--upload`

Specifies whether the subcommand uploads the file to the DAS. In most situations, this option can be omitted.
Valid values are as follows:

`false`

The subcommand does not upload the file and attempts to access the file through the specified file name. If the DAS cannot access the file, the subcommand fails.
For example, the DAS might be running as a different user than the administration user and does not have read access to the file. In this situation, the subcommand fails if the `--upload` option is `false`.

`true`

The subcommand uploads the file to the DAS over the network connection.
The default value depends on whether the DAS is on the host where the subcommand is run or is on a remote host.

- If the DAS is on the host where the subcommand is run, the default is `false`.
- If the DAS is on a remote host, the default is `true`.
  If a directory filepath is specified, this option is ignored.

`--retrieve`

Retrieves the client stub JAR file from the server machine to the local directory.

`--dbvendorname`

Specifies the name of the database vendor for which tables are created. Supported values include `h2`, `db2`, `mssql`, `oracle`, `derby`, `javadb`, `postgresql`, and `sybase`, case-insensitive. If not specified, the value of the `database-vendor-name` attribute in `glassfish-ejb-jar.xml` is used. If the connection cannot be established, or if the value is not valid, SQL-92 compliance is presumed.

`--deploymentplan`

Deploys the deployment plan, which is a JAR file that contains Payara Server descriptors. Specify this option when deploying a pure EAR file. A pure EAR file is an EAR without Payara Server descriptors.

`--altdd`

Deploys the application using a Jakarta EE standard deployment descriptor that resides outside of the application archive. Specify an absolute path or a relative path to the alternate deployment descriptor file. The alternate deployment descriptor overrides the top-level deployment descriptor packaged in the archive. For example, for an EAR, the `--altdd` option overrides `application.xml`. For a standalone module, the `--altdd` option overrides the top-level module descriptor such as `web.xml`.

`--runtimealtdd`

Deploys the application using a Payara Server runtime deployment descriptor that resides outside of the application archive. Specify an absolute path or a relative path to the alternate deployment descriptor file. The alternate deployment descriptor overrides the top-level deployment descriptor packaged in the archive. For example, for an EAR, the `--runtimealtdd` option overrides `payara-application.xml`. For a standalone module, the `--runtimealtdd` option overrides the top-level module descriptor such as `glassfish-web.xml` (deprecated) or `payara-web.xml`. Applies to Payara Server deployment descriptors only (`glassfish-.xml/payara-.xml`); the name of the alternate deployment descriptor file must begin with `glassfish-` (or `payara-` in specific cases). Does not apply to `sun-*.xml` deployment descriptors, which are deprecated.

`--deploymentorder`

Specifies the deployment order of the application. This is useful if the application has dependencies and must be loaded in a certain order at server startup. The deployment order is specified as an integer. The default value is 100. Applications with lower numbers are loaded before applications with higher numbers. For example, an application with a deployment order of 102 is loaded before an application with a deployment order of 110. If a deployment order is not specified, the default value of 100 is assigned. If two applications have the same deployment order, the first application to be deployed is the first application to be loaded at server startup.
The deployment order is typically specified when the application is first deployed but can also be specified or changed after initial deployment using the `set` subcommand. You can view the deployment order of an application using the `get` subcommand.

`--enabled`

Allows users to access the application. If set to `false`, users will not be able to access the application. This option enables the application on the specified target instance or cluster. If you deploy to the target `domain`, this option is ignored, since deploying to the domain doesn't deploy to a specific instance or cluster. The default is `true`.

`--generatermistubs`

If set to `true`, static RMI-IIOP stubs are generated and put into the `client.jar`. If set to `false`, the stubs are not generated. Default is `false`.

`--availabilityenabled`

This option controls whether high-availability is enabled for web sessions and for stateful session bean (SFSB) checkpointing and potentially passivation. If set to false (default) all web session saving and SFSB checkpointing is disabled for the specified application, web application, or EJB module. If set to true, the specified application or module is enabled for high-availability. Set this option to true only if high availability is configured and enabled at higher levels, such as the server and container levels.

`--asyncreplication`

This option controls whether web session and SFSB states for which high availability is enabled are first buffered and then replicated using a separate asynchronous thread. If set to `true` (default), performance is improved but availability is reduced. If the instance where states are buffered but not yet replicated fails, the states are lost. If set to `false`, performance is reduced but availability is guaranteed. States are not buffered but immediately transmitted to other instances in the cluster.

`--lbenabled`

This option controls whether the deployed application is available for load balancing. The default is `true`.

`--keepstate`

This option controls whether web sessions, SFSB instances, and persistently created EJB timers are retained between redeployments.

The default is false. This option is supported only on the default server instance, named `server`. It is not supported and ignored for any other target.

Some changes to an application between redeployments prevent this feature from working properly. For example, do not change the set of instance variables in the SFSB bean class.

For web applications, this feature is applicable only if in the `payara-web.xml` file the `persistence-type` attribute of the `session-manager` element is `file`.

For stateful session bean instances, the persistence type without high availability is set in the server (the `sfsb-persistence-type` attribute) and must be set to `file`, which is the default and recommended value.

If any active web session, SFSB instance, or EJB timer fails to be preserved or restored, none of these will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.

To preserve active state data, Payara Server serializes the data and saves it in memory. To restore the data, the class loader of the newly redeployed application deserializes the data that was previously saved.

`--warlibs`

If set to true, enables an application to make use of shared libraries installed to `domain_dir/lib/warlibs`. Default is false. This parameter takes precedence over enabling warlibs in --properties.

`--libraries`

A comma-separated list of library JAR files. Specify the library JAR files by their relative or absolute paths. Specify relative paths relative to domain-dir`/lib/applibs`. The libraries are made available to the application in the order specified.

`--target`

Specifies the target to which you are deploying. Valid values are:

`server`

Deploys the component to the default server instance `server` and is the default value.

`domain`

Deploys the component to the domain. If `domain` is the target for an initial deployment, the application is deployed to the domain, but no server instances or clusters reference the application. If `domain` is the target for a redeployment, and dynamic reconfiguration is enabled for the clusters or server instances that reference the application, the referencing clusters or server instances automatically get the new version of the application. If redeploying, and dynamic configuration is disabled, the referencing clusters or server instances do not get the new version of the application until the clustered or standalone server instances are restarted.

cluster_name

Deploys the component to every server instance in the cluster.

instance_name

Deploys the component to a particular stand-alone server instance.

`--type`

The packaging archive type of the component that is being deployed. Possible values are as follows:

`car`

The component is packaged as a CAR file.

`ear`

The component is packaged as an EAR file.

`ejb`

The component is an EJB packaged as a JAR file.

`osgi`

The component is packaged as an OSGi bundle.

`rar`

The component is packaged as a RAR file.

`war`

The component is packaged as a WAR file.

`--properties` **or** `--property`

Optional keyword-value pairs that specify additional properties for the deployment. The available properties are determined by the implementation of the component that is being deployed or redeployed. The `--properties` option and the `--property` option are equivalent. You can use either option regardless of the number of properties that you specify.
You can specify the following properties for a deployment:

`jar-signing-alias`

Specifies the alias for the security certificate with which the application client container JAR file is signed. Java Web Start will not run code that requires elevated permissions unless it resides in a JAR file signed with a certificate that the user's system trusts. For your convenience, Payara Server signs the JAR file automatically using the certificate with this alias from the domain's keystore. Java Web Start then asks the user whether to trust the code and displays the Payara Server certificate information. To sign this JAR file with a different certificate, add the certificate to the domain keystore, then use this property. For example, you can use a certificate from a trusted authority, which avoids the Java Web Start prompt, or from your own company, which users know they can trust. Default is `s1as`, the alias for the self-signed certificate created for every domain.

`java-web-start-enabled`

Specifies whether Java Web Start access is permitted for an application client module. Default is true.

`compatibility`

Specifies the Payara Server release with which to be backward compatible in terms of JAR visibility requirements for applications. The only allowed value is `v2`, which refers to Sun Java System Application Server version 2 or Sun Java System Application Server version 9.1 or 9.1.1. Beginning in Java EE 6, the Java EE platform specification imposed stricter requirements than Java EE 5 did on which JAR files can be visible to various modules within an EAR file. In particular, application clients must not have access to EJB JAR files or other JAR files in the EAR file unless references use the standard Java SE mechanisms (extensions, for example) or the Jakarta EE library-directory mechanism. Setting this property to `v2` removes these restrictions.

`keepSessions={false|true}`

Superseded by the `--keepstate` option.
This property can by used to specify whether active sessions of the application that is being redeployed are preserved and then restored when the redeployment is complete. Applies to HTTP sessions in a web

container. Default is `false`.

`false`

Active sessions of the application are not preserved and restored (default).

`true`

Active sessions of the application are preserved and restored.
If any active session of the application fails to be preserved or restored, none of the sessions will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.
To preserve active sessions, Payara Server serializes the sessions and saves them in memory. To restore the sessions, the class loader of the newly redeployed application deserializes any sessions that were previously saved.

`preserveAppScopedResources`

If set to `true`, preserves any application-scoped resources and restores them during redeployment. Default is `false`.

`warlibs={false|true}`

(This property will be overriden by `--warlibs`) If set to true, enables an application to make use of shared libraries installed to `domain_dir/lib/warlibs`. Default is `false`.
Libraries stored in this directory allows a developer to create and deploy skinny WARs, as the libraries stored in this directory are subject to additional annotation and extension scanning & processing for CDI, EJB, Servlet, and more. Unlike common and application libraries (those stored in `domain_dir/lib` and `domain_dir/lib/applibs` respectively), warlibs are cached and don't dynamically update if the files within the directory are modified.

```
Other available properties are determined by the implementation of the component
that is being redeployed. +
For components packaged as OSGi bundles (`--type=osgi`), the `deploy` subcommand
accepts properties arguments to wrap a WAR file as a WAB
(Web Application Bundle) at the time of deployment. The subcommand looks for a
key named `UriScheme` and, if present, uses the key as a
URL stream handler to decorate the input stream. Other properties are used in the
decoration process. For example, the Payara Server
OSGi web container registers a URL stream handler named `webbundle`, which is
used to wrap a plain WAR file as a WAB. For more information
about usage, see the related example in the xref:Technical Documentation/Payara
Server Documentation/Command Reference/deploy.adoc#deploy[`deploy`] help page.
```

Operands

file_archive|filepath

The path to the archive that contains the application that is being redeployed. This path can be a relative path or an absolute path.
The archive can be in either of the following formats:

- An archive file, for example, `/export/JEE_apps/hello.war`.

If the `--upload` option is set to `true`, this is the path to the deployable file on the local client machine. If the `--upload` option is set to `false`, this is the absolute path to the file on the server machine.

- A directory that contains the exploded format of the deployable archive. This is the absolute path to the directory on the server machine.
  If you specify a directory, the `--upload` option is ignored.
  Whether this operand is required depends on how the application was originally deployed:
- If the application was originally deployed from a file, the archive-path operand is required. The operand must specify an archive file.
- If the application was originally deployed from a directory, the archive-path operand is optional.
  The operand can specify a directory or an archive file.

Examples

Example 1 Redeploying a Web Application From a File

This example redeploys the web application `hello` from the `hello.war` file in the current working directory. The application was originally deployed from a file. Active sessions of the application are to be preserved and then restored when the redeployment is complete.

```
asadmin> redeploy --name hello --properties keepSessions=true hello.war
Application deployed successfully with name hello.
Command redeploy executed successfully
```

Example 2 Redeploying a Web Application From a Directory

This example redeploys the web application `hellodir`. The application was originally deployed from a directory.

```
asadmin> redeploy --name hellodir
Application deployed successfully with name hellodir.
Command redeploy executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

remove-expired-certificates

Removes all expired certificates from the target instance or listener's keystores and truststores.

Synopsis

```
asadmin remove-expired-certificates [--help]
[--reload={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
```

Description

This command removes all expired certificates from the target instance or listener's key and trust stores.

If the instance or listener is configured to use the default trust store, the command will instead synchronize the instance with the DAS (under the assumption the certificate has been removed from the default trust store of the DAS), since any certificates removed from the instance stores would be lost upon its next synchronisation.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are removing expired certificates. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--reload`

Whether the HTTP listeners should be reloaded. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

Examples

Example 1 Removes all expired certificates in the `production` domain

```
asadmin remove-expired-certificates --domainName --listener http-listener-2
--reload=true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- SSL Certificate Management,
- `remove-from-keystore`,
- `remove-from-truststore`

remove-from-keystore

Removes a key/certificate entry from the specified server keystore.

Synopsis

```
asadmin remove-from-keystore [--help]
[--reload={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[alias]
```

Description

This command removes a private key and certificate entry from the target instance or listener's keystore matching the provided alias.

If the instance or listener is configured to use the default key store, the command will instead synchronize the instance with the DAS (under the assumption the certificate has been removed from the default key store of the DAS), since any certificates removed from the instance stores would be lost upon its next synchronisation.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are removing from its keystore. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--reload`

Whether the HTTP listeners should be reloaded. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

Operands

alias

The alias name of the private key/certificate entry to remove.

Examples

Example 1 Remove the `mycert` entry from the `production` domain's keystore

```
asadmin remove-from-keystore --domainName production --listener http-listener-2 mycert
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- SSL Certificate Management,
- `remove-expired-certificates`,
- `remove-from-truststore`

remove-from-truststore

Removes a certificate entry from the specified server truststore.

Synopsis

```
asadmin remove-from-truststore [--help]
[--reload={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
[alias]
```

Description

This command removes a certificate from the target instance or listener's truststore matching the provided alias.

If the instance or listener is configured to use the default trust store, the command will instead synchronize the instance with the DAS (under the assumption the certificate has been removed from the default trust store of the DAS), since any certificates removed from the instance stores would be lost upon its next synchronisation.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are removing from its truststore. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--reload`

Whether the HTTP listeners should be reloaded. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

Operands

alias

The alias name of the certificate entry to remove.

Examples

Example 1 Remove the `mycert` entry from the `production` domain's truststore

```
asadmin remove-from-truststore --domainName production --listener http-listener-2
mycert
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- SSL Certificate Management,
- `remove-expired-certificates`,
- `remove-from-keystore`

remove-instance-from-deployment-group

Removes a standalone instance from an existing deployment group.

Synopsis

```
asadmin [asadmin-options] remove-instance-from-deployment-group [--help]
[--instance instanceName]
[--deploymentgroup deploymentGroupName]
```

Description

The `remove-instance-from-deployment-group` subcommand will remove the referenced instance from the referenced deployment group.

If the referenced instance doesn't belong to the deployment group the command will exit with an error.

Removing an instance from a deployment group does not delete it.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--instance`

The name of the standalone instance that will be removed from the deployment group. The command will fail if the name doesn't match to an existing standalone instance that belongs to the deployment group.

`--deploymentGroup`

The name of the deployment group from which the standalone instance will be removed. The command will fail if the name doesn't match to an existing deployment group.

Examples

Example 1 Removes an instance from a Deployment Group

This example removes the instance named `test-instance-1` from the deployment group named `test-dgroup`:

```
asadmin remove-instance-from-deployment-group --instance=test-instance-1
--deploymentGroup=test-dgroup
```

```
Command remove-instance-from-deployment-group executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`
- `create-deployment-group`,
- `delete-deployment-group`,
- `list-deployment-groups`

remove-library

Removes one or more library JAR files from Payara Server.

Synopsis

```
asadmin [asadmin-options] remove-library [--help]
[--type={common|ext|app}]
library-name [library-name ... ]
```

Description

The `remove-library` subcommand removes one or more library JAR files from Payara Server.

The `--type` option specifies the library type and the Payara Server directory from which the library is removed.

The library-name operand is the name of the JAR file that contains the library to be removed. To specify multiple libraries, specify multiple names separated by spaces.

The library archive file is removed from the DAS. For common and extension libraries, you must restart the DAS so the library removals are picked up by the server runtime. To remove the libraries from other server instances, synchronize the instances with the DAS by restarting them.

This command is not supported on the Windows operating system.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--type`

Specifies the library type and the Payara Server directory from which the library is removed. Valid values are as follows:

`common`

Removes the library files from the Common class loader directory, domain-dir`/lib`. This is the default.

`ext`

Removes the library files from the Java optional package directory, domain-dir`/lib/ext`.

`app`

Removes the library files from the application-specific class loader directory, `domain-dir/lib/applibs`.
For more information about these directories, see Class Loaders in the Payara Server Application Development section.

Operands

library-name

The names of the JAR files that contain the libraries that are to be removed.

Examples

Example 1 Removing Libraries

This example removes the library in the archive file `mylib.jar` from the application-specific class loader directory on the default server instance.

```
asadmin> remove-library --type app mylib.jar
Command remove-library executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `add-library`,
- `list-libraries`,
- Class Loaders in the Payara Server Application Development section.

renew-self-signed-certificates

Renews all self-signed certificates in the specified server's keystore.

Synopsis

```
asadmin renew-self-signed-certificates [--help]
[--reload={false|true}]
[--domainName=name]
[--domainDir=directory]
[--node=nodeName]
[--nodeDir=directory]
[--listener=listenername]
[--target=instanceName]
```

Description

The `renew-self-signed-certificates` subcommand renews all self-signed certificates in a keystore using the old distinguished name and alias.

These certificates are then placed in the key and trust stores of the target instance or listener, replacing the old ones.

Options

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are renewing its self-signed certificates. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--reload`

Whether the HTTP listeners should be reloaded. Defaults to `false`

`--listener`

The name of the HTTP or IIOP listener to add the certificate to.

`--domainname`

The name of the domain where the target instance exists.

Defaults to `domain1` or the existing domain if only one exists.

`--domainDir`

The path to the directory containing the target domain.

Defaults to `as-install/glassfish/domains`

`--node`

The name of the node where the target instance exists.

Defaults to `localhost-$domainname`

`--nodeDir`

The path to the directory containing the target node.

Defaults to `as-install/glassfish/nodes`

Examples

Example 1 Renews all self-signed certificates on the default domain

```
asadmin renew-self-signed-certificates
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

resource

Provide connectivity to various types of EIS and other integrated systems.

Description

Payara Server provides support for JDBC, JMS, and JNDI resources.

See Also

- `asadmin`

restart-cluster

Restarts all instances in a cluster.

Synopsis

```
asadmin [asadmin-options] restart-cluster [--help]
[--verbose=false]
[--rolling=true]
[--delay=0]
[--instanceTimeout=instanceTimeout]
[--timeout=timeout]
[clustername]
```

Description

The `restart-cluster` subcommand stops and starts a cluster by stopping and starting all Payara Server instances in the cluster that are already running.

This subcommand requires the secure shell (SSH) to be configured on the host where the domain administration server (DAS) is running and on all hosts where instances in the cluster reside.

If all instances reside on the same host as the DAS, SSH is not required. You might require to restart a cluster in which instances reside on hosts where SSH is not configured that are remote from the DAS.
In this situation, run the `restart-local-instance` subcommand for each instance from the host where the instance resides.

You may run this subcommand from any host that can contact the DAS.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--verbose`

Specifies whether additional status information is displayed when the cluster is started.

Valid values are as follows:

`true`

Displays the command to start each instance in the cluster and whether the attempt to start each instance succeeded.

`false`

Displays no additional status information (default).

`--rolling`

Performs a rolling restart which each instance restarted in turn. The default value is `true`.

`--delay`

Delay in (ms) between each instance restart in a rolling restart. The default value is `0`.

`--instanceTimeout`

Specify a timeout value of instances. The default value is `600`.

`--timeout`

Specify a timeout value of the command. The default value is `600`.

Operands

cluster-name

The name of the cluster to restart.

Examples

Example 1 Restarting a Cluster

This example restarts the cluster `c1`.

```
asadmin> restart-cluster c1
Command restart-cluster executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-cluster`,
- `delete-cluster`,
- `list-clusters`,
- `setup-ssh`,
- `start-local-instance`,
- `start-cluster`,
- `stop-cluster`

restart-deployment-group

Restarts all the instances in a Payara Server deployment group.

Synopsis

```
asadmin [asadmin-options] restart-deployment-group [--help]
[--instanceTimeout timeout]
[--timeout timeout]
[--verbose={false|true}]
[--rolling={false|true}]
[--delay delay]
name
```

Description

The `restart-deployment-group` subcommand will restart all instances that belong to a Payara Server deployment group. The command will fail if the deployment group doesn't contain any instances in it. To this effect, the command will:

1. Stop any running instances first and wait until all instances are stopped.
2. Start all instances that belong to the deployment group.

You can configure the command to execute a "rolling restart", that is, instead of stopping all instances first and then starting them, stop and start each instance in order by using the `--rolling` option.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--verbose`

`-v`

Whether to start the instances in verbose mode. Defaults to `false`.

`--timeout`

Specifies how long to take for command execution to be completed in seconds. If the execution takes longer than this amount then this command will fail.

The default value is `600`.

`--instanceTimeout`

Specifies how long to take for each instance to start/stop in seconds. If each operation takes longer than this amount then this command will fail.

The default value is `600`.

`--rolling`

Whether to execute a "rolling restart", that is, stop and start each instance in order to prevent a full shutdown of an application. Defaults to `false`.

`--delay`

Only applies when `--rolling` is set to `true`. Sets a delay wait time in milliseconds between each instance restart. Defaults to `5000`.

Operands

name

The name of the deployment group. If there are no deployment groups that match the name the command will exit with an error.

Examples

Example 1 Restart a Deployment Group

This example restarts a deployment group that is named `test-dgroup`:

```
asadmin restart-deployment-group test-dgroup
Command restart-deployment-group executed successfully.
```

Example 2 Execute a rolling restart of a Deployment Group

This example restarts a deployment group that is named `test-dgroup` in rolling mode using a delay of 30 seconds:

```
asadmin restart-deployment-group --rolling=true --delay=30000 test-dgroup
Command restart-deployment-group executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `create-deployment-group`,
- `start-instance`,
- `stop-instance`,
- `list-deployment-groups`,
- `start-deployment-group`,
- `stop-deployment-group`

restart-domain

Restarts the Domain Administration Server(DAS) of the specified domain.

Synopsis

```
asadmin [asadmin-options] restart-domain [--help]
[--debug ={true|false}]
[--domaindir domaindir]
[--timeout timeout]
[--force={true|false}] [--kill={false|true}]
[domain-name]
```

Description

The `restart-domain` subcommand stops and then restarts the domain administration server (DAS) of the specified domain. If a domain is not specified, the default domain is assumed. If the domains directory contains two or more domains, the domain-name operand must be specified. If the DAS is not already running, the subcommand attempts to start it.

The `restart-domain` subcommand does not exit until the subcommand has verified that the domain has been stopped and restarted.

This subcommand is supported in local or remote mode. If you specify a host name, the subcommand assumes you are operating in remote mode, which means you must correctly authenticate to the remote server. In local mode, you normally do not need to authenticate to the server as long as you are running the subcommand as the same user who started the server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--debug`

Specifies whether the domain is restarted with Java Platform Debugger Architecture (JPDA) (https://docs.oracle.com/javase/8/docs/technotes/guides/jpda/index.html) debugging enabled.
Possible values are as follows:

`true`

The domain is restarted with JPDA debugging enabled and the port number for JPDA debugging is displayed.

`false`

The domain is restarted with JPDA debugging disabled (default).
The default is the current setting of this option for the domain that is being restarted.

`--domaindir`

The domain root directory, which contains the directory of the domain that is to be restarted. If specified, the path must be accessible in the file system. The default location of the domain root directory is as-install`/domains`.

`--force`

Specifies whether the domain is forcibly stopped immediately before it is restarted.
Possible values are as follows:

`true`

The domain is forcibly stopped immediately (default).

`false`

The subcommand waits until all threads that are associated with the domain are exited before stopping the domain.

`--kill`

Specifies whether the domain is killed before it is restarted by using functionality of the operating system to terminate the domain process.
Possible values are as follows:

`false`

The domain is not killed. The subcommand uses functionality of the Java platform to terminate the domain process (default).

`true`

The domain is killed. The subcommand uses functionality of the operating system to terminate the domain process.

`--timeout`

Specifies how long to take for the domains to restart in seconds. If restarting the domains takes longer than this amount then this command will fail.

The default value is `600`.

Operands

domain-name

The name of the domain you want to restart. Default is the name specified during installation, usually `domain1`.

Examples

Example 1 Restarting a Domain

This example restarts `mydomain4` in the default domains directory.

```
asadmin> restart-domain mydomain4
Successfully restarted the domain
Command restart-domain executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

restart-domains

Restarts the Domain Administration Server(DAS) of the specified domains.

Synopsis

```
asadmin [asadmin-options] restart-domains [--help]
[--domainTimeout timeout]
[--timeout timeout]
[domain-name]
```

Description

The `restart-domains` subcommand can be used to restart the specified list of domains in the operand. This list must be specified as a comma separated string of values.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--timeout`

Specifies how long to take for the domains to restart in seconds. If restarting the domains takes longer than this amount then this command will fail.

The default value is `600`.

`--domainTimeout`

Specifies how long to take for each domain to restart in seconds. If restarting the domain takes longer than this amount then this command will fail.

The default value is `600`.

Operands

domain-names

The name of the domains you want to restart.

Examples

Example 1 Restarting Domains

This example restarts `domain1` and `testy` in the default domains directory.

```
asadmin restart-domains domain1,testy

Successfully restarted the domain
Restarted domain domain1

Successfully restarted the domain
Restarted domain testy

Command restart-domains executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

restart-hazelcast

Restarts the Data Grid/Hazelcast in an specific target.

Synopsis

```
asadmin [asadmin-options] restart-hazelcast
[--help]
[--target target]
```

Description

This command can be used to restart the Data Grid/Hazelcast subsystem in the specified target.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are restarting its corresponding Hazelcast member. Valid values are:

`server`

Applies to the default server instance. This is the default value.

instance_name

Applies to a specified server instance.

Examples

Example 1 Restarts the Data Grid/Hazelcast

This example restarts the Data Grid/Hazelcast with `instance1` as its target.

```
asadmin> restart-hazelcast --target instance1
instance1:
Hazelcast Restarted

Command restart-hazelcast executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

restart-http-listeners

```
Restarts all HTTP network listener of the targeted instance(s).
```

Synopsis

```
asadmin [asadmin-options] restart-http-listeners
[--help]
[--all={true|false}]
[target]
```

Description

The `restart-http-listeners` subcommand restarts an HTTP network listener of the targeted instance(s).

This command only restarts all HTTP listeners except `admin-listener`.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--all`

Applies the command to all instances. The default value is `false`.

Operands

target

Name of the target instance, deployment group or cluster to which restart the corresponding HTTP listeners.

Examples

Example 1 Restarting an HTTP Network Listener

The following command to restart all HTTP network listeners that belong to a particular instance named `i1`:

```
asadmin>restart-http-listeners i1
Command restart-http-listeners executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

- `restart-http-listeners`

restart-instance

Restarts a running Payara Server instance.

Synopsis

```
asadmin [asadmin-options] restart-instance [--help]
[--debug={false|true}] instance-name
```

Description

The `restart-instance` subcommand restarts a running Payara Server instance. This subcommand requires secure shell (SSH) to be configured on the machine where the domain administration server (DAS) is running and on the machine where the instance resides.

SSH is not required if the instance resides on a node of type `CONFIG` that represents the local host. A node of type `CONFIG` is not enabled for communication over SSH.

You may run this subcommand from any machine that can contact the DAS.

The subcommand can restart any Payara Server instance, regardless of how the instance was created. For example, this subcommand can restart an instance that was created by using the `create-local-instance` subcommand.

When this subcommand restarts an instance, the DAS synchronizes the instance with changes since the last synchronization as follows:

- For the `config` directory, the DAS synchronizes the instance with all changes.
- For the `applications` directory and `docroot` directory, only a change to a top-level subdirectory causes the DAS to synchronize all files under that subdirectory.
  If a file below a top level subdirectory is changed without a change to a file in the top level subdirectory, full synchronization is required. In normal operation, files below the top level subdirectories of these directories are not changed. If an application is deployed and undeployed, full synchronization is not necessary to update the instance with the change.

If different synchronization behavior is required, the instance must be stopped and restarted by using following sequence of subcommands:

1. `stop-instance`
2. `start-instance`

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--debug`

Specifies whether the instance is restarted with Java Platform Debugger Architecture (JPDA) (https://docs.oracle.com/javase/8/docs/technotes/guides/jpda/index.html/) debugging enabled.
Possible values are as follows:

`true`

The instance is restarted with JPDA debugging enabled and the port number for JPDA debugging is displayed.

`false`

The instance is restarted with JPDA debugging disabled.

The default is the current setting of this option for the instance that is being restarted.

Operands

instance-name

The name of the Payara Server instance to restart. If the instance is not running, the subcommand displays a warning message and attempts to start the instance.

Examples

Example 1 Restarting a Payara Server Instance

This example restarts the Payara Server instance `pmdsa1`.

```
asadmin> restart-instance pmdsa1
Instance pmdsa1 was restarted.

Command restart-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

restart-local-instance

Restarts a running Payara Server instance on the host where the subcommand is running.

Synopsis

```
asadmin [asadmin-options] restart-local-instance [--help]
[--nodedir nodedir] [--node node]
[--debug={false|true}]
[--force={true|false}] [--kill={false|true}]
[instance-name]
```

Description

The `restart-local-instance` subcommand restarts a Payara Server instance on the host where the subcommand is run. This subcommand does not require secure shell (SSH) to be configured. You must run this command from the host where the instance resides.

The subcommand can restart any Payara Server instance, regardless of how the instance was created. For example, this subcommand can restart an instance that was created by using the `create-instance` subcommand.

The `restart-local-instance` subcommand does not contact the domain administration server (DAS) to determine the node on which the instance resides. To determine the node on which the instance resides, the subcommand searches the directory that contains the node directories. If multiple node directories exist, the node must be specified as an option of the subcommand.

When this subcommand restarts an instance, the DAS synchronizes the instance with changes since the last synchronization as follows:

- For the `config` directory, the DAS synchronizes the instance with all changes.
- For the `applications` directory and `docroot` directory, only a change to a top-level subdirectory causes the DAS to synchronize all files under that subdirectory.
  If a file below a top level subdirectory is changed without a change to a file in the top level subdirectory, full synchronization is required. In normal operation, files below the top level subdirectories of these directories are not changed. If an application is deployed and undeployed, full synchronization is not necessary to update the instance with the change.

If different synchronization behavior is required, the instance must be stopped and restarted by using following sequence of subcommands:

1. `stop-local-instance`
2. `start-local-instance`

This subcommand is supported in local mode. However, to synchronize the instance with the DAS, this subcommand must be run in remote mode.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodedir`

Specifies the directory that contains the instance's node directory. The instance's files are stored in the instance's node directory. The default is as-install `/nodes `.

`--node`

Specifies the node on which the instance resides. This option may be omitted only if the directory that the `--nodedir` option specifies contains only one node directory. Otherwise, this option is required.

`--debug`

Specifies whether the instance is restarted with Java Platform Debugger Architecture (JPDA) (http://www.oracle.com/technetwork/java/javase/tech/jpda-141715.html) debugging enabled.
Possible values are as follows:

`true`

The instance is restarted with JPDA debugging enabled and the port number for JPDA debugging is displayed.

`false`

The instance is restarted with JPDA debugging disabled (default).
The default is the current setting of this option for the instance that is being restarted.

`--force`

Specifies whether the instance is forcibly stopped immediately before it is restarted.
Possible values are as follows:

`true`

The instance is forcibly stopped immediately (default).

`false`

The subcommand waits until all threads that are associated with the instance are exited before stopping the instance.

`--kill`

Specifies whether the instance is killed before it is restarted by using functionality of the operating system to terminate the instance process.
Possible values are as follows:

`false`

The instance is not killed. The subcommand uses functionality of the Java platform to terminate the instance process (default).

`true`

The instance is killed. The subcommand uses functionality of the operating system to terminate the instance process.

Operands

instance-name

The name of the Payara Server instance to restart. If the instance is not running, the subcommand displays a warning message and attempts to start the instance.

Examples

Example 1 Restarting an Instance Locally

This example restarts the instance `ymlsa1` in the domain `domain1` on the host where the subcommand is run.

```
asadmin> restart-local-instance --node localhost-domain1 ymlsa1
Command restart-local-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

restart-monitoring

This command can be used to set restart/reset the monitoring levels of the server

Synopsis

```
asadmin [asadmin-options] restart-monitoring
[--help]
[--verbose={false|true}]
[--target target]
```

Description

This command can be used to restart the monitoring levels of all modules per the specified target.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the monitoring level of a server module. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--verbose`

Enable verbose output.

Examples

Example 1 Restart monitoring in the DAS

```
asadmin restart-monitoring --target=server
```

This will generate an output similar to the following:

```
Restarted 3 modules
```

Example 2 Restart monitoring in the DAS using verbose mode

You can use the verbose mode to see which modules were affected and what monitoring level they are currently set to:

```
asadmin restart-monitoring --target=server --verbose
```

This will generate an output similar to the following:

```
Module                      Monitoring Level
cloud                       HIGH
cloud-elasticity            LOW
cloud-orchestrator          HIGH
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `set-monitoring-service-configuration`,
- `enable-monitoring`,
- `disable-monitoring`

restore-domain

Restore files from backup.

Synopsis

```
asadmin [asadmin-options] restore-domain [--help]
[--long[={false|true}]]
[--filename backup-filename]
[--domaindir domain-root-dir]
[--backupdirbackup-directory]
[--backupconfigbackup-config-name]
[--force[={false|true}]]
[domain-name]
```

Description

This command restores files under the domain from a backup directory.

The `restore-domain` command is supported in local mode only.

If a domain is restored on an already existing domain folder, all the files will be overwritten when the command is run.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--long`

`-l`

Displays detailed information about the restore operation.

The default value is `false`.

`--filename`

Specifies the name of the backup file to use as the source.

`--domaindir`

Specifies the domain root directory, the parent directory of the domain to restore.

The default value is `as-install/domains`.

`--backupdir`

Specifies the directory under which the backup file is stored.

The default value is `as-install/domains/domain-dir/backups`. If the domain is not in the default location, the location is `domain-dir/backups`.

`--backupconfig`

The name of the domain backup configuration in the backup directory under which the backup file is stored.

`--force`

Causes the restore operation to continue even when the name of the domain to restore does not match the name of the domain stored in the backup file.

The default value is `false`.

Operands

domain-name

Specifies the name of the domain to restore.

This operand is optional if only one domain exists in the Payara Server installation.

If the specified domain name does not match the domain name stored in the backup file, an error occurs unless the `--force` option is specified.

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

rollback-transaction

Rolls back the named transaction.

Synopsis

```
asadmin [asadmin-options] rollback-transaction [--help]
[--target target]
transaction_id
```

Description

The `rollback-transaction` subcommand rolls back the named transaction.

Before you can roll back a transaction, you must do the following:

1. Enable monitoring using the `set` subcommand. For example:

```
asadmin> set clstr1-config.monitoring-service.module-monitoring-levels.transaction-
service=HIGH
```

2. Use the `freeze-transaction-service` subcommand to halt in-process transactions.
3. Look up the active transactions using the `get` subcommand with the `--monitor` option. For example:

```
asadmin> get --monitor inst1.server.transaction-service.activeids-current
```

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are rolling back the transactions. Valid values are `server` or any other clustered or stand-alone instance.

Operands

transaction_id

Identifier for the transaction to be rolled back.

Examples

Example 1 Using rollback-transaction command

```
% asadmin rollback-transaction 0000000000000001_00
Command rollback-transaction executed succeessfully
```

Exit Status

0

command executed successfully

1

error in executing the command

rotate-log

Rotates the log file.

Synopsis

```
asadmin [asadmin-options] rotate-log [--help]
```

Description

The `rotate-log` subcommand rotates the server log by renaming the file with a timestamp name in the format `server.log_`date-and-time, and creating a new log file. Changes take effect dynamically, that is,server restart is not required.

The size of the log queue is configurable through the `logging.properties` file. Log rotation is based on file size or elapsed time since the last log rotation. In some circumstances, the queue might fill up, especially if the log level is set to `FINEST` and there is heavy activity on the server. In this case, the `rotate-log` subcommand can be used to rotate the server log immediately. This subcommand is also useful in creating scripts for rotating the log at convenient times.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The server, cluster, or server instance for which logs will be rotated. If this option is omitted, logs are rotated for the default server.

Operands

target

Valid values are:

- server_name - Default target is `server`. If no target is specified then logs are rotated for the server.
- cluster_name - The name of a target cluster.
- instance_name - The name of a target server instance.

Examples

Example 1 Rotating the Server Log

This example rotates the server log.

```
asadmin> rotate-log
Command rotate-log executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-admin-audit-configuration

Configures the Administrative Audit Service.

Synopsis

```
asadmin [asadmin-options] set-admin-audit-configuration [--help]
[--dynamic=false]
[--enabled={true|false}]
[--auditlevel=auditlevel]
[--target=server]
[--enablenotifiers=enablenotifiers]
[--disablenotifiers=disablenotifiers]
[--setnotifiers=setnotifiers]
```

Description

The `set-admin-audit-configuration` subcommand can be used to set the configuration settings of the Admin Audit Configuration.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

--dynamic

Applies changes dynamically to the running system without the need for a restart, allowing for immediate effect of the audit configuration adjustments.

--enabled

Turns the audit service on or off, controlling whether administrative actions are tracked and logged for security and compliance purposes.

--auditlevel

Sets the auditing level. One of:

- MODIFIERS (default)
- ACCESSORS
- INTERNAL

--target

Specifies the target for which to configure the audit settings, in this case, a server.

--enablenotifiers

Enables selected notification services for audit events.

--disablenotifiers

Disables selected notification services without affecting others.

--setnotifiers

Configures notification services, specifying event types and settings.

Examples

Example 1

```
asadmin> set-admin-audit-configuration --dynamic --enabled --auditlevel=MODIFIERS
--target=server --enablenotifiers=email,alert --disablenotifiers=log
--setnotifiers="email:critical,alert:all"

Command set-admin-audit-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-admin-audit-configuration`

set-amx-enabled

Enables or disables the AMX monitoring subsystem.

Synopsis

```
asadmin [asadmin-options] set-amx-enabled
[--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
```

Description

This command can be used to configure the boot AMX at startup or independently of the JMX Monitoring service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring AMX boot. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the monitoring service

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Examples

Example 1 Enables the AMX subsystem immediately for the DAS

```
asadmin set-amx-enabled --enabled=true --dynamic=true --target=server
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- Monitoring Basics
- `set-jmx-monitoring-configuration`

set-asadmin-recorder-configuration

Configures the Asadmin Recorder service.

Synopsis

```
asadmin [asadmin-options] set-asadmin-recorder-configuration [--help]
[--enabled={true|false}]
[--outputlocation=outputlocation]
[--filtercommands={true|false}]
[--filteredcommands=filteredcommands]
[--prependenabled={true|false}]
[--prependedoptions=prependedoptions]
```

Description

The `set-asadmin-recorder-configuration` subcommand adjusts the settings of the Asadmin Recorder. When enabled with --enabled true, it starts recording all asadmin commands issued through the Admin Console.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

--enabled

Activates or deactivates the Asadmin Recorder feature.

--outputLocation

-o

The absolute file path for the asadmin commands to be written to. This defaults to a file called asadmin-commands.txt in the domain directory.

--filterCommands

-f

Specifies whether the commands specified with the `--filteredcommands` option should be excluded from being recorded or not.

--filteredCommands

A comma separated list of asadmin commands and regular expressions to exclude from being recorded.

Examples

Example 1

The following will enable the asadmin recorder, set the output location to `/home/user/asadmin-commands.txt`, and prevent the start-instance command from being recorded (in addition to the

default configuration):

```
asadmin set-asadmin-recorder-configuration --enabled true --outputLocation
/home/user/asadmin-commands.txt --filterCommands true --filteredCommands
"version,_(.*),list(.*),get(.*),uptime,enable-asadmin-recorder,disable-asadmin-
recorder,set-asadmin-recorder-configuration,asadmin-recorder-enabled,start-instance"

Command set-asadmin-recorder-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

set-aws-config-source-configuration

Sets the configuration for the AWS Secrets configuration source.

Synopsis

```
asadmin [asadmin-options] set-aws-config-source-configuration [--help]
[--regionname=regionname]
[--secretname=secretname]
[--target=server]
[--dynamic={false|true}]
[--enabled={true|false}]
```

Description

The `set-aws-config-source-configuration` provides configuration options for the config source which fetches data from AWS Secrets Manager. Make sure that the password aliases `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` are registered first.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--regionname`

The region name of the AWS Secrets service.

`--secretname`

The name of the secret to fetch as a map of properties.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--dynamic`

Configure the config source dynamically, which will not require a restart.

`--enabled`

Enables or disables the config source, which fetches data from AWS Secrets Manager

Example

Example 1 Setting the configuration of the AWS secrets

This example configures the AWS Secrets Cloud Config Source.

```
asadmin set-aws-config-source-configuration --dynamic true --enabled true --secretName
payara/test/key --regionName eu-west-2
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-aws-config-source-configuration`

set-azure-config-source-configuration

Sets the configuration for an Azure Secrets configuration source.

Synopsis

```
asadmin [asadmin-options] set-azure-config-source-configuration [--help]
[--tenant-id=tenant-id]
[--client-id=client-id]
[--key-vault-name=key-vault-name]
[--private-key-file=private-key-file]
[--thumbprint=thumbprint]
[--target=server]
[--dynamic=false]
[--enabled={true|false}]
```

Description

The `set-azure-config-source-configuration` provides configuration options for the config source which fetches secrets from Azure Key Vault.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--key-vault-name`

Name of the Azure Key Vault to fetch secrets from.

`--tenant-id`

Tenant ID of your Azure Active Directory application.

`--client-id`

The Client (Application) ID of your Azure Active Directory application.

`--thumbprint`

The thumbprint of the certificate(certificate hash) that is tied to your Azure Active Directory application.

`--private-key-file`

The path to the Private key file which will be used for certificate-based authentication to request access token. This file will be copied to the config/ directory.

`--dynamic`

Configure the config source dynamically, which will not require a restart.

`--enabled`

Enables or disables the config source, which fetches data from Azure Key Vault.

Example

Example 1 Setting the configuration of the Azure secrets

This example configures the Azure Secrets Config Source.

```
asadmin set-azure-config-source-configuration --dynamic true --enabled true
--keyVaultName demo-secret-key-vault --tenantID 22b3bb26-e046-42df-9c96-65dbd72c1c81
--clientID 22b3bb26-e046-42df-9c96-65dbd72c1c81 --thumbprint
84E05C1D98BCE3A5421D225B140B36E86A3D5534 --privateKeyPath path/to/privatekey.pem
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-azure-config-source-configuration`

set-batch-runtime-configuration

Configures the batch runtime.

Synopsis

```
asadmin [asadmin-options] set-batch-runtime-configuration [--help]
[--target target]
[--datasourcelookupname datasource-lookup-name]
[--executorservicelookupname executor-service-lookup-name]
[--schemaName schema-name --tablePrefix table-prefix --tableSuffix table-suffix]
```

Description

The `set-batch-runtime-configuration` subcommand configures the batch runtime. The runtime uses a data source and a managed executor service to execute batch jobs. Batch runtime configuration data is stored in the`config` element in `domain.xml`.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--target`
: Specifies the target for which to configure the batch runtime. Valid values are as follows:

  `server`
  : Configures the batch runtime for the default server instance `server` and is the default value.

  cluster-name
  : Configures the batch runtime for every server instance in the cluster.

  instance-name
  : Configures the batch runtime for a particular server instance.

`--datasourcelookupname`

`-d`
: The JNDI lookup name of the data source to be used to store job information.

The default data source is `jdbc/__TimerPool`.

Do not change the data source after the first batch job has been submitted to the batch runtime for execution. If the data source must be changed, stop and restart the domain and then make the change before any jobs are started or restarted. However, once the data source has been changed, information stored in the previous data source becomes inaccessible.

`--executorservicelookupname`

`-x`

The JNDI lookup name of the managed executor service to be used to provide threads to jobs. The default managed executor service is `concurrent/__defaultManagedExecutorService`.
The managed executor service can be changed after a batch job has been submitted to the batch runtime without impacting execution of the job.

`--schemaName`

`-n`

The database schema that holds the batch tables.

Defaults to `APP`

`--tablePrefix`

The prefix to apply to the batch table name.

`--tableSuffix`

Sets the suffix to apply to the batch table name.

Examples

Example 1 Configuring the Batch Runtime

The following example configures the batch runtime for the default server instance to use an existing managed executor service named `concurrent/myExecutor`.

```
asadmin> set-batch-runtime-configuration --executorservicelookupname
concurrent/myExecutor
Command set-batch-runtime-configuration executed successfully.
```

Example 2 Configuring datasource and table data

The following command will set the data source and the prefix and suffix for the DAS:

```
asadmin> set-batch-runtime-configuration --target="server"
--datasourcelookupname="jdbc/BatchJobsDS" --tablePrefix="BATCHJ_" --tableSuffix="_JB"
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-cdieventbus-notifier-configuration

Configures the settings of the CDI Event Bus notifier

Synopsis

```
asadmin [asadmin-options] set-eventbus-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--loopBack={false|true}]
[--hazelcastEnabled={false|true}]
```

Description

This command can be used to configure the behaviour of the CDI EventBus notifier in Payara Server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the CDI Event Bus notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the notifier.

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--loopBack`

Defaults to `false`. Whether events should also be observed on the same instance that triggered the instance or not.

`--hazelcastEnabled`

Defaults to `false`. Whether to enable the Data Grid to send notification events to external instances.

Examples

Example 1 Enable the CDI Event Bus notifier

```
asadmin set-cdieventbus-notifier-configuration --loopBack=true --dynamic=true
--enabled=true --hazelcastEnabled=true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-cdieventbus-notifier-configuration`

set-config-cache

Provides a way to set the value of the cache duration of Eclipse MicroProfile configuration properties.

Synopsis

```
asadmin [asadmin-options] set-config-cache [--help]
[--duration=<duration.in.second>]
[--target=<target[default:server]>]
```

Description

The `set-config-cache` sets the value of the cache duration of Eclipse MicroProfile configuration properties in the targeted instances.

A value of zero (`0`) disables caching for MicroProfile configuration properties.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--duration`

Duration in seconds properties are cached. Defaults to 60.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Disable Caching

This example disables caching by setting the duration to `0`.

```
asadmin set-config-cache --duration=0 --target=myAppCluster
```

Example 2 Sets the caching duration

This example sets the cache TTL (time to live) for configuration properties to `30` seconds.

```
asadmin> set-config-cache --duration=30 --target=myAppCluster
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

set-config-dir

Provides a way to configure the **Directory** configuration source.

Synopsis

```
asadmin [asadmin-options] set-config-dir [--help]
[--directory=<full.path.to.dir>]
[--target=<target[default:server]>]
```

Description

The `set-config-dir` sets the directory to be used for the directory config source.

- **Leaf directory cannot start with a dot**, rendering `/home/payara/.secret` an invalid path ("." means hidden on a POSIX filesystem).
- If relative, will look beneath server instance location (usually to be found at `domain-dir/`)
- Defaults to `secrets`, targeting `domain-dir/secrets/`

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--directory`

Full path to the directory containing configuration files.

Leaf directory name cannot start with a dot. Defaults to `secrets`.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Setting the Config Directory.

This example sets the directory to be used for the directory config source.

```
asadmin set-config-dir --directory=/home/payara/secrets --target=myAppCluster
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`

- `get-config-dir`

set-config-ordinal

Provides a way to set the ordinal value of a configuration source.

Synopsis

```
asadmin [asadmin-options] set-config-ordinal [--help]
[--target target]
[--ordinalvalue]
[--source={domain|config|server|application|module|cluster}]
```

Description

The `set-config-ordinal` sets the ordinal value for the given config source. Where multiple configuration properties exist, the property from a source with a higher ordinal number is preferred.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--ordinal`

The value of the ordinal to set. This must be a number greater than `1`.

A lower number ordinal means lower order of precedence.

`--source`

The value of the source to change. Must be one of:

- `domain`
- `config`
- `server`
- `application`
- `module`
- `cluster`.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`
: Specifies the DAS (default).

instance-name
: Specifies a Payara Server instance.

cluster-name
: Specifies a cluster.

Example

Example 1 Setting the ordinal value

This example sets the ordinal value of the application configuration source to `600`.

```
asadmin set-config-ordinal --ordinal=600 --source=application
```

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `asadmin`
- `get-config-ordinal`

set-config-property

Provides a way to set the value of a MicroProfile Configuration property in a specific configuration source.

Synopsis

```
asadmin [asadmin-options] set-config-property [--help]
[--propertyName=<property.name>]
[--propertyValue=<property.val>]
[--source={domain|config|server|application|module|cluster}]
[--sourceName=<source.name>]
[--moduleName=<module.name>]
[--target=<target[default:server]>]
```

Description

The `set-config-property` sets the value of a MicroProfile Configuration property in one of the built-

in config sources. The source is specified with `--source` and, where there is ambiguity, the `--sourceName` and `--moduleName` options can be used.

For example, where the source is server, the `--sourceName` can be used to specify the name of the server where the config property is to be stored.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--propertyName`

The name of the configuration property to set.

`--propertyValue`

The value of the configuration property to set.

`--source`

The ConfigSource where the property is to be stored.

`--sourceName`

The name of the ConfigSource when there may be ambiguity, for example a ConfigSource of type application must specify the name of the application. This property is required for sources of type: config, server, application or module

`--moduleName`

The name of the module when the ConfigSource is of type module. When this is specified, the sourceName parameter must be provided and must have the name of the application where the module is deployed.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Setting the configuration property value

This example sets the `JMSBrokerURL` property to `my.jms.hostname` within the configuration source named `myApplication`, belonging to the module `myModule`, and targeting the `myAppCluster` cluster.

```
asadmin set-config-property --propertyName=JMSBrokerURL
--propertyValue=my.jms.hostname --source=module --sourceName=myApplication
--moduleName=myModule --target=myAppCluster
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `delete-config-property`
- `get-config-property`

set-datadog-notifier-configuration

Configures the settings of the DataDog notifier.

Synopsis

```
asadmin [asadmin-options] set-datadog-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--key key]
```

Description

This command can be used to configure the behaviour of the DataDog notifier in Payara Server.

This command is available as long as the Datadog notifier's core module is installed in the server.

> This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the DataDog notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the log notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--key`

Defines the license key to be used by the notifier.

Examples

Example 1 Enable the DataDog notifier and set its license key

```
asadmin set-datadog-notifier-configuration --dynamic=true
--key=af510f122026bc9107f7c5f4f049e597 --enabled=true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-discord-notifier-configuration

Configures the settings of the Discord notifier.

Synopsis

```
asadmin [asadmin-options] set-discord-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--webhookId id]
[--webhookToken token]
```

Description

This command can be used to configure the behaviour of the Discord notifier in Payara Server.

This command is available as long as the Discord notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the Discord notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the log notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--webhookId`

The ID of the webhook required to authenticate to the corresponding Discord channel.

`--webhookToken`

The token required to authenticate the webhook to the corresponding Discord channel.

Examples

Example 1 Enable the Discord notifier and set its required webhook settings

```
asadmin set-discord-notifier-configuration --enabled=true --dynamic=true
--webhookId=xxx --webhookToken=yyy
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-discord-notifier-configuration`

set-dynamodb-config-source-configuration

Sets the configuration for the DynamoDB Config Source.

Synopsis

```
asadmin [asadmin-options] set-dynamodb-config-source-configuration [--help]
[--region-name=region-name]
[--table-name=table-name]
[--key-column-name=key-column-name]
[--value-column-name=value-column-name]
[--limit=100]
[--target=server]
[--dynamic={false|true}]
[--enabled={true|false}]
```

Description

The `set-dynamodb-config-source-configuration` provides configuration options to set the properties required by DynamoDB config source to retrieves data from the configured DynamoDB database table.

Make sure that the password aliases `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` are created first.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--region-name`

The regional location of your DynamoDB service.

`--table-name`

Name of the table in the database.

`--key-column-name`

Name of the column containing the key.

`--value-column-name`

Name of the column containing the value.

`--limit`

The maximum number of items to retrieves from the database table. The default value is 100.

`--dynamic`

Configure the config source dynamically, which will not require a restart.

`--enabled`

Enables or disables the config source.

Example

Example 1 Setting the configuration of the DynamoDB Config Source

This example configures the DynamoDB Config Source.

```
asadmin> set-dynamodb-config-source-configuration --enabled true --dynamic true
--region-name eu-west-2 --table-name Books --key-column-name ISBN --value-column-name
Title --limit 10
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-dynamodb-config-source-configuration`

set-ejb-invoker-configuration

Enables or disables the endpoint that allows HTTP(S) transport based communication for remote EJBs.

Synopsis

```
asadmin [asadmin-options] set-ejb-invoker-configuration [--help]
[--target] target
[--enabled={true|false}]
[--securityenabled={true|false}]
[--roles] roles-list
[--authmoduleclass] sam-class
[--authmodule] security-provider-id
[--realmname] realm-name
[--authtype] auth-type
[--endpoint ] context-root
[--virtualservers] virtualserver-list
```

Description

The `set-ejb-invoker-configuration` can be used to configure the Remote EJB Lite HTTP endpoint settings.

The `set-ejb-invoker-configuration --enabled=true/false` commands actually deploy/undeploy an internal small WAR application that exposes the endpoint. This application is shown in all overviews that show deployed applications that are currently enabled.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which to configure the `ejb-invoker` endpoint. Valid values are as follows:

`server`

Configures the EJB invoker endpoint for the default server instance `server` and is the default value.

cluster-name

Configures the EJB invoker endpoint for every server instance in the cluster.

deployment-group-name

Configures the EJB invoker endpoint for every server instance in the deployment group.

instance-name

Configures the EJB invoker endpoint for a particular server instance.

`--enabled`

Enables or disables the `ejb-invoker` application.

Defaults to `true`

`--securityenabled`

Whether secure access to the `ejb-invoker` endpoint is enabled or not.

Defaults to `false`

`--roles`

If defined, the endpoint will be configured to be authorised for users that belong to the list of the roles specified (in comma-separated format).

`--endpoint`

The context root used to expose the `ejb-invoker` application endpoint.

Defaults to `ejb-invoker`

`--authmoduleclass`

Defines the full qualified class name implementing a `jakarta.security.auth.message.module.ServerAuthModule` subclass.

If defined and `securityenabled` is set to `true`, the HttpServlet Message security provider is created and `ejb-invoker` application secured with the configured authentication module.

`--authmodule`

Defines the existing message security provider ID.

If defined and `securityenabled` is set to `true`, the `ejb-invoker application` will be secured with it.

--realmname`

Defines the registered realm name.

If defined and `securityenabled` it set to `true`, the `ejb-invoker` application will be secured with the corresponding realm that will be used for authentication.

`--authtype`

If defined, the endpoint will be assigned to a list of **virtual servers** specified as a comma-separated list of names.

Otherwise, the endpoint will be assigned to all virtual servers available.

Examples

The following command will enable the endpoint on the DAS:

```
asadmin> set-ejb-invoker-configuration --enabled=true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- asadmin

set-email-notifier-configuration

Configures the settings of the Email notifier.

Synopsis

```
asadmin [asadmin-options] set-email-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--jndiName sessionName]
[--recipient recipient]
```

Description

This command can be used to configure the behaviour of the Email notifier in Payara Server.

This command is available as long as the Email notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the asadmin utility. For information about these options, see the asadmin help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the Email notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the log notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--jndiName`

Defines the JNDI name of the mail session resource used to send email notifications.

`--recipient`

The recipient's email address that will receive the notification events.

Examples

Example 1 Enable the Email notifier and configure it using a mail session

```
asadmin set-email-notifier-configuration --jndiName=mail/sampleSession
--recipient=notifications@example.com --enabled=true --dynamic=true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-email-notifier-configuration`

set-environment-warning-configuration

Allows customization of a warning bar for clear identification of the server environment in the Admin Console.

Synopsis

```
asadmin [asadmin-options] set-environment-warning-configuration [--help]
[--enabled={true|false}]
[--message=message]
[--backgroundcolour=backgroundcolour]
[--textcolour=textcolour]
```

Description

The `set-environment-warning-configuration` subcommand sets the environment warning properties and can enable/disable the warning.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

--enabled

Activates or deactivates the Environment Warning feature, enabling or disabling the display of the warning bar in the Admin Console based on the chosen setting.

--message

Specifies the custom text message to be displayed within the Environment Warning bar, allowing for tailored alerts or reminders specific to the current server environment.

--backgroundcolour

Sets the background color of the Environment Warning bar, providing a visual means to distinguish between different environments by color-coding the warning bar.

--textcolour

Determines the color of the text within the Environment Warning bar, ensuring readability and contrast against the background color, enhancing the visibility of the warning message.

Examples

Example 1

```
asadmin> set-environment-warning-configuration --enabled=true --message="Caution, this
is on production" --textcolour="#00ff00" --backgroundcolour="#ff00ff"
Command set-environment-warning-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

set-eventbus-notifier-configuration

Configures the settings of the Event Bus notifier

Synopsis

```
asadmin [asadmin-options] set-eventbus-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--topicName topicName]
```

Description

This command can be used to configure the behaviour of the EventBus notifier in Payara Server.

The Data Grid must be enabled for the Event Bus to be available.

Options

asadmin-options

Options for the asadmin utility. For information about these options, see the asadmin help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the Event Bus notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the notifier.

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--topicName`

Defines the name of the internal Hazelcast distributed topic which will be used by the event bus to subscribe to notification events.

Examples

Example 1 Enable the Event Bus notifier and set its topic

```
asadmin set-eventbus-notifier-configuration --topicName=testTopic --dynamic=true
--enabled=true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-eventbus-notifier-configuration`

set-fault-tolerance-configuration

Modifies the configuration settings of the MicroProfile Fault Tolerance service.

Synopsis

```
asadmin [asadmin-options] set-fault-tolerance-configuration [--help]
[--managedexecutorservicename=managedexecutorservicename]
[--managedscheduledexecutorservicename=managedscheduledexecutorservicename]
[--target=server-config]
```

Description

The `set-fault-tolerance-configuration` provides a way to modify the configuration of the MicroProfile Fault Tolerance service in the specified target.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--managedexecutorservicename`

The Logical JNDI name of the Managed Executor Service to look up. Changes to this configuration require a restart of the server to take effect.

Defaults to `java:comp/DefaultManagedExecutorService`

`--managedscheduledexecutorservicename`

The Logical JNDI name of the Managed Scheduled Executor Service to look up. Changes to this configuration require a restart of the server to take effect.

Defaults to `java:comp/DefaultManagedScheduledExecutorService`

`--target`

Specifies the target of this command.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

Example

Example 1 Setting MicroProfile Fault Tolerance configuration

This example sets the configuration of the MicroProfile Fault Tolerance service.

```
asadmin> set-fault-tolerance-configuration
--managedexecutorservicename=java:comp/DefaultManagedExecutorService --target
instance1
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-fault-tolerance-configuration`

set-gcp-config-source-configuration

Sets the configuration for the GCP secrets configuration source.

Synopsis

```
asadmin [asadmin-options] set-gcp-config-source-configuration [--help]
[--projectname=projectname]
[--jsonkeyfile=jsonkeyfile]
[--target=server]
[--dynamic={false|true}]
[--enabled={true|false}]
```

Description

The `set-gcp-config-source-configuration` provides configuration options for the config source

which fetches data from GCP Secrets Manager.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--projectname`

The name of the GCP project to fetch secrets from.

`--jsonkeyfile`

The path to the JSON key file which a service account uses to authenticate with GCP Secrets. This file will be copied to the config/ directory.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--dynamic`

Configure the config source dynamically, which will not require a restart.

`--enabled`

Enables or disables the config source.

Example

Example 1 Setting the configuration of the GCP Config Source

This example configures the GCP Config Source.

```
asadmin set-gcp-config-source-configuration --dynamic true --enabled true
--jsonKeyFile /path/to/token/file.json --projectName project-name
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-gcp-config-source-configuration`

set-hashicorp-config-source-configuration

Sets the configuration for the HashiCorp secrets Config Source.

Synopsis

```
asadmin [asadmin-options] set-hashicorp-config-source-configuration [--help]
[--api-version=2]
[--secrets-engine-path=secrets-engine-path]
[--secrets-path=secrets-path]
[--vault-address=vault-address]
[--target=server]
[--dynamic={false|true}]
[--enabled={true|false}]
```

Description

The `set-hashicorp-config-source-configuration` provides configuration options for the Hashicorp configuration source which fetches secrets from HashiCorp Vault. Hashicorp config source only supports the Vault KV secrets engine.

Make sure that the password aliases `HASHICORP_VAULT_TOKEN` is registered.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--api-version`

KV Secrets Engine API version.

`--secrets-engine-path`

The path where the KV secrets engine is enabled.

`--secrets-path`

The path where your secrets are stored.

`--vault-address`

Vault's address represented as URL and port. For example, "http://127.0.0.1:8200".

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--dynamic`

Configure the config source dynamically, which will not require a restart.

`--enabled`

Enables or disables the config source.

Example

Example 1 Setting the configuration of the HashiCorp Config Source

This example configures the HashiCorp Config Source.

```
asadmin set-hashicorp-config-source-configuration --enabled true --dynamic true --api
-version 2 --vault-address https://127.0.0.1:8200 --secrets-engine-path secret
--secrets-path my-secret
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- asadmin
- get-hashicorp-config-source-configuration

set-hazelcast-configuration

Configures the underlying Data Grid (Hazelcast) instance.

Synopsis

```
asadmin [asadmin-options] set-hazelcast-configuration
[--help]
[--target target]
[--enabled={true|false}]
[--dynamic={true|false}]
[--hazelcastconfigurationfile hazelcastconfigurationfile]
[--startport startport]
[--publicaddress publicaddress]
[--daspublicaddress daspublicaddress]
[--dasbindaddress dasbindaddress]
[--dasport dasport]
[--clustermode clustermode]
[--tcpipmembers tcpipmembers]
[--dnsmembers dnsmembers]
[--interfaces interfaces]
[--multicastgroup multicastgroup]
[--multicastport multicastport]
[--clustername clustername]
[--jndiname name]
[--cachemanagerjndiname name]
[--cachingproviderjndiname name]
[--executorpoolsize executorpoolsize]
[--executorqueuecapacity executorqueuecapacity]
[--scheduledexecutorpoolsize scheduledExecutorPoolsize]
[--scheduledexecutorqueuecapacity scheduledexecutorQueueCapacity]
[--licensekey=licensekey]
[--lite={true|false}]
[--hostawarePartitioning={true|false}]
[--membername membername]
[--membergroup membergroup]
[--kubernetesNamespace namespace]
[--kubernetesServicename serviceName]
[--autoIncrementport={true|false}]
[--configSpecificDatagridStartport startPort]
[--encryptDatagrid={true|false}]
```

Description

This command can be used to configure the settings of the underlying Data Grid (Hazelcast) instance.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are executing this operation. Valid values are:

`server`

Applies to the default server instance. This is the default value.

instance_name

Applies to a specified server instance.

`--enabled`

Enables the Data Grid (Hazelcast).

If no `target` is specified, this will enable Hazelcast on the domain configuration `server-config`.

If no arguments are specified, defaults to `true`. If other options are specified, asadmin will interactively prompt for `--enabled`.

The default value is `true`.

`--dynamic`

Enable or disable dynamic stopping and starting of the embedded Hazelcast member. The default value is `false`.

`--hazelcastconfigurationfile`

`-f`

The Hazelcast configuration file to use.

This path is relative to the domain config directory, `domain-dir/config/`.

The default value is `hazelcast-config.xml`.

`--startport`

The port to run the Data Grid (Hazelcast) on for Payara Server Instances.

If this port is busy, the port specified will be incremented until a valid port is found.

The default value is `5900`.

`--publicaddress`

The Public Address to use for this Data Grid Node.

Used when the node is behind a NAT.

`--daspublicaddress`

This is the public IP Address that the DAS should use if the DAS is behind a NAT firewall and other Payara Server Instances need to connect via the public NAT address rather than the internal IP Address.

`--dasbindaddress`

Explicitly specifies the IP Address the DAS should bind the Hazelcast instance to.

By default, Hazelcast will try to choose the correct bind address from the IP addresses available on the host.

If you find the DAS is binding to an incorrect IP Address the correct address can be specified here.

`--dasport`

The port to run Hazelcast on for the DAS.

If this port is busy, the port specified will be incremented until a valid port is found.

The default value is `4900`.

`--clustermode`

Sets the Data Grid cluster discovery mode.

Can be one of `domain`, `tcpip`, `multicast` or `kubernetes`.

See Discovery Modes for a detailed description of each mode.

`--tcpipmembers`

Comma separated list of `IP-Address:port` used to discover cluster members if `tcpip` is selected as the cluster mode.

`--dnsmembers`

Sets the list of DNS names and ports of all Data Grid members when DNS Discovery Mode is used.

`--interfaces`

Similar to DAS Bind address by default Hazelcast will choose the correct IP Address to bind to.

If you find Hazelcast is binding to the incorrect address a comma separated list of IP Addresses can be specified here.

`--multicastgroup`

`-g`

The multicast group for communications in the Hazelcast instance if `multicast` is selected as cluster mode. The default value is `224.2.2.3`.

`--multicastport`

The multicast port for communications in the Hazelcast instance if `multicast` is selected as cluster mode. The default value is `54327`.

`--clustername`

Specifies the Hazelcast group name, to be optionally used to help divide clusters into logical, segregated groups (i.e. `dev-group`, `prod_group`).

`--jndiname`

`-j`

Specifies the JNDI name to bind the Hazelcast instance to.

`--cacheManagerJndiname`

Specified the JNDI name to bind the JCache Caching provider.

`--cachingProviderJndiname`

The JNDI name to bind the JCache Caching Provider to.

`--executorpoolsize`

The thread pool's size for the Hazelcast Executor service.

`--executorqueuecapacity`

Queue Capacity of the Data Grid Executor Service.

Executions are queued until a thread is available.

`--scheduledexecutorpoolsize`

The thread pool's size for the Hazelcast Scheduled Executor service.

`--scheduledexecutorqueuecapacity`

Queue Capacity of the Data Grid Scheduled Executor Service. Executions are queued until a thread is available.

`--licensekey`

`-lk`

Used to set the license key to start Hazelcast using an equivalent Hazelcast Enterprise edition compatible build.

Hazelcast Enterprise binaries have to be properly patched in the server installation for the Data Grid to be started correctly.

`--lite`

Sets the cluster to lite mode, where it will cluster but **not** store any cluster data. The default value is `false`.

`--hostawarePartitioning`

Whether to enable host-aware partitioning for the cluster.

Host aware partitioning **must be** enabled on all members of the cluster (including Payara Micro instances) for this feature to work correctly. The default value is `false`.

`--membername`

Member name. The default value is `instance name`.

`--membergroup`

Instance group name for all Server Instances using the configuration. Future functionality may use this name. The default value is `config name`.

`--kubernetesNamespace`

Sets the Kubernetes namespace when Kubernetes Discovery Mode is used.

If a namespace is not specified, Payara Server will use the `default` namespace.

`--kubernetesServicename`

Sets the Kubernetes service name when Kubernetes Discovery Mode is used.

`--autoincrementport`

By default, the Data Grid uses the next unoccupied port that is available starting with the start port.

When auto-increment is turned off an occupied start port results in a startup failure instead.

The default value is `false`.

`--configSpecificDataGridStartPort`

Sets a specific Data Grid start port to the instance.

This argument is only applicable when targeting standalone instances.

If set to `0` the Domain wide start port will be used instead.

`--encryptdatagrid`

Enables or disables encryption of data stored in the Domain Data Grid store using a key created using the `generate-encryption-key` command.

The default value is `false`.

Examples

Example 1 Basic configuration of the Data Grid settings

This example demonstrates configuring the Data Grid settings for a Hazelcast cluster called `cluster1`.

```
asadmin> set-hazelcast-configuration --enabled=true --target=cluster1 --dynamic=true
-f hazelcast-config.xml --startPort=5902 -g 224.2.2.3 --multicastPort=6666
--clustermode multicast --hostawarePartitioning=true -j payara/Hazelcast
Command set-hazelcast-configuration executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-healthcheck-configuration

Configures the Healthcheck service.

Synopsis

```
asadmin [asadmin-options] set-healthcheck-configuration
[--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--historic-trace-enabled={false|true}]
[--historic-trace-store-size size]
[--historic-trace-store-timeout integer.value {s|m|h|d}]
[--set-notifiers notifiers]
[--enable-notifiers notifiers]
```

```
[--disable-notifiers notifiers]
```

Description

Enables and disables the HealthCheck service. This includes configuration for tracing historic health check events for later inspection.

This command can also be used to configure which notifiers will be used to broadcast notification events from the Healthcheck service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the Healthcheck service. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the healthcheck service

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

`--historic-trace-enabled`

Defaults to `false`. Enables storing traces in a rolling store for later inspection.

`--historic-trace-store-size`

Defaults to `20`. Sets the maximum number of health checks to store.

`--historic-trace-store-timeout`

Sets the time period after which a historic health check event entry is removed from history.

The time expression should consist of a number followed by a time unit; `s` for seconds, `m` for

minutes, `h` for hours or `d` for days.

If no time unit is given the number specifies seconds.

If the parameter is zero or unspecified there is no timeout for entries.

`--set-notifiers`

Use the option to set the notifiers that will receive notifications generated by the Healthcheck Service.

A comma-separated list can be used to represent multiple notifiers.

This option will replace all the notifiers that have already been set to the HealthCheck Service.

`--enable-notifiers`

Use the option to enable one or more notifiers for the Healthcheck service.

A comma-separated list can be used to represent multiple notifiers.

`--disable-notifiers`

Use the option to disable one or more notifiers for the Healthcheck service.

A comma-separated list can be used to represent multiple notifiers.

Examples

Example 1 Basic Configuration

The following example will enable the Healthcheck service such that it will only activate from the next time the server is restarted.

It sets the log notifier and JMS notifiers and the historical trace store to retain 20 health checks.

```
asadmin set-healthcheck-configuration --enabled=true --dynamic=false --historic-trace
-enabled=true --historic-trace-store-size=20 --set-notifiers=log-notifier,jms-notifier
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `get-healthcheck-configuration`,
- `list-healthcheck-services`

set-healthcheck-service-configuration

Enables or disables the Healthcheck of a specific performance metric service.

Synopsis

```
asadmin [asadmin-options] set-healthcheck-service-configuration
[--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--service=serviceName]
[--checker-name=checkerName]
[--add-to-microprofile-health={true|false}]
[--time=time]
[--time-unit={DAYS|HOURS|MINUTES|SECONDS|MILLISECONDS}]
[--threshold-critical=threshold]
[--threshold-warning=threshold]
[--threshold-good=threshold]
[--hogging-threads-threshold=threshold]
[--hogging-threads-retry-count=count]
[--stuck-threads-threshold=threshold]
[--stuck-threads-threshold-unit={DAYS|HOURS|MINUTES|SECONDS|MILLISECONDS}]
[--add-metric=metricName]
[--delete-metric=metricName]
```

Description

Enables and disables the monitoring of a HealthCheck performance metric service. The command also configures the frequency of monitoring for that metric.

The command can also be used to configures performance metric specific properties.

If this command is run before running the `set-healthcheck-configuration` command, it will succeed and the configuration will be saved, but the Healthcheck service will not be enabled until the command is used.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the Healthcheck performance metric service. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the healthcheck performance metric service

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

`--service`

The performance service metric name. Required.

One of:

- `connection-pool` or `cp`
- `cpu-usage` or `cu`
- `garbage-collector` or `gc`
- `heap-memory-usage` or `hmu`
- `hogging-threads` or `ht`
- `machine-memory-usage` or `mmu`
- `stuck-thread` or `st`
- `mp-health` or `mh`
- `mp-metrics` or `mm`

`--checker-name`

A user determined name for easy identification of the checker.

This should be unique among the services you have configured, to avoid confusion on the notification messages.

Depends on the service checker. One of:

- `CONP`
- `CPUC`
- `GBGC`

- `HEAP`
- `HOGT`
- `MEMM`
- `MP`
- `MPM`

`--add-to-microprofile-health`

Defaults to `false`. When enabled, the checker results are displayed on MicroProfile Health REST endpoints as a readiness check.

`--time`

Defaults to `5`. The amount of time units that the service will use to periodically monitor the metric.

`--time-unit`

Defaults to `MINUTES`. The time unit to set the frequency of the metric monitoring.

Must correspond to a valid `java.util.concurrent.TimeUnit`

`--threshold-critical`

Defaults to `90`. The threshold value that this metric must surpass to generate a `CRITICAL` event.

A value between *WARNING VALUE* and `100` must be used.

Available for the `cp`, `cu`, `gc`, `hmu` and `mmu` metric services.

`--threshold-warning`

Defaults to `50`. The threshold value that this metric must surpass to generate a `WARNING` event.

A value between *GOOD VALUE* and *WARNING VALUE* must be used.

Available for the `cp`, `cu`, `gc`, `hmu` and `mmu` metric services.

`--threshold-good`

Defaults to `0`. The threshold value that this metric must surpass to generate a `GOOD` event.

A value between `0` and *WARNING VALUE* must be used.

Available for the `cp`, `cu`, `gc`, `hmu` and `mmu` metric services.

`--hogging-threads-threshold`

Defaults to `95`. The threshold value that this metric will be compared to mark threads as hogging the CPU.

Only available for the `ht` metric service.

`--hogging-threads-retry-count`

Defaults to `3`. The number of retries that the checker service will execute in order to identify a hogging thread.

Only available for the `ht` metric service.

`--stuck-threads-threshold`

The threshold above which a thread is considered stuck. Must be `1` or greater.

Only available for the `st` metric service.

`--stuck-threads-threshold-unit`

The unit for the threshold for when a thread should be considered stuck.

Must correspond to a valid `java.util.concurrent.TimeUnit`

Only available for the `st` metric service.

`--add-metric`

Adds a metric exposed by Eclipse MicroProfile Metrics to monitor.

Takes a string of the format `'metricName=MetricName description=Description'`, where `metricName` is a mandatory value.

`--delete-metric`

Removes a metric exposed by MicroProfile Metrics that has been added to monitor. Takes a string of the format `'metricName=MetricName'`, where `metricName` is required.

Examples

Example 1 Basic Configuration

A very basic example command to simply enable the Garbage Collector checker service and activate it without needing a restart would be as follows:

```
asadmin set-healthcheck-service-configuration --enabled=true --service=gc
--dynamic=true
```

Example 2 Setting up thresholds for configuring JDBC Connection Pools health monitoring

Monitoring the health of JDBC connection pools is a common need. In that scenario, it is very unlikely that on-the-fly configuration changes would be made, so a very high `CRITICAL` threshold can be set.

Likewise, a nonzero `GOOD` threshold is needed because an empty or unused connection pool may not be healthy either.

The following command would apply these settings to the connection pool checker:

```
asadmin set-healthcheck-service-configuration --service=cp --dynamic=true --threshold
-critical=95 --threshold-warning=70 --threshold-good=30
```

Example 3 Setting up thresholds for identifying CPU hogging threads

Monitoring which threads hog the CPU is extremely important since this can lead to performance degradation, deadlocks and extreme bottlenecks issues that web applications can incur.

In some cases the defaults are all that is needed, but imagine that in a critical system you want to set the threshold percentage to **90%**, and you want to make sure that the health check service guarantees the state of such threads with a retry count of **5**.

Additionally, you want to set the frequency of this check for every *20 seconds*.

The following command would apply these settings to the Hogging threads checker service:

```
asadmin> set-healthcheck-service-configuration --service=ht --dynamic=true --hogging
-threads-threshold=90 --hogging-threads-retry-count=5 --time=20 --time-unit=SECONDS
```

Example 4 Setting up thresholds for identifying stuck threads

The following example configures the stuck threads checker to check every 30 seconds for any threads which have been stuck for more than 5 minutes and applies the configuration change without needing a restart:

```
asadmin set-healthcheck-service-configuration --service=st --enabled=true
--dynamic=true --time=30 --time-unit=SECONDS --stuck-threads-threshold=5 --stuck
-threads-threshold-unit=MINUTES
```

Example 5 Setting up thresholds adding a MicroProfile Metrics check for the maximum thread count:

The following example configures the Microprofile Metrics Checker to add `base_thread_max_count` metrics for monitoring, adds the checker to MicroProfile Health to display its result on MicroProfile Health REST endpoints and applies the configuration change without needing a restart:

```
asadmin set-healthcheck-service-configuration --service=mp-metrics --enabled=true
--dynamic=true --add-to-microprofile-health=true --add
-metric='metricName=base_thread_max_count'
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-jdbc-config-source-configuration

Configures the JDBC configuration source.

Synopsis

```
asadmin [asadmin-options] set-jdbc-config-source-configuration [--help]
[--jndiname=jndiname]
[--tablename=tablename]
[--keycolumnname=keycolumnname]
[--valuecolumnname=valuecolumnname]
[--target=server]
```

Description

The `set-jdbc-config-source-configuration` provides configuration options to set the properties required by JDBC config source to read the values from the configured database.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--jndiName`

JNDI (Java Naming and Directory Interface) name under which the JDBC resource will be registered in the application server's JNDI namespace.

`--tablename`

Name of the table in the database.

`--keycolumnname`

Name of the column in the specified table that serves as the key for retrieving data.

`--valuecolumnname`

Name of the column in the specified table that contains the values associated with the keys.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

Example

Example 1 Configuring the JDBC Config Source.

This example configures the JDBC config source.

```
asadmin set-jdbc-config-source-configuration --jndiName jndi-name --tableName Books
--keyColumnName ISBN --valueColumnName Title
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-jdbc-config-source-configuration`

set-jms-notifier-configuration

Configures the settings of the JMS notifier

Synopsis

```
asadmin [asadmin-options] set-jms-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--contextFactoryClass className]
[--connectionFactoryName connectionFactoryName]
```

```
[--queueName queueName]
[--url url]
[--userName userName]
[--password password]
```

Description

This command can be used to configure the behaviour of the JMS notifier in Payara Server Full Profile.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the JMS notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--contextFactoryClass`

Defines the naming context factory class used to provision the JMS resources required to send the notification events.

The referenced class name should point to a valid implementation of `javax.naming.spi.InitialContextFactory` and should be located in the server's classpath.

In most cases, using the default context factory class (`com.sun.enterprise.naming.SerialInitContextFactory`) is enough.

`--connectionFactoryName`

Defines the JNDI name of an existing JMS connection factory which will be used to send the notification messages.

`--queueName`

Defines the physical name of an existing JMS queue destination used to send the messages to.

`--url`

Defines the URL of a JMS broker server that will handle the sending and reception of the notification message.

`--userName`

Defines the user that will authentication to the JMS broker server (if required).

`--password`

Defines the password credential of the user that will authentication to the JMS broker server (if required).

Examples

Example 1 Enable the JMS Notifier and Configure it using OpenMQ

This example enables the JMS notifier and sets it up to connect to the default, local OpenMQ broker server and use a queue named `testQueue`:

```
asadmin set-jms-notifier-configuration --dynamic=true --enabled=true
--contextFactoryClass=com.sun.enterprise.naming.SerialInitContextFactory
--connectionFactoryName=jms/__defaultConnectionFactory --queueName=testQueue
--url=localhost:7676 --username=testUser --password=******** --target=server-config
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,

- `get-jms-notifier-configuration`

set-jmx-monitoring-configuration

Configures the JMX monitoring service subsystem.

Synopsis

```
asadmin [asadmin-options] set-jmx-monitoring-configuration
[--help]
[--target target]
[--enabled={false|true}]
[--logFrequency frequency]
[--logFrequencyUnit={DAYS|HOURS|MINUTES|SECONDS|MILLISECONDS}]
[--addAttribute="attributes"]
[--delAttribute="name"]
[--set-notifiers notifiers]
[--enable-notifiers notifiers]
[--disable-notifiers notifiers]
```

Description

This command can be used to configure the settings of the JMX Monitoring subsystem.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the JMX monitoring service. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the JMX monitoring service

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

`--addAttribute`

Provides a way to add a new **MBean** attribute to monitor using the service.

This argument takes in a string of space-delimited key-value pairs corresponding to the values of a JMX MBean definition. The `attributeName` and `objectName` fields are required, but `description` is not.

For example, providing `attributeName=HeapMemoryUsage` denotes that the name of the **MBean** attribute to log is `HeapMemoryUsage`, while `objectName=java.lang:type=Memory` denotes the `ObjectName` of the **MBean** to look for the attribute on is `java.lang:type=Memory`.

`--delAttribute`

Provides a way to remove an **MBean** attribute that is being monitored by the JMX Monitoring service.

Use the name of the attribute that you want to remove from the monitoring output.

`--logFrequency`

Defaults to `15`. The frequency that the service will use to periodically log monitoring entries.

`--logFrequencyUnit`

Defaults to `SECONDS`. The time unit to set the frequency of the log done by the JMX Monitoring service.

`--set-notifiers`

Use the option to set the notifiers that will receive notifications generated by the JMX Monitoring service.

A comma-separated list can be used to represent multiple notifiers.

This option will replace all the notifiers that have already been set to the JMX Monitoring Service.

`--enable-notifiers`

Use the option to enable one or more notifiers for the JMX Monitoring service.

A comma-separated list can be used to represent multiple notifiers.

`--disable-notifiers`

Use the option to disable one or more notifiers for the JMX Monitoring service.

A comma-separated list can be used to represent multiple notifiers.

Examples

Example 1 Enables JMX monitoring service along with the AMX subsystem

```
asadmin set-jmx-monitoring-configuration --enabled=true --dynamic=true --target=server
```

Example 2 Enables JMX monitoring service and monitors the amount of used Heap memory of the server's JVM

```
asadmin set-jmx-monitoring-configuration --addAttribute
'attributeName=HeapMemoryUsage.used objectName=java.lang:type=Memory' --enabled true
```

Example 3 Enables JMX monitoring service and configures the logging frequency to 5 minutes

```
asadmin set-jmx-monitoring-configuration --logFrequency 5 --logFrequencyUnit MINUTES
--enabled true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-ldap-config-source-configuration

Sets the LDAP Config Source

Synopsis

```
asadmin [asadmin-options] set-ldap-config-source-configuration [--help]
[--enabled={true|false}]
[--dynamic={true|false}]
[--url=<ldap-server-url>]
[--authType={simple|none}]
[--startTLSEnabled={true|false}]
[--bindDN=<user-distinguished-name>]
[--bindDNPassword=<user-credential>]
[--searchBase={subtree|onelevel|object}]
[--searchFilter=<search-filter>]
[--searchScope=<search-scope>]
```

```
[--connectionTimeout=<integer-value-in-milliseconds>]
[--readTimeout=<integer-value-in-milliseconds>]
[--target=<target[default:server]>]
```

Description

The `set-ldap-config-source-configuration` provides a way to configure the MicroProfile LDAP configuration source.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Defaults to `false`. Enables or disables the config source

`--dynamic`

Defaults to `false`. If set to true, applies the changes instantly without a restart. Otherwise, a restart is required.

`--url`

URL where the LDAP server can be reached

`--authType`

Defaults to `none`. Type of the Authentication method used during the connection with the LDAP server.

The MicroProfile LDAP config source supports simple and none auth type. If simple auth type is selected then Bind DN and Bind DN Password are mandatory. If none auth type is selected then **Search Base** and **Search Filter** are mandatory otherwise optional.

If **Search Base** and **Search Filter** are not defined then data fetched from direct binding.

`--startTLSEnabled`

Defaults to `false`. Secure the LDAP server connection using LDAP over TLS (STARTTLS) protocol

`--bindDN`

Distinguished name for the application that will be used to access the LDAP server

`--bindDNPassword`

Password for the application defined by the Bind DN member. In place of the password, you can enter an alias which corresponds to the password in the form: ${ALIAS=<password-alias-name>}

`--searchBase`

Overrides 'Base DN' and causing the search to be used instead of direct binding

`--searchFilter`

Search filter to find values starting from the 'Search Base DN' with the scope specified by 'Search Scope'.

`--searchScope`

Search scope determines the depth of the search in the LDAP tree

`--connectionTimeout`

The timeout for connecting to the LDAP server in milliseconds. The value should be greater than zero. If this value is not specified or less than one, then wait for the response until it is received.

`--readTimeout`

The timeout for fetching the results from the LDAP server in milliseconds. The value should be greater than zero. If this value is not specified or less than one, then wait for the response until it is received.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

Example

Example 1 Setting the LDAP configuration

This example enables and configures LDAP authentication on the Payara Server instance, specifying the LDAP server's URL, authentication type, binding credentials and other settings.

```
asadmin set-ldap-config-source-configuration --enabled=true --dynamic=true
--url=ldap://ldap.forumsys.com:389 --authType=simple --bindDnPassword=password
--bindDn=cn=read-only-admin,dc=example,dc=com
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-ldap-config-source-configuration`

set-log-attributes

Sets the logging attributes for one or more loggers.

Synopsis

```
asadmin [asadmin-options] set-log-attributes [--help]
[--target=target]
attribute-name=attribute-value[:attribute-name=attribute-value]*
```

Description

The `set-log-attributes` subcommand sets logging attributes for one or more loggers. The attributes you can set correspond to the attributes that are available in the `logging.properties` file for the domain.Depending on the attributes you set, a server restart may be necessary.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The server domain, instance, or cluster for which logger attributes will be set. If this option is omitted, attributes are set for the default server.

Operands

target

Valid values are:

- server_name - Default target is `server`. If no target is specified then log attributes are set for the server.
- cluster_name - The name of a target cluster.
- instance_name - The name of a target server instance.

attribute-name

The fully scoped name of the logging attribute. The `list-log-attributes` subcommand can be used to list the names of all currently defined attributes.

attribute-value

The value to apply to the specified attribute.
The attribute values that can be specified include the following. Refer to "Administering the Logging Service" in Payara Server General Administration section for complete explanations of each of these values.

`com.sun.enterprise.server.logging.GFFileHandler.alarms`

Default is `false`.

`com.sun.enterprise.server.logging.GFFileHandler.excludeFields`

Default is an empty string.

`com.sun.enterprise.server.logging.GFFileHandler.file`

Default is `${com.sun.aas.instanceRoot}/logs/server.log`.

`com.sun.enterprise.server.logging.GFFileHandler.flushFrequency`

Default is `1`.

`com.sun.enterprise.server.logging.GFFileHandler.formatter`

Default is `com.sun.enterprise.server.logging.UniformLogFormatter`.

`com.sun.enterprise.server.logging.GFFileHandler.logtoConsole`

Default is `false`.

`com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles`

Default is `0`.

`com.sun.enterprise.server.logging.GFFileHandler.multiLineMode`

Default is `true`.

`com.sun.enterprise.server.logging.GFFileHandler.retainErrorsStasticsForHours`

Default is `0`.

`com.sun.enterprise.server.logging.GFFileHandler.rotationLimitInBytes`

Default is `2000000`.

`com.sun.enterprise.server.logging.GFFileHandler.rotationTimelimitInMinutes`

Default is `0`.

`com.sun.enterprise.server.logging.SyslogHandler.useSystemLogging`

Default is `false`.

`handlers`

Default is `java.util.logging.ConsoleHandler`.

`java.util.logging.ConsoleHandler.formatter`

Default is `com.sun.enterprise.server.logging.UniformLogFormatter`.

`java.util.logging.FileHandler.count`

Default is `1`.

`java.util.logging.FileHandler.formatter`

Default is `java.util.logging.XMLFormatter`.

`java.util.logging.FileHandler.limit`

Default is `50000`.

`java.util.logging.FileHandler.pattern`

Default is `%h/java%u.log`.

`log4j.logger.org.hibernate.validator.util.Version`

Default is `warn`.

Examples

Example 1 Setting the Maximum Number of Log History Files to Maintain

This example sets to 8 the maximum number of log history files for the server as a whole.

```
asadmin> set-log-attributes --target=server \
com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles=8
com.sun.enterprise.server.logging.GFFileHandler.maxHistoryFiles logging
attribute set with value 8.
These logging attributes are set for server.
Command set-log-attributes executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-log-file-format

Sets the formatter to be used for the server log file.

Synopsis

```
asadmin [asadmin-options] set-log-file-format [--help]
[--target target]
[formatter]
```

Description

The `set-log-file-format` subcommand sets the formatter to be used for the server log file for the specified target.

Payara Server provides the ULF (UniformLogFormatter) and ODL (Oracle Diagnostics Logging) formatters. A custom formatter can also be used by specifying the fully qualified name of a class that extends the `java.util.logging.Formatter` class.

The custom formatter class can be packaged in a JAR file and placed in domain `/lib/ext`, or implemented as an HK2 service and the JAR containing the formatter implementation installed in `glassfish/modules`.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

Specifies the target for which the formatter is being set. Specify the name of the server domain, instance, or cluster. If this option is omitted, logger attributes are set for the default server.

Operands

formatter

Specifies the fomatter to be used for the server log file. Valid values are ULF, ODL, or the fully qualified name of the custom formatter class to be used to render the log files. The default value is ODL.

Examples

Example 1 Setting the Log File Format

This example sets the server log file format to `ULF` for `server1`.

```
asadmin> set-log-file-format --target server1 ULF
Command set-log-file-format executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-loggers`,
- Administering the Logging Service in the Payara Server General Administration section

set-log-levels

Sets the log level for one or more loggers.

Synopsis

```
asadmin [asadmin-options] set-log-levels [--help]
[--target=target]
logger-name=logger-level[:logger-name=logger-level]*
```

Description

The `set-log-levels` subcommand sets the log level for one or more loggers. Changes take effect dynamically. Depending on the log levels you set, a server restart may be necessary.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

The server instance or cluster for which log levels will be set. Valid values are:

- `server` - The default server instance. If no target is specified then log levels are set for the default server instance.
- cluster-name - The name of a cluster.
- instance-name - The name of a standalone server instance.

Operands

logger-name

The name of the logger. The `list-log-levels` subcommand can be used to list the names of the current loggers.

logger-level

The level to set for the logger. Log level values are `SEVERE`, `WARNING`, `INFO`, `CONFIG`, `FINE`, `FINER`, and `FINEST`. The default setting is `INFO`.

Examples

Example 1 Setting a Log Level for a Logger

This example sets the log level of the web container logger to `WARNING`.

```
asadmin> set-log-levels jakarta.enterprise.system.container.web=WARNING
Command set-log-level executed successfully.
```

Example 2 Setting the Log Level for Multiple Loggers

This example sets the log level of the web container logger to `FINE` and the log level of the EJB container logger to `SEVERE`:

```
asadmin set-log-levels jakarta.enterprise.system.container.web=FINE:
jakarta.enterprise.system.container.ejb=SEVERE
Command set-log-level executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-log-notifier-configuration

Configures the settings of the Log notifier

Synopsis

```
asadmin [asadmin-options] set-log-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--useseparatelogfile={false|true}]
```

Description

This command can be used to configure the behaviour of the log notifier in Payara Server.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`
: Displays the help text for the subcommand.

`--target`
: This option helps specify the target on which you are configuring the log notifier. Valid values are:

  `server`
  : Applies to the default server instance. This is the default value.

  cluster_name
  : Applies to every server instance in the cluster.

  instance_name
  : Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--useseparatelogfile`

Defaults to `false`. Whether to use a separate log file to store notifications.

Examples

Example 1 Enable the Log Notifier and Configure Filter level

```
asadmin> set-log-notifier-configuration --enabled=true --dynamic=true --filter=INFO
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-log-notifier-configuration`,

set-metrics-configuration

Modifies the configuration settings of the MicroProfile Metrics service.

Synopsis

```
asadmin [asadmin-options] set-metrics-configuration [--help]
[--enabled={true|false}]
[--securityEnabled={true|false}]
[--roles=<role-list>]
[--dynamic={true|false}]
[--endpoint=<context-root[default:metrics]>]
[--target=<instance-name[default:server]>]
[--virtualservers=<virtualserver-list>]
```

Description

The `set-metrics-configuration` provides a way to set the configuration of the metrics service of the targeted config.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Defaults to `true`. Enables or disables the Metrics service.

`--securityEnabled`

Defaults to `false`. Specifies whether secure access to the metrics endpoint is enabled or disabled.

`--roles`

Defaults to `microprofile`. If defined, the endpoint will be assigned to a list of the role specified as a comma-separated.

`--dynamic`

Defaults to `true`. If set to `true`, applies the changes instantly without a restart.

Otherwise, a restart is required.

`--endpoint`

Defaults to `metrics`. Specifies the context root used to expose the metrics endpoint.

`--target`

Specifies the target for its respective configuration.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--virtualservers`

If defined, the endpoint will be assigned to a list of virtual servers specified as a comma-separated list of names.

Otherwise, the endpoint will be assigned to all virtual servers available.

Example

Example 1 Setting the configuration of the Metrics service

This example sets the metrics service configuration for the specified target `instance1`.

```
asadmin set-metrics-configuration --enabled=true --securityEnabled=true --dynamic=true
--target instance1
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-metrics-configuration`

set-microprofile-healthcheck-configuration

Configures the settings of the MicroProfile HealthCheck service.

Synopsis

```
asadmin [asadmin-options] set-microprofile-healthcheck-configuration [--help]
[--enabled={true|false}]
[--securityEnabled={true|false}]
[--roles=<role-list>]
[--endpoint=<context-root[default:health]>]
[--target=<target[default:server]>]
[--virtualservers=<virtualserver-list>]
```

Description

The `set-microprofile-healthcheck-configuration` enables or disables the MicroProfile healthcheck service and configures the endpoint where all registered health checks are exposed.

Changes made with this command will only be applied when the server or

> instance is restarted.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Defaults to true. Enables or disables the service.

`--securityenabled`

Defaults to false. Whether to secure access to the health-check endpoint is enabled.

`--roles`

Defaults to `microprofile`. If defined, the endpoint will be assigned to a list of the role specified as a comma-separated.

`--endpoint`

Defaults to health. The context root used to expose the health checks endpoint.

`--target`

Specifies the target of this command.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--virtualservers`

If defined, the `/health`` endpoint will be assigned to the list of virtual servers specified as a comma-separated list of names.

Otherwise, the endpoint will be assigned to all virtual servers available.

Example

Example 1 Configure the MicroProfile HealthCheck service

This example configures MicroProfile Health Check with security enabled, specifies the roles allowed to access the endpoint, sets a custom endpoint context root, and associates it with the specified virtual servers:

```
asadmin set-microprofile-healthcheck-configuration \
    --enabled=true \
    --securityEnabled=true \
    --roles=ADMIN \
    --endpoint=myhealth \
    --target=server \
    --virtualservers=myapp
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-microprofile-healthcheck-configuration`

set-monitoring-level

This command can be used to set the monitoring level of a module.

Synopsis

```
asadmin [asadmin-options] set-monitoring-level
[--help]
[--target target]
[--module module]
[--level={HIGH|LOW|OFF}]
```

Description

This command can be used to set the monitoring level (`HIGH`/`LOW`) of a module. Monitoring can also be disabled by setting the level to `OFF`.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the monitoring level of a server module. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--module`

The name of the module. Mandatory value.

Multiple module names can be set in a comma separated string.

`--level`

Allows you to change monitoring level for a module to `OFF`, `LOW` or `HIGH`.

Examples

Example 1 Configure the monitoring level of the JVM module to `HIGH`

```
asadmin set-monitoring-level --module=jvm --level=HIGH --target=server
```

Example 2 Configure the monitoring level of both the JVM and HTTP Service modules to `LOW`

```
asadmin set-monitoring-level --module=jvm,http-service --level=LOW --target=server
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- Monitoring Basics,
- `set-monitoring-service-configuration`,
- `enable-monitoring`,
- `disable-monitoring`

set-monitoring-service-configuration

Configures the monitoring service.

Synopsis

```
asadmin [asadmin-options] set-monitoring-service-configuration
[--help]
[--target target]
[--enabled={false|true}]
[--mbeansenabled={false|true}]
[--dtraceenabled={false|true}]
```

Description

This command can be used to configure the basic settings of the Monitoring service.

Options

asadmin-options
: Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`
`-?`
: Displays the help text for the subcommand.

`--target`
: This option helps specify the target on which you are configuring the monitoring service. Valid values are:

  `server`
  : Applies to the default server instance. This is the default value.

  cluster_name
  : Applies to every server instance in the cluster.

  instance_name
  : Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the monitoring service

`--mbeansenabled`

Defaults to `false`. Whether to enable or disable MBean monitoring.

`--dtraceenabled`

Defaults to `false`. Whether to enable or disable the DTrace monitoring.

Examples

Example 1 Basic configuration of the monitoring service

```
asadmin set-monitoring-service-configuration --enabled=true --mbeansenabled=true
--target=server
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

set-network-listener-configuration

Helps to modify an existing network listener.

Synopsis

```
asadmin [asadmin-options] set-network-listener-configuration [--help]
[--enabled={true|false}]
[--dynamic={}true|false}]
[--address=address]
[--listenerport=port]
[--listenerportrange=portrange]
[--threadpool=threadpool]
[--protocol=protocol]
[--transport=transport]
```

```
[--jkenabled=true|false]
[--target target]
listener-name
```

Description

The `set-network-listener-configuration` subcommand modifies an existing network listener.

If you edit the `admin-listener` network listener, you must restart the server for the changes to take effect. The Administration Console will not tell you that a restart is required in this case.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--address`

The IP address or the hostname (resolvable by DNS).

`--listenerport`

The port on which the network listener is going to be listening.

`--listenerPortRange`

Port range which the network listener can bind to.

`--threadpool`

The name of the thread pool for this listener. Specifying a thread pool is optional. The default is `http-thread-pool`.

`--protocol`

The name of the protocol for this listener.

`--transport`

The name of the transport for this listener. Specifying a transport is optional. The default value is `tcp`.

`--enabled`

If set to `true`, the default, the listener is enabled at runtime.

`--jkenabled`

If enabled, the network listener will become an Apache `mod-jk` listener. The default value is `false`.

`--target`

Creates the network listener only on the specified target. Valid values are as follows:

`server`

Creates the network listener on the default server instance. This is the default value.

`configuration-name`

Creates the network listener in the specified configuration.

`cluster-name`

Creates the network listener on all server instances in the specified cluster.

`standalone-instance-name`

Creates the network listener on the specified standalone server instance.

Operands

name

The name of the network listener.

Examples

Example 1 Modifying a Network Listener

The following command modifies a network listener named `sampleListener`:

```
asadmin set-network-listener-configuration --dynamic true --enabled=false
--listenerport 8080 sampleListener

Command set-network-listener-configuration executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

set-newrelic-notifier-configuration

Configures the settings of the New Relic notifier.

Synopsis

```
asadmin [asadmin-options] set-newrelic-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--accountId accountId]
[--key key]
```

Description

This command can be used to configure the behaviour of the New Relic notifier in Payara Server.

This command is available as long as the New Relic notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the New Relic notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the log notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--accountId`

Defines the New Relic account Id.

`--key`

Defines the license key to be used by the notifier.

Examples

Example 1 Enable the New Relic and set its license and account configuration

```
asadmin set-newrelic-notifier-configuration --dynamic=true --enabled=true
--accountId=1658989 --key=b5815wdxj6lF_tmMBljQa5y1603JTiLh
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-newrelic-notifier-configuration`

set-notification-configuration

Configures the notification service along with the log notifier.

Synopsis

```
asadmin [asadmin-options] set-notification-configuration
[--help]
[--target target]
[--enabled={false|true}]
```

```
[--dynamic={false|true}]
[--notifierEnabled={false|true}]
[--notifierDynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--useseparatelogfile={false|true}]
```

Description

This command can be used to set the configuration of the Notification Service and the Log Notifier at the same time.

It functions as a combination of the `notification-configure` and `set-log-notifier-configuration` Asadmin commands.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the notification service. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the notification service

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

`--notifierEnabled`

Defaults to `false`. Enables or disables the log notifier

`--notifierDynamic`

Defaults to `false`. When set to `true`, applies the changes to the log notifier without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--useseparatelogfile`

Defaults to `false`. Whether to use a separate log file to store notifications.

Examples

Example 1 Enables the notification service

```
asadmin set-notification-configuration --enabled=true --dynamic=true
--notifierEnabled=true --notifierDynamic=true --useSeparateLogfile=false
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `notification-configure`,
- `set-log-notifier-configuration`

set-openapi-configuration

Configures the settings of the MicroProfile OpenAPI service.

Synopsis

```
asadmin [asadmin-options] set-openapi-configuration [--help]
[--enabled={true|false}]
[--corsHeaders={true|false}]
[--securityEnabled={true|false}]
[--roles=<role-list>]
[--endpoint=<context-root[default:openapi]>]
[--target=<target[default:server]>]
[--virtualservers=<virtualserver-list>]
```

Description

This command enables or disables the OpenAPI service.

When the OpenAPI service is disabled, the `/openapi` endpoint will always return a `403` error and any applications deployed during this period will **not** have an OpenAPI document built.
Enabling the service again will not cause a documents to be built for any currently deployed applications.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Whether the service should be enabled/disabled. Defaults to `true`.

`--corsHeaders`

Defaults to `false`. Whether CORS protection headers (e.g. `Access-Control-Allow-Origin=*`) should be added to OpenAPI endpoint responses.

`--securityEnabled`

Defaults to `false`. Whether to secure access to the OpenAPI endpoint is enabled.

`--roles`

Defaults to `microprofile`.

If defined, the endpoint will be assigned to a list of the role specified as a comma-separated.

`--endpoint`

Defaults to `openapi`. The context root used to expose the OpenAPI endpoint.

`--target`

Specifies the target of this command.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

configuration-name

Specifies a named configuration.

`--virtualservers`

If defined, the `/openapi` endpoint will be assigned to the list of virtual servers specified as a comma-separated list of names.

Otherwise, the endpoint will be assigned to all virtual servers available.

Examples

Example 1 Configures OpenAPI service

This example configures OpenAPI service with CORS headers enabled, security enabled, a custom endpoint context root, and association with the specified virtual servers.

```
asadmin set-openapi-configuration --enabled=true --corsHeaders=true
--securityEnabled=true --roles=ADMIN --endpoint=myapi --target=server
--virtualservers=myapp
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-openapi-configuration`

set-requesttracing-configuration

Configures the Request Tracing service.

Synopsis

```
asadmin [asadmin-options] set-requesttracing-configuration [--help]
[--enabled={false|true}]
[--dynamic={false|true}]
[--sampleRate] rate
[--adaptiveSamplingEnabled={false|true}]
[--adaptiveSamplingTargetCount] targetCount
[--adaptiveSamplingTimeValue] value
[--adaptiveSamplingTimeUnit] timeUnit
[--applicationsOnlyEnabled={false|true}]
[--thresholdValue] value
```

```
[--thresholdUnit] timeUnit
[--sampleRateFirstEnabled={false|true}]
[--traceStoreSize] size
[--traceStoreTimeout] timeout
[--reservoirSamplingEnabled={false|true}]
[--historicTraceStoreEnabled={false|true}]
[--historicTraceStoreSize] size
[--historicTraceStoreTimeout] timeout
```

Description

This command can be used to configure several aspects of the Request Tracing service.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--enabled`

Defaults to `false`. Enables or disables the Request Tracing service

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--sampleRate`

The probability of a trace being sampled.

The rate must be a positive number between `0` and `1.0`

`--adaptiveSamplingEnabled`

Defaults to `false`. Whether to use an adaptive sampling rate.

`--adaptiveSamplingTargetCount`

The target number of traces to sample per the configured time window.

Defaults to `6`.

`--adaptiveSamplingTimeValue`

The period of time to attempt to hit the adaptive sample target count in.

Defaults to `1`.

`--adaptiveSamplingTimeUnit`

The time unit for the `adaptiveSampleTimeValue` option.

Defaults to `MINUTES`.

`--applicationsOnlyEnabled`

Defaults to `true`. Whether to exclusively sample traces related to applications.

`--thresholdValue`

Sets the number of time units which trigger the tracing of a request.

Only used if `adaptiveSamplingEnabled` is set to `false`.

`--thresholdUnit`

Sets the time unit to use for the threshold.

Only used if `adaptiveSamplingEnabled` is set to `false`.

`--sampleRateFirstEnabled`

Defaults to `true`. Whether to perform the sampling check before or after the threshold calculation.

`--traceStoreSize`

Sets how many request traces will be stored.

Defaults to `20` trace records.

`--traceStoreTimeout`

Sets how long before Request Tracing messages are removed.

This field is specified in the format `%d %h %m %s` where `%` is an integer. Any of the units can also be omitted.

This option is ignored when reservoir sampling is enabled.

`--reservoirSamplingEnabled`

Defaults to `false`. Whether to use reservoir sampling, or time based sampling.

`--historicTracestoreEnabled`

Defaults to `false`. When present, enables storage of the slowest sampled historical request traces in a separate trace store.

`--historicTracestoreSize`

Sets how many request traces will be stored for historical purposes.

Defaults to `20` trace records.

`--historicTracestoreTimeout`

Sets how long before Request Tracing messages are removed from the historical trace store.

This field is specified in the format `%d %h %m %s` where `%` is an integer. Any of the units can also be omitted.

This option is ignored when reservoir sampling is enabled.

Examples

Example 1 Configure the Request Tracing Service Threshold and Historic Trace Storage

Enables the Request Tracing service with a 10 seconds threshold and to store the last 20 traces from 1 day, 2 hours and 3 minutes ago:

```
asadmin> set-requesttracing-configuration
    --enabled=true
    --thresholdValue=10
    --thresholdUnit="SECONDS"
    --dynamic=true
    --historicTraceStoreEnabled=true
    --historicTraceStoreSize=20
    --historicTraceStoreTimeout='1d 2h 3m 30s'
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-requesttracing-configuration`,

set-rest-monitoring-configuration

Configures the REST monitoring service subsystem.

Synopsis

```
asadmin [asadmin-options] set-rest-monitoring-configuration
[--help]
[--target target]
[--enabled={false|true}]
```

```
[--securityEnabled={false|true}]
[--contextRoot contextRoot]
[--applicationName name]
```

Description

This command can be used to configure the settings of the REST Monitoring subsystem.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the REST monitoring service. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified server instance.

`--enabled`

Defaults to `false`. Enables or disables the REST monitoring service

`--securityEnabled`

Defaults to `false`. Whether to secure access to the REST Monitoring application is enabled.

`--contextRoot`

Defaults to `/rest-monitoring`. The context root of the REST Monitoring application.

`--applicationName`

Defaults to `__restmonitoring`. The name of the REST Monitoring application.

Examples

Example 1 Enables REST monitoring service on the `/rest-mon` context root

```
asadmin set-rest-monitoring-configuration --enabled=true --contextRoot /rest-mon
--target=server
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- Monitoring Basics
- `get-rest-monitoring-configuration`

set-slack-notifier-configuration

Configures the settings of the Slack notifier.

Synopsis

```
asadmin [asadmin-options] set-slack-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--token1 token]
[--token2 token]
[--token3 token]
```

Description

This command can be used to configure the behaviour of the Slack notifier in Payara Server.

This command is available as long as the Slack notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the Slack notifier. Valid values

are:

`server`
: Applies to the default server instance. This is the default value.

cluster_name
: Applies to every server instance in the cluster.

instance_name
: Applies to a specified sever instance.

`--enabled`
: Defaults to `false`. Enables or disables the log notifier

`--dynamic`
: Defaults to `false`. When set to `true`, applies the changes without a server restart.

  Otherwise, a restart is required.

`--filter`
: Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--token1`
: The first token required to authenticate to the corresponding Slack channel.

`--token2`
: The second token required to authenticate to the corresponding Slack channel.

`--token3`
: The third token required to authenticate to the corresponding Slack channel.

Examples

Example 1 Enable the Slack notifier and set its required tokens

```
asadmin set-slack-notifier-configuration --enabled=true --dynamic=true
--token1=T43CHENUC --token2=B441EFQB1 --token3=Jas8P3jCZ4wK8Y2m88dCxGkn
```

Exit Status

0
: subcommand executed successfully

1
: error in executing the subcommand

See Also

- `asadmin`,
- `get-slack-notifier-configuration`

set-snmp-notifier-configuration

Configures the settings of the SNMP notifier.

Synopsis

```
asadmin [asadmin-options] set-snmp-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[--hostname hostname]
[--snmpPort port]
[--community community]
[--oid oid]
[--version version]
```

Description

This command can be used to configure the behaviour of the SNMP notifier in Payara Server.

This command is available as long as the SNMP notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the SNMP notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the log notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

`--hostName`

Defines the hostname of the SNMP server.

`--snmpPort`

Defaults to `162`. Defines the port number of the SNMP server.

`--version`

Defines the version of the SNMP protocol. Will be set to a default value if not set by the user.

`--community`

The community string used in the SNMP query. Will be set to a default value if not set by the user.

`--oid`

The Object ID used in the SNMP query. Will be set to a default value if not set by the user.

Examples

Example 1 Enable the SNMP notifier and configure the SNMP trap settings

```
asadmin set-snmp-notifier-configuration --enabled=true --dynamic=true
--hostname=localhost --snmpPort=162 --community=public --oid=".1.3.6.1.2.1.1.8"
--version=v2c
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `get-snmp-notifier-configuration`

set-teams-notifier-configuration

Configures the settings of the MS Teams notifier.

Synopsis

```
asadmin [asadmin-options] set-teams-notifier-configuration [--help]
[--target target]
[--enabled={false|true}]
[--dynamic={false|true}]
[--filter={INFO|WARNING|SEVERE}]
[webhook-url]
```

Description

This command can be used to configure the behaviour of the MS Teams notifier in Payara Server.

This command is available as long as the Datadog notifier's core module is installed in the server.
This notifier's extension is installed by default on Payara Server Enterprise.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option helps specify the target on which you are configuring the MS Teams notifier. Valid values are:

`server`

Applies to the default server instance. This is the default value.

cluster_name

Applies to every server instance in the cluster.

instance_name

Applies to a specified sever instance.

`--enabled`

Defaults to `false`. Enables or disables the log notifier

`--dynamic`

Defaults to `false`. When set to `true`, applies the changes without a server restart.

Otherwise, a restart is required.

`--filter`

Defaults to `WARNING`. The notifier only responds to events at or above this level. (INFO, WARNING, SEVERE)

Operands

webhook-url

The url of the MS Teams channel webhook to link the notifier to.

Examples

Example 1 Enable the MS Teams notifier and set its webhook URL

```
asadmin set-teams-notifier-configuration --enabled=true --dynamic=true
https://outlook.office.com/webhook/xyz
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,

set-toml-config-source-configuration

Configures the toml configuration source.

Synopsis

```
asadmin [asadmin-options] set-toml-config-source-configuration [--help]
[--path=<path>]
[--depth=<depth>]
[--dynamic={true|false}]
[--enabled={true|false}]
[--target=<target[default:server]>]
```

Description

The `set-toml-config-source-configuration` provides configuration options to set the properties required by toml config source to read the values from the configured file.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--path`

Absolute path of the TOML file or relative path to the current domain.

`--depth`

Maximum recursion depth for nested tables/arrays.

`--dynamic`

Configure the config source dynamically, which will not require a restart.

`--enabled`

Enables or disables the config source.

`--target`

Specifies the target where the configuration source resides.
Valid values are as follows:

`server`

Specifies the DAS (default).

instance-name

Specifies a Payara Server instance.

cluster-name

Specifies a cluster.

Example

Example 1 Configuring the toml Config Source.

This example configures the toml config source.

```
asadmin set-toml-config-source-configuration --path /Users/payara/config.toml --depth
5 --enabled true --dynamic true
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`
- `get-toml-config-source-configuration`

set-web-context-param

Sets a servlet context-initialization parameter of a deployed web application or module.

Synopsis

```
asadmin [asadmin-options] set-web-context-param [--help]
--name=context-param-name
{--value=value|--ignoredescriptoritem={false|true}}
[--description=description] application-name[/module]
```

Description

The `set-web-context-param` subcommand sets a servlet context-initialization parameter of one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

The application must already be deployed. Otherwise, an error occurs.

This subcommand enables you to change the configuration of a deployed application without the need to modify the application's deployment descriptors and repackage and redeploy the application.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

The name of the servlet context-initialization parameter that is to be set.

`--value`

The value to which the servlet context-initialization parameter is to be set.
Either the `--value` option or the `--ignoredescriptoritem` option must be set.

`--ignoredescriptoritem`

Specifies whether the servlet context-initialization parameter is ignored if it is set in the application's deployment descriptor. When a parameter is ignored, the application behaves as if the parameter had never been set in the application's deployment descriptor. The behavior of an application in this situation depends on the application.
The possible values are as follows:

`false`

The value is not ignored (default).

`true`

The value is ignored.
Either the `--value` option or the `--ignoredescriptoritem` option must be set.

Do not use the `--ignoredescriptoritem` option to unset a servlet context-initialization parameter that has previously been set by using the `set-web-context-param` subcommand. Instead, use the `unset-web-context-param` subcommand for this purpose.

`--description`

An optional textual description of the context parameter that is being set.

Operands

application-name

The name of the application. This name can be obtained from the Administration Console or by using the `list-applications` subcommand.
The application must already be deployed. Otherwise, an error occurs.

module

The relative path to the module within the application's enterprise archive (EAR) file. The path to the module is specified in the `module` element of the application's `application.xml` file.
module is required only if the servlet context-initialization parameter applies to a web module of a Jakarta EE application. If specified, module must follow application-name, separated by a slash (/).
For example, the `application.xml` file for the `myApp` application might specify the following web module:

```
<module>
    <web>
```

```
        <web-uri>myWebModule.war</web-uri>
    </web>
</module>
```

The module would be specified as the operand of this command as `myApp/myWebModule.war`.

Examples

Example 1 Setting a Servlet Context-Initialization Parameter for a Web Application

This example sets the servlet context-initialization parameter `javax.faces.STATE_SAVING_METHOD` of the web application `basic-ezcomp` to `client`. The description `The location where the application's state is preserved` is provided for this parameter.

```
asadmin> set-web-context-param --name=javax.faces.STATE_SAVING_METHOD
--description="The location where the application's state is preserved"
--value=client basic-ezcomp

Command set-web-context-param executed successfully.
```

Example 2 Ignoring a Servlet Context-Initialization Parameter That Is Defined in a Deployment Descriptor

This example ignores the servlet context-initialization parameter `javax.faces.PROJECT_STAGE` of the web application `basic-ezcomp`.

```
asadmin> set-web-context-param --name=javax.faces.PROJECT_STAGE
--ignoredescriptoritem=true
basic-ezcomp
Command set-web-context-param executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `list-web-context-param`,
- `unset-web-context-param`

set-web-env-entry

Sets an environment entry for a deployed web application or module.

Synopsis

```
asadmin [asadmin-options] set-web-env-entry [--help]
--name=env-entry-name --type=env-entry-type
{--value=value|--ignoredescriptoritem={true|false}}
[--description=description] application-name[/module]
```

Description

The `set-web-env-entry` subcommand sets an environment entry for one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

The application must already be deployed. Otherwise, an error occurs.

An application uses the values of environment entries to customize its behavior or presentation.

This subcommand enables you to change the configuration of a deployed application without the need to modify the application's deployment descriptors and repackage and redeploy the application.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

The name of the environment entry that is to be set. The name is a JNDI name relative to the `java:comp/env` context. The name must be unique within a deployment component.

`--type`

The fully-qualified Java type of the environment entry value that is expected by the application's code. This type must be one of the following Java types:

- `java.lang.Boolean`
- `java.lang.Byte`
- `java.lang.Character`

- java.lang.Double
- java.lang.Float
- java.lang.Integer
- java.lang.Long
- java.lang.Short
- java.lang.String

`--value`

The value to which the environment entry is to be set. If the `--type` is `java.lang.Character`, the value must be a single character. Otherwise, the value must be a string that is valid for the constructor of the specified type.
Either the `--value` option or the `--ignoredescriptoritem` option must be set.

`--ignoredescriptoritem`

Specifies whether the environment entry is ignored if it is set in the application's deployment descriptor. When an environment entry is ignored, the application behaves as if the entry had never been set in the application's deployment descriptor. The behavior of an application in this situation depends on the application.
The possible values are as follows:

`false`

The value is not ignored (default).

`true`

The value is ignored.
Either the `--value` option or the `--ignoredescriptoritem` option must be set.

Do not use the `--ignoredescriptoritem` option to unset an environment entry that has previously been set by using the `set-web-env-entry` subcommand. Instead, use the `unset-web-env-entry` subcommand for this purpose.

`--description`

An optional textual description of the environment entry that is being set.

Operands

application-name

The name of the application. This name can be obtained from the Administration Console or by using the `list-applications` subcommand.
The application must already be deployed. Otherwise, an error occurs.

module

The relative path to the module within the application's enterprise archive (EAR) file. The path to the module is specified in the `module` element of the application's `application.xml` file.
module is required only if the environment entry applies to a web module of a Java EE application. If specified, module must follow application-name, separated by a slash (/).

For example, the `application.xml` file for the `myApp` application might specify the following web module:

```
<module>
    <web>
        <web-uri>myWebModule.war</web-uri>
    </web>
</module>
```

The module would be specified as the operand of this command as `myApp/myWebModule.war`.

Examples

Example 1 Setting an Environment Entry for a Web Application

This example sets the environment entry `Hello User` of the application hello to `techscribe`. The Java type of this entry is `java.lang.String`.

```
asadmin> set-web-env-entry --name="Hello User"
--type=java.lang.String --value=techscribe
--description="User authentication for Hello appplication" hello
Command set-web-env-entry executed successfully.
```

Example 2 Ignoring an Environment Entry That Is Defined in a Deployment Descriptor

This example ignores the environment entry `Hello Port` of the web application `hello`.

```
asadmin> set-web-env-entry --name="Hello Port"
--type=java.lang.Integer --ignoredescriptoritem=true hello
Command set-web-env-entry executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `list-applications`,
- `list-web-env-entry`,
- `unset-web-env-entry`

set

Sets the values of configurable attributes.

Synopsis

```
asadmin [asadmin-options] set [--help]
attribute-name=value
```

Description

The `set` subcommand uses dotted names to modify the values of one or more configurable attributes.

Attributes from the monitoring hierarchy are read-only, but configuration attributes can be modified. You can use the `list` subcommand to display the dotted names that represent individual server components and subsystems. For example, a dotted name might be `server.applications.web-module`. After you discover the particular component or subsystem, you can then use the `get` subcommand to access the attributes. For more detailed information on dotted names, see the `dotted-names` help page.

Characters that have special meaning to the shell or command interpreter, such as * (asterisk), should be quoted or escaped as appropriate to the shell, for example, by enclosing the argument in quotes. In multimode, quotes are needed only for arguments that include spaces, quotes, or backslash.

By modifying attributes, you can enable and disable services, and customize how an existing element functions. An `asadmin` subcommand is provided to update some elements. For example, `update-password-alias`.However, to update other elements, you must use the `set` command. For example, you create a JDBC connection pool by using the `create-jdbc-connection-pool` subcommand. To change attribute settings later, you use the `set` command.

Any change made by using the `asadmin` utility subcommands or the Administration Console are automatically applied to the associated Payara Server configuration file.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

attribute-name=value

Identifies the full dotted name of the attribute name and its value.

Examples

Example 1 Setting a JDBC Connection Pool Attribute

This example changes the steady pool size of the `DerbyPool` connection pool to 9.

```
asadmin> set resources.jdbc-connection-pool.DerbyPool.steady-pool-size=9
Command set executed successfully.
```

Example 2 Enabling the Monitoring Service for a Monitorable Object

This example enables monitoring for the JVM.

```
asadmin> set server.monitoring-service.module-monitoring-levels.jvm=HIGH
Command set executed successfully.
```

Example 3 Turning on Automatic Recovery for the Transaction Service

This example turns on automatic recovery for the transaction service.

```
asadmin> set server.transaction-service.automatic-recovery=true
Command set executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

- `get`
- `list`
- `dotted-names`

setup-ssh

Sets up an SSH key on specified hosts.

Synopsis

```
asadmin [asadmin-options] setup-ssh [--help]
[--sshport ssh-port] [--sshuser ssh-user]
```

```
[--sshkeyfile ssh-keyfile] [--sshpublickeyfile ssh-public-keyfile]
[--generatekey={false|true}]
host-list
```

Description

The `setup-ssh` subcommand sets up a secure shell (SSH) key on the hosts that are specified as the operand of the subcommand. This key enables Payara Server to use public-key authentication for authentication of the user's SSH login on remote hosts.

SSH ensures that Payara Server clusters that span multiple hosts can be administered centrally. When a user runs a subcommand for cluster administration that acts on multiple hosts, the subcommand is propagated from the domain administration server (DAS) host to remote hosts. To propagate subcommands that act on a Payara Server instance that is not running, or on a node where no instances are running, Payara Server uses SSH. SSH provides confidentiality and security for data that is exchanged between the DAS and remote hosts.

Public-key authentication uses an SSH key pair that comprises the following keys:

- A private key, which is stored in a secure location on the DAS host and which may be protected with a passphrase
- The public key, which is stored on all the remote hosts with which the DAS communicates

The subcommand does not require any configuration information from the DAS and does not modify the configuration of the DAS.

This subcommand is supported in local mode only.

Prerequisites for Using the `setup-ssh` Subcommand

To use the `setup-ssh` subcommand, the SSH user must be able to use SSH to log in to remote hosts where SSH is to be set up. Specifically, the following prerequisites must be met:

- The `ssh` client is installed on the DAS host and is accessible through the DAS user's path.
- The `sshd` daemon is installed and running on all hosts where an SSH key is to be set up.
- The user that the `--sshuser` option specifies has an SSH login on all hosts where an SSH key is to be set up.
- The `ssh-keygen` utility is installed on the DAS host either at the default location or in a location that is defined in the DAS user's path.
- On Windows systems, the SSH package for Cygwin or an MKS Software toolkit that provides SSH is installed.

Behavior of the `setup-ssh` Subcommand

The subcommand sets up SSH connectivity between the DAS host and remote hosts by automating the following tasks:

- Generating an SSH key pair. If no SSH key pair exists, the default behavior of the subcommand

is to prompt the user to generate an SSH key pair. The SSH key pair is generated without an encryption passphrase. If a passphrase-protected key pair is required, the key pair must be generated manually by using the SSH command `ssh-keygen`.

- Distributing the public key. The subcommand appends the content of the public key file to the user-home`/.ssh/authorized_keys` file on each remote host. By default, the subcommand locates the public key file in the user-home`/.ssh` directory on the host where the subcommand is run. If the user-home`/.ssh/authorized_keys` file does not exist on a host, the subcommand creates the file. user-home is the user's home directory on a host.
  To distribute the public key, authentication of the user's SSH login is required. If the private key is protected by a passphrase, the passphrase is also required. By default, the subcommand prompts the user for the password and, if necessary, the passphrase. To distribute the public key without being prompted, run the subcommand as follows:
  - Set the `--interactive` option of the `asadmin` utility to `false`.
  - Set the `--passwordfile` option of the `asadmin` utility to a file in which the `AS_ADMIN_SSHPASSWORD` entry specifies the SSH user's password for logging in to the specified hosts.
  - If a passphrase is required, ensure that the file that `--passwordfile` option of the `asadmin` utility specifies also contains an entry for `AS_ADMIN_SSHKEYPASSPHRASE`.
    If public key authentication is already set up on a host, the subcommand informs the user that public key authentication is already set up and does not distribute the key to the host.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--sshport`

The port to use for SSH connections to the host where SSH is being set up. The default is 22.

`--sshuser`

The SSH user on the remote host that is to run the process for setting up SSH on that host. The default is the user that is running this subcommand. To ensure that the DAS can read this user's SSH private key file, specify the user that is running the DAS process.

`--sshkeyfile`

The absolute path to the SSH private key file for user that the `--sshuser` option specifies. This file is used for authentication to the `sshd` daemon on the host.
The user that is running this subcommand must be able to reach the path to the key file and read the key file.
The default is a key file in the user's `.ssh` directory on the host where the subcommand is run. If multiple key files are found, the subcommand uses the following order of preference:

1. `id_rsa`

2. `id_dsa`
3. `identity`

`--sshpublickeyfile`

The absolute path to the SSH public key file for user that the `--sshuser` option specifies. The content of the public key file is appended to the user's `.ssh/authorized_keys` file on each host where SSH is being set up. If the `.ssh/authorized_keys` file does not exist on a host, the subcommand creates the file.
The user that is running this subcommand must be able to reach the path to the key file and read the key file.
The default is a key file in the user's `.ssh` directory on the host where the subcommand is run. If multiple key files are found, the subcommand uses the following order of preference:

1. `id_rsa.pub`
2. `id_dsa.pub`
3. `identity.pub`

`--generatekey`

Specifies whether the subcommand generates the SSH key files without prompting the user.
Possible values are as follows:

`true`

The subcommand generates the SSH key files without prompting the user.

`false`

The behavior of the subcommand depends on whether the SSH key files exist:

- If the SSH key files exist, the subcommand does not generate the files.
- If the SSH key files do not exist, the behavior of the subcommand depends on the value of the `--interactive` option of the `asadmin` utility:
  - If the `--interactive` option is `true`, the subcommand prompts the user to create the files.
  - If the `--interactive` option is `false`, the subcommand fails.
    This value is the default.

Operands

host-list

A space-separated list of the names of the hosts where an SSH key is to be set up.

Examples

Example 1 Setting Up an SSH Key

This example sets up an SSH key for the user `gfuser` on the hosts `sj03` and `sj04`. The key file is not generated but is copied from the user's `.ssh` directory on the host where the subcommand is running.

```
asadmin> setup-ssh sj03 sj04
Enter SSH password for gfuser@sj03>
Copied keyfile /home/gfuser/.ssh/id_rsa.pub to gfuser@sj03
Successfully connected to gfuser@sj03 using keyfile /home/gfuser/.ssh/id_rsa
Copied keyfile /home/gfuser/.ssh/id_rsa.pub to gfuser@sj04
Successfully connected to gfuser@sj04 using keyfile /home/gfuser/.ssh/id_rsa
Command setup-ssh executed successfully.
```

Example 2 Generating and Setting Up an SSH Key

This example generates and sets up an SSH key for the user `gfuser` on the hosts `sua01` and `sua02`.

```
asadmin> setup-ssh --generatekey=true sua01 sua02
Enter SSH password for gfuser@sua01>
Created directory /home/gfuser/.ssh
/usr/bin/ssh-keygen successfully generated the identification /home/gfuser/.ssh/id_rsa
Copied keyfile /home/gfuser/.ssh/id_rsa.pub to gfuser@sua01
Successfully connected to gfuser@sua01 using keyfile /home/gfuser/.ssh/id_rsa
Copied keyfile /home/gfuser/.ssh/id_rsa.pub to gfuser@sua02
Successfully connected to gfuser@sua02 using keyfile /home/gfuser/.ssh/id_rsa
Command setup-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

show-component-status

Displays the status of the deployed component.

Synopsis

```
asadmin [asadmin-options] show-component-status [--help]
```

```
[--target target] component-name
```

Description

The `show-component-status` subcommand gets the status (either enabled or disabled) of the deployed component.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are showing the component status. Valid values are:

`server`

Shows the component status for the default server instance `server` and is the default value.

`domain`

Shows the component status for the domain.

cluster_name

Shows the component status for the cluster.

instance_name

Shows the component status for a clustered or stand-alone server instance.

Operands

component-name

The name of the component whose status is to be listed.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. To list multiple versions, you can use an asterisk (`*`) as a wildcard character. For more information about module and application versions, see Module and Application Versions in Payara Server Application Deployment section.

Examples

Example 1 Showing the Status of a Component

This example gets the status of the `MEjbApp` component.

```
asadmin> show-component-status MEjbApp
Status of MEjbApp is enabled
Command show-component-status executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `list-applications`,
- `list-sub-components`

start-cluster

Starts a cluster.

Synopsis

```
asadmin [asadmin-options] start-cluster [--help]
[--verbose={false|true}] cluster-name
```

Description

The `start-cluster` subcommand starts a cluster by starting all Payara Server instances in the cluster that are not already running. This subcommand requires the secure shell (SSH) to be configured on the host where the domain administration server (DAS) is running and on all hosts where instances in the cluster reside.

If all instances reside on the same host as the DAS, SSH is not required. You might require to start a cluster in which instances reside on hosts where SSH is not configured that are remote from the DAS. In this situation, run the `start-local-instance` subcommand for each instance from the host where the instance resides.

You may run this subcommand from any host that can contact the DAS.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--verbose`

Specifies whether additional status information is displayed when the cluster is started.

Valid values are as follows:

`true`

Displays the command to start each instance in the cluster and whether the attempt to start each instance succeeded.

`false`

Displays no additional status information (default).

Operands

cluster-name

The name of the cluster to start.

Examples

Example 1 Staring a Cluster

This example starts the cluster `ymlcluster`. Additional status information is displayed when the cluster is started.

```
asadmin> start-cluster --verbose ymlcluster
start-instance yml-i-sr1-usca-02
start-instance yml-i-sr1-usca-01

The command start-instance executed successfully for:
yml-i-sr1-usca-02 yml-i-sr1-usca-01

Command start-cluster executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

start-database

Starts a standalone H2 database in server mode.

Synopsis

```
asadmin [asadmin-options] start-database [--help]
[--jvmoptions jvm-options]
[--dbhost host] [--dbport port-no]
[--dbhome db-file-path]
```

Description

The `start-database` subcommand starts the H2 database server that is available for use with Payara Server. Use this subcommand only for working with applications deployed to the server.

When you start the H2 server by using the `start-database` subcommand, the database server is started in Network Server mode. Clients connecting to it must use the corresponding H2 JDBC client driver. For details on how to connect to the database, refer to the official H2 documentation.

When the database server starts, or a client connects to it successfully, the following files are created:

- The `h2.log` file that contains the database server process log along with its standard output and standard error information
- The database files that contain your schema (for example, database tables)

These files are created at the location that is specified by the `--dbhome` option. To create the database files at a particular location, you must set the `--dbhome` option. If the `--dbhome` option is not specified, the `start-database` subcommand determines where to create these files as follows:

- If the current working directory contains a file that is named `h2.log`, the `start-database` subcommand creates the files in the current working directory.
- Otherwise, the `start-database` subcommand creates the files in the `as-install/databases` directory.

The `start-database` subcommand starts the database process, even if it cannot write to the log file.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--jvmoptions`

A space-separated list of command-line options that are passed to the Java application launcher when the database is started. By default, no options are passed.

The format of an option depends on whether the option has a name and a value or only a name:

- If the option has a name and a value, the format is option-name=value.
- If the option has only a name, the format is option-name. For example, `-Xmx512m`.

`--dbhost`

The host name or IP address of the H2 database server process. The default is the IP address 0.0.0.0, which denotes all network interfaces on the host where you run the `start-database` subcommand.

`--dbport`

The port number where the H2 database server listens for client connections. This port must be available for the listen socket, otherwise the database server will not start.

`--dbhome`

The absolute path to the directory where the database files and the `h2.log` file are created. If the `--dbhome` option is not specified, the `start-database` subcommand determines where to create these files as follows:

- If the current working directory contains a file that is named `h2.log`, the `start-database` subcommand creates the files in the current working directory.
- Otherwise, the `start-database` subcommand creates the files in the as-install`/databases` directory.

To create the database files at a particular location, you must set the `--dbhome` option.

Examples

Example 1 Starting Java DB

This example starts H2 on the host `host1` and port 5001.

```
asadmin> start-database --dbhost host1 --dbport 5001 --terse=true

Starting database in Network Server mode on host 0.0.0.0 and port 9092.
tcp://10.228.1.149:9092
Starting database in the background.
Log redirected to /opt/databases/h2.log.
```

Example 2 Starting H2 with Options for the Java Application Launcher

This example starts H2 with the options for setting the minimum heap memory size to 128 megabytes and the maximum heap memory size to 512 megabytes.

```
asadmin> start-database --jvmoptions="-Xms128m -Xmx512m" --terse=true

Starting database in Network Server mode on host 0.0.0.0 and port 9092.
tcp://10.228.1.149:9092
Starting database in the background.
Log redirected to /opt/payara/glassfish/databases/h2.log.
```

Exit Status

The exit status applies to errors in executing the `asadmin` utility.For information on database errors, see the `h2.log` file. This file is located in the directory you specify by using the `--dbhome` option when you run the `start-database` subcommand. If you did not specify `--dbhome`, the value of `H2_INSTALL` defaults to `as-install/h2`.

0

subcommand executed successfully

start-deployment-group

Starts all the instances in a Payara Server deployment group.

Synopsis

```
asadmin [asadmin-options] start-deployment-group [--help]
[--instanceTimeout timeout]
[--timeout timeout]
[--verbose={false|true}]
name
```

Description

The `start-deployment-group` subcommand starts all instances that belong to a Payara Server deployment group. The command will fail if the deployment group doesn't contain any instances in it.

Internally this command works in the same manner that the `start-instance` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--verbose`

`-v`

Whether to start the instances in verbose mode. Defaults to `false`.

`--timeout`

Specifies how long to take for the instances to start in seconds. If starting the instances takes longer than this amount then this command will fail.

The default value is `600`.

`--instanceTimeout`

Specifies how long to take for each instance to start in seconds. If starting the instances takes longer than this amount then this command will fail.

The default value is `600`.

Operands

name

The name of the deployment group. If there are no deployment groups that match the name the command will exit with an error.

Examples

Example 1 Start a Deployment Group

This example starts a deployment group that is named `test-dgroup` that contains one instance:

```
asadmin start-deployment-group test-dgroup
50%: start-deployment-group: Executing start-instance on 1 instances.
Command start-deployment-group executed successfully.
```

Example 2 Start a Deployment Group with timeout

This example starts a deployment group that is named `test-dgroup` that contains one instance using an instance timeout of 30 seconds:

```
asadmin start-deployment-group --instanceTimeout 30 test-dgroup
50%: start-deployment-group: Executing start-instance on 1 instances.
Command start-deployment-group executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `restart-deployment-group`

start-domain

Starts the Domain Administration Server(DAS) of the specified domain.

Synopsis

```
asadmin [asadmin-options] start-domain [--help]
[--debug={true|false}]
[--domaindir domain-dir]
[--dry-run={true|false}]
[--verbose={true|false}]
[--watchdog={true|false}]
[--timeout timeout]
[--warmup={true|false}]
[--prebootcommandfile path-to-file]
[--postbootcommandfile path-to-file]
[domain-name]
```

Description

The `start-domain` subcommand starts the domain administration server (DAS) of the specified domain. If a domain is not specified, the default domain is assumed. If the domains directory contains two or more domains, the domain-name operand must be specified.

On the Windows platform, processes can bind to the same port. To avoid this problem, do not start multiple domains with the same port number at the same time.

This subcommand is supported in local mode only.

In Payara Server, the `start-domain` subcommand prompts for a new admin user password if no password has been set for the admin user.
Additionally, the admin user password must not be blank if secure administration is enabled; otherwise, the `start-domain` subcommand fails.
To provide the new admin user password, you can use the `--passwordfile` utility option of the `asadmin` command after adding the entry `AS_ADMIN_NEWPASSWORD` to the password file.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--debug`

`-d`

Specifies whether the domain is started with Java Platform Debugger Architecture (JPDA) debugging enabled. With debugging enabled extra exceptions can be printed.

Possible values are as follows:

`true`

The instance is started with JPDA debugging enabled and the port number for JPDA debugging is displayed.

`false`

The instance is started with JPDA debugging disabled (default).

`--dry-run`

`-n`

Suppresses actual starting of the domain. Instead, `start-domain` displays the full java command that would be used to start the domain, including all options. Reviewing this command can be useful to confirm JVM options and when troubleshooting startup issues.

The default value is `false`.

`--domaindir`

The domain root directory, which contains the directory of the domain that is to be restarted. If specified, the path must be accessible in the file system. The default location of the domain root directory is `as-install/domains`.

`--verbose`

`-v`

Specifies whether detailed information about the domain is displayed in the console window where the subcommand is run.

Possible values are as follows:

`true`

Detailed startup messages and log messages about the domain are displayed in the console window where the subcommand is run. If the domain is later restarted by running the `restart-domain` subcommand from a different console window, messages continue to be displayed in the original console window.

You can kill the Payara Server process by typing `CTRL-C` in the console window.

You can kill the Payara Server process and obtain a thread dump for the server by typing one of the following key combinations in the console window:

- `CTRL-\` on UNIX systems
- `CTRL-Break` on Windows systems

`false`

Detailed information is not displayed (default).

`--watchdog`

`-w`

Specifies whether limited information about the domain is displayed in the console window

where the subcommand is run. The `--watchdog` option is similar to `--verbose` but does not display the detailed startup messages and log messages. This option is useful when running the `asadmin` utility in the background or with no attached console.

Possible values are as follows:

`true`
: Limited information is displayed in the console window.

`false`
: Limited information is not displayed in the console window (default).

`--prebootcommandfile`
: Path to file containing commands to run before booting the server. Only a limited amount of commands will work at this point.

`--postbootcommandfile`
: Path to file containing commands to run after the server's boot sequence is completed.

`--timeout`
: Specifies how long to take for the domain to start in seconds. If starting the domain takes longer than this amount then this command will fail.

  The default value is `600`.

`--warmup`
: Specifies if the server will stop after setting configurations.

  The default value is `false`.

Operands

domain-name
: The unique name of the domain you want to start.

  This operand is optional if only one domain exists in the Payara Server installation.

Examples

Example 1 Starting a Domain

This example starts `mydomain4` in the default domains directory.

```
asadmin> start-domain mydomain4
Waiting for DAS to start. ...........
Started domain: mydomain4
Domain location: /myhome/payara7/glassfish/domains/mydomain4
Log file: /myhome/payara7/glassfish/domains/mydomain4/logs/server.log
Admin port for the domain: 4848
```

```
Command start-domain executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `stop-domain`,
- `stop-domains`,
- `stop-all-domains`

start-domains

Starts the Domain Administration Server(DAS) of the specified domains.

Synopsis

```
asadmin start-domains [--help]
[--domainTimeout timeout]
[--timeout timeout]
[domain-name]
```

Description

The `start-domains` subcommand can be used to start the specified list of domains in the operand. This list must be specified as a comma separated string of values.

The domains will be started assuming default values for all options you would specify when running the start-domain command against one domain (default domain directory, debug mode off, verbose mode off, etc.)

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--timeout`

Specifies how long to take for the domains to start in seconds. If starting the domains takes longer than this amount then this command will fail.

The default value is `600`.

`--domainTimeout`

Specifies how long to take for each domain to start in seconds. If starting the domains takes longer than this amount then this command will fail.

The default value is `600`.

Operands

domain-names

The list of unique names of the domains you want to start.

Examples

Example 1 Starting multiple Domains

This example starts `domain1` and `testy` in the default domains directory.

```
asadmin> start-domains domain1,testy
Waiting for domain1 to start ..............................
Successfully started the domain : domain1
domain  Location: /myhome/payara7/glassfish/domains/domain1
Log File: /myhome/payara7/glassfish/domains/domain1/logs/server.log
Admin Port: 4848
Started domain domain1
Waiting for testy to start ................................
Successfully started the domain : testy
domain  Location: /myhome/payara7/glassfish/domains/testy
Log File: /myhome/payara7/glassfish/domains/domain1/logs/server.log
Admin Port: 6048
Started domain testy
Command start-domains executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `stop-all-domains`

start-instance

Starts a Payara Server instance.

Synopsis

```
asadmin [asadmin-options] start-instance [--help]
[--debug={false|true}] [--sync={normal|full|none}]
[--timeout timeout] instance-name
```

Description

The `start-instance` subcommand starts a Payara Server instance. This subcommand requires the secure shell (SSH) to be configured on the machine where the domain administration server (DAS) is running and on the machine where the instance resides.

SSH is not required if the instance resides on a node of type `CONFIG` that represents the local host. A node of type `CONFIG` is not enabled for remote communication over SSH.

You may run this subcommand from any machine that can contact the DAS.

The subcommand can start any Payara Server instance, regardless of how the instance was created. For example, this subcommand can start an instance that was created by using the `create-local-instance` subcommand.

This command is supported in remote mode only.

Options

These are not the same options available for the `start-local-instance` command.

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--debug`

Specifies whether the instance is started with Java Platform Debugger Architecture (JPDA) debugging enabled.

Possible values are as follows:

`true`

The instance is started with JPDA debugging enabled and the port number for JPDA debugging is displayed.

`false`

The instance is started with JPDA debugging disabled (default).

`--sync`

The type of synchronization between the DAS and the instance's file when the instance is started.

Possible values are as follows:

`none`

The DAS does not synchronize the instance's files with any changes. This type of synchronization minimizes the time that is required to start the instance.

`normal`

The DAS synchronizes the instance with changes since the last synchronization as follows:

- For the `config` directory, the DAS synchronizes the instance with all changes.
- For the `applications` directory and `docroot` directory, only a change to a top-level subdirectory causes the DAS to synchronize all files under that subdirectory.

  If a file below a top level subdirectory is changed without a change to a file in the top level subdirectory, full synchronization is required. In normal operation, files below the top level subdirectories of these directories are not changed. If an application is deployed and undeployed, full synchronization is not necessary to update the instance with the change.

  This value is the default.

`full`

The DAS synchronizes the instance with all of the instance's files, regardless of whether the files have changed since the last synchronization. This type of synchronization might delay the startup of the instance while the DAS updates all files in the instance's directories.

Using full synchronization will cause the configuration to be deleted if the DAS cannot be reached.

`--timeout`

Specifies how long to take for the instance to start in seconds. If starting the instance takes longer than this amount then this command will fail (but the instance may still continue its startup process).

The default value is `120`.

`--terse`

Specifies whether information on the result is output

The default value is `false`.

Operands

instance-name

The name of the Payara Server instance to start.

Examples

Example 1 Starting a Payara Server Instance

This example starts the Payara Server instance `pmdsa1`.

```
asadmin start-instance pmdsa1
Waiting for the server to start ..............................
Successfully started the instance: pmdsa1
instance Location: /export/payara7/glassfish/nodes/localhost/pmdsa1
Log File: /export/payara7/glassfish/nodes/localhost/pmdsa1/logs/server.log
Admin Port: 24848
Command start-local-instance executed successfully.
The instance, pmdsa1, was started on host localhost

Command start-instance executed successfully.
```

Example 2 Starting a Payara Server Instance With JPDA Debugging Enabled

This example starts the Payara Server instance `ymlsa1` with JPDA debugging enabled.

```
asadmin start-instance --debug=true ymlsa1
Waiting for the server to start ..............................
Successfully started the instance: ymlsa1
instance Location: /export/payara7/glassfish/nodes/localhost/ymlsa1
Log File: /export/payara7/glassfish/nodes/localhost/ymlsa1/logs/server.log
Admin Port: 24849
Debugging is enabled. The debugging port is: 29010
Command start-local-instance executed successfully.
The instance, ymlsa1, was started on host localhost
```

```
Command start-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

start-local-instance

Starts a Payara Server instance on the host where the subcommand is run.

Synopsis

```
asadmin [asadmin-options] start-local-instance [--help]
[--nodedir node-dir]
[--node node]
[--debug={false|true}]
[--dry-run={true|false}]
[--sync={normal|full|none}]
[--verbose={false|true}]
[--watchdog={true|false}]
[--timeout timeout]
[instance-name]
```

Description

The `start-local-instance` subcommand starts a Payara Server instance on the host where the subcommand is run. This subcommand does not require the secure shell (SSH) to be configured. You must run this command from the host where the instance resides.

The subcommand can start any Payara Server instance, regardless of how the instance was created. For example, this subcommand can start an instance that was created by using the `create-instance` subcommand.

The `start-local-instance` subcommand does not contact the domain administration server (DAS) to determine the node on which the instance resides. To determine the node on which the instance resides, the subcommand searches the directory that contains the node directories. If multiple node directories exist, the node must be specified as an option of the subcommand.

This subcommand is supported in local mode. However, to synchronize the instance with the DAS, this subcommand must be run in remote mode.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

These are not the same as the options available for the start-instance command.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodedir`

Specifies the directory that contains the instance's node directory. The instance's files are stored in the instance's node directory.

The default is `as_install/nodes/`.

`--node`

Specifies the node on which the instance resides. This option may be omitted only if the directory that the `--nodedir` option specifies contains only one node directory. Otherwise, this option is required.

`--debug`

`-d`

Specifies whether the instance is started with Java Platform Debugger Architecture (JPDA) debugging enabled.

Possible values are as follows:

`true`

The instance is started with JPDA debugging enabled and the port number for JPDA

debugging is displayed.

`false`

The instance is started with JPDA debugging disabled (default).

`--dry-run`

`-n`

Suppresses actual starting of the instance. Instead, `start-local-instance` displays the full command that would be used to start the instance, including all options. Reviewing this command can be useful when troubleshooting startup issues.

The default value is `false`.

`--sync`

The type of synchronization between the DAS and the instance's files when the instance is started.

Possible values are as follows:

`none`

The DAS does not synchronize the instance's files with any changes. This type of synchronization minimizes the time that is required to start the instance.

`normal`

The DAS synchronizes the instance with changes since the last synchronization as follows:

- For the `config` directory, the DAS synchronizes the instance with all changes.
- For the `applications` directory and `docroot` directory, only a change to a top-level subdirectory causes the DAS to synchronize all files under that subdirectory.

  If a file below a top level subdirectory is changed without a change to a file in the top level subdirectory, full synchronization is required. In normal operation, files below the top level subdirectories of these directories are not changed. If an application is deployed and un-deployed, full synchronization is not necessary to update the instance with the change.

  This value is the default.

`full`

The DAS synchronizes the instance with all of the instance's files, regardless of whether the files have changed since the last synchronization. This type of synchronization might delay the startup of the instance while the DAS updates all files in the instance's directories.

If the DAS is not running or is unreachable from the host where you are running this subcommand, do not set the `--sync` option to `full`. To perform a full synchronization, the subcommand removes the instance's cache. If the DAS cannot be contacted to replace the cache, the subcommand fails and the instance cannot be restarted until it is resynchronized with the DAS.

`--verbose`

`-v`

Specifies that the server log is printed to the console from where the subcommand is run. Control is not returned to the console after the instance has started. The instance can be stopped and control returned by inputting CTRL-C.

Possible values are as follows:

`true`

Detailed startup messages and log messages about the instance are displayed in the console window where the subcommand is run. If the instance is later restarted by running the `restart-local-instance` subcommand from a different console window, messages continue to be displayed in the original console window.

You can kill the Payara Server process by typing `CTRL-C` in the console window.

You can kill the Payara Server process and obtain a thread dump for the server by typing one of the following key combinations in the console window:

- `CTRL-\` on UNIX systems
- `CTRL-Break` on Windows systems

`false`

Detailed information is not displayed (default).

`--watchdog`

`-w`

Specifies whether limited information about the instance is displayed in the console window where the subcommand is run. The `--watchdog` option is similar to `--verbose` but does not display the detailed startup messages and log messages. This option is useful when running the `asadmin` utility in the background or with no attached console.

Possible values are as follows:

`true`

Limited information is displayed in the console window.

`false`

Limited information is not displayed in the console window (default).

`--timeout`

Specifies how long to take for the local instance to start in seconds. If starting the instance takes longer than this amount then this command will fail (but the instance may still continue its startup process)

The default value is `600`.

Operands

instance-name

The name of the instance to start.

Examples

Example 1 Starting an Instance Locally

This example starts the instance `yml-i-sj01` on the host where the subcommand is run.

```
asadmin start-local-instance --node sj01 yml-i-sj01
Waiting for the server to start ..............................
Successfully started the instance: yml-i-sj01
instance Location: /export/payara7/glassfish/nodes/sj01/yml-i-sj01
Log File: /export/payara7/glassfish/nodes/sj01/yml-i-sj01/logs/server.log
Admin Port: 24849
Command start-local-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

stop-all-domains

Stops the Domain Administration Server(DAS) of all current running domains on the server's installation.

Synopsis

```
asadmin stop-all-domains [--help]
[--force={true|false}]
[--kill={true|false}]
[--timeout timeout]
[--domainTimeout timeout]
```

Description

The `stop-all-domains` subcommand can be used to stop ALL current running domains on the server's installation.

Options

`--force`

Specifies whether each domain is forcibly stopped immediately.

The default value is `true`.

`--kill`

Specifies whether the domain is killed by using functionality of the operating system to terminate the domain process.

The default value is `false`.

`--timeout`

Specifies how long to take for the domains to stop in seconds. If stopping the domains takes longer than this amount then this command will fail.

The default value is `600`.

`--domainTimeout`

Specifies how long to take for each domain to stop in seconds. If stopping the domain takes longer than this amount then this command will fail

The default value is `600`.

Examples

Example 1 Stopping Domains

This example stops all currently running domains on the server's installation.

```
asadmin stop-all-domains
```

```
Stopping domain domain1
Stopped domain
Stopping domain production
Stopped domain
Stopping domain test
Stopped domain
Stopping domain testy
Stopped domain
Command stop-all-domains executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

stop-cluster

Stops a Payara Server cluster.

Synopsis

```
asadmin [asadmin-options] stop-cluster [--help]
[--verbose={false|true}]
[--kill={false|true}]
cluster-name
```

Description

The `stop-cluster` subcommand stops a Payara Server cluster by stopping all running Payara Server instances in the cluster.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--verbose`

Specifies whether additional progress messages about the status of instances in the cluster are displayed while the cluster is being stopped.

Possible values are as follows:

`true`

Additional progress messages about the status of instances in the cluster are displayed.

`false`

No messages about the status of instances in the cluster are displayed.

`--kill`

Specifies whether each instance in the cluster is killed by using functionality of the operating system to terminate the instance process.

Possible values are as follows:

`false`

No instances are killed. The subcommand uses functionality of the Java platform to terminate each instance process (default).

`true`

Each instance is killed. The subcommand uses functionality of the operating system to terminate each instance process.

Operands

cluster-name

The name of the cluster to stop.

Examples

Example 1 Stopping a Cluster

This example stops the cluster `pmdcluster`. Additional progress messages about the status of instances in the cluster are displayed while the cluster is being stopped.

```
asadmin> stop-cluster --verbose pmdcluster
stop-instance pmd-i-sj01
stop-instance pmd-i-sj02

The command stop-instance executed successfully for: pmd-i-sj01 pmd-i-sj02

Command stop-cluster executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

stop-database

Stops a running H2 database server.

Synopsis

```
asadmin [asadmin-options] stop-database [--help]
[--dbuser db-user]
[--dbhost host] [--dbport port-no]
```

Description

The `stop-database` subcommand stops a running H2 database server process. The database is typically started with the `start-database` subcommand. A single host can have multiple database server processes running on different ports. The `stop-database` subcommand stops the database server process for the specified port only.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--dbuser`

The username of the Java DB user that is to stop the server process. If this option is omitted, no user is specified.

`--dbhost`

The host name or IP address of the Java DB server process. The default is the IP address 0.0.0.0, which denotes all network interfaces on the host where you run the `stop-database` subcommand.

`--dbport`

The port number where the H2 database server listens for client connections.

Examples

Example 1 Stopping Java DB

This example stops Java DB on host host1 and port 5001.

```
asadmin> stop-database --dbhost host1 --dbport 5001

Command stop-database executed successfully.
```

Exit Status

The exit status applies to errors in executing the `asadmin` utility. For information on database errors, see the `h2.log` file. This file is located in the directory you specify by using the `--dbhome` option when you run the `start-database` subcommand.

If you did not specify `--dbhome`, the value of `H2_INSTALL` defaults to `as-install/h2`.

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,

- `start-database` "Administering Database Connectivity" in the Payara Server General Administration section

stop-deployment-group

Stops all the instances in a Payara Server deployment group.

Synopsis

```
asadmin [asadmin-options] stop-deployment-group [--help]
[--instanceTimeout timeout]
[--timeout timeout]
[--kill={false|true}]
[--verbose={false|true}]
name
```

Description

The `sop-deployment-group` subcommand sop all instances that belong to a Payara Server deployment group. Initially the deployment group contains no Payara Server instances, applications, or resources.

Internally this command works in the same manner that the `stop-instance` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--verbose`

`-v`

Whether to stop the instances in verbose mode. Defaults to `false`.

`--timeout`

Specifies how long to take for the instances to stop in seconds. If starting the instances takes longer than this amount then this command will fail.

The default value is `600`.

`--instanceTimeout`

Specifies how long to take for each instance to stop in seconds. If stopping the instances takes longer than this amount then this command will fail.

The default value is `600`.

`--kill`

Whether to kill the instance processes if they do not stop gracefully. Defaults to `false`.

Operands

name

The name of the deployment group. If there are no deployment groups that match the name the command will exit with an error.

Examples

Example 1 Stop a Deployment Group

This example stops a deployment group that is named `test-dgroup` that contains one instance:

```
asadmin stop-deployment-group test-dgroup
50%: stop-deployment-group: Executing stop-instance on 1 instances.
Command stop-deployment-group executed successfully.
```

Example 2 Stop a Deployment Group with timeout

This example stops a deployment group that is named `test-dgroup` that contains one instance, using an instance timeout of 30 seconds:

```
asadmin stop-deployment-group --instanceTimeout 30 test-dgroup
50%: stop-deployment-group: Executing stop-instance on 1 instances.
Command stop-deployment-group executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

stop-domain

Stops the Domain Administration Server(DAS) of the specified domain.

Synopsis

```
asadmin [asadmin-options] stop-domain [--help]
[--domaindir domaindir]
[--force={true|false}]
[--kill={false|true}]
[--timeout timeout]
[domain-name]
```

Description

The `stop-domain` subcommand stops the Domain Administration Server (DAS) of the specified domain. If the domain directory is not specified, the domain in the default domains directory is stopped. If there are two or more domains in the domains directory, the domain-name operand must be specified.

This subcommand is supported in local or remote mode. If you specify a host name, the subcommand assumes you are operating in remote mode, which means you must correctly authenticate to the remote server. In local mode, you normally do not need to authenticate to the server as long as you are running the subcommand as the same user who started the server.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--domaindir`

Specifies the directory of the domain that is to be stopped. If specified, the path must be accessible in the file system. If not specified, the domain in the default `as-install/domains` directory is stopped.

`--force`

Specifies whether the domain is forcibly stopped immediately.
Possible values are as follows:

`true`

The domain is forcibly stopped immediately (default).

`false`

The subcommand waits until all threads that are associated with the domain are exited before stopping the domain.

`--kill`

Specifies whether the domain is killed by using functionality of the operating system to terminate the domain process.
Possible values are as follows:

`false`

The domain is not killed. The subcommand uses functionality of the Java platform to terminate the domain process (default).

`true`

The domain is killed. The subcommand uses functionality of the operating system to terminate the domain process.

`--timeout`

Specifies how long to take for the domain to stop in seconds. If stopping the domain takes longer than this amount then this command will fail.

The default value is `600`.

Operands

domain-name

The name of the domain you want to stop. Default is the name specified during installation, usually `domain1`.

Examples

Example 1 Stopping a Domain

This example stops the domain named `sampleDomain` in the default domains directory.

```
asadmin> stop-domain sampleDomain
Waiting for the domain to stop ..................
Command stop-domain executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-domain`,
- `delete-domain`,

- `list-domains`,
- `restart-domain`,
- `restart-domains`,
- `start-domain`,
- `start-domains`,
- `stop-domains`,
- `stop-all-domains`

stop-domains

Stops the Domain Administration Server(DAS) of the specified domains.

Synopsis

```
asadmin stop-domains [--help]
[--domainTimeout timeout]
[--timeout timeout]
[domain-name]
```

Description

The `stop-domains` subcommand can be used to stop the specified list of domains in the operand. This list must be specified as a comma separated string of values.

Options

`--timeout`

Specifies how long to take for the domains to stop in seconds. If stopping the domains takes longer than this amount then this command will fail.

The default value is `600`.

`--domainTimeout`

Specifies how long to take each domain to stop in seconds. If stopping the domain takes longer than this amount then this command will fail.

The default value is `600`.

Operands

domain-names

The names of the domains you want to stop.

Examples

Example 1 Stopping Domains

This example stops the domains named `domain1` and `testy` in the default domains directory.

```
asadmin stop-domains domain1,testy

Stopping domain domain1
Stopped domain

Stopping domain testy
Stopped domain

Command stop-domains executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

stop-instance

Stops a running Payara Server instance.

Synopsis

```
asadmin [asadmin-options] stop-instance [--help]
[--force={false|true}]
[--kill={false|true}]
instance-name
```

Description

The `stop-instance` subcommand stops a running Payara Server instance.

The subcommand can stop any Payara Server instance, regardless of how the instance was created. For example, this subcommand can stop an instance that was created by using the `create-local-instance` subcommand.

This command is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--force`

Specifies whether the instance is forcibly stopped immediately.
Possible values are as follows:

`true`

The instance is forcibly stopped immediately (default).

`false`

The subcommand waits until all threads that are associated with the instance are exited before stopping the instance.

`--kill`

Specifies whether the instance is killed by using functionality of the operating system to terminate the instance process.
Possible values are as follows:

`false`

The instance is not killed. The subcommand uses functionality of the Java platform to terminate the instance process (default).

`true`

The instance is killed. The subcommand uses functionality of the operating system to terminate the instance process.

Operands

instance-name

This is the name of the Payara Server instance to stop.

Examples

This example stops the Payara Server instance `yml-i-sj01`.

Example 1 Stopping a Payara Server Instance

```
asadmin> stop-instance yml-i-sj01
The instance, yml-i-sj01, was stopped.
Command stop-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-instance`,
- `create-local-instance`,
- `delete-instance`,
- `delete-local-instance`,
- `start-domain`,
- `start-instance`,
- `start-local-instance`,
- `stop-domain`,
- `stop-local-instance`

stop-local-instance

Stops a Payara Server instance on the machine where the subcommand is run.

Synopsis

```
asadmin [asadmin-options] stop-local-instance [--help]
[--nodedir node-dir] [--node node]
[--force={true|false}] [--kill={false|true}]
[instance-name]
```

Description

The `stop-local-instance` subcommand stops a Payara Server instance on the machine where the

subcommand is run. This subcommand does not require secure shell (SSH) to be configured. You must run this command from the machine where the instance resides.

The subcommand can stop any Payara Server instance, regardless of how the instance was created. For example, this subcommand can stop an instance that was created by using the `create-instance` subcommand.

The `stop-local-instance` subcommand does not contact the DAS to determine the node on which the instance resides. To determine the node on which the instance resides, the subcommand searches the directory that contains the node directories. If multiple node directories exist, the node must be specified as an option of the subcommand.

This subcommand is supported in local mode.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodedir`

Specifies the directory that contains the instance's node directory. The instance's files are stored in the instance's node directory. The default is as-install`/nodes`.

`--node`

Specifies the node on which the instance resides. This option may be omitted only if the directory that the `--nodedir` option specifies contains only one node directory. Otherwise, this option is required.

`--force`

Specifies whether the instance is forcibly stopped immediately.
Possible values are as follows:

`true`

The instance is forcibly stopped immediately (default).

`false`

The subcommand waits until all threads that are associated with the instance are exited before stopping the instance.

`--kill`

Specifies whether the instance is killed by using functionality of the operating system to terminate the instance process.
Possible values are as follows:

`false`

The instance is not killed. The subcommand uses functionality of the Java platform to terminate the instance process (default).

`true`

The instance is killed. The subcommand uses functionality of the operating system to terminate the instance process.

Operands

instance-name

The name of the instance to stop.

Examples

Example 1 Stopping an Instance Locally

This example stops the instance `yml-i-sj01` on the machine where the subcommand is run.

```
asadmin> stop-local-instance --node sj01 yml-i-sj01
Waiting for the instance to stop ...
Command stop-local-instance executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

undeploy

Removes a deployed component.

Synopsis

```
asadmin [asadmin-options] undeploy [--help]
[--target target]
[--cascade={false|true}] name
```

Description

The `undeploy` subcommand uninstalls a deployed application or module and removes it from the repository.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--cascade`

If set to `true`, deletes all the connection pools and connector resources associated with the resource adapter being undeployed. If set to `false`, the undeploy fails if any pools and resources are still associated with the resource adapter. Then, either those pools and resources must be deleted explicitly, or the option must be set to `true`. If the option is set to `false`, and if there are no pools and resources still associated with the resource adapter, the resource adapter is undeployed. This option is applicable to connectors (resource adapters) and applications. Default value is false.

`--target`

Specifies the target from which you are undeploying. Valid values are:

`server`

Undeploys the component from the default server instance `server` and is the default value.

`domain`

Undeploys the component from the domain.

cluster_name

Undeploys the component from every server instance in the cluster.

instance_name

Undeploys the component from a particular stand-alone server instance.

Operands

name

Name of the deployed component.
The name can include an optional version identifier, which follows the name and is separated from the name by a colon (`:`). The version identifier must begin with a letter or number. It can contain alphanumeric characters plus underscore (`_`), dash (`-`), and period (`.`) characters. To delete multiple versions, you can use an asterisk (`*`) as a wildcard character. For more information about module and application versions, see Module and Application Versions in Payara Server Application Deployment section.

Examples

Example 1 Undeploying an Enterprise Application

This example undeploys an enterprise application named `Cart.ear`.

```
asadmin> undeploy Cart
Command undeploy executed successfully.
```

Example 2 Undeploying a Connector (Resource Adapter)

This example undeploys the connector module named `jdbcra` and performs a cascading delete to remove the associated resources and connection pools.

```
asadmin> undeploy --cascade=true jdbcra
Command undeploy executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

unfreeze-transaction-service

Resumes all suspended transactions.

Synopsis

```
asadmin [asadmin-options] unfreeze-transaction-service [--help]
[--target target]
```

Description

The `unfreeze-transaction-service` subcommand restarts the transaction subsystem and resumes all in-flight transactions. Invoke this subcommand on an already frozen transaction subsystem.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--target`

This option specifies the target on which you are unfreezing the transaction service. Valid values are:

`server`

Unfreezes the transaction service for the default server instance `server` and is the default value.

configuration_name

Unfreezes the transaction service for all server instances that use the named configuration.

cluster_name

Unfreezes the transaction service for every server instance in the cluster.

instance_name

Unfreezes the transaction service for a particular server instance.

Examples

Example 1 Using unfreeze-transaction-service

```
% asadmin unfreeze-transaction-service
Command unfreeze-transaction-service executed successfully
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

uninstall-node-ssh

Uninstalls Payara Server software from specified SSH-enabled hosts.

Synopsis

```
asadmin [asadmin-options] uninstall-node-ssh [--help]
[--installdir as-install-parent]
[--sshport ssh-port] [--sshuser ssh-user]
[--sshkeyfile ssh-keyfile]
[--force={false|true}]
host-list
```

Description

The `uninstall-node-ssh` subcommand uninstalls Payara Server software from the hosts that are specified as the operand of the subcommand. This subcommand requires secure shell (SSH) to be configured on the host where the subcommand is run and on each host where the Payara Server software is being uninstalled.

This subcommand is equivalent to the `uninstall-node` subcommand.

By default, if any node except the predefined node `localhost-`domain resides on any host from which Payara Server software is being uninstalled, the subcommand fails. To uninstall the Payara Server software from a host on which user-defined nodes reside, set the `--force` option to `true`. If the `--force` option is `true`, the subcommand removes the entire content of the parent of the base installation directory.

If a file under the parent of the base installation directory is open, the subcommand fails.

If multiple hosts are specified, the configuration of the following items must be the same on all hosts:

- Parent of the base installation directory for the Payara Server software
- SSH port
- SSH user
- SSH key file

The subcommand does not modify the configuration of the domain administration server (DAS).

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--installdir`

The absolute path to the parent of the base installation directory where the Payara Server software is installed on each host, for example, `/export/payara7/`.
The user that is running this subcommand must have write access to the specified directory. Otherwise, an error occurs.
The specified directory must contain the installation of the Payara Server software on the host. Otherwise, an error occurs.
The default is the parent of the base installation directory of the Payara Server software on the host where this subcommand is run.

`--sshport`

The port to use for SSH connections to the host where the Payara Server software is to be uninstalled. The default is 22.

`--sshuser`

The user on the host where the Payara Server software is to be uninstalled that is to run the process for connecting through SSH to the host. The default is the user that is running this subcommand. To ensure that the DAS can read this user's SSH private key file, specify the user that is running the DAS process.

`--sshkeyfile`

The absolute path to the SSH private key file for user that the `--sshuser` option specifies. This file is used for authentication to the `sshd` daemon on the host.
The user that is running this subcommand must be able to reach the path to the key file and read the key file.
The default is a key file in the user's `.ssh` directory. If multiple key files are found, the subcommand uses the following order of preference:

1. `id_rsa`

2. `id_dsa`
3. `identity`

`--force`

Specifies whether the subcommand uninstalls the Payara Server software from a host even if a user-defined node resides on the host. Possible values are as follows:

`false`

If a user-defined node resides on a host, the software is not uninstalled and the subcommand fails (default).
If the `--force` option is `false`, the subcommand removes only the Payara Server software files. Other content if the parent of the base installation directory, such as configuration files, are not removed.

`true`

The subcommand uninstalls the Payara Server software from the host even if a user-defined node resides on the host.
If the `--force` option is `true`, the subcommand removes the entire content of the parent of the base installation directory.

Operands

host-list

A space-separated list of the names of the hosts from which the Payara Server software is to be uninstalled.

Examples

Example 1 Uninstalling Payara Server Software From the Default Location

This example uninstalls Payara Server software on the hosts `sj03.example.com` and `sj04.example.com` from the default location.

```
asadmin> uninstall-node-ssh sj03 sj04
Successfully connected to gfuser@sj03.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Successfully connected to gfuser@sj04.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Command uninstall-node-ssh executed successfully.
```

Example 2 Forcibly Uninstalling Payara Server Software

This example uninstalls Payara Server software on the host `sj02.example.com`.

The software is uninstalled even if a user-defined node resides on the host. The entire content of the `/export/payara7` directory is removed.

Some lines of output are omitted from this example for readability.

```
asadmin> uninstall-node-ssh --force --installdir /export/payara7 sj02.example.com
Successfully connected to gfuser@sj02.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Force removing file /export/payara7/mq/lib/help/en/add_overrides.htm
Force removing file /export/payara7/mq/lib/help/en/add_connfact.htm
...
Force removing directory /export/payara7/glassfish/lib/appclient
Force removing directory /export/payara7/glassfish/lib
Force removing directory /export/payara7/glassfish
Command uninstall-node-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `install-node`,
- `install-node-ssh`,
- `uninstall-node`

uninstall-node

Uninstalls Payara Server software from specified hosts.

Synopsis

```
asadmin [asadmin-options] uninstall-node [--help]
[--installdir as-install-parent]
[--sshport ssh-port] [--sshuser ssh-user]
[--sshkeyfile ssh-keyfile]
[--force={false|true}]
host-list
```

Description

The `uninstall-node` subcommand uninstalls Payara Server software from the hosts that are specified as the operand of the subcommand. This subcommand requires secure shell (SSH) to be configured on the host where the subcommand is run and on each host where the Payara Server software is being uninstalled.

This subcommand is equivalent to the `uninstall-node-ssh` subcommand.

By default, if any node except the predefined node `localhost-`domain resides on any host from which Payara Server software is being uninstalled, the subcommand fails. To uninstall the Payara Server software from a host on which user-defined nodes reside, set the `--force` option to `true`. If the `--force` option is `true`, the subcommand removes the entire content of the parent of the base installation directory.

If a file under the parent of the base installation directory is open, the subcommand fails.

If multiple hosts are specified, the configuration of the following items must be the same on all hosts:

- Parent of the base installation directory for the Payara Server software
- SSH port
- SSH user
- SSH key file

The subcommand does not modify the configuration of the domain administration server (DAS).

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--installdir`

The absolute path to the parent of the base installation directory where the Payara Server software is installed on each host, for example, `/export/payara7/`.
The user that is running this subcommand must have write access to the specified directory. Otherwise, an error occurs.
The specified directory must contain the installation of the Payara Server software on the host. Otherwise, an error occurs.
The default is the parent of the base installation directory of the Payara Server software on the host where this subcommand is run.

`--sshport`

The port to use for SSH connections to the host where the Payara Server software is to be uninstalled. The default is 22.

`--sshuser`

The user on the host where the Payara Server software is to be uninstalled that is to run the process for connecting through SSH to the host. The default is the user that is running this subcommand. To ensure that the DAS can read this user's SSH private key file, specify the user that is running the DAS process.

`--sshkeyfile`

The absolute path to the SSH private key file for user that the `--sshuser` option specifies. This file is used for authentication to the `sshd` daemon on the host.
The user that is running this subcommand must be able to reach the path to the key file and read the key file.
The default is a key file in the user's `.ssh` directory. If multiple key files are found, the subcommand uses the following order of preference:

1. `id_rsa`
2. `id_dsa`
3. `identity`

`--force`

Specifies whether the subcommand uninstalls the Payara Server software from a host even if a user-defined node resides on the host. Possible values are as follows:

`false`

If a user-defined node resides on a host, the software is not uninstalled and the subcommand fails (default).
If the `--force` option is `false`, the subcommand removes only the Payara Server software files. Other content if the parent of the base installation directory, such as configuration files, are not removed.

`true`

The subcommand uninstalls the Payara Server software from the host even if a user-defined node resides on the host.
If the `--force` option is `true`, the subcommand removes the entire content of the parent of the base installation directory.

Operands

host-list

A space-separated list of the names of the hosts from which the Payara Server software is to be uninstalled.

Examples

Example 1 Uninstalling Payara Server Software From the Default Location

This example uninstalls Payara Server software on the hosts `sj03.example.com` and `sj04.example.com` from the default location.

```
asadmin> uninstall-node sj03 sj04
Successfully connected to gfuser@sj03.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Successfully connected to gfuser@sj04.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Command uninstall-node executed successfully.
```

Example 2 Forcibly Uninstalling Payara Server Software

This example uninstalls Payara Server software on the host `sj02.example.com`.

The software is uninstalled even if a user-defined node resides on the host. The entire content of the `/export/payara7` directory is removed.

Some lines of output are omitted from this example for readability.

```
asadmin> uninstall-node --force --installdir /export/payara7 sj02.example.com
Successfully connected to gfuser@sj02.example.com using keyfile /home/gfuser
/.ssh/id_rsa
Force removing file /export/payara7/mq/lib/help/en/add_overrides.htm
Force removing file /export/payara7/mq/lib/help/en/add_connfact.htm
...
Force removing directory /export/payara7/glassfish/lib/appclient
Force removing directory /export/payara7/glassfish/lib
Force removing directory /export/payara7/glassfish
Command uninstall-node executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

- `uninstall-node-ssh`

unset-web-context-param

Unsets a servlet context-initialization parameter of a deployed web application or module.

Synopsis

```
asadmin [asadmin-options] unset-web-context-param [--help]
--name=context-param-name application-name[/module]
```

Description

The `unset-web-context-param` subcommand unsets a servlet context-initialization parameter of one

of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

When a parameter is unset, its value reverts to the value, if any, that is set in the application's deployment descriptor.

The application must already be deployed. Otherwise, an error occurs.

The parameter must have previously been set by using the `set-web-context-param` subcommand. Otherwise, an error occurs.

Do not use the `unset-web-context-param` subcommand to change the value of a servlet context-initialization parameter that is set in an application's deployment descriptor. Instead, use the `set-web-context-param` subcommand for this purpose.

This subcommand enables you to change the configuration of a deployed application without the need to modify the application's deployment descriptors and repackage and redeploy the application.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

The name of the servlet context-initialization parameter that is to be unset. This parameter must have previously been set by using the `set-web-context-param` subcommand. Otherwise, an error occurs.

Operands

application-name

The name of the application. This name can be obtained from the Administration Console or by using the `list-applications` subcommand.
The application must already be deployed. Otherwise, an error occurs.

module

The relative path to the module within the application's enterprise archive (EAR) file. The path to the module is specified in the `module` element of the application's `application.xml` file.
module is required only if the servlet context-initialization parameter applies to a web module of a Jakarta EE application. If specified, module must follow application-name, separated by a

slash (/).
For example, the `application.xml` file for the `myApp` application might specify the following web module:

```
<module>
    <web>
        <web-uri>myWebModule.war</web-uri>
    </web>
</module>
```

The module would be specified as the operand of this command as `myApp/myWebModule.war`.

Examples

Example 1 Unsetting a Servlet Context-Initialization Parameter for a Web Application

This example unsets the servlet context-initialization parameter `javax.faces.STATE_SAVING_METHOD` of the web application `basic-ezcomp`. The parameter reverts to the value, if any, that is defined in the application's deployment descriptor.

```
asadmin> unset-web-context-param
--name=javax.faces.STATE_SAVING_METHOD basic-ezcomp

Command unset-web-context-param executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `list-applications`,
- `list-web-context-param`,
- `set-web-context-param`

unset-web-env-entry

Unsets an environment entry for a deployed web application or module.

Synopsis

```
asadmin [asadmin-options] unset-web-env-entry [--help]
```

```
--name=env-entry-name application-name[/module]
```

Description

The `unset-web-env-entry` subcommand unsets an environment entry for one of the following items:

- A deployed web application
- A web module in a deployed Jakarta EE application

When an entry is unset, its value reverts to the value, if any, that is set in the application's deployment descriptor.

The application must already be deployed. Otherwise, an error occurs.

The entry must have previously been set by using the `set-web-env-entry` subcommand. Otherwise, an error occurs.

Do not use the `unset-web-env-entry` subcommand to change the value of an environment entry that is set in an application's deployment descriptor. Instead, use the `set-web-env-entry` subcommand for this purpose.

This subcommand enables you to change the configuration of a deployed application without the need to modify the application's deployment descriptors and repackage and redeploy the application.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--name`

The name of the environment entry that is to be unset. The name is a JNDI name relative to the `java:comp/env` context. The name must be unique within a deployment component. This entry must have previously been set by using the `set-web-env-entry` subcommand. Otherwise, an error occurs.

Operands

application-name

The name of the application. This name can be obtained from the Administration Console or by using the `list-applications` subcommand.
The application must already be deployed. Otherwise, an error occurs.

module

The relative path to the module within the application's enterprise archive (EAR) file. The path to the module is specified in the `module` element of the application's `application.xml` file.
module is required only if the environment entry applies to a web module of a Java EE application. If specified, module must follow application-name, separated by a slash (/).
For example, the `application.xml` file for the `myApp` application might specify the following web module:

```
<module>
    <web>
        <web-uri>myWebModule.war</web-uri>
    </web>
</module>
```

The module would be specified as the operand of this command as `myApp/myWebModule.war`.

Examples

Example 1 Unsetting an Environment Entry for a Web Application

This example unsets the environment entry `Hello User` of the web application `hello`. The entry reverts to the value, if any, that is defined in the application's deployment descriptor.

```
asadmin> unset-web-env-entry --name="Hello User" hello

Command unset-web-env-entry executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `list-applications`,
- `list-web-env-entry`,
- `set-web-env-entry`

unset

Removes one or more variables from the multimode environment.

Synopsis

```
asadmin [asadmin-options] unset [--help]
variable-list
```

Description

The `unset` subcommand removes one or more environment variables that are set for the multimode environment. After removal, the variables and their associated values no longer apply to the multimode environment.

To list the environment variables that are set, use the `export` subcommand without options. If the `export` subcommand lists no environment variables, no environment variables are set.

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

variable-list

A space-separated list of the environment variables to remove.

Examples

Example 1 Listing the Environment Variables That Are Set

This example uses the `export` subcommand to list the environment variables that have been set.

```
asadmin> export
AS_ADMIN_USER = admin
AS_ADMIN_HOST = bluestar
AS_ADMIN_PREFIX = server1.jms-service
AS_ADMIN_PORT = 8000
Command export executed successfully
```

Example 2 Removing an Environment Variable

This example removes the `AS_ADMIN_PREFIX` environment variable.

```
asadmin> unset AS_ADMIN_PREFIX
```

```
Command unset executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `export`,
- `multimode`

update-connector-security-map

Modifies a security map for the specified connector connection pool.

Synopsis

```
asadmin [asadmin-options] update-connector-security-map [--help]
--poolname connector_connection_pool_name
[--addprincipals principal_name1[,principal_name2]*]
[--addusergroups user_group1[,user_group2]*]
[--removeprincipals principal_name1[,principal_name2]*]
[--removeusergroups user_group1[,user_group2]*]
[--mappedusername username]
mapname
```

Description

The `update-connector-security-map` subcommand modifies a security map for the specified connector connection pool.

For this subcommand to succeed, you must have first created a connector connection pool using the `create-connector-connection-pool` subcommand.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--poolname`

Specifies the name of the connector connection pool to which the security map that is to be updated belongs.

`--addprincipals`

Specifies a comma-separated list of EIS-specific principals to be added. Use either the `--addprincipals` or `--addusergroups` options, but not both in the same command.

`--addusergroups`

Specifies a comma-separated list of EIS user groups to be added. Use either the `--addprincipals` or `--addusergroups` options, but not both in the same command.

`--removeprincipals`

Specifies a comma-separated list of EIS-specific principals to be removed.

`--removeusergroups`

Specifies a comma-separated list of EIS user groups to be removed.

`--mappedusername`

Specifies the EIS username.

Operands

mapname

The name of the security map to be updated.

Examples

Example 1 Updating a Connector Security Map

This example adds principals to the existing security map named `securityMap1`.

```
asadmin> update-connector-security-map --poolname connector-pool1
--addprincipals principal1,principal2 securityMap1
Command update-connector-security-map executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- asadmin,
- create-connector-security-map,
- delete-connector-security-map,
- list-connector-security-maps

update-connector-work-security-map

Modifies a work security map for the specified resource adapter.

Synopsis

```
asadmin [asadmin-options] update-connector-work-security-map [--help]
--raname raname
[--addprincipals eis-principal1=server-principal1[, eis-principal2=server-
principal2]*]
[--addgroups eis-group1=server-group1[, eis-group2=server-group2]*]
[--removeprincipals eis-principal1[,eis-principal2]*]
[--removegroups eis-group1[, eis-group2]*]
mapname
```

Description

The update-connector-work-security-map subcommand modifies a security map for the specified resource adapter.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the asadmin utility. For information about these options, see the asadmin help page.

--help

-?

Displays the help text for the subcommand.

--addgroups

Specifies a comma-separated list of EIS groups to be added. Use either the --addprincipals option or the --addgroups option, but not both.

--addprincipals

Specifies a comma-separated list of EIS-specific principals to be added. Use either the --addprincipals option or the --addgroups option, but not both.

--removegroups

Specifies a comma-separated list of EIS groups to be removed.

`--removeprincipals`

Specifies a comma-separated list of EIS-specific principals to be removed.

`--raname`

Indicates the connector module name with which the work security map is associated.

Operands

mapname

The name of the work security map to be updated.

Examples

Example 1 Updating a Connector Work Security Map

This example updates `workSecurityMap2` by removing `eis-group-2`.

```
asadmin> update-connector-work-security-map
--raname my-resource-adapter --removegroups eis-group-2 workSecurityMap2
Command update-connector-work-security-map executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `create-connector-work-security-map`,
- `delete-connector-work-security-map`,
- `list-connector-work-security-maps`

update-file-user

Updates a current file user as specified.

Synopsis

```
asadmin [asadmin-options] update-file-user [--help]
[--groups user_groups[:user_groups]*]
[--target target
[--authrealmname authrealm_name]
username
```

Description

Th `update-file-user` subcommand updates an existing entry in the keyfile using the specified user name, password and groups. Multiple groups can be entered by separating them, with a colon (:).

If a new password is not provided, this subcommand fails if secure administration is enabled and the user being updated is an administrative user.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--groups`

This is the name of the group to which the file user belongs.

`--authrealmname`

Name of the authentication realm where the user to be updated can be found.

`--target`

This option helps specify the target on which you are updating a file user. Valid values are:

`server`

Updates the file user in the default server instance. This is the default value.

cluster_name

Updates the file user on every server instance in the cluster.

instance_name

Updates the file user on a specified sever instance.

Operands

username

This is the name of the file user to be updated.

Examples

Example 1 Updating a User's Information in a File Realm

The following example updates information for a file realm user named `sample_user`.

```
asadmin> update-file-user
--groups staff:manager:engineer sample_user
Command update-file-user executed successfully
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

update-node-config

Updates the configuration data of a node.

Synopsis

```
asadmin [asadmin-options] update-node-config [--help]
[--nodehost node-host]
[--installdir as-install-parent] [--nodedir node-dir]
node-name
```

Description

The `update-node-config` subcommand updates the configuration data of a node.

This subcommand can update any node, regardless of whether the node is enabled for remote communication. If a node that is enabled for remote communication is updated, the node is not enabled for remote communication after the update.

Options of this subcommand specify the new values of the node's configuration data. The default for these options is to leave the existing value unchanged.

This subcommand does not require the secure shell (SSH) to be configured to update the node. You may run this subcommand from any host that can contact the DAS.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodehost`

The name of the host that the node is to represent after the node is updated.

`--installdir`

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara7`.

`--nodedir`

The path to the directory that is to contain Payara Server instances that are created on the node. If a relative path is specified, the path is relative to the as-install directory, where as-install is the base installation directory of the Payara Server software on the host.

Operands

node-name

The name of the node to update. The node must exist. Otherwise, an error occurs.

Examples

Example 1 Updating the Host That a Node Represents

This example updates the host that the node `sj04` represents to `hsj04`.

```
asadmin> update-node-config --nodehost hsj04 sj04
Command update-node-config executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,

update-node-docker

Updates the configuration data of a DOCKER node.

Synopsis

```
asadmin [asadmin-options] update-node-docker [--help]
[--installdir as-install-parent]
[--nodedir node-dir]
[--dockerpasswordfile filepath]
[--dockerimage imageName]
[--dockerport port]
[--useTls={false|true}]
node-name
```

Description

The `update-node-docker` subcommand updates the configuration data of a DOCKER node. The domain administration server (DAS) contacts a Docker node's host through the Docker engine's REST API on its specific configured host and port. By default, the subcommand fails and the node is not created if the DAS cannot reach the configured Docker engine's process.

The setup of a Docker node is more involved that other types of nodes, so it is recommended reading about the requirements and conditions for this command to work properly in corresponding section in Payara Server's High Availability section.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodehost`

The name of the host where the Docker engine process is listening through its REST API. This option is mandatory, otherwise the command fails.

`--installdir`

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara/`. The default is the parent of the default base installation directory of the Payara Server software for the DAS.

When creating a Docker node this parameter is mostly irrelevant when using the official Payara Server Node images. Use this parameter to point to custom server installations in case of using different images.

`--nodedir`

The path to the directory that is to contain Payara Server instances that are created on the node. The default is `as-install/nodes`, where as-install is the base installation directory of the Payara Server software on the host.

If a relative path is specified, the path is relative to the `as-install` directory.

`--dockerPasswordFile`

This is the fully-qualified path of the password file that the Docker instance will use for authentication against the DAS.

Please note, that this path should be the path to the file on the **remote** machine where . This file should be a standard Payara Server password file as you would use with asadmin. This must be specified, as Docker instances require secure admin to be enabled to start.

`--dockerImage`

The Docker image to use for creating the Docker container.

Defaults to `payara/server-node:main-7`.

`--dockerPort`

The port where the Docker engine's REST API endpoint is exposed.

Defaults to `2376`.

`--useTls`

Specifies whether the Docker engine's REST API endpoint is contacted through secure communication, as recommended in most environments. Defaults to `false`.

Operands

node-name

The name of the node to update. The node must exist. Otherwise, an error occurs.

Examples

Example 1 Updating the Host where the Docker Engine REST API is hosted

This example updates the host where the Docker Engine's REST API is hosted for the `docker-node-1` node:

```
asadmin update-node-docker --nodehost test.payara.fish docker-node-1
Command update-node-docker executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-node-docker`,
- `delete-node-docker`,
- `list-nodes`

update-node-ssh

Updates the configuration data of a SSH node.

Synopsis

```
asadmin [asadmin-options] update-node-ssh [--help]
[--nodehost node-host]
[--installdir as-install-parent] [--nodedir node-dir]
[--sshport ssh-port] [--sshuser ssh-user]
[--sshkeyfile ssh-keyfile]
[--force={false|true}]
node-name
```

Description

The `update-node-ssh` subcommand updates the configuration data of an SSH node. This subcommand requires secure shell (SSH) to be configured on the machine where the domain administration server (DAS) is running and on the machine where the node resides. You may run this subcommand from any machine that can contact the DAS.

This subcommand can update any node, regardless of whether the node is enabled for remote communication. If the node is not enabled for remote communication, the subcommand enables SSH communication for the node and updates any other specified configuration data.

Options of this subcommand specify the new values of the node's configuration data. The default for most options is to leave the existing value unchanged. However, if this subcommand is run to enable SSH communication for a node, default values are applied if any of the following options is omitted:

- `--sshport`
- `--sshuser`
- `--sshkeyfile`

By default, the subcommand fails and the node is not updated if the DAS cannot contact the node's host through SSH. To force the node to be updated even if the host cannot be contacted through SSH, set the `--force` option to `true`.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--nodehost`

The name of the host that the node is to represent after the node is updated.

`--installdir`

The full path to the parent of the base installation directory of the Payara Server software on the host, for example, `/export/payara`.

`--nodedir`

The path to the directory that is to contain Payara Server instances that are created on the node. If a relative path is specified, the path is relative to the as-install directory, where as-install is the base installation directory of the Payara Server software on the host.

`--sshport`

The port to use for SSH connections to this node's host. The default depends on whether this subcommand is run to enable SSH communication for the node:

- If the node is already enabled for communication over SSH, the default is to leave the port unchanged.
- If this subcommand is run to enable SSH communication for the node, the default port is `22`. If the `--nodehost` is set to `localhost`, the `--sshport` option is ignored.

`--sshuser`

The user on this node's host that is to run the process for connecting to the host through SSH. The default depends on whether this subcommand is run to enable SSH communication for the node:

- If the node is already enabled for communication over SSH, the default is to leave the user unchanged.
- If this subcommand is run to enable SSH communication for the node, the default is the user

that is running the DAS process.
If the `--nodehost` option is set to `localhost`, the `--sshuser` option is ignored.

`--sshkeyfile`

The absolute path to the SSH private key file for user that the `--sshuser` option specifies. This file is used for authentication to the `sshd` daemon on the node's host.

Payara Server also supports password authentication through the `AS_ADMIN_SSHPASSWORD` entry in the password file. The password file is specified in the `--paswordfile` option of the `asadmin` utility.

If the SSH private key file is protected by a passphrase, the password file must contain the `AS_ADMIN_SSHKEYPASSPHRASE` entry. The path to the key file must be reachable by the DAS and the key file must be readable by the DAS.
The default depends on whether this subcommand is run to enable SSH communication for the node:
* If the node is already enabled for communication over SSH, the default is to leave the key file unchanged. * If this subcommand is run to enable SSH communication for the node, the default is the key file in the user's `.ssh` directory. If multiple key files are found, the subcommand uses the following order of preference: . `id_rsa` . `id_dsa` . `identity` `--force`:: Specifies whether the node is updated even if validation of the node's parameters fails. To validate a node's parameters, the DAS must be able to contact the node's host through SSH. Possible values are as follows:
`false`;; The node is not updated if validation of the node's parameters fails (default). `true`;; The node is updated even if validation of the node's parameters fails.

Operands

node-name

The name of the node to update. The node must exist. Otherwise, an error occurs.

Examples

Example 1 Updating the Host That a Node Represents

This example updates the host that the node `lssh` represents to `sj04`.

```
asadmin> update-node-ssh --nodehost sj04 lssh
Command update-node-ssh executed successfully.
```

Example 2 Forcing the Update of a Node

This example forces the update of the node `sj01` to enable the node to communicate over SSH.

```
asadmin> update-node-ssh --force sj01
Warning: some parameters appear to be invalid.
Could not connect to host sj01 using SSH.
Could not authenticate. Tried authenticating with specified key at
/home/gfuser/.ssh/id_rsa
```

```
Continuing with node update due to use of --force.
Command update-node-ssh executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

- `uninstall-node-ssh`,
- `update-node-config`

update-password-alias

Updates a password alias.

Synopsis

```
asadmin [asadmin-options] update-password-alias [--help]
aliasname
```

Description

This subcommand updates the password alias IDs in the named target. An alias is a token of the form `${ALIAS=password-alias-password}`. The password corresponding to the alias name is stored in an encrypted form.The `update-password-alias` subcommand takes both a secure interactive form (in which the user is prompted for all information) and a more script-friendly form, in which the password is propagated on the command line.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Operands

aliasname

This is the name of the password as it appears in `domain.xml`.

Examples

Example 1 Updating a Password Alias

```
asadmin> update-password-alias jmspassword-alias
Please enter the alias password>
Please enter the alias password again>
Command update-password-alias executed successfully.
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `create-password-alias`,
- `delete-password-alias`,
- `list-password-aliases`

uptime

Returns the length of time that the DAS has been running.

Synopsis

```
asadmin [asadmin-options] uptime [--help]
```

Description

The `uptime` subcommand returns the length of time that the domain administration server (DAS) has been running since it was last restarted.

This subcommand is supported in remote mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

Examples

Example 1 Showing How Long the DAS Has Been Running

This example shows the length of time that the DAS has been running.

```
asadmin> uptime
Uptime: 2 days, 1 hours, 30 minutes, 18 seconds, Total milliseconds: 178218706
Command uptime executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

See Also

- `asadmin`,
- `list-domains`,
- `start-domain`,
- `stop-domain`

validate-multicast

Validates that multicast transport is available for clusters.

Synopsis

```
asadmin [asadmin-options] validate-multicast [--help]
```

```
[--multicastport multicastport]
[--multicastaddress multicastaddress]
[--bindaddress bindaddress]
[--sendperiod sendperiod]
[--timeout timeout]
[--timetolive timetolive]
[--verbose={false|true}]
```

Description

The `validate-multicast` subcommand validates that multicast transport is available for clusters. You should run this subcommand at the same time on each of the hosts to be validated. This subcommand is available in local mode.

Do not run the `validate-multicast` subcommand using the DAS and cluster's multicast address and port values while the DAS and cluster are running. Doing so results in an error.
The `validate-multicast` subcommand must be run at the same time on two or more machines to validate whether multicast messages are being received between the machines.

As long as all machines see each other, multicast is validated to be working properly across the machines. If the machines are not seeing each other, set the `--bindaddress` option explicitly to ensure that all machines are using interface on same subnet, or increase the `--timetolive` option from the default of `4`. If these changes fail to resolve the multicast issues, ask the network administrator to verify that the network is configured so the multicast messages can be seen between all the machines used to run the cluster.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--multicastport`

The port for the multicast socket on which the Group Management Service (GMS) listens for group events. Specify a standard UDP port number in the range 2048-49151. The default is `2048`.

`--multicastaddress`

The address for the multicast socket on which the GMS listens for group events. Specify a class D IP address. Class D IP addresses are in the range `224.0.0.0` to `239.255.255.255`, inclusive. The address `224.0.0.0` is reserved and should not be used. The default is `228.9.3.1`.

`--bindaddress`

The local interface to receive multicast datagram packets for the GMS. The default is to use all

available binding interfaces.
On a multi-home machine (possessing two or more network interfaces), this attribute enables you to indicate which network interface is used for the GMS. This value must be a local network interface IP address.

`--sendperiod`

The number of milliseconds between test messages sent between nodes. The default is `2000`.

`--timeout`

The number of seconds before the subcommand times out and exits. The default is `20`. You can also exit this subcommand using Ctrl-C.

`--timetolive`

The default time-to-live for multicast packets sent out on the multicast socket in order to control the scope of the multicasts. The time-to-live value must be between zero and 255 inclusive. The default is the JDK default or a minimum defined by a constant in the GMS subsystem, whichever is lower. To see the time-to-live value being used, use the `--verbose` option.

`--verbose`

If used without a value or set to `true`, provides additional debugging information. The default is `false`.

Examples

Example 1 Validating multicast transport

Run from host `machine1`:

```
asadmin> validate-multicast
Will use port 2,048
Will use address 228.9.3.1
Will use bind address null
Will use wait period 2,000 (in milliseconds)

Listening for data...
Sending message with content "machine1" every 2,000 milliseconds
Received data from machine1 (loopback)
Received data from machine2
Exiting after 20 seconds. To change this timeout, use the --timeout command line
option.
Command validate-multicast executed successfully
```

Run from host `machine2`:

```
asadmin> validate-multicast
Will use port 2,048
Will use address 228.9.3.1
Will use bind address null
```

```
Will use wait period 2,000 (in milliseconds)

Listening for data...
Sending message with content "machine2" every 2,000 milliseconds
Received data from machine2 (loopback)
Received data from machine1
Exiting after 20 seconds. To change this timeout, use the --timeout command line
option.
Command validate-multicast executed successfully
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`,
- `get-health`

verify-domain-xml

Verifies the contents of the domain.xml file.

Synopsis

```
asadmin [asadmin-options] verify-domain-xml [--help]
[--domaindir domain-dir] [domain-name]
```

Description

Verifies the content of the `domain.xml` file by checking the following details:

- That the `domain.xml` file can be parsed
- That the names for elements that have them are unique

This subcommand is supported in local mode only.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`-h --help`

Displays the help text for the subcommand.

`--domaindir`

Specifies the domain root directory, where the domains are located. The path must be accessible in the file system. The default is `as-install/domains`.

Operands

domain_name

Specifies the name of the domain. The default is `domain1`.

Examples

Example 1 Using verify-domain-xml

```
asadmin> verify-domain-xml
All Tests Passed.
domain.xml is valid
```

Exit Status

0

command executed successfully

1

error in executing the command

See Also

- `asadmin`

version

Displays version information for Payara Server.

Synopsis

```
asadmin [asadmin-options] version [--help]
[--verbose={false|true}]
[--local={false|true}]
```

Description

The `version` subcommand displays version information for Payara Server. By default, if the subcommand cannot contact the domain administration server (DAS), the subcommand retrieves the version information locally and displays a warning message.

This subcommand is supported in remote mode and local mode.

Options

asadmin-options

Options for the `asadmin` utility. For information about these options, see the `asadmin` help page.

`--help`

`-?`

Displays the help text for the subcommand.

`--verbose`

`-v`

If this option is set to `true`, the subcommand provides the version of the Java Runtime Environment (JRE) that the server is running. The default is `false`.

`--local`

If this option is set to `true`, the subcommand obtains the version locally from the installation of Payara Server on the host where the subcommand is run.

If this option is set to `false` (default), the subcommand attempts to contact the DAS to obtain the version. If the attempt to contact the DAS fails, the subcommand retrieves the version locally and displays a warning message.

Examples

Example 1 Obtaining Version Information From a Running DAS

```
asadmin> version
Version = Payara Server main-7 #badassfish (build 00)
Command version executed successfully.
```

Example 2 Obtaining Version Information When the DAS Cannot be Reached

```
asadmin> version
Version string could not be obtained from Server [localhost:4848].
(Turn debugging on e.g. by setting AS_DEBUG=true in your environment, to see the
details.)
Using locally retrieved version string from version class.

Version = Payara Server main-7 #badassfish (build 00)
Command version executed successfully.
```

Exit Status

0

subcommand executed successfully

1

error in executing the subcommand

Extensions

Overview

Payara Server Enterprise Edition allows plugin extensions to expand the features of the server's runtime. These extensions are not included in the default server's runtime and they must be installed before considering their usage.

Currently, the following extensions are provided:

link:/Technical Documentation/Payara Server Documentation/Extensions/gRPC Support/Overview.adoc[gRPC Support,role=unresolved]

The gRPC Support module allows web applications to define gRPC services which can be consumed by client applications.

gRPC Support

Overview

The gRPC extension has not yet been updated to support Payara Platform Enterprise 7

What is gRPC?

gRPC is a modern open-source high performance Remote Procedure Call (RPC) framework that use HTTP2 and simplifies the communication with protocol buffers to share data between client and server. By enabling gRPC Payara Server gives more options to create binary adaptable services.

What can we do with it?

- We can create services more efficient than REST.
- Use HTTP/2 to provide full duplex communication between the client and the service.
- Use protocol buffers to optimize and simplify communication.
- Enables bidirectional streaming out-of-the-box.

gRPC supports the means for users to implement gRPC style service programming.

See also

- You can find detailed information about gRPC here: https://grpc.io/docs/what-is-grpc/introduction/

- You can find detailed information about to define a grpc service and client here: https://grpc.io/docs/languages/java/basics/ .
- You can find detailed information about `protobuf` protocol here: https://grpc.io/docs/what-is-grpc/introduction/#working-with-protocol-buffers.

Installation

The gRPC extension has not yet been updated to support Payara Platform Enterprise 7

You need to download the following artifact from enterprise nexus repository: https://nexus.payara.fish/repository/payara-enterprise .

You must have an active Payara Enterprise subscription to access this Nexus repository.

This is the reference of the artifact to download:

```
<dependency>
  <groupId>fish.payara.extensions.grpc</groupId>
  <artifactId>grpc-support</artifactId>
  <version>1.0.0</version>
</dependency>
```

To download the artifact use the following command:

```
mvn dependency:get -DrepoUrl=https://nexus.payara.fish/repository/payara-enterprise
-Dartifact=fish.payara.extensions.grpc:grpc-support:1.0.0 -Dpackaging=jar
-Dclasifier=sources -Ddest=.
```

The previous command will download the JAR file to the current folder, then you need to drop the JAR into the `${PAYARA_HOME}/glassfish/modules` directory of your Payara Server Installation.

```
cp grpc-support-1.0.0.jar ${PAYARA_HOME}/glassfish/modules
```

Restart the domain and any running instances to enable the module.

Usage

The gRPC extension has not yet been updated to support Payara Platform Enterprise 7

This page documents how to use gRPC support in web applications.

Preparing a gRPC Service in a Web Application.

To prepare the service gRPC application you need the following:

1. Create a sample web application.
2. Include configuration for empty context root.
3. Create the `protobuf` service definition file.
4. Include build dependencies.
5. Configure build section.
6. Build service.
7. Extend service implementation.
8. Rebuild service.
9. Deploy service application.

Create a sample web application

Create a sample web application project using the following Maven archetype:

Example:

```
mvn archetype:generate -DgroupId=fish.payara.samples -DartifactId=payara-web
-DarchetypeArtifactId=maven-archetype-webapp -DinteractiveMode=false
```

Include configuration for empty context root

You need to create a Maven web application with empty context-root `/`. You can add the following `payara-web.xml` deployment descriptor to the `WEB-INF` folder of your application:

```
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app>
 <context-root>/</context-root>
</payara-web-app>
```

gRPC services must be deployed under the context-root `/`, since this is a constraint of the gRPC style programming as standard clients expect no base path on HTTP requests.

Create the `protobuf` service definition file

You need to use the `protobuf` protocol in order to define your service. Here's a sample "Hello World" snippet:

```
syntax = "proto3";
```

```
option java_multiple_files = true;
option java_package = "fish.payara.samples.grpc";
option java_outer_classname = "PayaraProto";
package fish.payara.samples.grpc;
service PayaraService {
  rpc communicate (PayaraReq) returns (PayaraResp) {}
}
message PayaraReq {
  string message = 1;
}
message PayaraResp {
  string message = 1;
}
```

To summarize the snippet above, this file is defining a service named `PayaraService` with a single method named `communicate` that handles a request named `PayarReq` and a returns a response named `PayaraResp`. We can see also the structure of these objects as they each have a string field named `message`. That will be the content of the messages to process by the service.

The `protobuf` file should be added under the following folder:

- src
  - main
    - proto
      - payara.proto

The name of the file is irrelevant, it only matters that its extension is `.proto`.

Include build dependencies

It is needed to declare the following dependencies to build the service and generate its stubs:

Example:

```
<dependency>
    <groupId>io.grpc</groupId>
    <artifactId>grpc-protobuf</artifactId>
    <version>1.43.1</version>
    <scope>provided</scope>
</dependency>
<dependency>
    <groupId>io.grpc</groupId>
    <artifactId>grpc-stub</artifactId>
    <version>1.43.1</version>
    <scope>provided</scope>
</dependency>
<dependency>
    <groupId>jakarta.platform</groupId>
```

```
    <artifactId>jakarta.jakartaee-api</artifactId>
    <version>10.0.0</version>
    <scope>provided</scope>
</dependency>
```

- The `grpc-protobuf` artifact is used to parse the `protobuf` files and generate the correspondent stubs class files.
- The `grpc-stub` artifact is used to resolve internal types for the stub classes.

Configure the build section

The build section is needed to generate the stubs and service implementation.

Example:

```
<build>
    <extensions>
        <extension>
            <groupId>kr.motd.maven</groupId>
            <artifactId>os-maven-plugin</artifactId>
            <version>1.6.2</version>
        </extension>
    </extensions>
    <plugins>
        <plugin>
            <groupId>org.xolstice.maven.plugins</groupId>
            <artifactId>protobuf-maven-plugin</artifactId>
            <version>0.6.1</version>
            <configuration>

<protocArtifact>com.google.protobuf:protoc:3.19.2:exe:${os.detected.classifier}</proto
cArtifact>
                <pluginId>grpc-java</pluginId>
                <pluginArtifact>io.grpc:protoc-gen-grpc-
java:1.43.1:exe:${os.detected.classifier}</pluginArtifact>
            </configuration>
            <executions>
                <execution>
                    <goals>
                        <goal>compile</goal>
                        <goal>compile-custom</goal>
                    </goals>
                </execution>
            </executions>
        </plugin>
    </plugins>
</build>
```

- The `os-maven-plugin` extension is used to identify OS properties used during generation of stubs

classes.

- The `protobuf-maven-plugin` plugin calls the `protobuf` compiler (`protoc`) to generate the stubs classes.

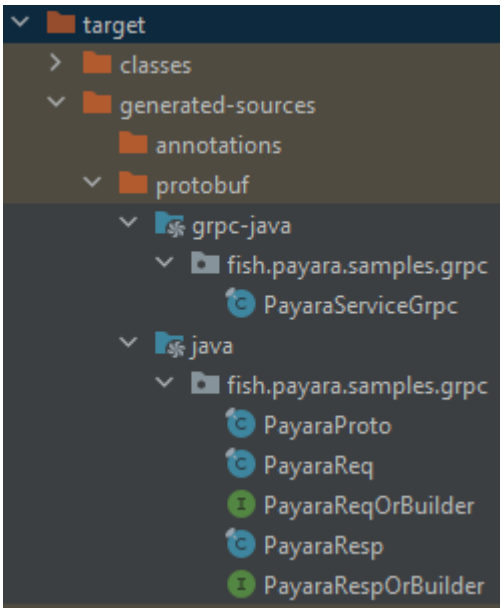
Build the Service

After doing the previous steps, you can build the project to generate the stubs. These stubs are needed to resolve the types used in the service implementation.

Example:

```
${webapp root folder} > mvn clean install
```

The stubs should be generated with similar structure like the following:



target/generated-sources/protobuf/grpc-java/fish.payara.samples.grpc

Here you can see the service class

target/generated-sources/protobuf/java/fish.payara.samples.grpc

Here you can see the types associated to the service

Extending service implementation class

To implement the service's endpoint you'll have to extend the implementation base class that is nested inside the recently compiled gRPC stub class located under `/target/generated-sources/protobuf/grpc-java`:

```
package fish.payara.samples.grpc;
import jakarta.enterprise.context.Dependent;
import java.util.logging.Logger;

@Dependent
public class PayaraService extends PayaraServiceGrpc.PayaraServiceImplBase {
```

```
    private final static Logger log = Logger.getLogger(PayaraService.class.getName());
    @Override
    public void communicate(fish.payara.samples.grpc.PayaraReq request,

io.grpc.stub.StreamObserver<fish.payara.samples.grpc.PayaraResp> responseObserver) {
        final String message = request.getMessage(); //getting message from the
request
        log.info(String.format("Processing message: %s", message)); //printing
incoming message from the request
        responseObserver.onNext(response(message)); //setting the message to the
response
        responseObserver.onCompleted(); //indicating that the response is complete
    }

    private static final fish.payara.samples.grpc.PayaraResp response(String message)
{
        return fish.payara.samples.grpc.PayaraResp.newBuilder() //creating builder
                .setMessage(message) //setting response message
                .build(); //build the response
    }
}
```

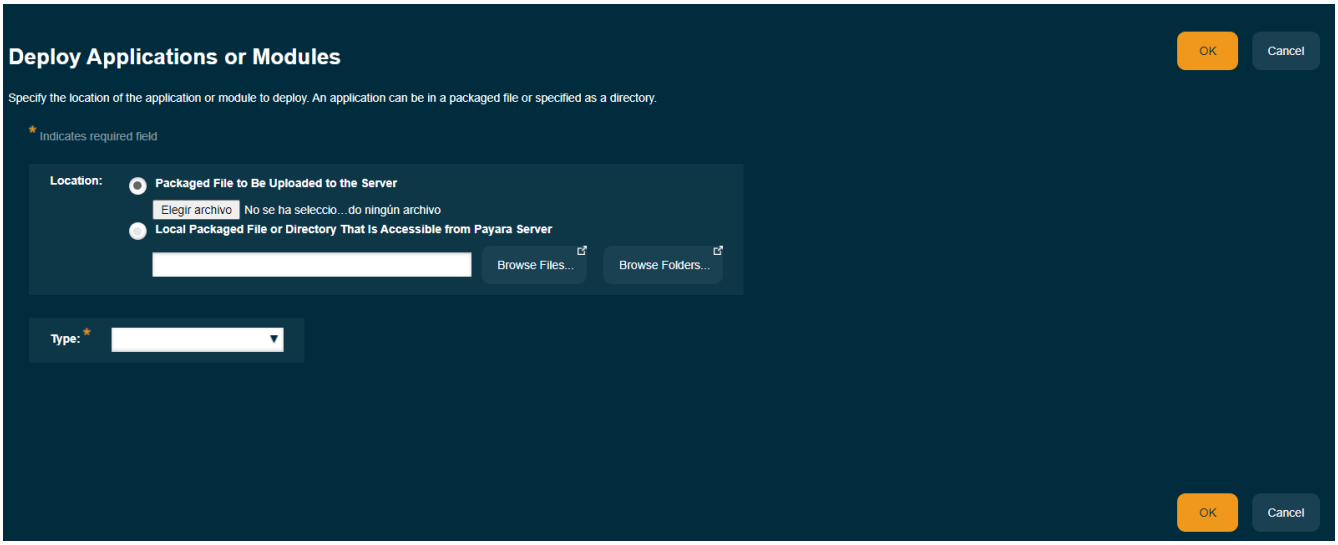
Our example is a simple "echo" service that will print a "Hello World" message. We can see that the `communicate` method receives the `PayaraReq` and the `StreamObserver<fish.payara.samples.grpc.PayaraResp>` parameters which are needed to process the incoming request with the 'Hello World' message and create the response using the same message.

Rebuild service

After doing the previous steps, you need to rebuild the project to include the service implementation.

Deploy service application

The final step is to deploy the application in a Payara Server domain. We can do this by using the Admin Console or the Asadmin CLI:



Here's an example running the Asadmin CLI equivalent from the command line:

```
 ${PAYARA_HOME}/glassfish/bin > asadmin deploy [filelocation]/service.war
```

Creating a sample gRPC client application

After deploying the service we'll proceed to create a client. To achieve this let's follow these steps:

1. Create client application
2. Copy stubs files to the client source directories
3. Add client dependencies
4. Create client implementation
5. Execution of the `HelloWorld` application

Create the client application

We can create a client application using the following Maven archetype:

```
mvn archetype:generate -DgroupId=fish.payara.samples -DartifactId=payara-client
-DarchetypeArtifactId=maven-archetype-quickstart -DinteractiveMode=false
```

Copy stubs files to the client source folder

Now, we'll manually copy the service stub files that were generated in the previous section to the following locations in the client application's source directories:

```
cp ${server app folder}/target/generated-sources/protobuf/grpc-
java/fish.payara.samples.grpc  ${client app}/src/main/java/fish/payara/samples/grpc

cp ${server app folder}/target/generated-
sources/protobuf/java/fish.payara.samples.grpc ${client
app}/src/main/java/fish/payara/samples/grpc
```

Add Client dependencies

The following Maven dependencies are needed to build and run the client application:

Example:

```
<dependency>
    <groupId>io.grpc</groupId>
    <artifactId>grpc-netty-shaded</artifactId>
    <version>1.43.1</version>
    <scope>runtime</scope>
</dependency>
<dependency>
```

```
    <groupId>io.grpc</groupId>
    <artifactId>grpc-protobuf</artifactId>
    <version>1.43.1</version>
</dependency>
<dependency>
    <groupId>io.grpc</groupId>
    <artifactId>grpc-stub</artifactId>
    <version>1.43.1</version>
</dependency>
```

- The `grpc-netty-shaded` it is needed at runtime to create the communication channel and send the message to the service.
- The `grpc-protobuf` artifact is used to parse the `protobuf` files and generate the correspondent stubs class files.
- The `grpc-stub` artifact is used to resolve internal types for the stub classes.

Create client implementation

Finally, here is the client code to call the gRPC service deployed in Payara Server:

```
package fish.payara.samples.grpc;

import io.grpc.Channel;
import io.grpc.ManagedChannelBuilder;
import io.grpc.stub.StreamObserver;
import java.net.MalformedURLException;
import java.net.URISyntaxException;
import java.net.URL;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicReference;
import java.util.logging.Level;
import java.util.logging.Logger;

public class GrpcClient {

    private static final Logger LOGGER = Logger.getLogger(GrpcClient.class.getName());
    private final PayaraServiceGrpc.PayaraServiceStub stub; //reference to the stub
service implementation class
    private CountDownLatch latch;
    private AtomicReference<Throwable> error;

    public static void main(String[] args) throws InterruptedException,
MalformedURLException, URISyntaxException {
        URL myURL = new
URL("http://localhost:8080/fish.payara.samples.grpc.PayaraService"); // URL for the
deployed gRPC service
        final GrpcClient client = new GrpcClient(myURL); // creating client
        client.communicate(); // call service
```

```
    }

    public GrpcClient(URL url) throws URISyntaxException {
        final Channel channel = ManagedChannelBuilder.forAddress(url.getHost(),
url.getPort())
                .usePlaintext().build(); //creating channel to start communication to
the service
        this.stub = PayaraServiceGrpc.newStub(channel); //creating stub from the
channel reference
        this.error = new AtomicReference<>(null);
    }

    public void communicate() throws InterruptedException {
        latch = new CountDownLatch(1); //this is to wait until the communication
finish with the current thread
        stub.communicate(request("Hello World"), new ResponseObserver()); //calling
service and adding a ResponseObserver to process response
        latch.await(20, TimeUnit.SECONDS); //timeout to wait response
    }

    public Throwable getError() {
        return error.get();
    }

    private final class ResponseObserver implements StreamObserver<PayaraResp> {

        @Override
        public void onNext(PayaraResp response) { //to process the service response
            LOGGER.log(Level.INFO, "Response received: \"{0}\".",
response.getMessage()); // printing the response from the service
        }

        @Override
        public void onError(Throwable t) { //method to process errors
            LOGGER.log(Level.SEVERE, "Error received", t);
            error.set(t);
            latch.countDown();
        }

        @Override
        public void onCompleted() {
            latch.countDown(); //indicating that the communication complete for the
current thread
        }

    }

    private static final PayaraReq request(String message) {
        return PayaraReq.newBuilder().setMessage(message).build(); //creating request
with a String message
    }
```

```
}
```

Execution of the "HelloWorld" application

To execute the client application, build the project and run the following command:

```
${client app} mvn compile exec:java
-Dexec.mainClass="fish.payara.samples.grpc.GrpcClient"
```

And you'll see the following log entries on the server that the service prints after processing the corresponding message:

```
[#|2022-03-02T14:15:10.947-0600|INFO|Payara
6.2022.1|jakarta.enterprise.system.container.web.com.sun.web.security|_ThreadID=118;_T
hreadName=http-thread-pool::http-listener-
1(2);_TimeMillis=1646252110947;_LevelValue=800;|
  Context path from ServletContext:  differs from path from bundle: /|#]

[#|2022-03-02T14:15:10.990-0600|INFO|Payara
6.2022.1|fish.payara.samples.grpc.PayaraService|_ThreadID=234;_ThreadName=grpc-
default-executor-0;_TimeMillis=1646252110990;_LevelValue=800;|
  Processing message: Hello World|#]
```

While the following entries are printed out on the client side:

```
mar 02, 2022 2:26:37 PM fish.payara.samples.grpc.GrpcClient$ResponseObserver onNext
INFO: Response received: "Hello World".
```

This shows that both client and server are running correctly.

Payara Server Docker Image

Overview of the usage and details of the official Payara Server Enterprise Docker image.

Quick start

Launch a new Payara Server domain running in a container listening in port `8080` with the following command:

```
docker run -p 8080:8080 nexus.payara.fish:5000/payara/server-full
```

Keep in mind the following:

- The container starts the `production` domain in the foreground so the server's DAS becomes the main process.

- The *tini* utility is used to guarantee that the server runs seamlessly as the single child process.
- The server's JVM process runs under the `payara` user.

It is recommended to specify the tag of the correct Payara Enterprise version that will be used on your production environment for guaranteed long-term stability

Using a specific version

```
docker run -p 8080:8080 nexus.payara.fish:5000/payara/server-full:main-7
```

AMD64 & ARM64 compatible images are provided. The Docker client should automatically download the appropriate image for your architecture.

Other distributions

Besides the Full Profile version, the Payara Server Web Profile distribution is also available as a Docker Image under the `payara/server-web` name. The image for this distribution behaves the same as its Full Profile counterpart.

Exposed ports

The default ports that are exposed by this image are:

- 8080 - HTTP listener
- 8181 - HTTPS listener
- 4848 - Admin Service HTTPS listener
- 9009 - JDWP Debug port

Administration Details

To access the DAS' administration interface (either by remote asadmin commands or by using the Web Admin Console), just map the container's Admin Service port when launching the container:

```
docker run -p 4848:4848 -p 8080:8080 nexus.payara.fish:5000/payara/server-full:main-7
```

By default, the admin service will be secure-enabled, meaning that HTTPS communication will be used exclusively.

The default administrator user with access to the admin interface will use the `admin/admin` credentials.

Make sure to update the administrator credentials after the domain has started.

Installation Details

The Payara Server installation is located in the `/opt/payara/appserver` directory (identified by the

PAYARA_DIR environment variable). The /opt/payara/ parent directory is the default working directory of the docker image.

The directory name is deliberately free of any versioning so that any scripts written to work with one version can be seamlessly migrated to the latest docker image.

Application Deployment

Deploy Applications from a Directory

The default entrypoint will scan the $DEPLOY_DIR directory (which defaults to /opt/payara/deployments) for files and sub-folders and deploy them automatically after the domain is started.

Any RAR files artefacts found in the directory will always be deployed first

To deploy your applications, you can mount this directory as a Docker volume mapped to a local directory that hosts your application artefacts.

The following sample command will launch a new Payara Server container and deploy all applications located in the ~/payara/apps directory:

```
docker run -p 8080:8080 -v ~/payara/apps:/opt/payara/deployments
nexus.payara.fish:5000/payara/server-full:main-7
```

Deploy Applications using a Custom Image

You can also prepare a custom image based on the official Payara Server Docker image and copy all application artifacts to the $DEPLOY_DIR directory. This way, you can re-package your applications in a simple distributable unit.

The following sample *Dockerfile* can be used to prepare a custom Payara Server image that deploys the myapplication.war artefact at runtime:

```
FROM nexus.payara.fish:5000/payara/server-full:main-7
COPY myapplication.war $DEPLOY_DIR
```

And to launch the container, simply build and run the image like this:

```
docker build -t mycompany/myapplication:1.0 .
docker run -p 8080:8080 mycompany/myapplication:1.0
```

Configuration

Using Environment Variables

The following environment variables can be used to configure multiple settings of the Payara Server's DAS before the domain is started. They can be either specified in a custom image's `Dockerfile`, passed to the `docker run` command via the `--env` or `--env-file` arguments or modified by an init script before the `startInForeground.sh` script is executed:

Name	Description	Default Value
`PREBOOT_COMMANDS`	The name of the file containing commands to be executed before the domain is started. The file will not be modified by the Docker container	`$CONFIG_DIR/post-boot-commands.asadmin` and `$CONFIG_DIR/pre-boot-commands.asadmin`
`POSTBOOT_COMMANDS`	The name of the file containing commands to be executed after the domain is started. This is the file written to in the `generate_deploy_commands.sh` script. The file will not be modified by the Docker container	`$CONFIG_DIR/post-boot-commands.asadmin`
`MEM_MAX_RAM_PERCENTAGE`	Value for the JVM argument `-XX:MaxRAMPercentage` which indicates the percentage of memory assigned to the container that can be used by the Java process	`70`
`MEM_XSS`	Value for the JVM argument `-Xss` which controls the stack size	`512K`
`DEPLOY_PROPS`	Specifies a list of properties to be passed with the deploy commands generated in the `generate_deploy_commands.sh` script	
`PAYARA_ARGS`	Additional arguments passed to the `start-domain` command that starts the DAS. *Use with caution.*	
`JVM_ARGS`	Additional JVM arguments which will be used to configure the Payara Servers DAS JVM settings	

Preboot and post-boot command files will not be modified by the Docker container

The following is a list of variables used by the Docker image to configure the Payara Server domain, so it is not recommended to alter their values:

Name	Description	Value
`HOME_DIR`	The home directory for the `payara` user	`/opt/payara`
`PAYARA_DIR`	The root directory of the Payara installation	`/opt/payara/appserver`

Name	Description	Value
SCRIPT_DIR	The directory where the generate_deploy_commands.sh and startInForeground.sh scripts can be found	/opt/payara/scripts
CONFIG_DIR	The directory where the post and pre boot files are generated to by default	/opt/payara/config
DEPLOY_DIR	The directory where applications are searched for in generate_deploy_commands.sh script	/opt/payara/deployments
ADMIN_USER	The default username credential for the default administrator user	admin
ADMIN_PASSWORD	The default password credential for the default administrator user. Can only be set when the basic image is created	admin
PASSWORD_FILE	The location of the password file for asadmin. This can be passed to asadmin using the --passwordfile parameter	/opt/payara/passwordFile
DOMAIN_NAME	The name of the domain running within the container	production
AS_ADMIN_MASTERPASSWORD	The master password to pass to Payara Server. This is overridden if one is specified in the $PASSWORD_FILE	changeit

Executing Administration Commands at Domain Startup

It's possible to run a set of custom administration commands during the domain startup. You can either specify the PREBOOT_COMMANDS or POSTBOOT_COMMANDS environment variables to point to the absolute path of a custom script file, or you can just copy the file to the expected paths (See above).

For example, the following sample command will execute all commands listed in the post-boot-commands.asadmin file inside the /local/path/with/boot/file directory mounted volume:

```
docker run -p 8080:8080 -v /local/path/with/boot/file:/config -e
POSTBOOT_COMMANDS=/config/post-boot-commands.asadmin
nexus.payara.fish:5000/payara/server-full:main-7
```

Alternatively, the same outcome can be achieved by defining a custom Docker image:

```
FROM nexus.payara.fish:5000/payara/server-full:main-7
COPY post-boot-commands.asadmin $POSTBOOT_COMMANDS
```

Enable Logging to a File

By default, Payara Server logs are written to the Docker standard output instead of the usual server.log file. However, you can configure the server to also log to this server.log file using the

following command with a pre-boot command file:

```
set-log-attributes com.sun.enterprise.server.logging.GFFileHandler.logtoFile=true
```

Alternatively, you can redirect the container logs to a file when running the container:

```
docker run -p 8080:8080 nexus.payara.fish:5000/payara/server-full:{page-version} >
payara-logs.txt 2>&1
```

Executing Custom Scripts before Domain Startup

If preboot command files are not enough, you can add your customized shell scripts to the `${SCRIPT_DIR}/init.d` directory. This will allow you to modify the environment before the Payara Server domain starts.

Scripts added to this folder should be Bash scripts and they should end with the `.sh` suffix.

Scripts in `${SCRIPT_DIR}/init.d` will be executed in the standard file order. If you need to start them in a specific order, we recommend prepending a prefix number to their name, for example, `01_script1.sh`, `02_script2.sh`, and so on.

As with the preboot command file, you may either create a custom Docker image that already contains the script files in question or you can also mount a volume mapped to the `${SCRIPT_DIR}/init.d` directory instead.

The Default Docker Entrypoint

The default entry point of the Docker image is defined using the tini utility, to allow the DAS's JVM to run as a single child process.

The default `CMD` argument for *tini* runs the `bin/entrypoint.sh` shell script in `exec` mode, which in turn runs the following scripts in order:

1. `${SCRIPT_DIR}/init_1_generate_deploy_commands.sh`: This script outputs deploy commands to the post-boot command file located at `$POSTBOOT_COMMANDS` (default `$CONFIG_DIR/post-boot-commands.asadmin`). If deploy commands are already found in that file, this script does nothing.
2. `${SCRIPT_DIR}/init.d/*.sh`: As described above, these scripts can be provided by you to run and configure the environment **before** the domain startup.
3. `${SCRIPT_DIR}/startInForeground.sh`. This script starts the domain in the foreground, in a manner that allows the JVM to be controlled by the docker host.

Browsing the Container

You can override the default entrypoint if needed to test or browse the container to examine that everything's in place. The following command will start the container at a bash prompt, without starting the domain.

```
docker run -p 8080:8080 -it nexus.payara.fish:5000/payara/server-full:main-7 bash
```

Read Only Support Considerations

The Payara Server Docker image requires write access to the `PAYARA_DIR`, `CONFIG_DIR`, and `/tmp` directories to function. If you wish to use `--read-only` Docker containers (or the equivalent `--readOnlyRootFilesystem` property in Kubernetes), you must mount volumes at these directories which the `payara` user has write access to. This can be done using anonymous or tmpfs volumes if you do not wish to persist the data outside the life of the container. Named volumes or bind mounts may be used if you wish the data to persist outside the life of the container.

Here is an example `run` command for a read-only Docker container which will delete itself and its anonymous volumes when stopped:

```
docker run -p 8080:8080 -p 4848:4848 --read-only --rm -v /opt/payara -v /tmp
nexus.payara.fish:5000/payara/server-full:main-7
```

Payara InSight

Payara InSight allows real-time visualization and alerting for server and web application metrics.

It consists of a server module responsible for collecting a multitude of metrics from all nodes which are accumulated on the DAS to feed data to its frontend which visualizes the data as a web-application deployed on the DAS.

The metrics include server metrics from different sources within the server as well as metrics defined in user applications using *MicroProfile Metrics* and metrics derived from *MicroProfile Health* checks.

Enabling the GUI

By default, the Payara Insight GUI is automatically enabled for the `production` domain. Links can be found on the *Common Tasks* home page of the Admin GUI in section *Monitoring* or on the *Monitoring Data* page.

For `domain1` the GUI is not enabled by default and the `set-monitoring-console-configuration` is used to enable it on demand.

To enable the GUI manually run the following asadmin command:

```
asadmin> set-monitoring-console-configuration --enabled=true
```

Payara InSight is available at `http://localhost:8080/monitoring-console/` . Like the Admin console's user interface, it only runs on the DAS.

To stop Payara Insight run this command:

```
asadmin> set-monitoring-console-configuration --enabled=false
```

Stopping the application does not disable the data collection.
This is a background process that is controlled separately as described in the next section.

Enabling Data Collection

The collection of monitoring data gets enabled and disabled in connection with the general configuration: *Monitoring* ⇒ *Monitoring Service* ⇒ *Enabled*. By default, this setting is enabled.

If you want to remove the monitoring data collection from the server's runtime without disabling the monitoring service itself you must delete the `monitoring-console-core.jar` from the `as-install/modules` folder of your server installation and restart the server.

Enabling Data Aggregation (History)

By default, InSight has a sliding window of data per metric of usually one minute length which contains 1 point per second. This allows typical "real-time" monitoring. These points represent the raw data as it is probed/collected.

Without a history points that get "pushed" out of the sliding window are "forgotten".

A history can be enabled which aggregates the points per seconds to 1 aggregated point per minute, the minutes to 1 point per hour, the hours to 1 point per day. These aggregations equally have sliding windows, so they hold the recent hour, day or month worth of data.

The longer points are in the past the fewer points per fixed time-frame there are:

- In the most recent minute there are the raw (not aggregated) points per second.
- In the most recent hour there is 1 point per minute from aggregating the seconds within the last minute.
- In the most recent day there is 1 point per hour from aggregating the minutes within the last hour.
- In the most recent month there is 1 point per day from aggregating the hours within the last day.

The aggregation of points must be enabled using the following Asadmin command:

```
asadmin> set-monitoring-console-configuration --history-enabled=true
```

This command starts the aggregation which increases over time. The aggregated data is only stored in memory. Widgets can choose to show this data using the *Extras - History* setting.

The aggregation of points can be disabled again using the following asadmin command:

```
asadmin> set-monitoring-console-configuration --history-enabled=false
```

All aggregated data is discarded and cannot be restored. Equally, history is lost when the server is restarted.

The aggregated history feature is designed to keep memory usage fairly low. 1000 metrics require in the range of single digit MBs of memory.

In typical environments the extra memory and CPU effort for the history should not be an issue.

Graphical User Interface

After enabling Payara InSight open the home page at `/monitoring-console/` (usually on port `8080`).

The GUI ships with a set of preconfigured pages each focussing on a different aspect of the server.

Some metrics are only available when the monitoring configuration of certain server parts is set to `HIGH`. Widgets that do depend on such a configuration changes let you know how to enable the metrics.

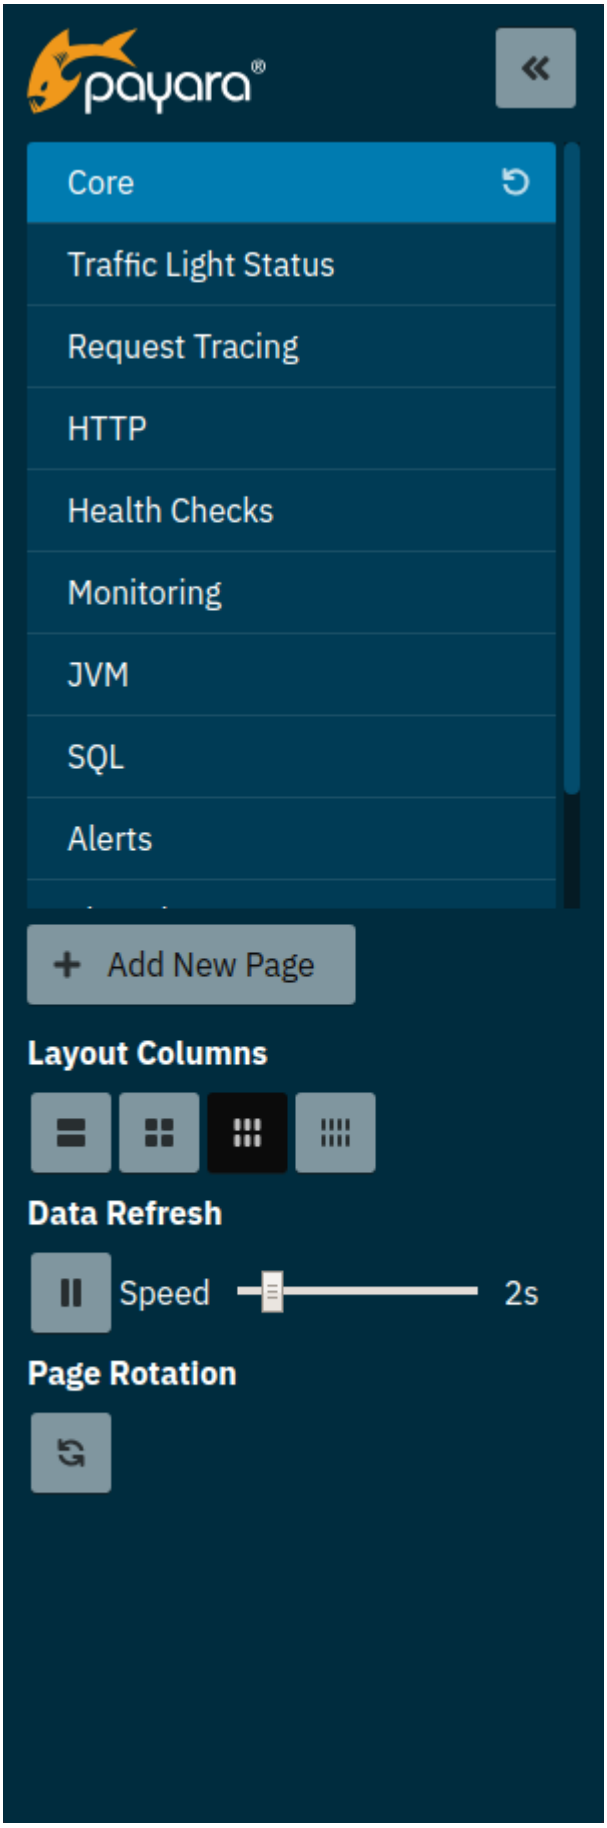
Pages

Payara InSight is organized in fully customizable pages. A page is a collection of widgets arranged in columns. Usually, pages are focused on visualizing metrics of a specific area of the server, like HTTP or request tracing.

The pre-configured pages are a starting point that can be changed and extended by the user. New custom pages can be created and populated with arbitrary metrics.

Switching Pages

To switch page use the left menu.



payara
Core
Traffic Light Status
Request Tracing
HTTP
Health Checks
Monitoring
JVM
SQL
Alerts
Add New Page
Layout Columns
Data Refresh
Speed
2s
Page Rotation

Each page switch also updates the URL making them "bookmarkeable". URLs can be copied and shared with others to share particular pages with them.

Updating URLs after switching pages also means that once the page is changed using the dropdown navigation, the browser's page history based navigation can be used to go back to already visited pages.

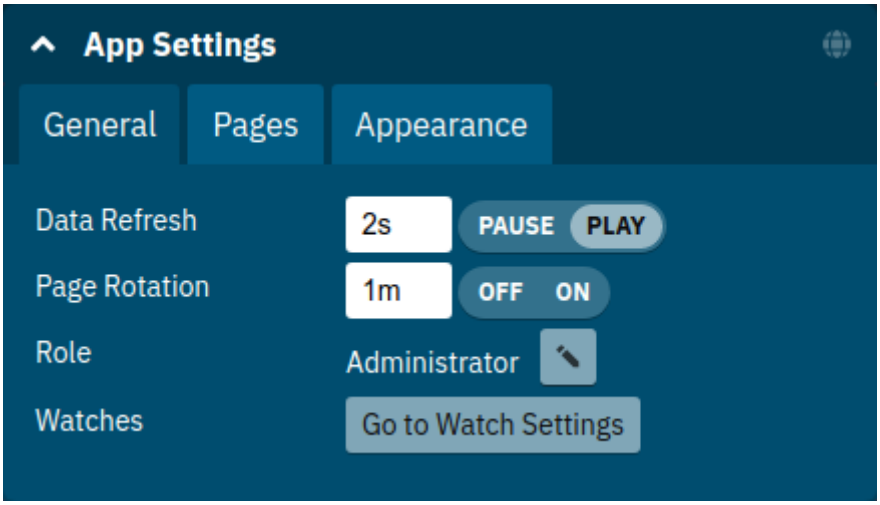
Changing Page Layout

Each page uses a column layout of one or more columns. The number of columns for a page can be changed using one of the *Layout Columns* quick access buttons.

Changing the column layout of a page does not change the preferred position of the widgets. If a widget is set to column 3 but a 2-column layout is used all widgets of the 3rd or 4th column get pushed to the 2nd column instead. This allows switching layouts based on the viewing device without redoing the configuration entirely.

Changing Page Update Interval

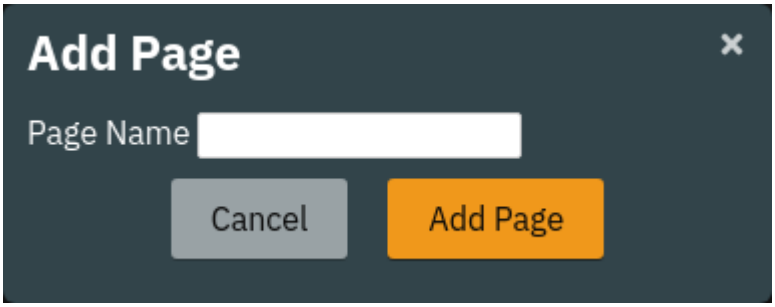
By default, the graphs on a page update every 2 seconds. To control the interval use quick access on the left side menu or *General* application settings.



The interval can be paused and continued without changing the interval duration by using the *play/pause* toggle next to the interval setting.

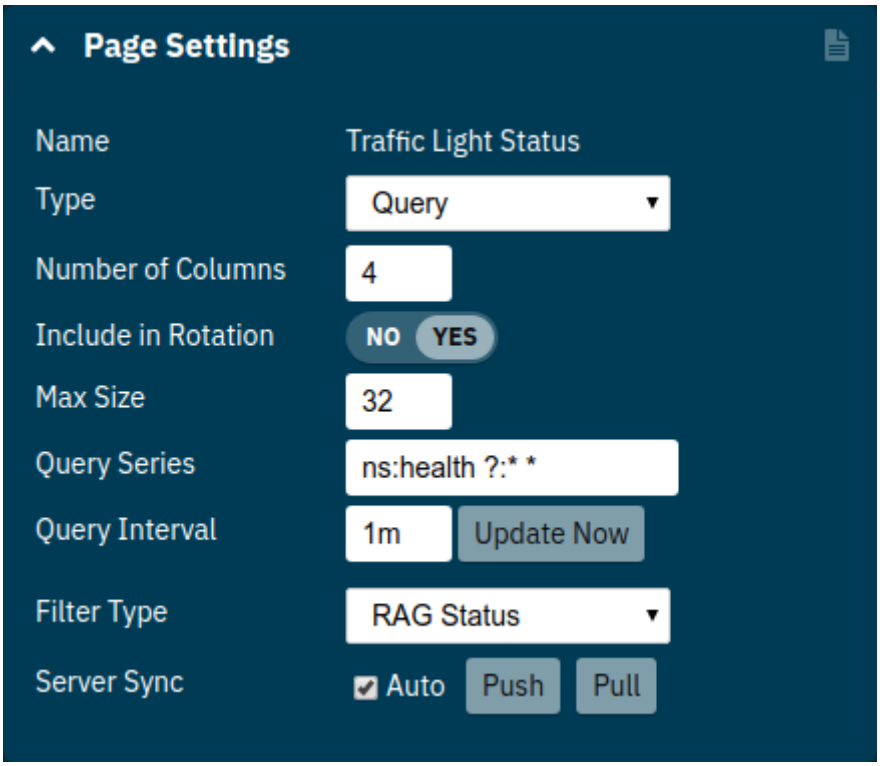
Adding Pages

To add a new page expand the left menu, click the *Add New Page* button below the list of pages and enter a name for the new page in the dialogue.



Usually pages are populated manually. Use the *Add New Widgets* button in the right sidebar (+ when minimized) to populate the page and configure the added widgets.

Alternatively pages can use a query to automatically populate the page with widgets for those metrics that match the query. To use a query page open the page settings and switch the *Type* to *Query*:



Fill in *Query Series* and *Query Interval* and click the *Update Now* button.

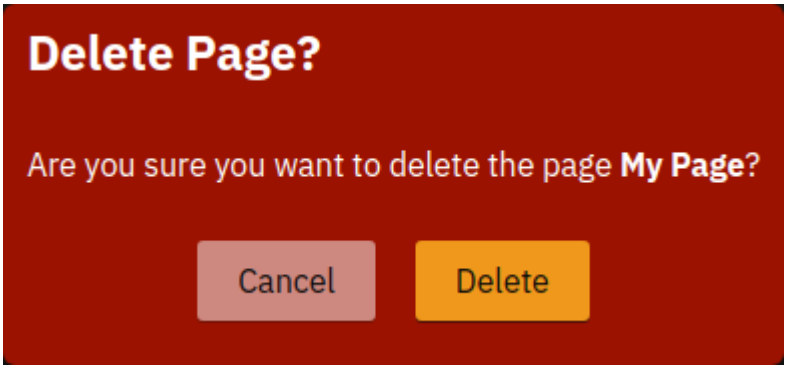
Query pages are repopulated in intervals. Any changes to individual widget settings will be overridden with the next population. However, queries can be used to initially populate a page and then switch the page back to *Type: Manual* so that changes to the widgets are kept.
Naturally this comes at the downside that metrics no longer are added to the page automatically.

Learn more about series patterns as used by query pages.

Deleting a Page

To delete a page open the left sidebar and click the on the trash icon next to the page name in the list of pages you want to delete.

Confirm the deletion.

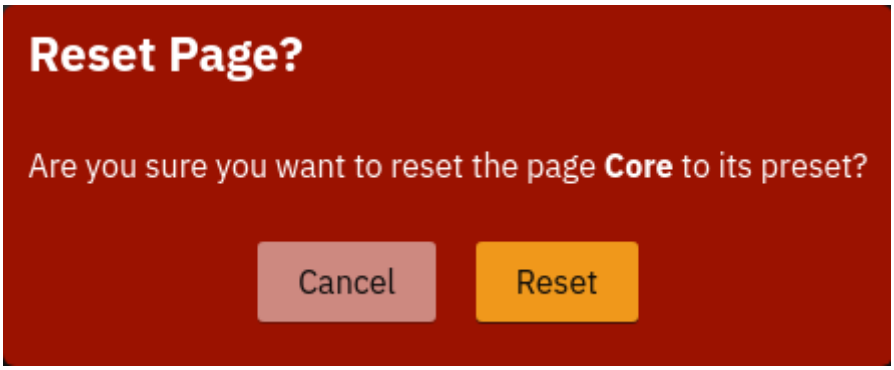


Pages that are based on a preset cannot be deleted. They can only be reset to their preset configuration.

Reset a Page

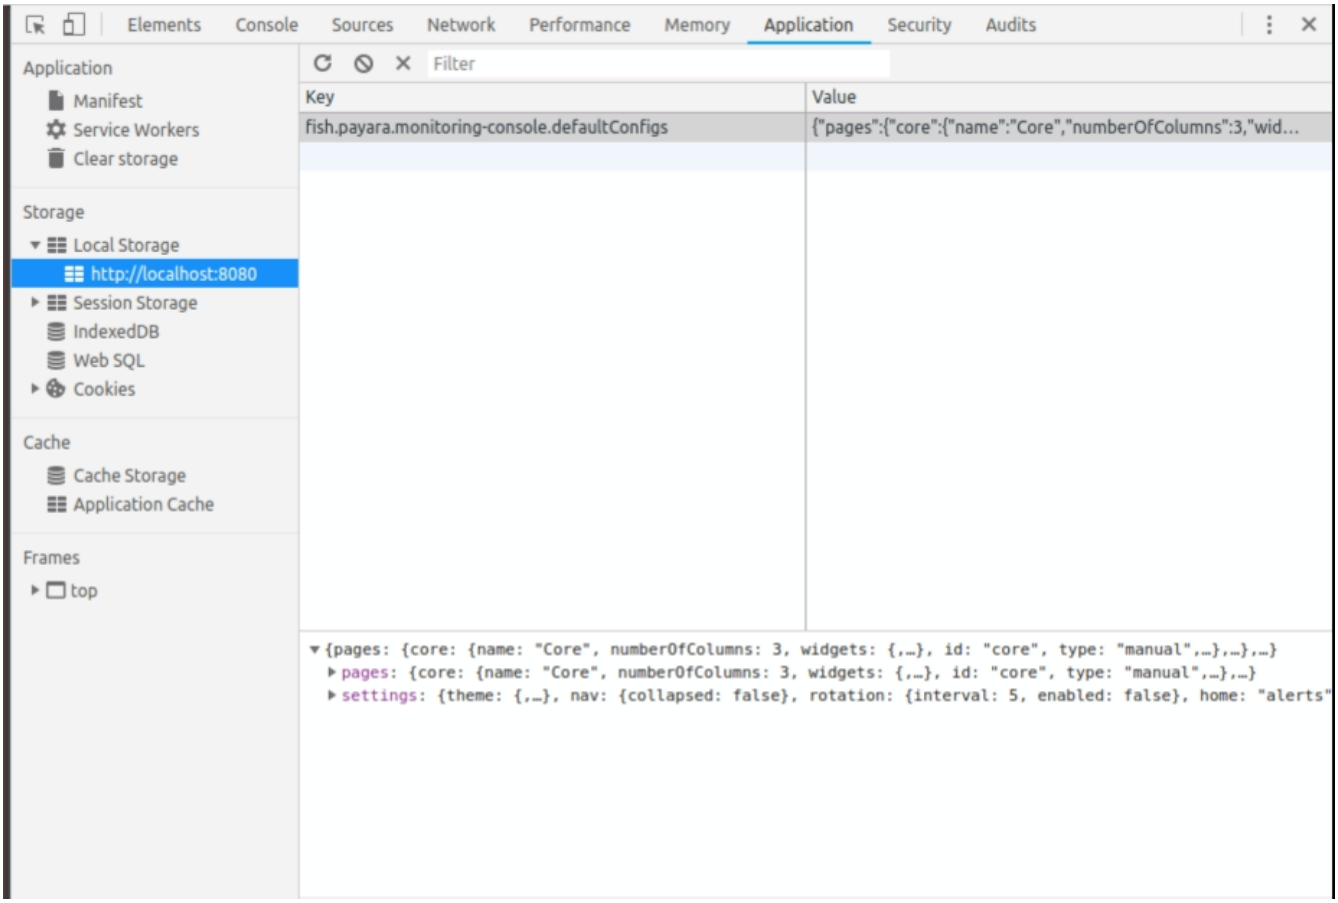
When the configuration of a preconfigured page or any of the widgets on it was changed by the user the page can be reset by clicking the *Reset* icon next to the page name in the expanded left side menu.

Confirm the reset.



The reset will affect all widgets and the general page settings of the currently shown page. All changes made previously by a user will be overridden.

To reset all pages and remove all user-created pages, clear the browser's local storage of Payara InSight.



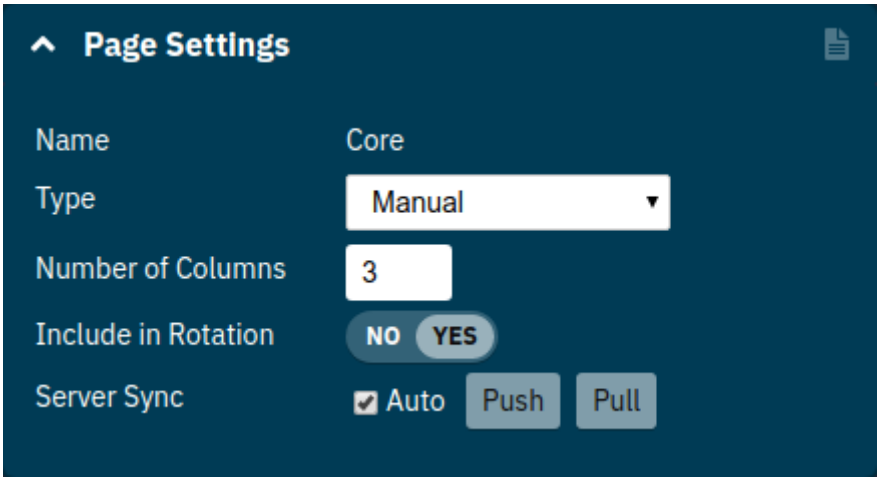
Page Rotation

Payara InSight is meant to be used to display metrics on status monitors. To allow viewing a variety of pages and their metrics on a single screen the pages can be automatically rotated showing each page for a configured interval duration.

To start or stop page rotation either use the quick access button at the button of the left side menu or use the toggle switch in the *General* application settings. This starts or stops the rotation immediately and each page is shown for the configured duration starting with the currently shown page.

The duration can be adjusted by changing the text field of the *Page Rotation* to another time value. Use units to express the duration, as for example: `1min`, `30sec`. Changes take effect immediately.

Individual pages can be excluded from rotation by toggling the *Include In Rotation* toggle to *No* in the page settings.



Page Management

Payara InSight uses the browser's local storage to store the page configuration (which includes the widgets placed on a page). This means by default changes to page configurations do not affect other users.

To make pages available to others and to start from a common base configuration pages are explicitly synchronised with a persistent server page configuration.

The monitoring console can be used in one of three roles:

- *Guest*: A user that uses Payara Insight only on occasion to check existing metrics on existing pages ("read-only" user).
- *User*: A user that uses the console to experiment with its features without affecting others.
- *Administrator*: A user that uses the console to configure the configuration that is the basis for other users.

The chosen role controls the behaviour and available options for the page synchronisation:

Administrator

This role that is meant to manage the persistent server page configuration. The *Administrator* pushes local changes to the server to update the base configuration.

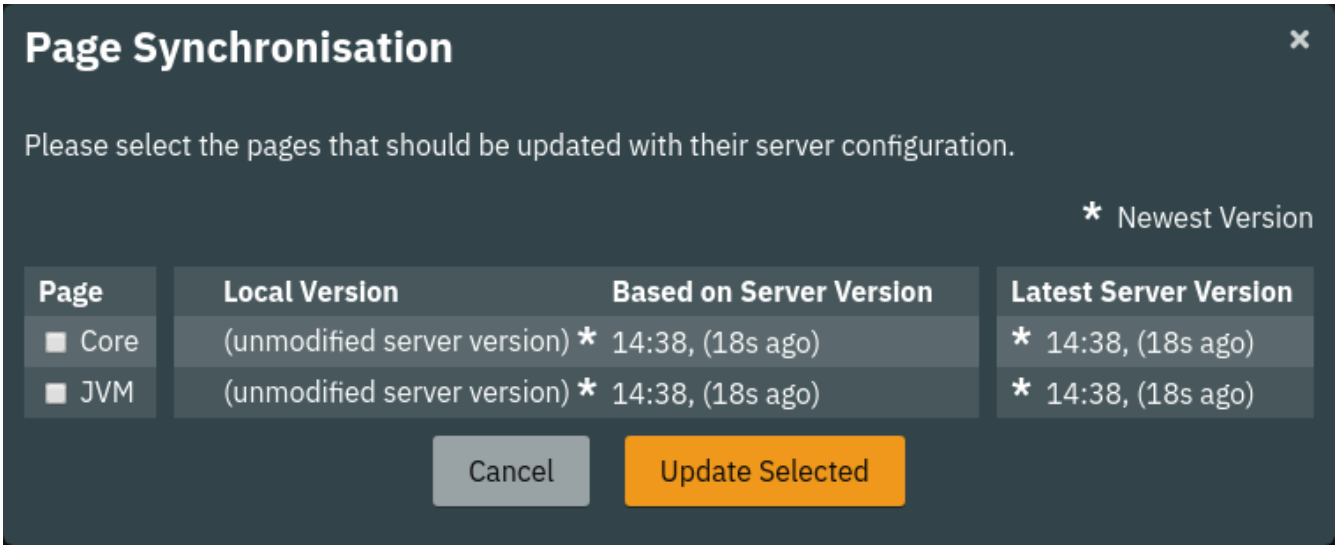
User

Guest

They pull the server configuration to update their local configuration with the base.

The control remains with each user.

The *Page Synchronisation* dialogue shown when entering the GUI allows the user to pick the pages that should be updated (pulled).

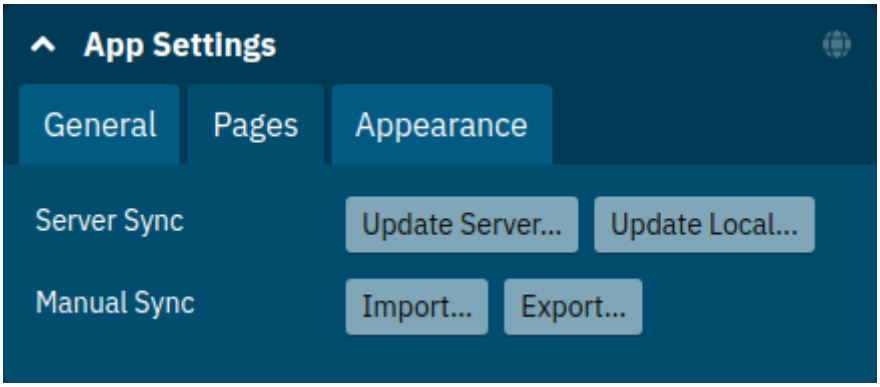


By default, all pages available remotely that have not been changed locally are preselected.

Guests automatically pull the servers base configuration, no dialogue is used

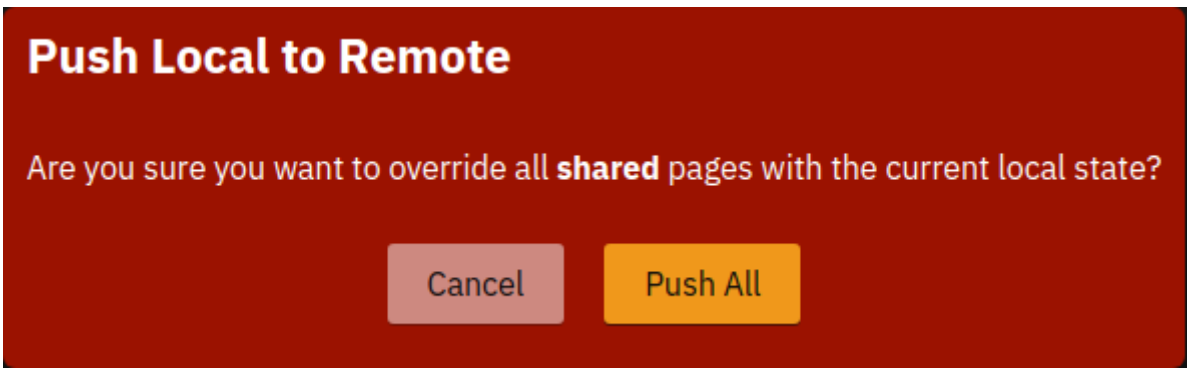
The newest version is marked with an asterisk for easier orientation.

This dialogue can also be opened from the *Pages* application settings by clicking the *Update Local…* button for the *Page Sync* property.

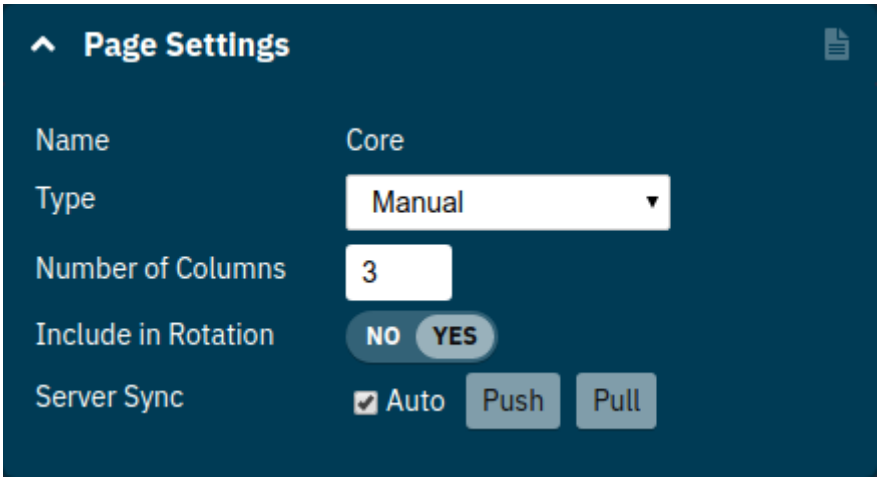


Administrators also find a button to *Update Server…* pages with any changes applied to local changes. This is only needed for pages that are not using automatic updates in their page settings.

This simply should give administrators different approaches to managing the configuration of shared pages. To bulk update all server pages click the *Update Server…* button and confirm the update:

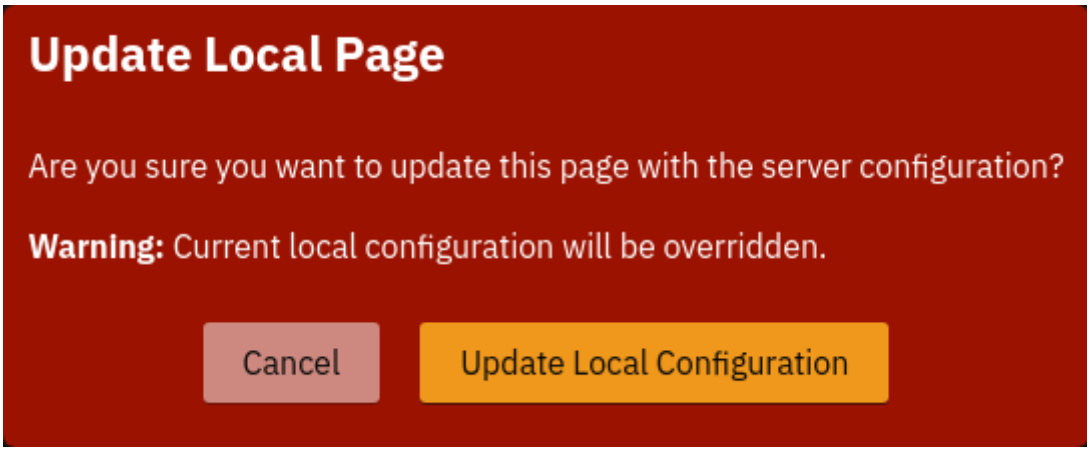


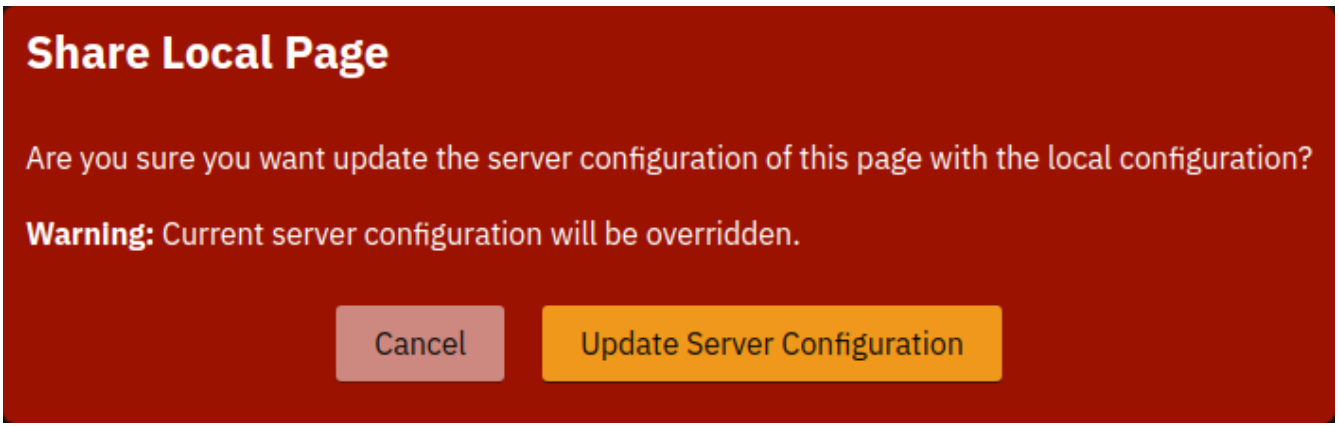
To share a page that so far is not part of the persistent server configuration open the *Page* settings and look for the *Server Sync* property.



Users and *Administrators* can both *Push* a page to share or update the persistent server configuration or *Pull* the server configuration to update the local page. *Administrators* can also enable or disable the *automatic* page synchronisation. When enabled any local change done by an *Administrator* is automatically pushed to the remote configuration.

Both *Push* and *Pull* need to be confirmed.

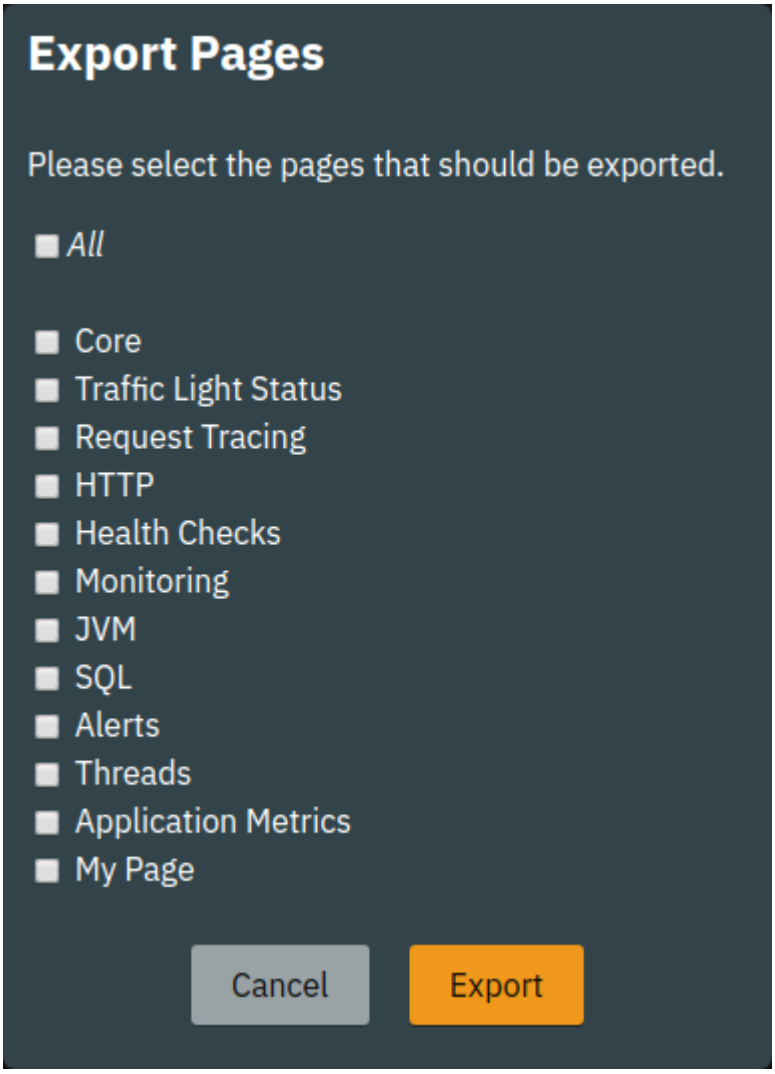




Page Export

Besides the managed page synchronisation which is using the persistent server configuration the local configuration can also be managed manually. To manually export pages click the *Export...* button and select the set of pages to export in the dialogue and confirm your selection by pressing

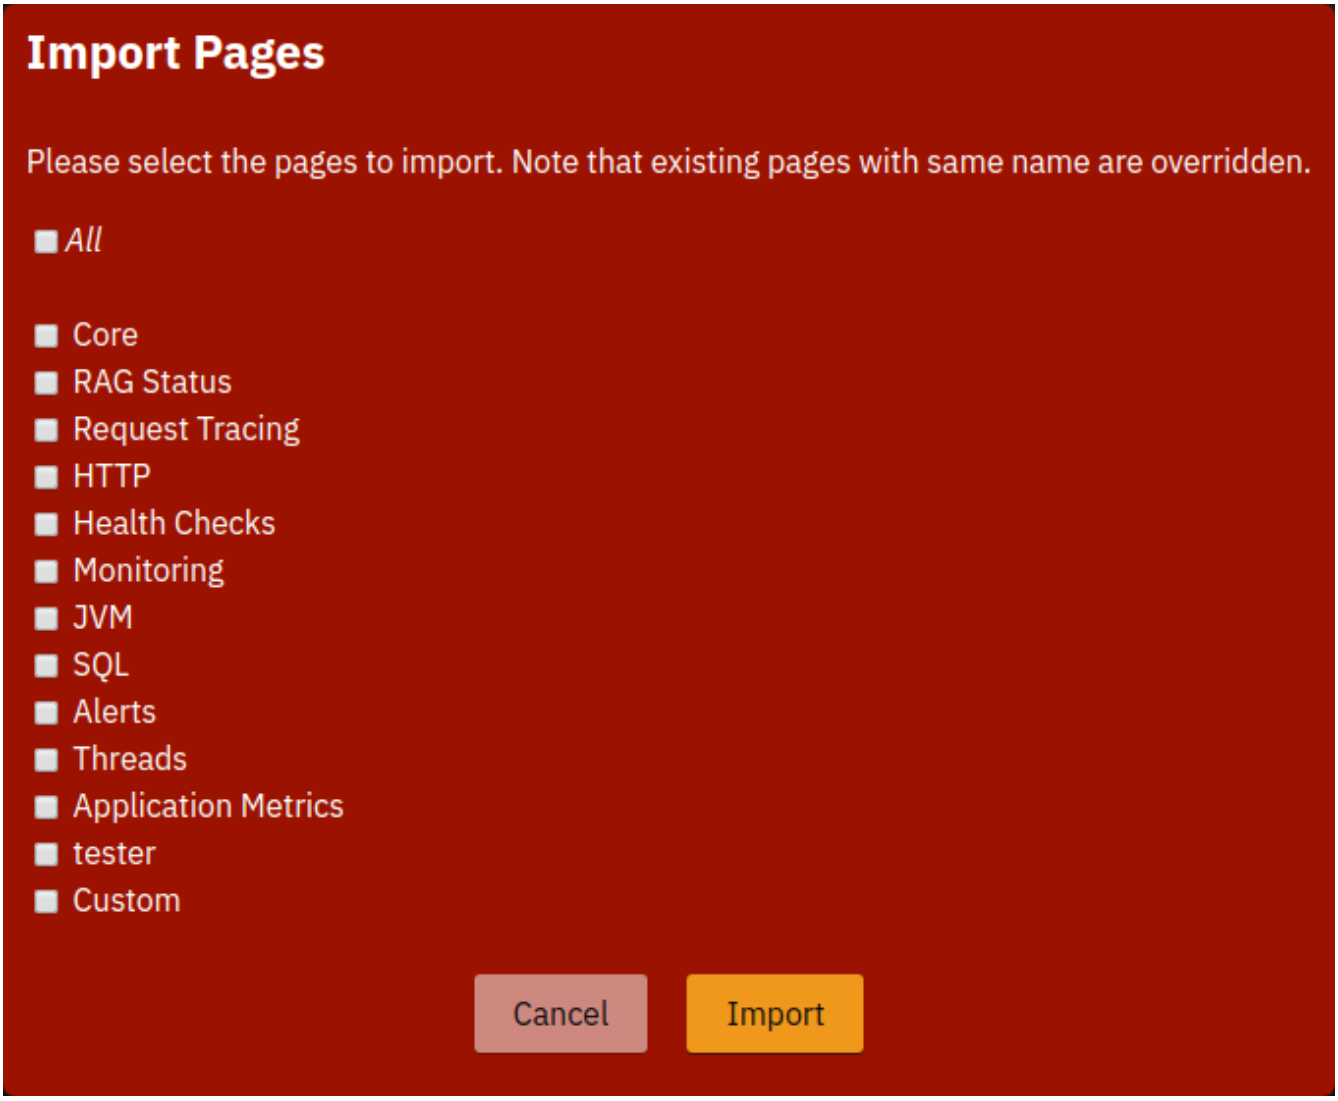
Export



Page Import

To manually import pages click the *Import…* button and select a file. The dialogue will show the list of pages contained in the file.

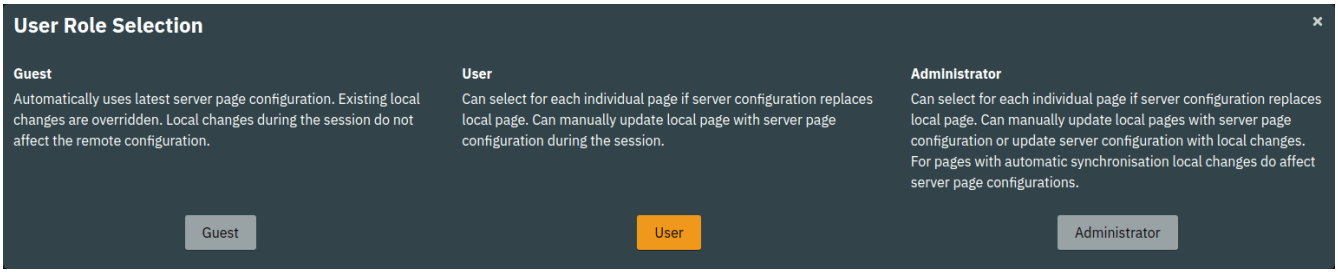
Select the pages that should be imported:



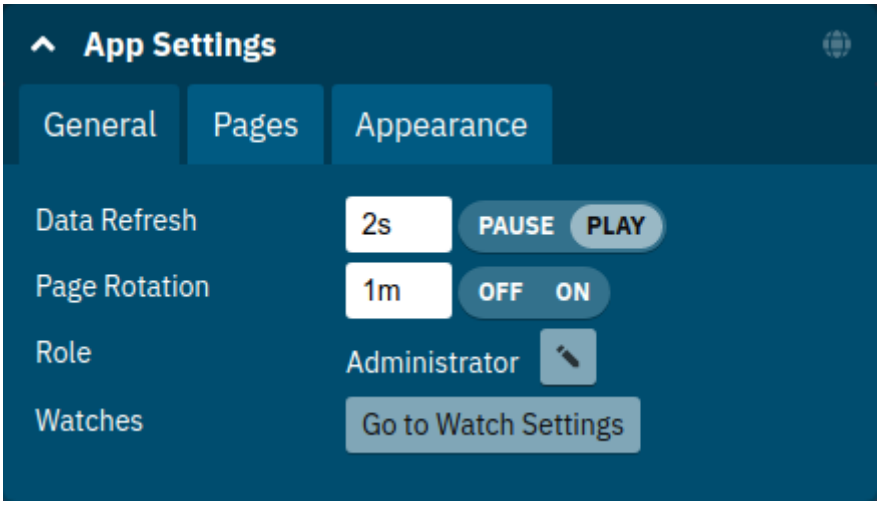
Importing a page will override the local page with the same ID (name). Any customisation made to the local page will be lost.

Changing User Role

When no role is set from previous sessions the user is asked to choose a role when opening the Payara InSight application.



The selection can be changed at any time in the *General* application settings for *Role*.



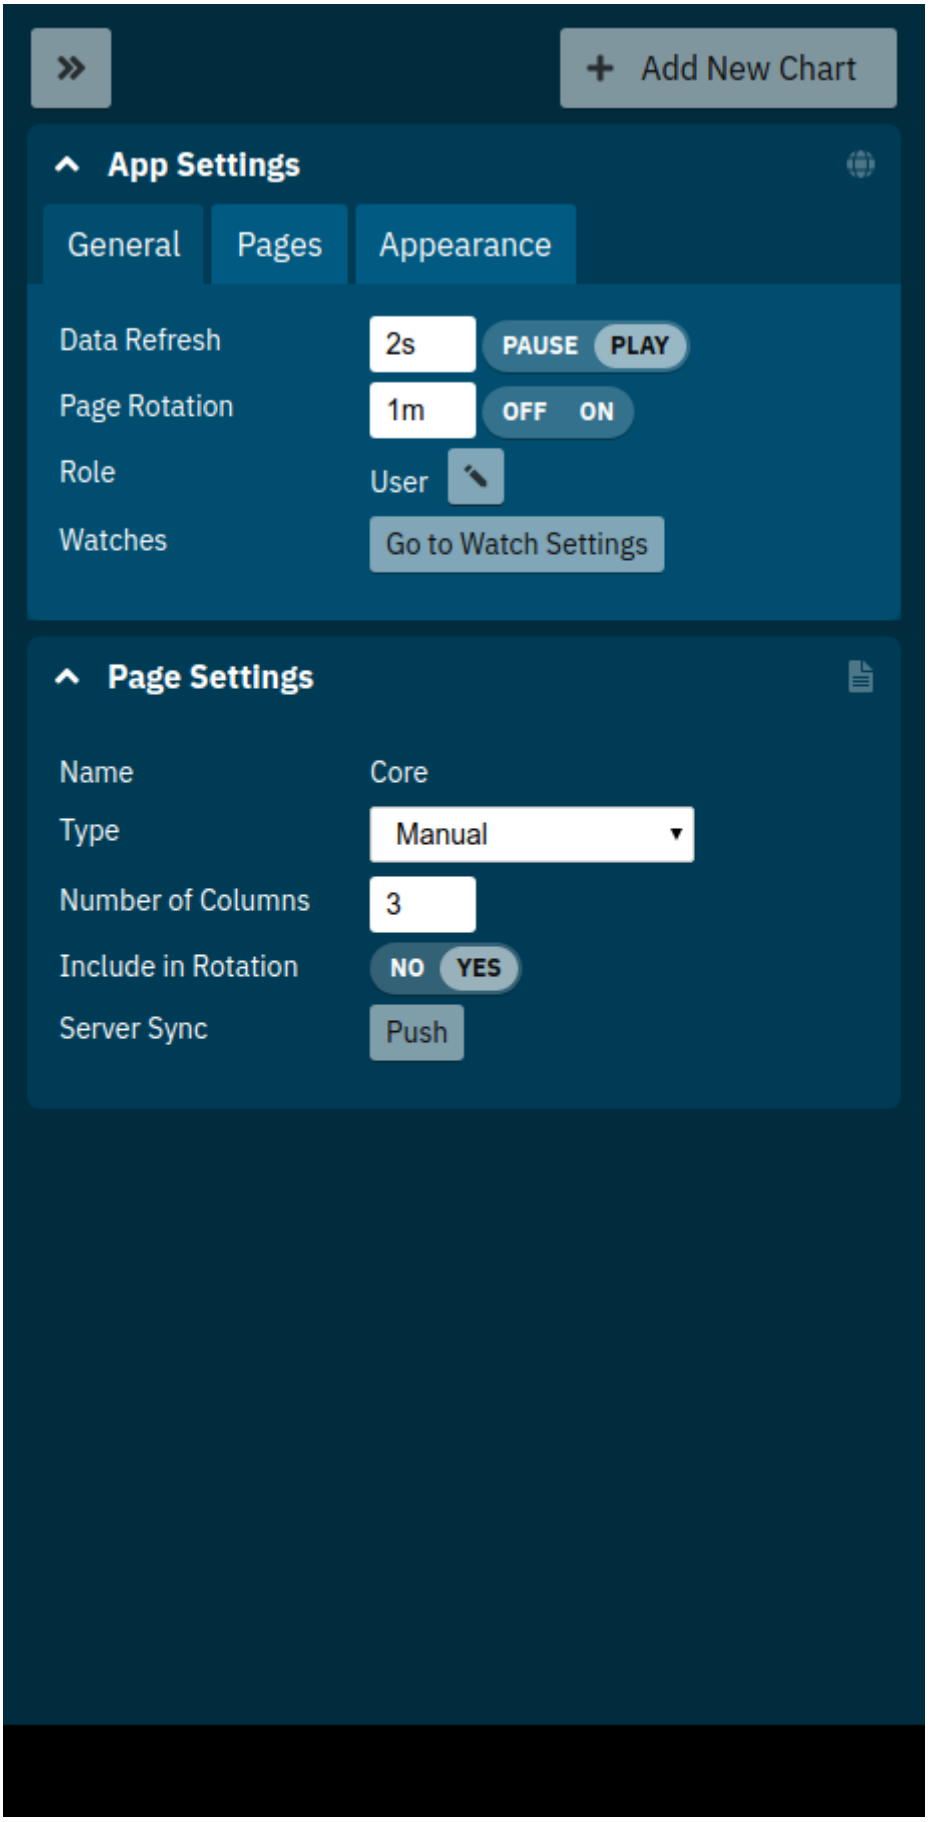
Roles are not connected to accounts or other forms of permission management. Users can switch between the roles to suit their current intentions when using Payara InSight.

Widgets

Widgets are the components that can be placed on a page to show a particular metric or a set of metrics. While there are different types of widgets usually a widget shows a line graph of one or more metrics for the entire cluster.

Adding a Widget

Widgets can be added to any page. Click the plus button in the minimized right side menu or the *Add New Chart* button when it is expanded:



Add New Chart
App Settings
General
Pages
Appearance
Data Refresh
2s
PAUSE
PLAY

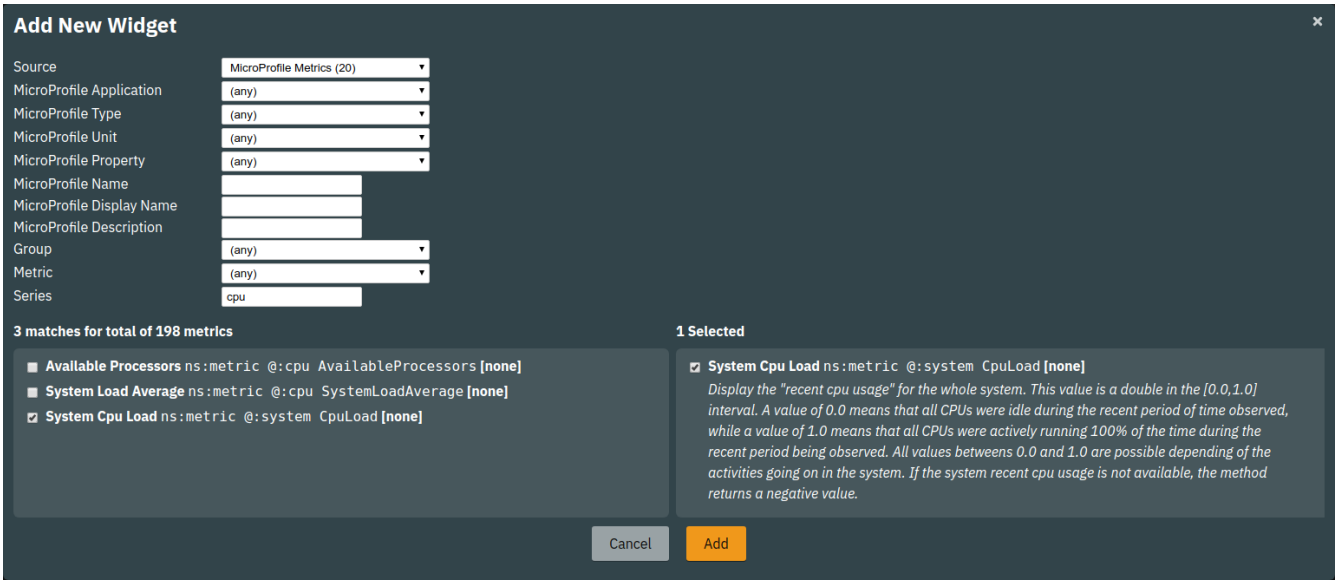
OFF
ON
Role
User
Watches
Go to Watch Settings
Page Settings
Name
Core
Type
Manual
Number of Columns
3
Include in Rotation
NO
YES
Server Sync
Push

This opens the *Add New Widget* dialogue.



Use any one of combination of the filter dropdowns to select a subset of metrics and/or enter a query text in any of the free text search input fields to further narrow down the results. All matching metrics will be shown in the list on the left.

Select one or more items. Selected metrics are shown in the list on the right. The search can be changed between selections.

Finally, confirm the selection by clicking the *Add* button of the dialogue.

Newly added widgets are automatically placed in a column so that widgets are evenly distributed on the page.

Use the side panel widget settings to change the column, width, height or item position of the widget or use the quick menu for the widget by clicking the pencil symbol in the top right corner of the widget.

Configuring Widgets

To configure a widget select it by clicking on its title or the pencil icon in the top right corner of the widget.

This opens the right settings side panel and shows the detailed configuration of the widget. The side panel can be closed by either deselecting the widget, by clicking on its title again, or by clicking the collapse icon of the right sidebar.

If the settings have been opened explicitly through the *Settings* menu an empty selection will not close the settings side panel.

The *General* widget settings are concerned with the widget's position within the page and its general appearance.

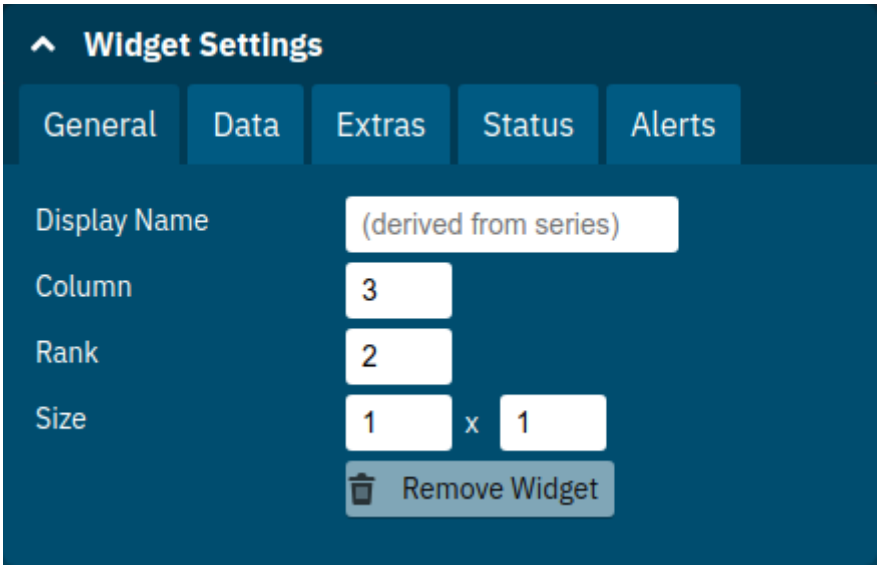


Table 165. Widget General Settings

Property	Default	Description
Display Name	`(undefined)`	Optional name to customise the displayed widget title. If no name is given the *Data* ⇒ *Series* is shown.
Column	1	The column in the layout the widget **prefers** to be in.
Rank	1	Within columns widgets are sorted by their item value, lowest values first. The item position is automatically updated during page layout should it be needed.
Size	1 / 1	How many width (number of columns) and height (number of rows) the widget should span. Note that this is a target size. If the number of columns is reduced the width might be reduced to match the page layout.

The *Data* settings are concerned with what and how the data is shown in the graph of a widget.

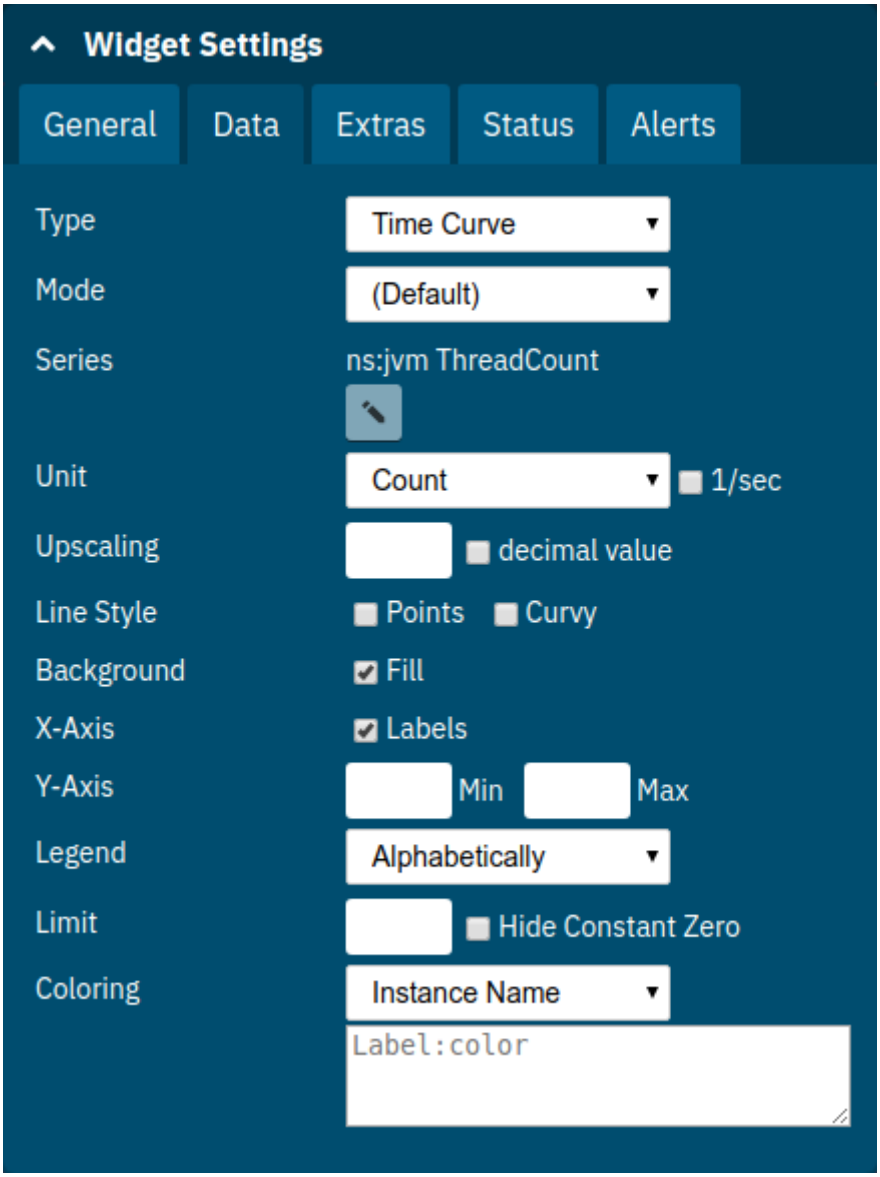

Table 166. Widget Data Settings

Property	Default	Description
Type	`Time Curve`	Changes the type of graph used to show the metric. This also affects which data of the metric a widget is focussed on. Possible choices: • `Time Curve`: a line chart of current values (usually last 60 seconds), • `Range Indicator`: show distributions of values (of last 60 seconds), • `Alerts`: shows a table of alerts, • `Annotations`: shows a table or list of annotations; these are key-value attributes associated with a metric series. • `RAG Status`: Shows UP/DOWN status generally used in connection with health checks • `Top N`: Shows just the numbers (legend), use with *Legend* ordering by value for top highest or lowest table
Mode	*(Default)*	If available for the type of widget the display mode can be switched between *Table* and *List*. Table view is best fitted for annotations that share common attributes, lists are better fitted for annotations with potentially differing attributes.
Series	-	The metric key as given when adding the metric, use pencil icon to edit
Unit	`Count`	The unit controls how the raw number of a metric is interpreted and represented e.g. when displaying in axis labels. The unit also controls what values are accepted as input for numbers, like thresholds, that are on the same axis. Possible units are: `Count`, `Milliseconds`, `Nanoseconds`, `Bytes`, `Percentage` and `Up/Down`.
Unit 1/sec	`false`	Whether to show the metric as a change per second (delta between two points in the series normalised to average delta per second).
Upscaling	`(undefined)`	When defined all values are multiplied by this factor. This can e.g. be used to move a decimal range between zero and one to a percentage range `0-100`.

Property	Default	Description
Upscaling *decimal value*	`false`	Check to mark the metric as one that is provided as a decimal value during collection (floats or doubles and alike). This will then revert the conversion applied during collection which converts decimal values to an integer number with 4 available decimal digits by multiplying them by `10,000`. This divides values by 10,000 again to move them back into their original value range.
Line Style	`(none checked)`	Options on how to display the current value line in the graph: Check *Points* to show individual data points on the line, check *Curvy* to use Bézier curves instead of straight line connections.
Background	*Fill*	When *Fill* is checked the area between line and axis is filled. The background transparency can be configured globally in the *Appearance* application settings.
X-Axis	*Labels*	Whether to show labels for the x-axis.
Y-Axis	`(undefined)`	Set a minimum or maximum number for the y-axis instead. When not set range is derived automatically from the data points.
Legend	*Alphabetical*	The order applied to the legend. Possible choices: `None`: Items are shown as send by the server, `Alphabetically`: Items are shown in alphabetical order (instance name first, series based label second), `Increasing Value`: Items are shown ordered from smallest to largest current value, `Decreasing Value`: Items are shown ordered from largest to smallest current value,
Limit	(undefined)	When set the maximum number of legend items shown (especially useful when ordering legend items)
Limit Hide Constant Zero	`false`	When set series that have been zero for a while are not shown in legend and line graph
Coloring	*Instance Name*	Used to select the colours the data is shown with. *Instance Name* will show data in the same colour that belongs to the same instance. *Series Name* shows the metric series in the same colour (independent of instance). This is individual to each widget. *Result Set Index* will show each matching series in a different colour. *Instance and Series Name* shows the same instance and series in the same colour. This is global. This means another widget using this colouring with the same instance and series will have the same colour as well.

Property	Default	Description
Coloring Mapping	(undefined)	A space separated mapping of series group values to a named colour value as defined by the application appearance *Defaults* settings. For example to color a series shown with label *AmberAck* in amber color the entry is `AmberAck:amber` (`amber` here refers to the default name used for *Degraded* (internal name)).

Configuring Widget Extras

The *Extras* settings are concerned with additional information shown in or around the graph or widget content in general.

This includes visual helpers that can be added to a graph of a widget in order to make it easier to for the user to quickly understand the data displayed.

In particular these are reference lines and threshold indications.

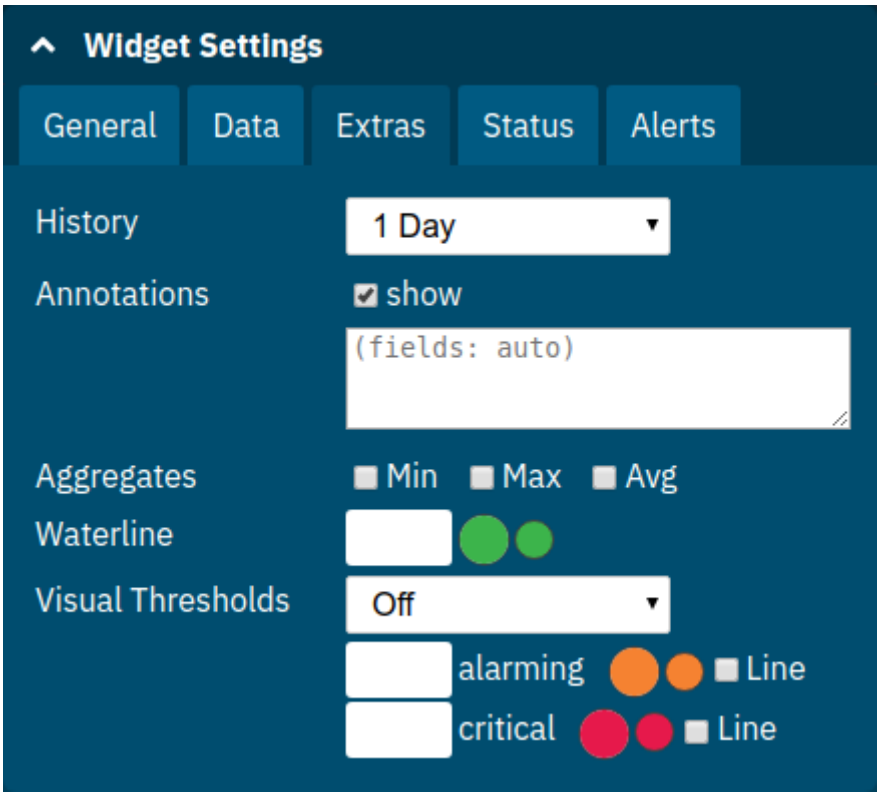

Table 167. Widget Extras Settings

Property	Default	Description
History	*None*	What period of additional aggregated data to show in the graph: • *None* shows just the recent minute ("real-time") • *1 Hour* adds 1 point per minute in the recent hour (the most recent minute continues to show 1 point per second) • *1 Day* adds 1 point per hour in the recent day (the recent hour continues to show 1 point per minute, the recent minute 1 per second) • *1 Month* adds 1 point per day in the recent 31 days (again recent day continues 1 point per hour, recent hour per minute and recent minute per second). This data is only available after enabling the history aggregation using the asadmin command.
Annotations	(checked)	Whether to show annotations for in an alert table.
Annotations (Fields)	*(blank)*	A comma or space separated list of fields to show for an annotation list or table. The given field order is reflected in the view.
Aggregates	(none checked)	Check to add the all time minimum, maximum or average line to the graph
Waterline	(undefined)	Adds a simple reference line that could mark an upper or lower limit. Enter in unit of y-axis, e.g. 20ms, 5s, 2GB, 4%, 123
Threshold Reference	`Off`	Controls what value the *Alarming Threshold* and *Critical Threshold* are compared to. Usually this is the most recent value but in some cases the all time minimum, maximum or average are useful too.
Alarming Threshold	(undefined)	The limit for the *"Alarming"* state. If *Critical Threshold* is undefined or if its value is larger than this value the alarming threshold is exceeded if the reference value is larger than the threshold. Otherwise, if the *Critical Threshold* is lower than the *Alarming Threshold*, the threshold becomes 'inverse', and is exceeded when the reference value falls below the alarming value. When exceeded the status becomes *"Alarming"*. Enter in unit of y-axis, e.g. `20ms, 5s, 2GB, 4%, 123`

Property	Default	Description
Critical Threshold	(undefined)	The limit of the *"Critical"* state. If *Alarming Threshold* is undefined or its value is smaller than this value the critical threshold is exceeded if the reference value is larger than the threshold. Otherwise, if the *Critical Threshold* is lower than the *Alarming Threshold*, the threshold becomes 'inverse', and is exceeded when the reference value falls below the critical value. When exceeded the status becomes *"Critical"*, overrides status *"Alarming"*. Enter in unit of y-axis, e.g. `20ms, 5s, 2GB, 4%, 123`

Besides adding a reference line to the graph the critical and alarming thresholds affect the status evaluation.

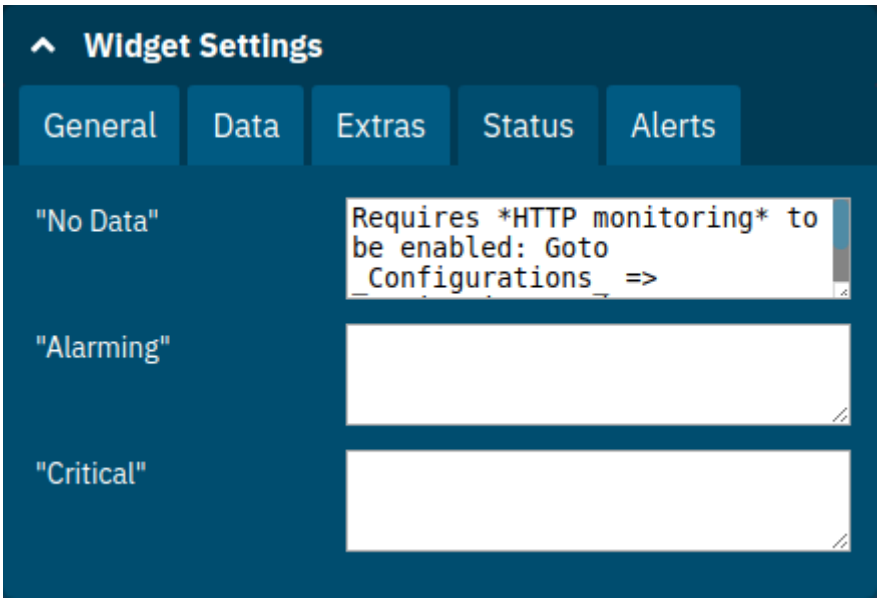
Use the colour input to individually override the widget's colour for waterline, alarming line or critical line in graphs.

Press the button right next to it which shows the default colour as configured in the *Appearance* application settings to reset the individual colour to use the default setting instead. A colour set to the default changes with the default.

Configuring Widget Status Messages

The current value of a metric can automatically be categorised as a certain status.

For example based on the threshold values of decorations or by encountered errors or missing data. The *Status* settings allows to set a custom message for a particular status.



Property	Default	Description
`No Data`	`(undefined)`	The message to show when no data for a metric is available. For example to hint about configurations needed to make the metric available.
`Alarming`	`(undefined)`	The message to show when the threshold got exceeded and the status evaluates to *Alarming*.
`Critical`	`(undefined)`	The message to show when the threshold got exceeded and the status evaluates to *Critical*.

The messages support simple markup using `*bold*` and `_italic_`.

Configuring Widget Alerts

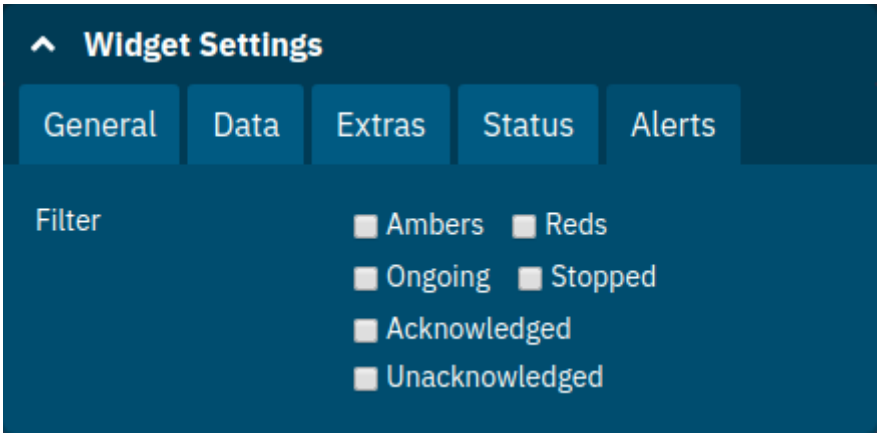
The values of metric series can be tracked by the server to report values that out of a healthy range.

This is represented by states:

- *Red*: values in this range indicate an unhealthy state
- *Amber*: values in this range indicate a degraded state
- *Green*: values in this range indicate a healthy state
- *White*: values in this range are in no particular state (neither good nor bad, maybe undecidable)

State changes to amber or red are reported as alerts. This is shown in the widget they affect.

The settings allow filtering these related alerts to prevent them from showing. This makes sense on pages that have dedicated widgets to show alerts or just if users prefer to see the graph instead.



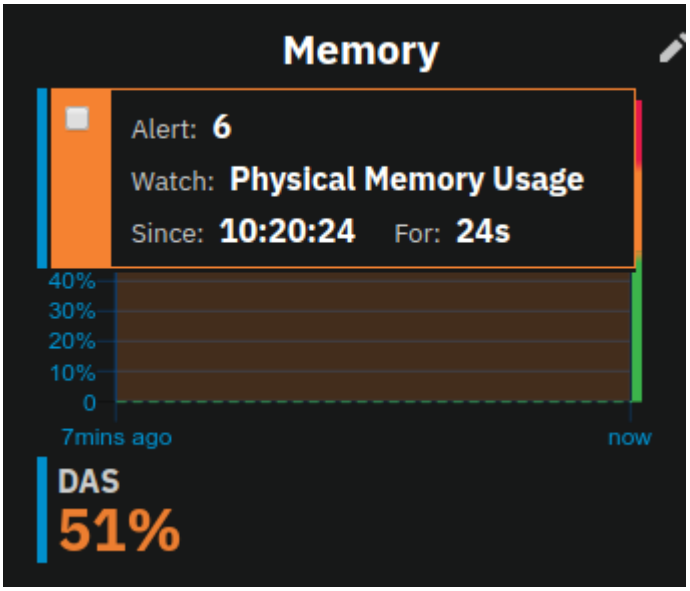
Property	Default	Description
Filter	(none checked)	Do not show (when checked) *Amber* and/or *Red* alerts, *Ongoing* and/or *Stopped* alerts, *Acknowledged* and/or *Unacknowledged* alerts. If for any of these 3 groups of pairs both are checked no alerts would be shown. Widgets of type *Time Curve* automatically exclude stopped and acknowledged alerts to avoid cluttering the graph with alerts that aren't relevant anymore. Use a widget of type *Alerts Table* to show all alerts according to the filter at all times.

Handling Alerts

Alerts can occur when a watch is configured for a metric series.

A watch describes the conditions and thresholds used to determine a state from the recent values of a metric series. It is either *Red* (unhealthy), *Amber* (degraded), *Green* (healthy) or *White* (undetermined).

A *Red* or *Amber* state causes an alert that is shown on top of the graph.

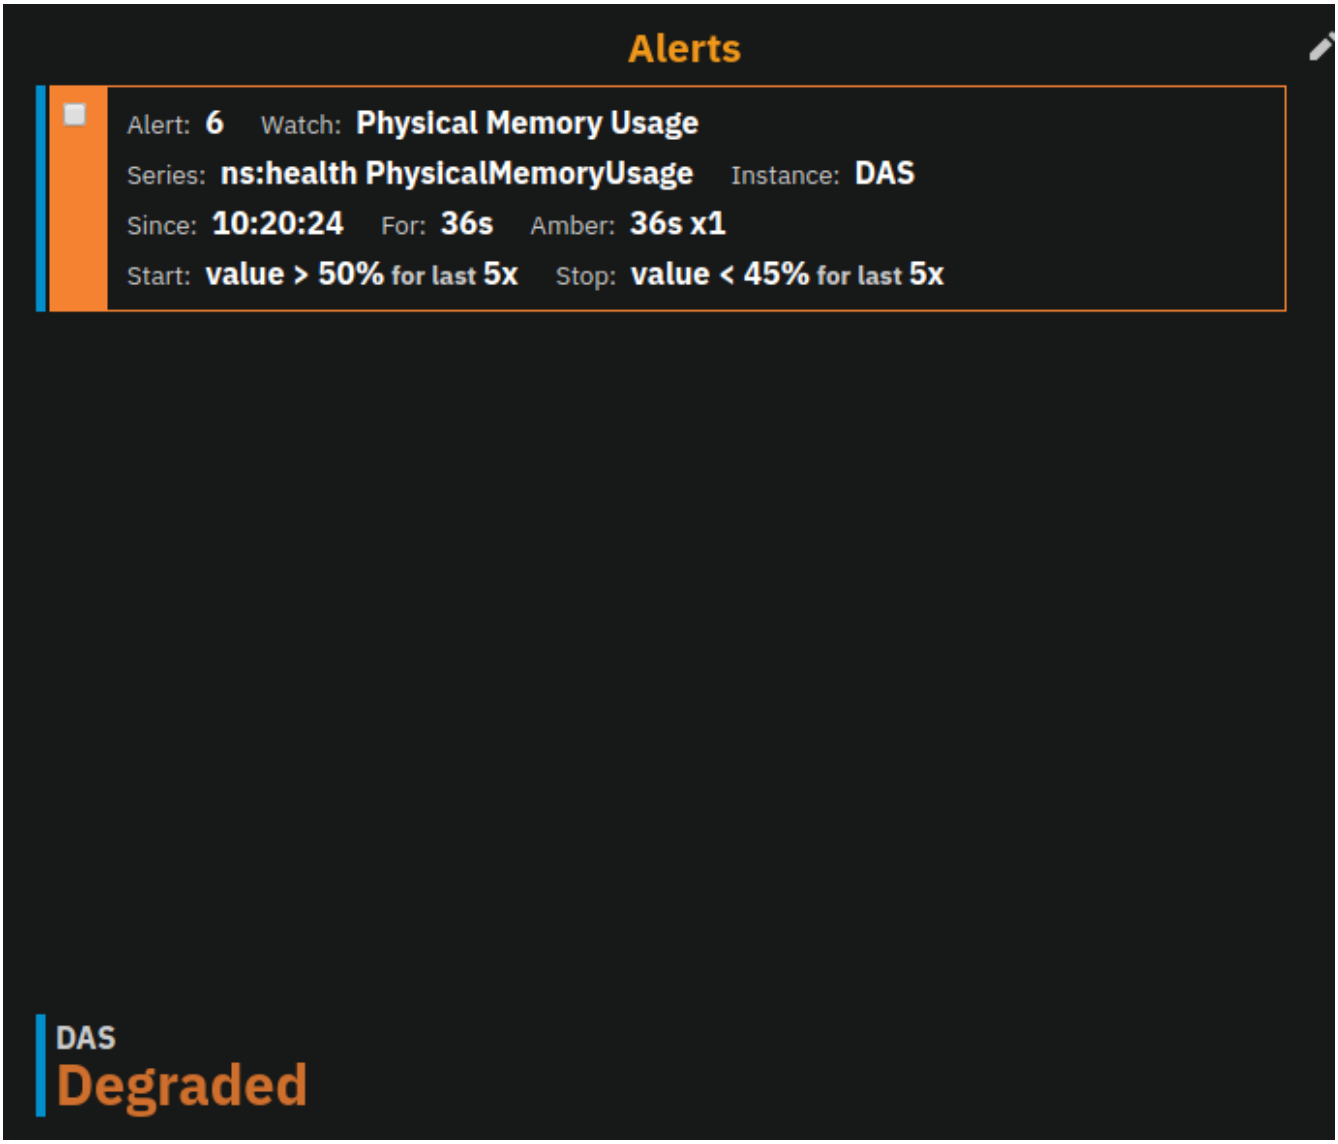


When an alert occurred for a metric shown in a graph the background of the line causing the alert is coloured in *Red* or *Amber* default colour until the alert is stopped.

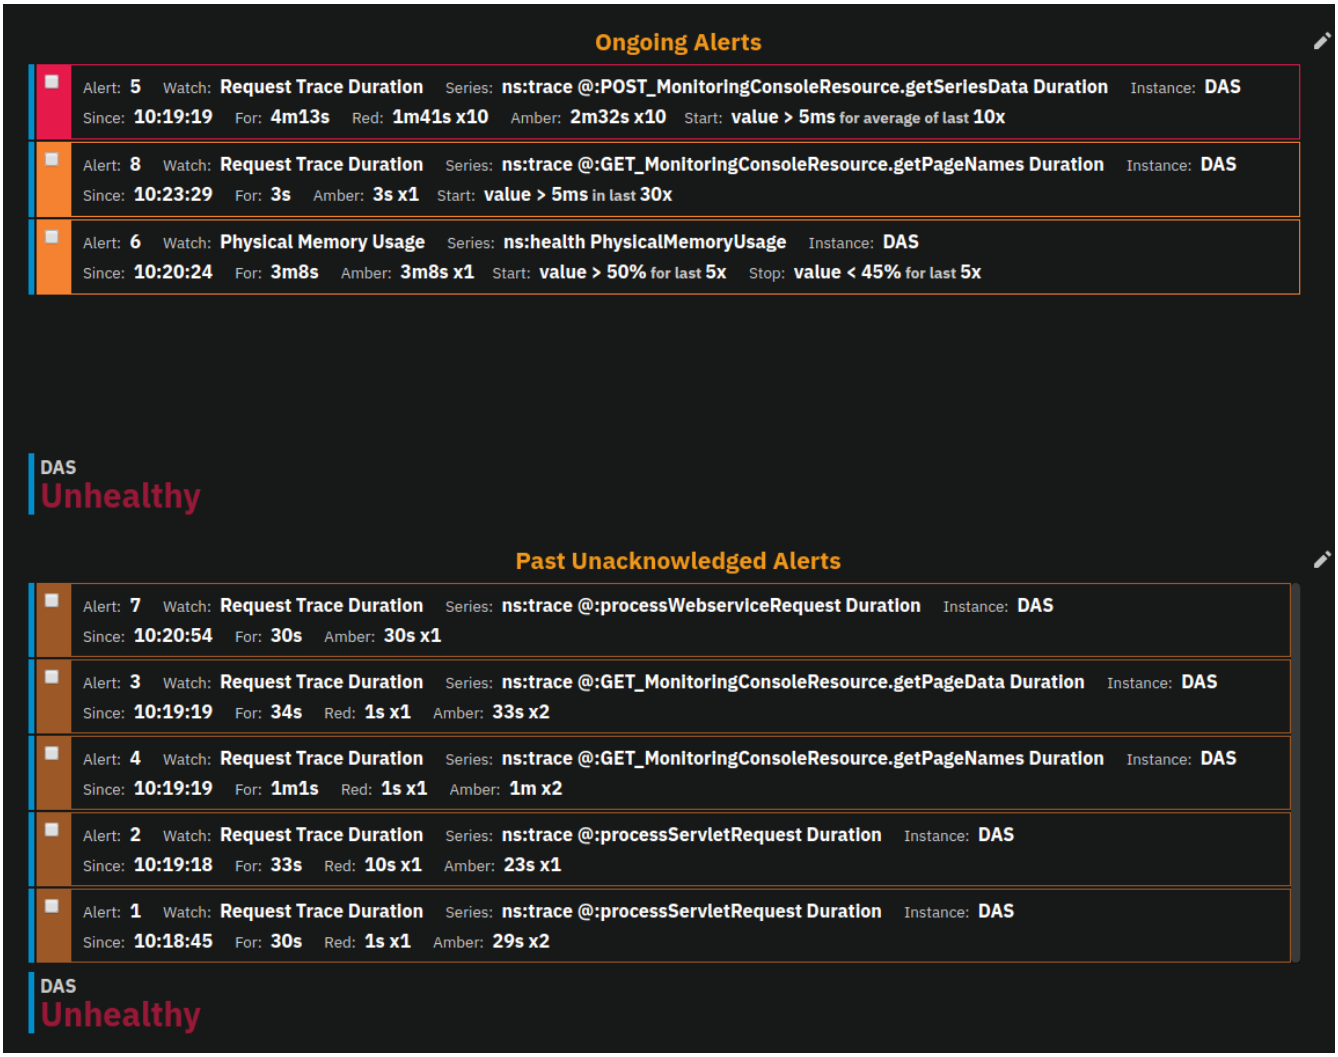
Alerts are considered ongoing as long as the state is *Red* or *Amber*. If it is evaluated to *Green* or *White* ("unspecified") the alert stops. Stopped or acknowledged alerts are no longer shown on top of line graphs.

Other ways to hide an alert from a line graph is to acknowledge the alert by checking its checkbox or to configure the widget's *Alerts Filter* setting so that alerts generally aren't shown for that widget.

To see stopped or acknowledged alerts add a widget of type *Alert Table*.



Alerts
Alert: 6 Watch: Physical Memory Usage
Series: ns:health PhysicalMemoryUsage Instance: DAS
Since: 10:20:24 For: 36s Amber: 36s x1
Start: value > 50% for last 5x Stop: value < 45% for last 5x
DAS
Degraded



By default, an alert table shows all alerts including stopped and acknowledged alerts. Use the widget *Alerts* settings to exclude alerts with certain properties.

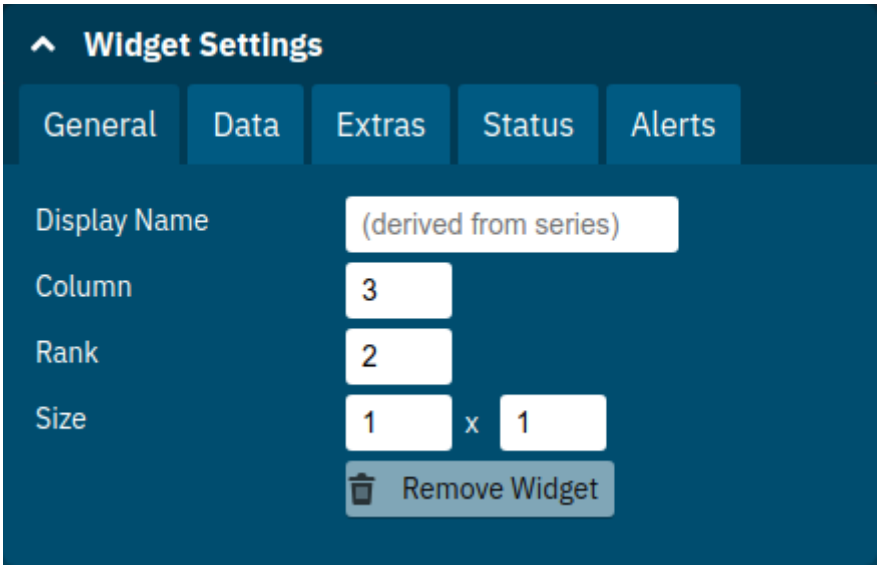
An alert table shows the overall state of each instance in the table's legend.

As mentioned before the *Alerts* settings can equally be used for line graphs to create a more restrictive setting.

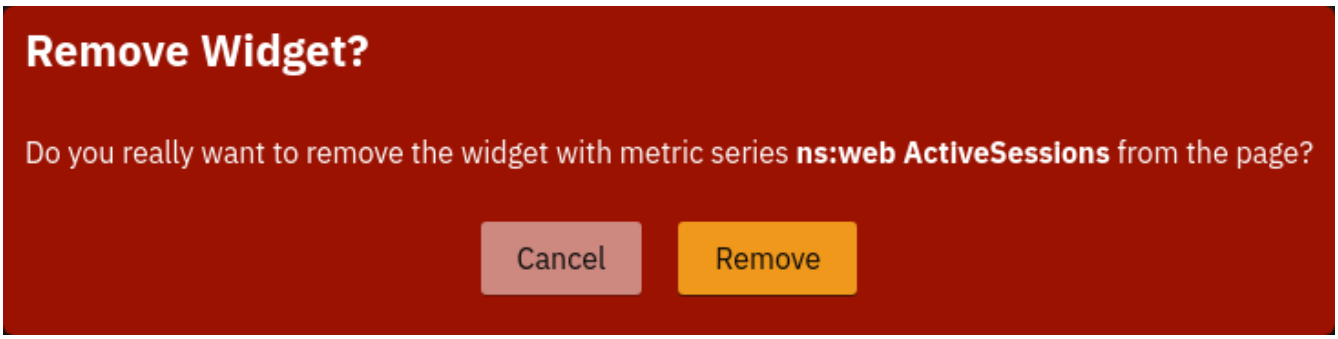
Removing a Widget

Any widget can be removed from any page. Click the pencil symbol in the top right of the widget or its title to open the widget's settings.

On the *General* widget settings tab you find the *Remove* button.



Confirm you want to remove the widget.



Remember that a page originating from a preset can be reset to recover a widget that was removed accidentally.

Common Page Settings

Most of the page settings have already been described in context of the different page related user actions. The following tables are included for reference.

The common page settings are those used by pages of *Type Manual* and *Query*.

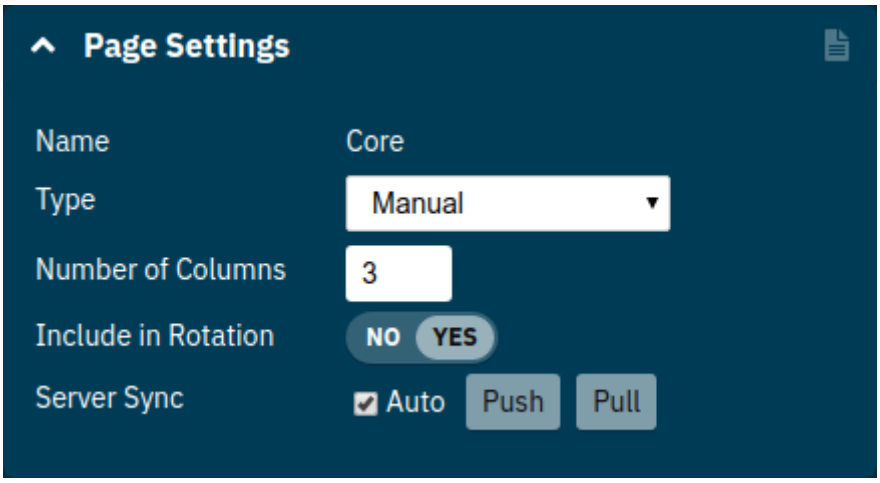


Table 168. Common Page Settings

Property	Default	Description
Name	-	The name as given by the user when the page was created or as defined in the page preset, only user-created pages can be renamed
Type	`Manual`	• `Manual`: user populates pages with widget using add widget • `Query`: a query is used to populate page in intervals
Number Of Columns	1	The number of columns available to place widgets in
Include In Rotation	Yes	• Yes: Page is included in the set of pages rotated during page rotation • No: page is excluded from this set
Fill Empty Cells	No	• Yes: empty cells in widget grid are filled by extending the span of the widget above • No: empty cells left empty shown with a button to add a widget
Server Sync	(checked)	`Auto`: Changes made by an administrator to the page or the widgets of this page are automatically pushed to the shared configuration if and only if the page has been explicitly pushed to the shared configuration at some point in the past.

Pages of *Type: Query* have more settings to configure the contents of the page.

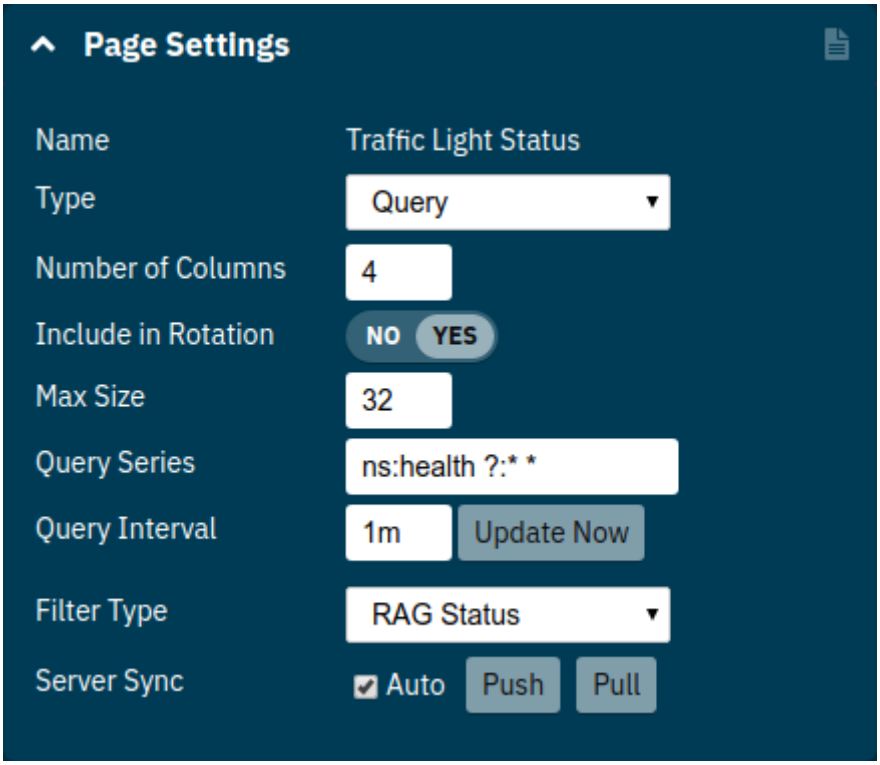

Table 169. Query Page Settings

Property	Default	Description
Max Size	32	Maximum number of widgets added to the page when populating it from query matches (even if there are more metrics matching the query)
Query Series	-	A series pattern used to query for metrics, matches are used to populate the page
Query Interval	1m	The interval in which the query is run and the page is repopulated with matches
Filter Type	-	When selecting a type only metrics inferred to prefer that type are shown on the page

See Application Metrics page for an example of a query page.

Global Configurations

The configuration that controls global properties of the Payara InSight user interface. It is stored in the browser's local storage and thereby individual for each user.

These settings cannot be shared.

General Application Settings

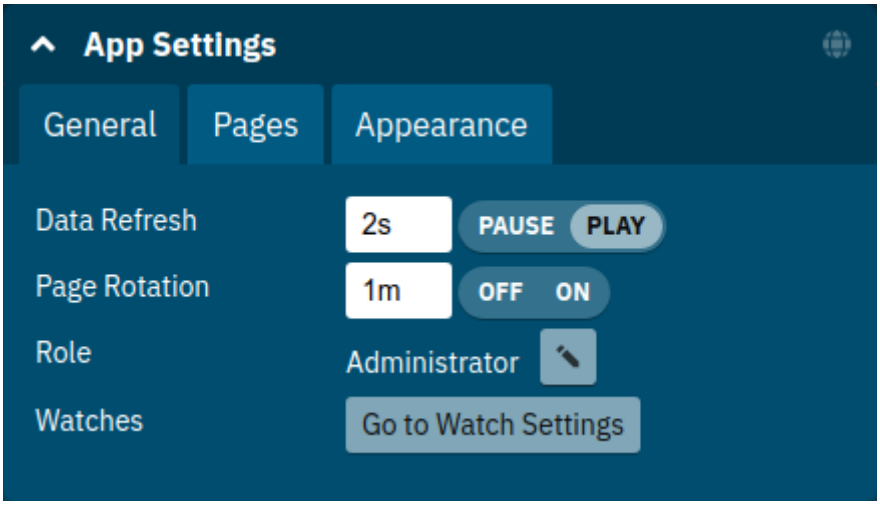

Table 170. Application General Settings

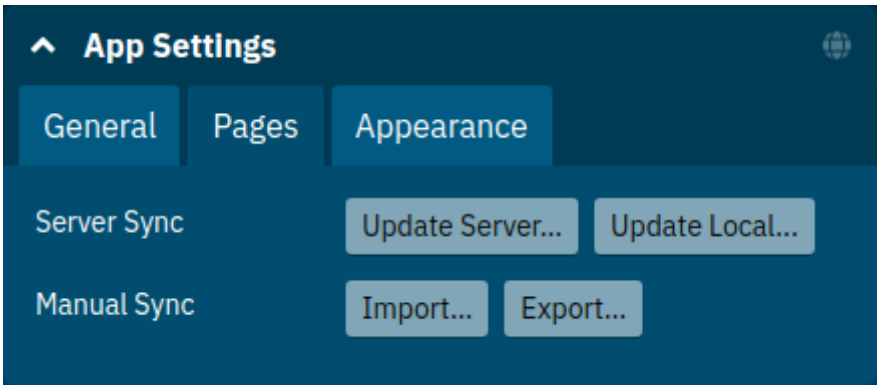
Property	Default	Description
Data Refresh	2s	Interval duration used to update the currently shown page with new data (poll duration). To pause data update toggle the *play/pause* toggle switch.
Page Rotation	1m	Duration each page is shown during a page rotation. To run or stop the rotation toggle the *on/off* toggle switch. See section Page Rotation for details.
Role	*User*	Select the used user role. See section Changing User Role for details.

Property	Default	Description
Watches	-	Click the *Go to Watch Settings* button to open the Watch Management

Pages Settings

The *Pages* application settings give access to different page management operations as described in detain in section Page Management



Alerts Settings

The *Alerts* application settings contain general alert configuration that applies globally (to any page).

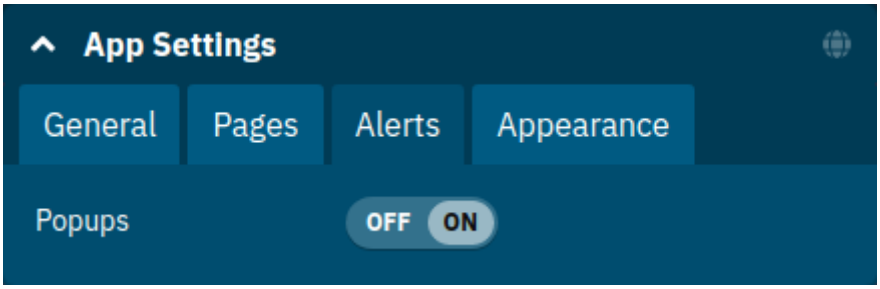


Table 171. Alerts Settings

Property	Default	Description
Popups	*On*	When *On* any alert status change is shown in form of a pop-up dialogue regardless of the currently viewed page. With this feature no alarms will be missed.

Appearance Settings

Payara InSight allows you to configure the colours used in graphs. There is a global colour configuration affecting all graphs.

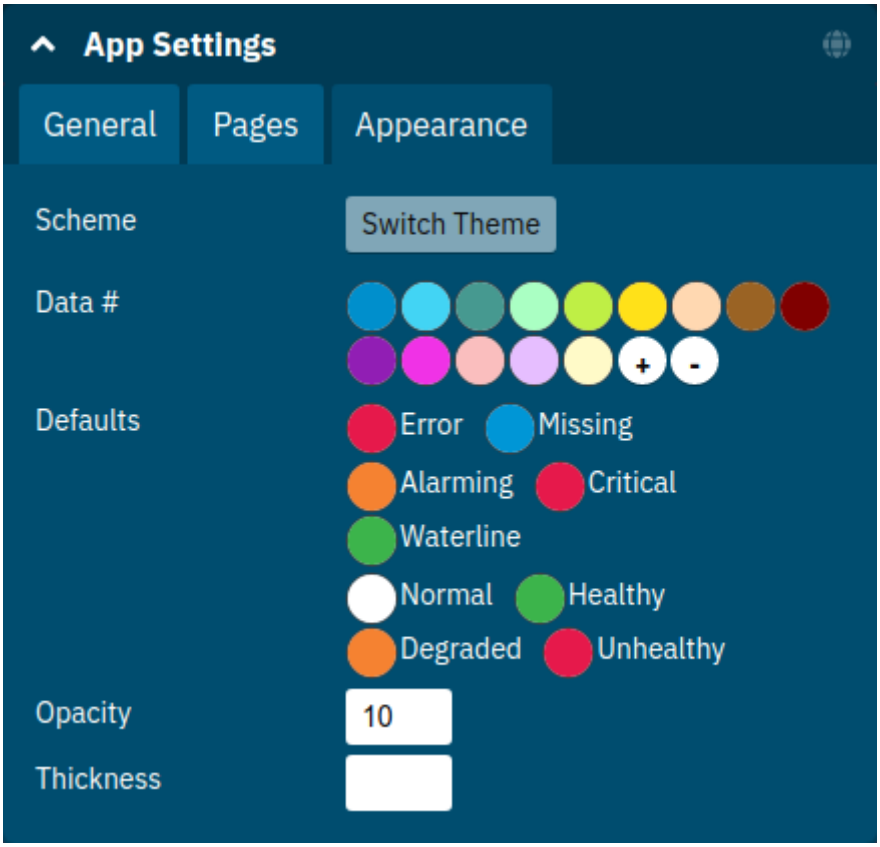

Table 172. Appearance Settings

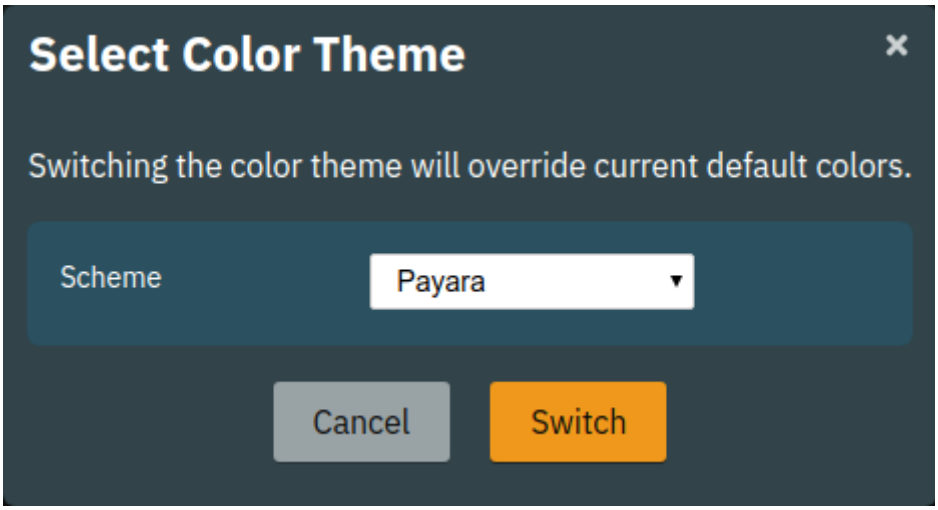
Property	Default	Description
Scheme	(Payara Branding)	The selected scheme is applied to set the colour palette for *Data* as well as *Defaults* and *Opacity*. This is only a convenient way to switch all of these between different settings. The individual properties can be changed afterward as usual without affecting the scheme.

Property	Default	Description
Data # (Palette)	(colours of *Payara Branding* scheme)	The list of colours to use when colouring data series in graphs. This is the line colour in line charts or the bar colour in bar charts. Background will use the same colour with *Opacity*. Add new colours by using the + button. The - button removes the last colour of the list. If there are fewer colours in this palette than needed for different lines in a graph new colours are derived based on this palette. The derived colours focus on bright colours with high contrast but might not always fit well with the rest of the palette. In such case consider adding more colours to the palette.
Defaults	(default of *Payara* scheme)	Sets the default colours for *Waterline*, *Alarming* and *Critical* as well as *Red*, *Amber*, *Green* and *White* state lines, backgrounds and texts. Some of these can be individually overridden in the widget's configuration for these lines.
Opacity	10	Background opacity for lines or bars in graphs, 0 (fully transparent) to 100 (solid).
Thickness	(3)	Line width on a scale 1-8. Each point corresponds to 0.5px with. Default for lines in a line graph is 3, so 1.5px.

Themes act as a (p)reset of the data colour palette, default colours and *Opacity* setting. When switching theme these settings are reset to the theme's value:



Any further customisation of individual colours can and should be done after applying the theme of choice as switching theme would reset such customisations again.

Alerts Management

The values of series can be monitored using watches. If values fulfil all aspects of a start condition of a watch an alert is created.

While alerts transition between the states *Unhealthy*, *Degraded*, *Healthy* and possibly *Normal* based on the watch definition they originated from there are two manual status fields available for each alert:

Global

Acknowledged/*Unacknowledged*: When an alert transitions to a more severe state it resets to *Unacknowledged* waiting for users to manually acknowledge that they took notice (and care) of the degrading state transition.

User

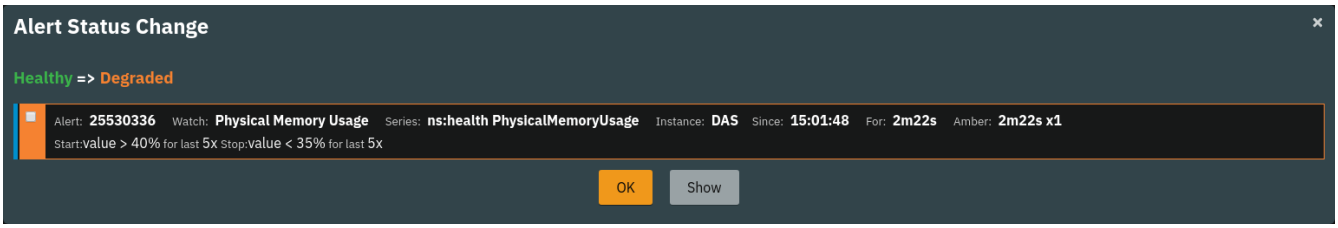
Confirmed/*Unconfirmed*: Alerts are unconfirmed for a user if that user has not seen and confirmed the alert transition yet.

Both of these manual states should help users to keep track of alert transitions and the alerts they have dealt with.

Acknowledge Alerts

Alerts are manually acknowledged by system operators when they have checked and reacted to the alert and consider it done. It is a form of alert management tool that is shared by all users.

To acknowledge alerts click the checkbox on left of an alert row.

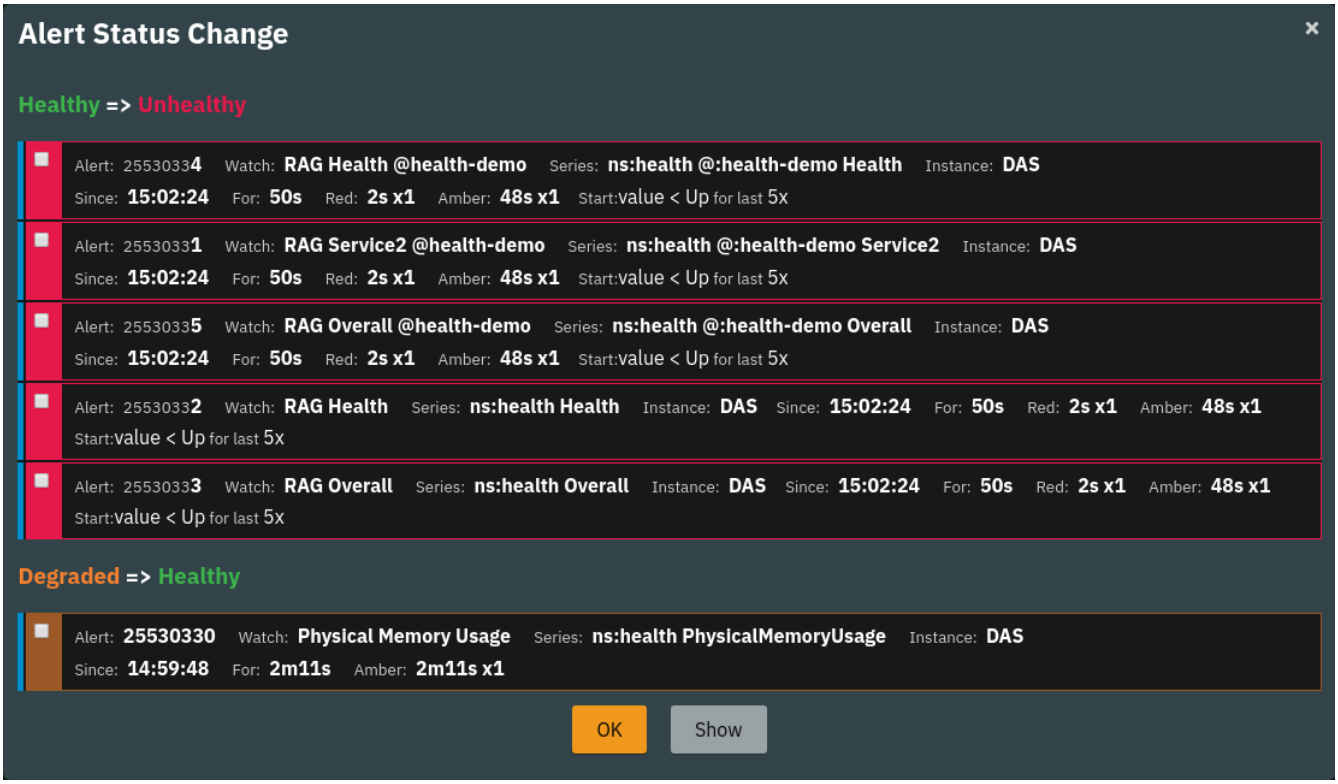


An alert can be acknowledged:

- When shown as part of the *Alert Status Change* pop-up dialogue
- When shown on top of a line graph widget
- When shown as part of an alert table widget

Confirming Alerts

When the state of alerts changed compared to the last state that has been confirmed by a user the change is indicated by the *Alert Status Change* pop-up dialogue. It shows all transitions that took place since the user last confirmed alert status changes.



When a user confirmed the change by either pressing *OK* or *Show* the shown transitions are considered as confirmed and are no longer shown.

The confirmation status is individual for the user (browser local state) so each user has its own confirmed state and based on his/her last confirmation will get different updates.

The confirmation pop-ups can be disabled in the Application Alerts Popups setting. When disabled transitions are implicitly confirmed until the setting is enabled again. This is a more modest setting where alerts are only indicated globally by the alert indicator in the footer.

Alert Status Indicator

All alerts are indicated in the bottom right corner of the footer so that users do not miss alerts that would otherwise not show on the current page.

The indicator gives a summary of the ongoing alerts:

- In Red: # of Unacknowledged *Unhealthy* state alerts (# of acknowledged *Unhealthy* state alerts)
- In Amber: # of Unacknowledged *Degraded* state alerts (# of acknowledged *Degraded* state alerts)

Click on the indicator to jump to the alerts overview page.

Watch Management

A watch describes the conditions to meet to start and stop alerts in relation to a specific metric. For example to get an alert every time an HTTP request causes a server error (responds with any of the 5xx status codes) a custom watch is installed.

This is very similar to a custom health check that could be linked to any metric available where the thresholds are defined as part of the watch. There are many varieties of conditions that can be formulated. Each watch has a start condition which when met starts a new alert.

Optionally a stop condition can be given which when met will stop the alert. If no such stop condition is given an alert stops as soon as its start condition is no longer met.

Such pairs of start and stop conditions can be defined for 3 levels:

Unhealthy
: corresponds to a "red" alert

Degraded
: corresponds to an "amber" alert

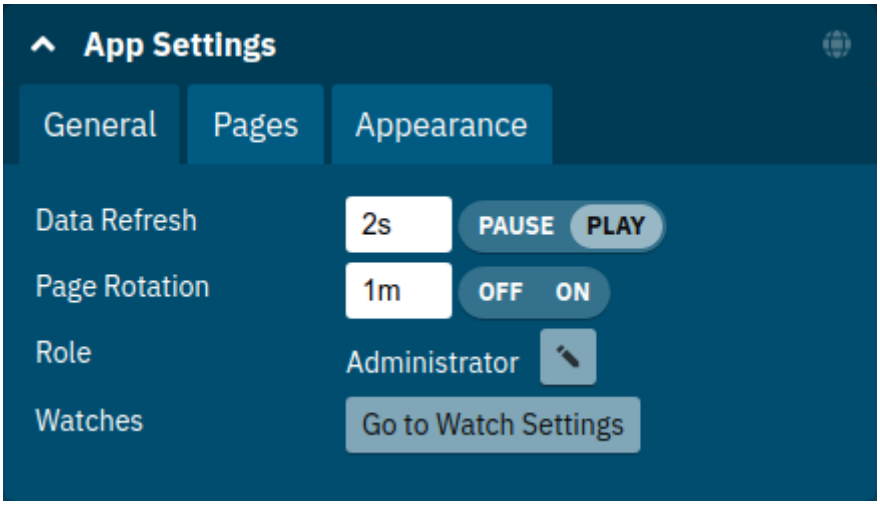
Healthy
: conditions for particularly good values, these will not cause alerts but can be used to mark a *healthy* range in graphs.

Each watch must have at least an *Unhealthy* or a *Degraded* condition. When both are given alerts can transition between *Degraded* and *Unhealthy* as the same issue or alert.

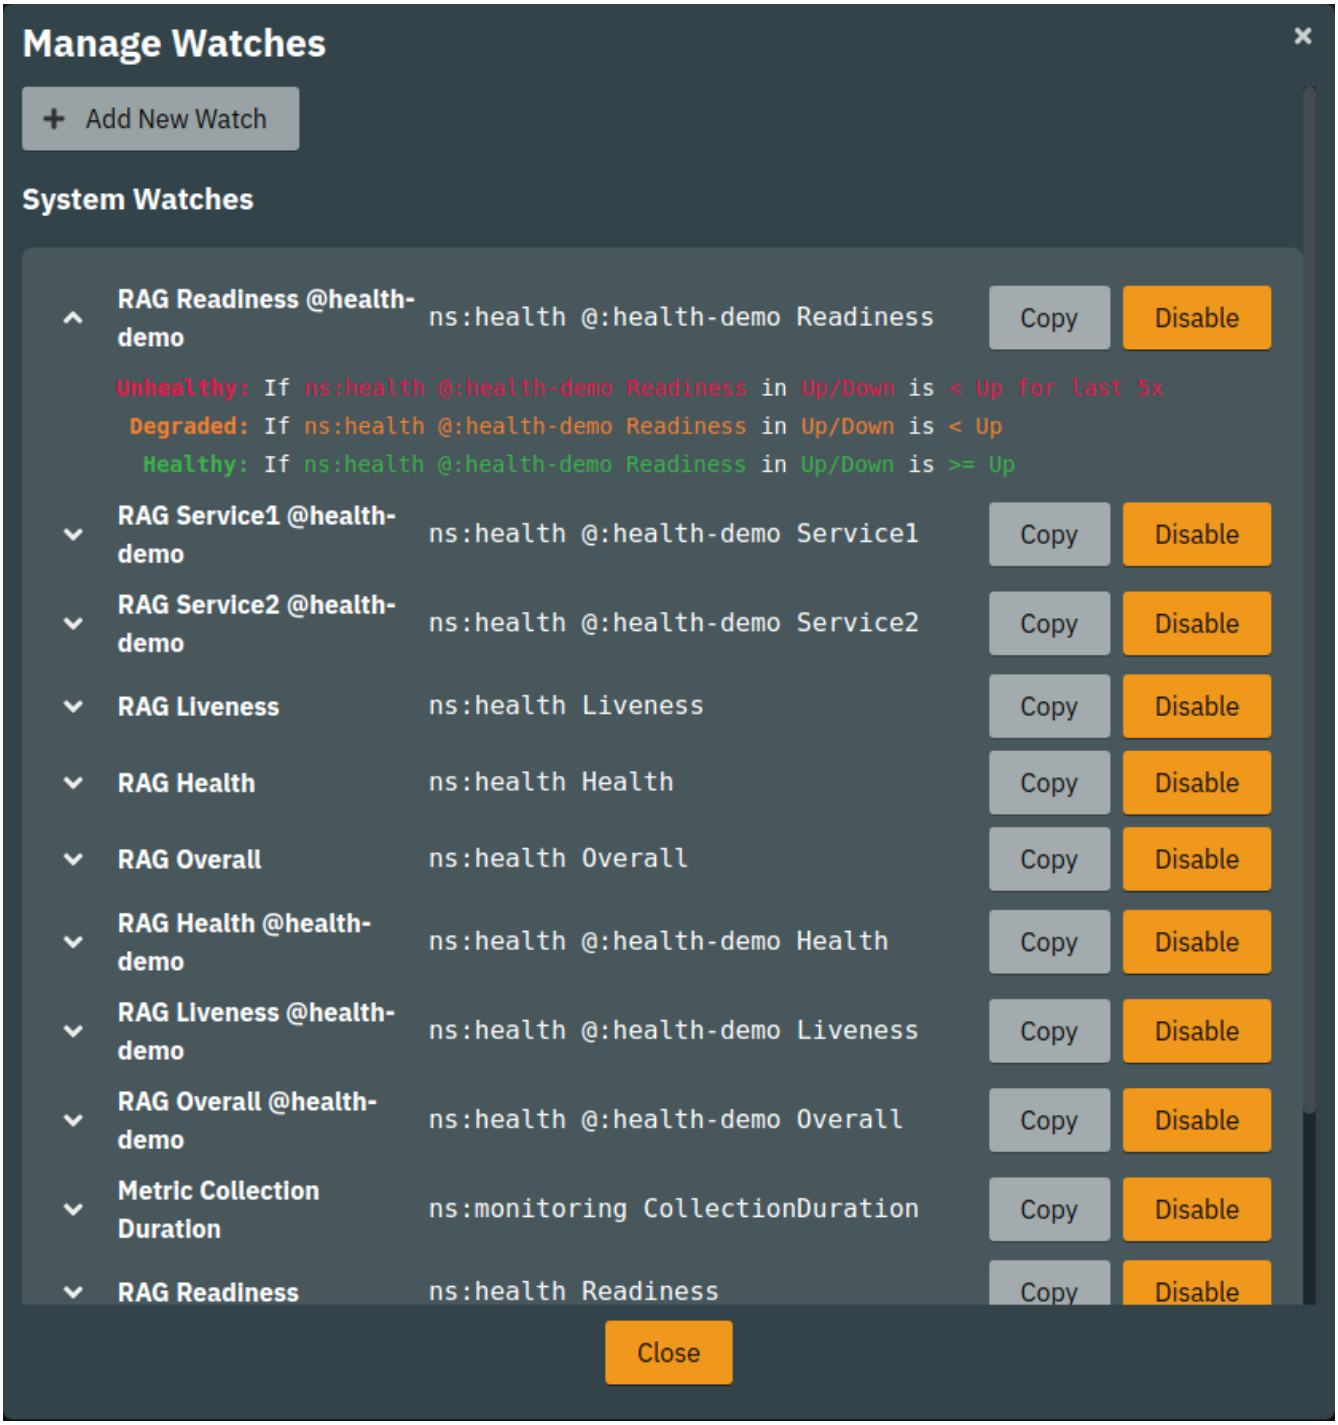
Unhealthy takes precedence over *Degraded* and *Healthy*, *Degraded* takes precedence over *Healthy* should their condition be met at the same time.

Should a *Degraded* alert be acknowledged, but it transitions to *Unhealthy* afterward the acknowledgement is reset so this change is not missed.

To open the watch management click the *Go to Watch Settings* button in the *General* application settings:



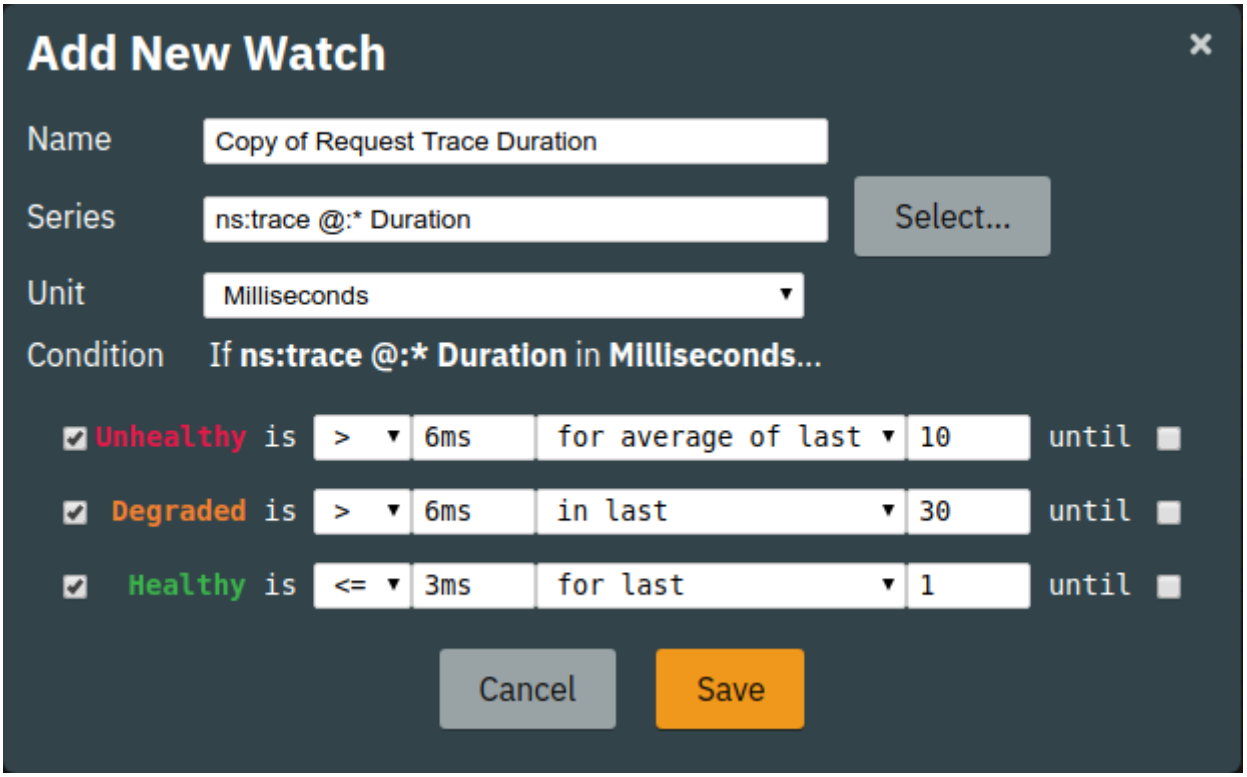
Generally the appearance of the watch management and the available options are dependent on the user role. Full access in given to *Administrators*. *Users* are restricted to viewing and creating new user watches. *Guests* can only view the settings.



The list shows *System Watches* and *User Watches* (below if any exists). To expand and see a watches' conditions click on the down arrow or its name to toggle the details.

Creating a Watch

Open the watch management as described above and click the *Add New Watch* button at the top.



The above example shows a relatively simple watch first copied from an existing watch which then is customised. The name of the watch can be anything as long as it is unique.

Each watch should have either an *Unhealthy* and/or a *Degraded* level. It is also recommended to add a *Healthy* level. Any value that is not matching any of the levels is *White* (unspecified).

After giving your watch a unique name select the metric that should be watched. Only single metrics are supported.

Select the appropriate unit for the selected metric. Depending on the chosen unit thresholds can be given in values of this unit, e.g. when selecting *Milliseconds* the threshold can be given as `1s` for 1 second.

There is limited knowledge what the raw number of the metrics means as not all sources do include this information.

When the name, watched metric and unit attributes are set, check any of the states a condition should be formulated for and enter the comparison operator, the threshold and the scope.

The below table describes possible choices for each step of a watch condition.

Table 173. Watch Condition Segments

Segment	Type	Description
`is` *operator*	Start	Select the comparison operator to use when comparing the actual value(s) to the threshold. The comparison is of form *actual operator threshold*.

Segment	Type	Description
`is` *threshold*	Start	The numeric threshold. The upper/lower limit. With the right unit selected the number can be given with a unit such as `5min` for time units, or `4KB` for bytes.
`is` *scope*	Start	Select a scope for the actual values that are compared to the threshold. The semantics of different scopes are described in a separate table below.
`is` *scope-length*	Start	The length defines how many of the most recent data points of the watched metric are included in the scope of the comparison. A number with time unit refers to the number of the points, a number with time unit to the duration of points to consider for the scope.
`until` *operator*	Stop	same as for `start`
`until` *scope*	Stop	same as for `start`
`until` *scope-length*	Stop	same as for `start`

The below table describes the semantics of the different types of comparison scopes.

Table 174. Watch Condition Scopes

Scope	Description
`for last`	The comparison must be true for each point in the scope for the condition to be met. Similar to an *all* logic. The number of points included is specified afterward. This is either a bare number referring number of points to include or a number with a time unit referring to a duration where all points within the duration from most recent point backwards are included in the scope.
`for average of last`	The comparison must be true for the single average value of all points in the scope for the condition to be met. The number of points included is specified afterward as number of duration from which to consider points.
`in last`	The comparison must be true for at least one of the points included in the scope for the condition to be met. Similar to an *any* logic. The number of points included is specified afterward as number of duration from which to consider points.

Scope	Description
`in sample`	The comparison must be true for at least one of the points available for the condition to be met. For this scope type no length is given as all available points are considered. This can vary but usually consists of the last minute of data.

After composing the watch conditions press *Save* to install the watch.

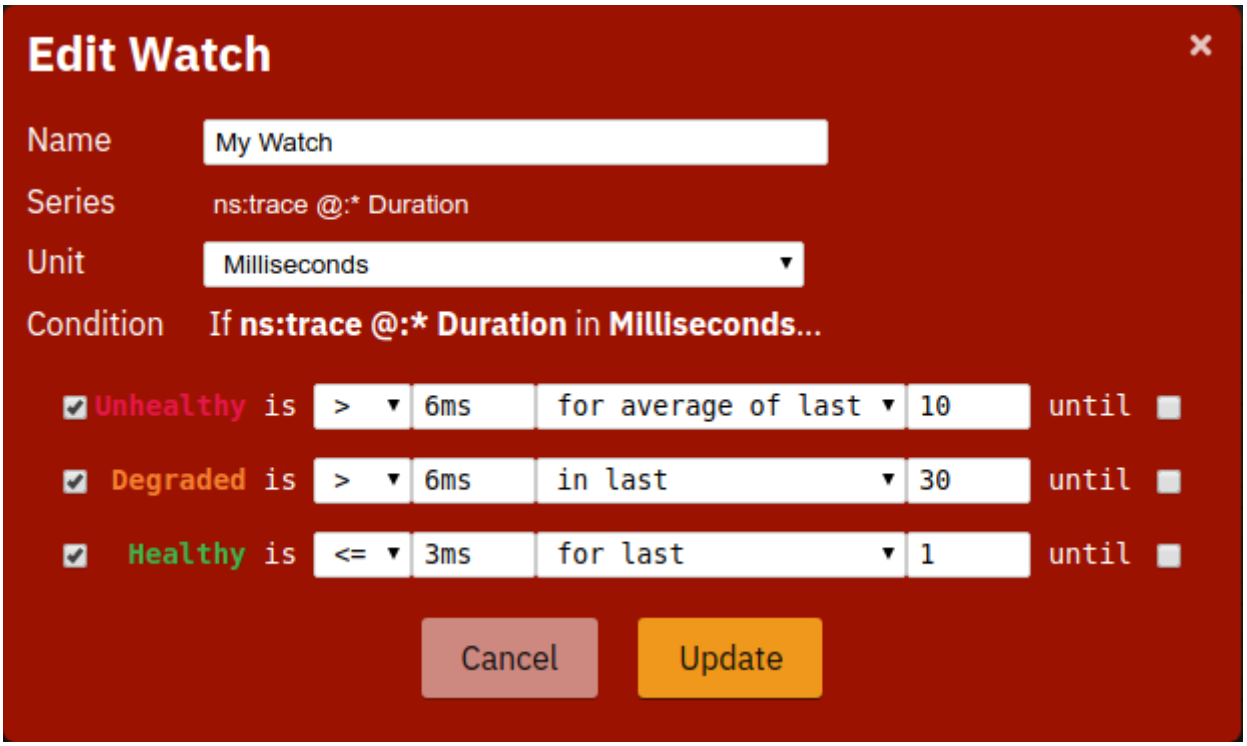
If a watch of the same name already exists the existing watch is replaced.

System watches that originate from server modules cannot be changed. But they can be disabled and copied to effectively make them editable. Find more in the edit section below.

Watches operate on the DAS server. Their configuration is common for all users. Any change will affect other users.

Editing a Watch

To edit a user watch open the watch manager, scroll down to the list of *User Watches* and click the *Edit* button of the watch that should be edited.



Confirm changes by clicking *Update*.

When changing the name of the watch a new watch is created with the new name and the old watch continues to exist. It can be deleted afterward using the *Delete* button in the *User Watches* list.

When changing the name of a watch to a name of an already existing watch this

overrides that watch. In other words watches are always identified by their name.

System watches cannot be edited. To achieve the effect of a changed system watch disable and copy it. The copy is a user watch that can be adjusted freely. The suggested name *Copy of {original name}* can be changed as long as it is unique.

Enabling or Disabling a Watch

Open the watch manager as an *Administrator* and click the *Disable* or *Enable* button of the watch that should be disabled or enabled.

The change has immediate effect and can easily be "undone" by toggling the state again. If there were any ongoing alerts due to a watch that gets disabled, these alerts stops.

Enabling such a watch again then requires matching the watches start condition again.

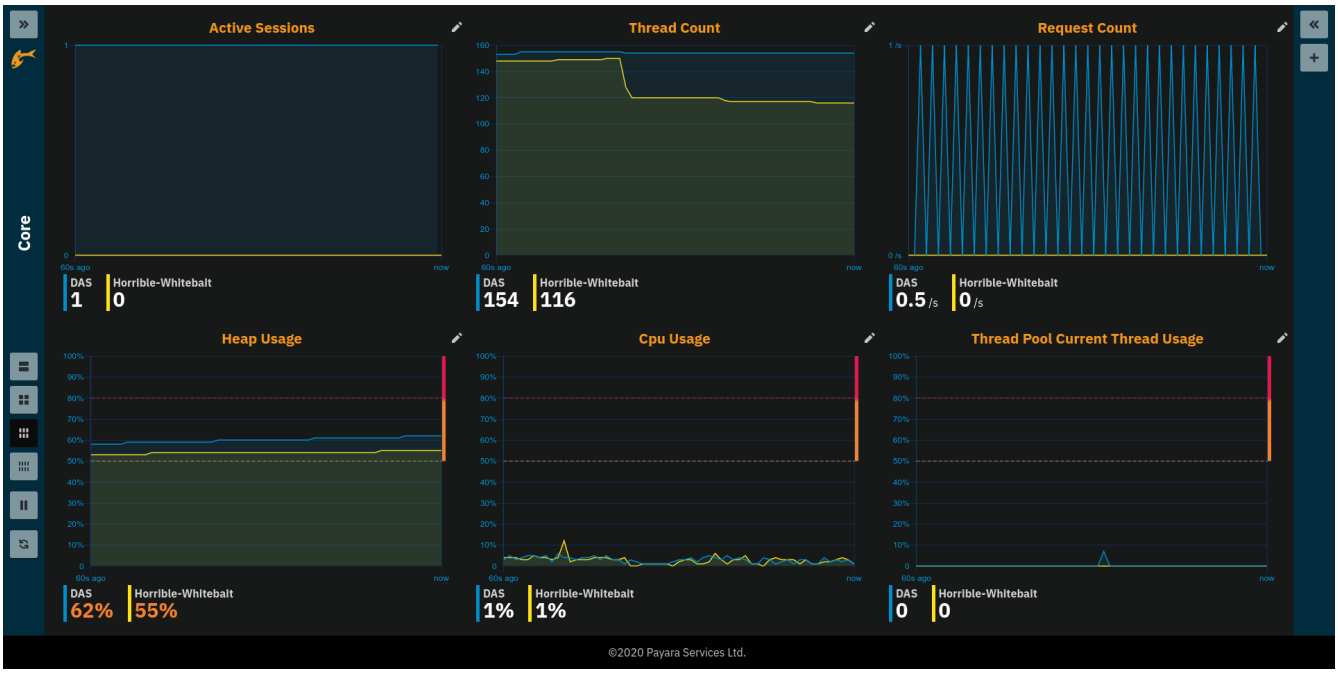
Preconfigured Pages

Payara InSight is shipped with a dozen of preconfigured pages. These are in no way privileged over the user-created pages. It is simply a configuration identical to one user can create manually that is hard coded as a preset.

Users can modify these pages freely, but they cannot be deleted.

Core Page

The *Core* page gives an overview of some of the important instance metrics. Each instance in the grid is shown separately.

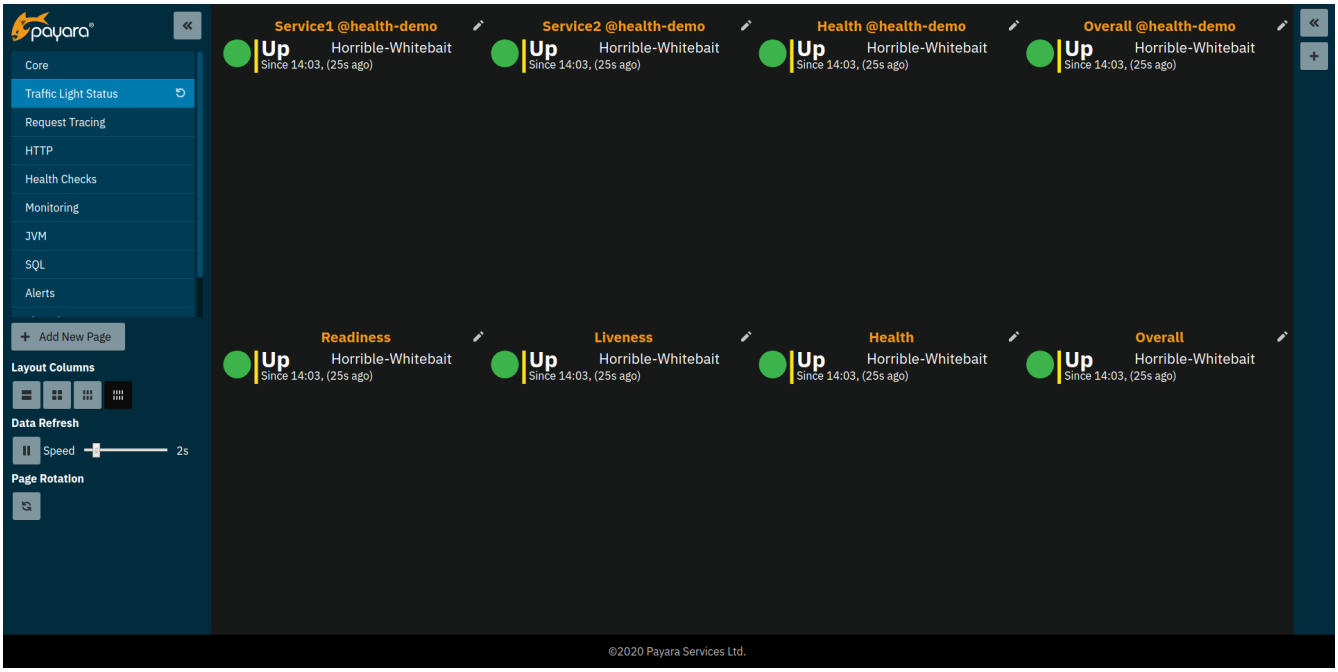


- *Active Sessions*: Total number of active session for the instance.
- *Thread Count*: Total number of threads used by the instance.
- *Request Count*: Number of HTTP request per second processed by the instance.

- *Heap Usage*: Percentage of the current instance maximum heap memory already used.
- *CPU Usage*: Percentage CPU usage by the instance (not the machine but the process).
- *Thread Pool Current Thread Usage*: Percentage of HTTP thread pool threads currently in use by the instance.

Traffic Light Status Page

The *Traffic Light Status* page (a.k.a. RAG Status for Red-Amber-Green Status) indicates the health status of the server and deployed application using traffic light signals to visualise the current state.



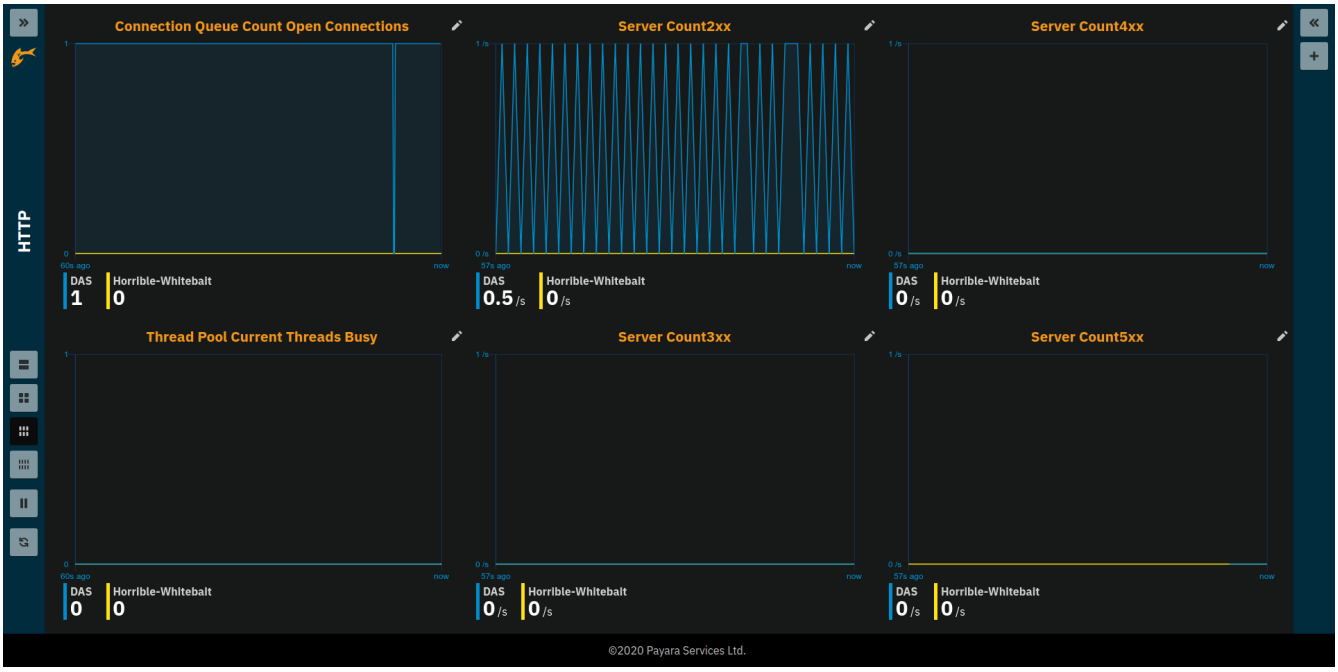
The content of the page is based on Payara Health Checks (needs to be enabled in the server configuration) and MicroProfile Heath checks of deployed applications.

In contrast to most pages this page is not static based on a manually created configuration. Instead, the page is populated with widgets based on a query.

For more details on query pages see sections Adding Pages and Page Settings.

HTTP Page

The *HTTP* page gives a rough overview of the state of the HTTP services of each instance.



- *Connection Queue Count Open Connections*: Total number of open connection in the connection queue
- *Thread Pool Current Threads Busy*: Number of threads in the HTTP thread pool currently processing an HTTP request.
- *Server Count2xx*: Requests per seconds and instance responding with Success.
- *Server Count3xx*: Requests per seconds and instance responding with Redirection.
- *Server Count4xx*: Requests per seconds and instance responding with Client Error.
- *Server Count5xx*: Requests per seconds and instance responding with Server Error.

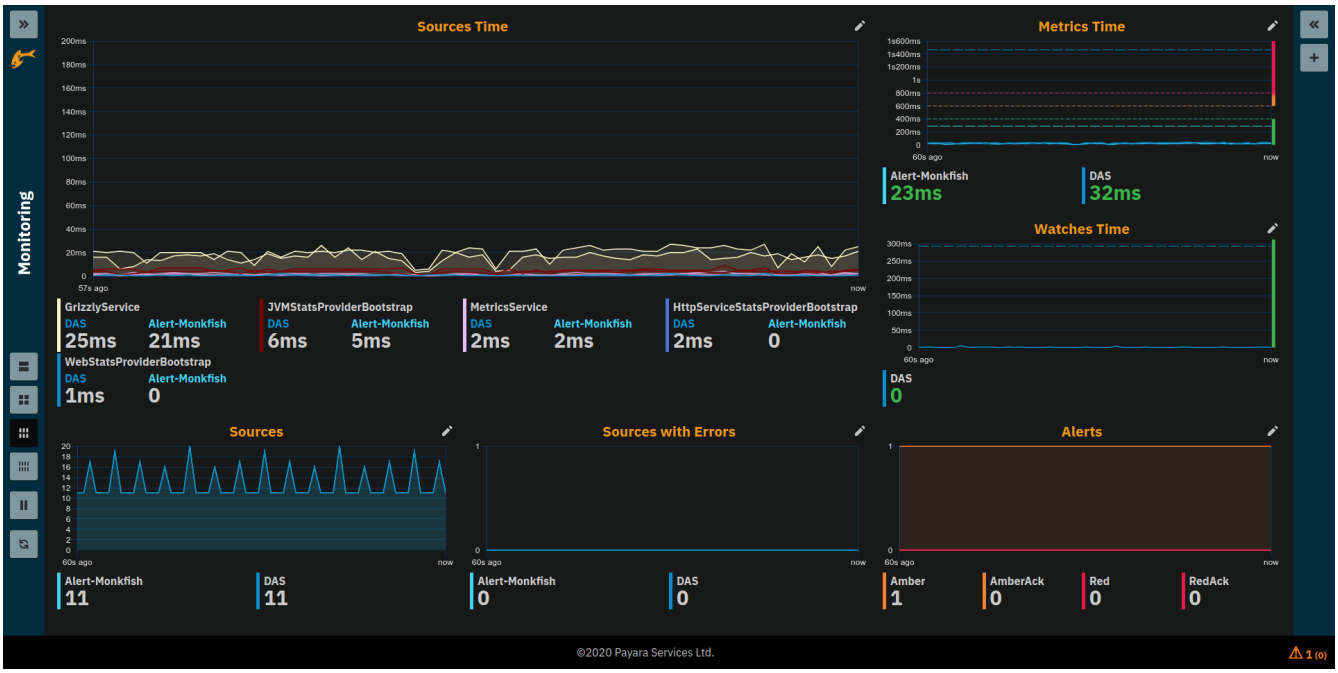
JVM Page

The *JVM* pages gives a general overview of the state of the JVM running Payara Server.

- *Used Heap*: Total size of the used heap memory
- *Heap Size*: Size of the committed (reserved) heap memory (OS level)
- *Loaded Classes*: Total number of loaded classes
- *Unloaded Classes*: Total number of unloaded classes
- *Live Threads*: Total number of threads used by the JVM (including daemon threads)
- *Daemon Threads*: Total number of daemon threads used by the JVM

Monitoring Page

This is mostly useful to identify problems with the monitoring system or to cross-check that unexpected metric values aren't caused by general problems with monitoring.



- *Source Times*: Shows the duration it took to collect metric data from the individual sources within the server. Durations should be well below a second. Usually in two digit millisecond range.
- *Sources*: Number of sources metrics are collected from in a particular second. This varies as some sources are collected in an interval of several seconds.
- *Sources with Errors*: Shows how many of the sources that were collected caused an error during collection that potentially ends the collection of that source so that some metrics usually provided by that source might no longer be collected. This can explain "missing" metrics.
- *Metrics Time*: The total time it took to collect all sources. As collection happens once every second this should be well below 1 second.

  This metric is watched and alerts are created should the time exceed 600ms for multiple times in a row.

  This time can vary a lot depending on the server configurations as sources are enabled and disabled. It can also be influenced strongly by the deployed applications as they can contribute metrics in large numbers.

- *Watches Time*: The total time it took to collect and evaluate all watches. This time is less critical, but it should usually be well below 1 second.

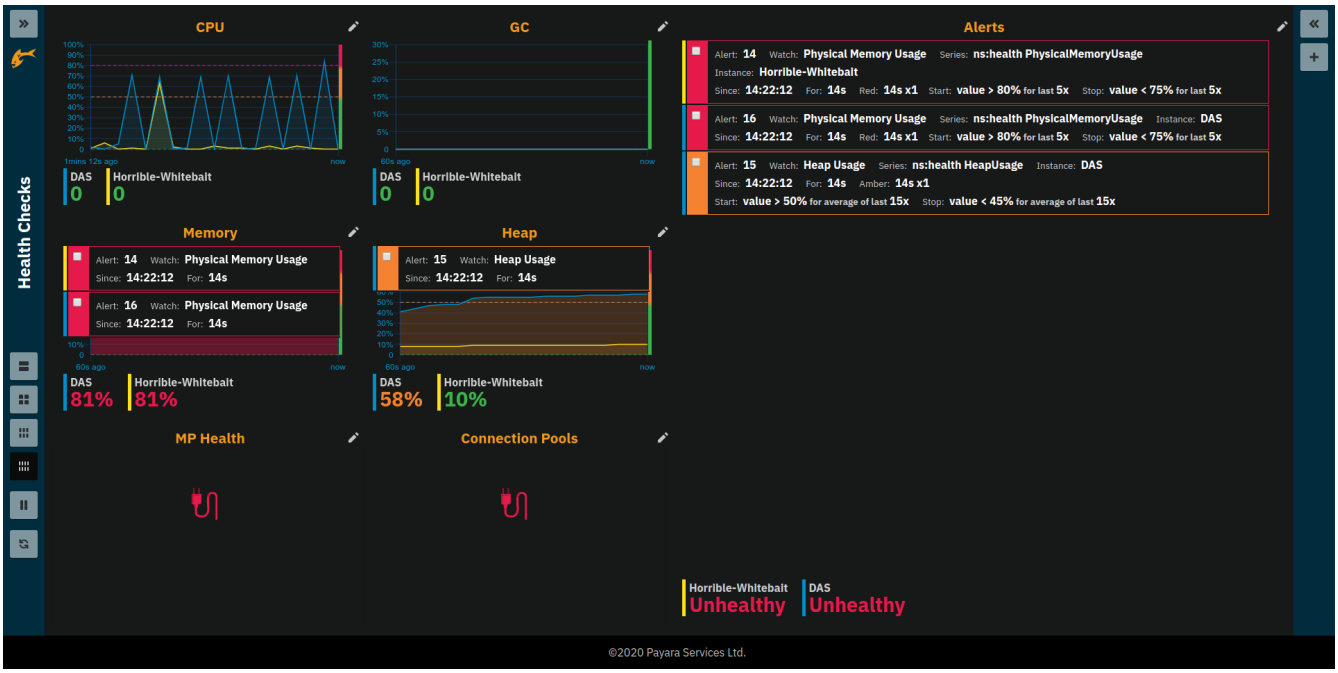
  Typically, in the range of two digit milliseconds.

- *Alerts*: The total number of ongoing (active) alerts.

Health Checks Page

A page that gives an overview of the state of the server health checks. The individual checks need to be enabled in the server's *HealthCheck* configuration.

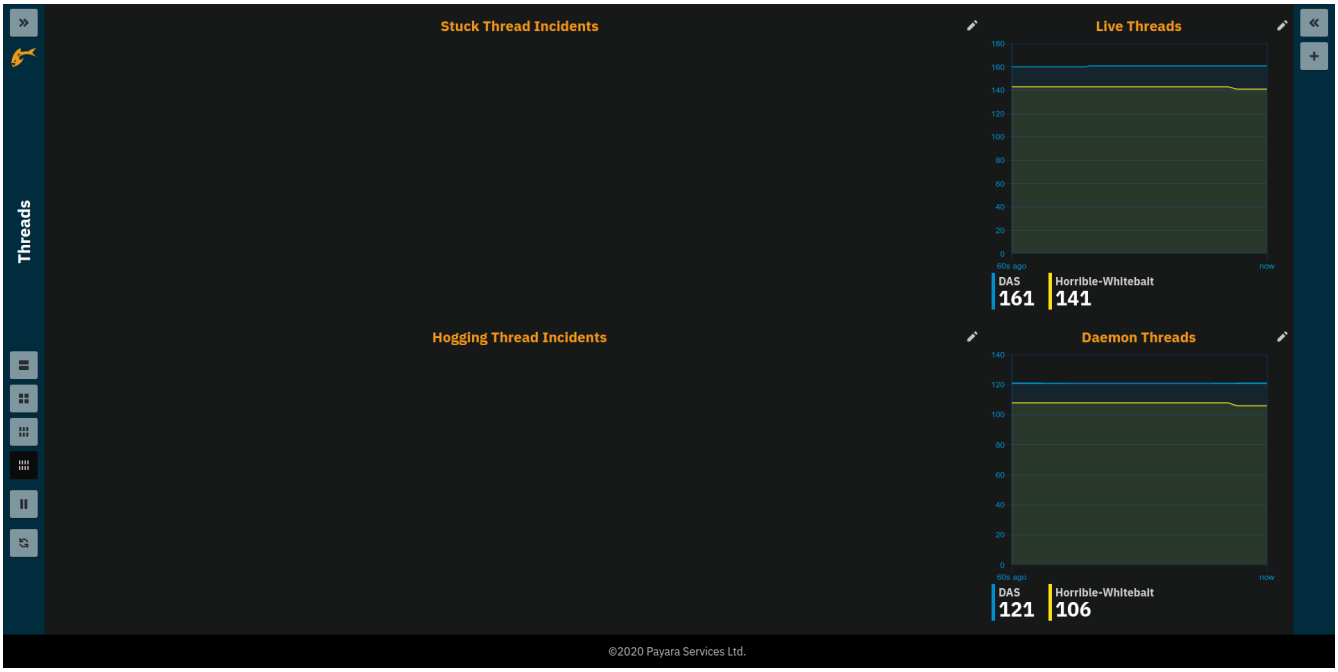
It is not required to enable the *HealthCheck service* in the *General* tab in case the checks should only be enabled for metrics based monitoring without causing health check notifier messages.



- *CPU*: CPU Health Check, average percentage of CPU used by the server instance during last 4 seconds
- *GC*: Garbage Collection Health Check, percentage of time used to collect garbage objects during the last 4 seconds
- *Memory*: Machine Memory Usage Health Check, percentage of the total available physical memory used
- *Heap*: Heap Memory Usage Health Check, percent of total available heap memory used by the JVM
- *MP Health*: MicroProfile Health Check, percent of instances that respond with `UP` status to a liveliness health endpoint request (this includes the DAS that is the only instance that is performing this check every 12 seconds)
- *Connection Pool*: Connection Pool Health Check, percent of connections currently used for each JDBC connection pool
- *Alerts*: A list of all health check related alerts

Thread Health Page

The *Threads* page gives detailed information on thread health of the cluster and lists information on stuck or hogging threads. The total number of live and daemon threads are given for reference.



- *Stuck Thread Incidents*: Table listing the most recent information for threads that are considered stuck.

  This is the case if the time passed since a thread started a not yet finished unit of work becomes longer than the set threshold in the *Stuck Threads* health check configuration.

  This could be because it is waiting at a lock or the operation takes a considerable amount of time.

- *Hogging Thread Incidents*: Table listing the most recent information for threads that are considered hogging.

  This is the case if the thread's use of the CPU in percent points is higher than the threshold value configured in the *Hogging Threads* health check configuration for `n` times in a row, where `n is 1 + the configured number of retries`.

- *Live Threads*: Total number of threads used by the JVM (including daemon threads)
- *Daemon Threads*: Total number of daemon threads used by the JVM

Be aware that the number shown in the example image might not be characteristic. For demonstration purposes the thresholds might be set uncharacteristically low to be able to "force" entries.
Usually the threshold for stuck threads should be in region of some seconds to a few minutes. The threshold for hogging threads should be well above 90% with a few retries.

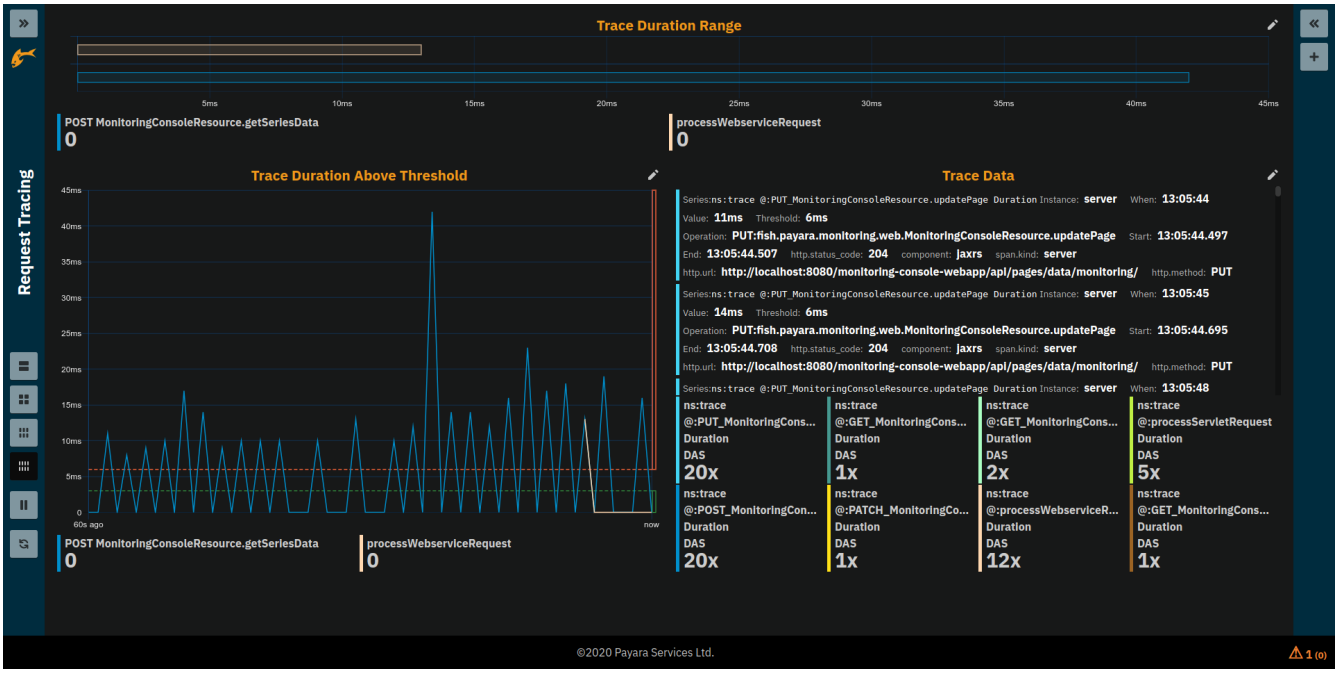
Request Tracing Page

The *Request Tracing* page overview page shows traces that exceeded the set threshold configures as part of the request tracing server configuration.

If this page does not show any data, no request has exceeded the threshold or the request tracing has not been enabled. Check server config *Configuration* ⇒ *Request Tracing*.

The *Trace Duration Range* widget shows all traces for the same method as a single bar. The length and position of the bar gives the range of total trace duration for all the occurrences that exceeded the threshold.

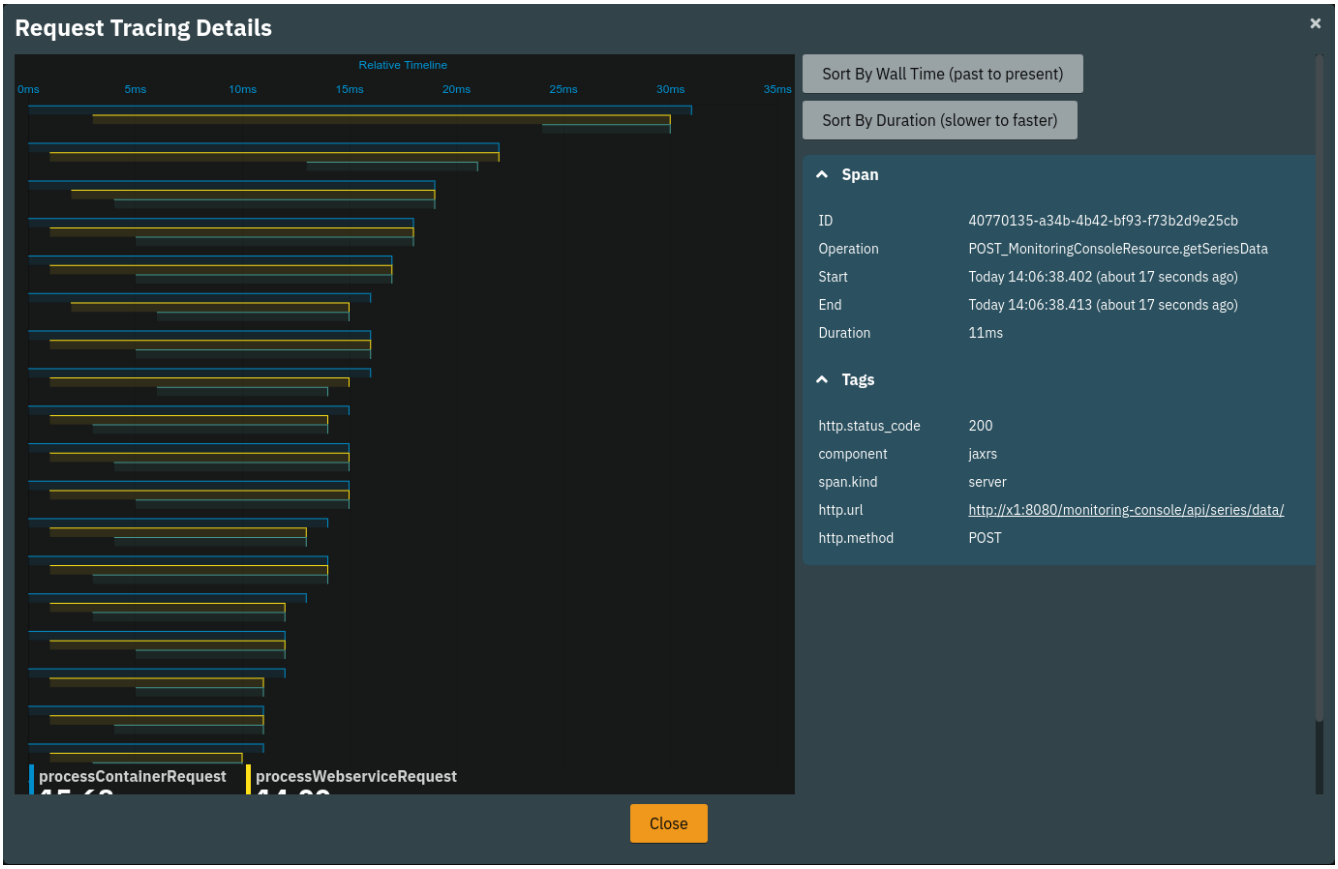
The bar starts at the minimum duration observed and ends at the maximum duration observed in the last minute. The legend shows the average duration and the method traced (innermost trace span operation)



When checking the minimum and/or maximum checkbox in the widgets *Extras* settings the bar starts and/or ends at these "all time" values instead of the minimum and/or maximum within the last minute.

The *Trace Duration Above Threshold* widget shows a graph where each point marks the duration of a "slow" request at the moment the requests occurred. Possible alerts are shown on top of the graph.

By clicking on one of the bars in the overview's *Trace Duration Range* widget the details of all kept traces for this method can be viewed.



This data corresponds to the traces stored in the trace-store. For each trace, each of the spans corresponds to a bar in this graph.

The details can be sorted by wall-time or by total duration. By default, the traces are sorted longest (slowest) to shortest (fastest) total duration.

On the time axis the spans are shown relative to the start of the trace.

The legend gives average durations for each of the spans occurring for the traced method.

The detail view shows a snapshot of the data found in the trace store. Changing the sorting will reload data and reflect an updated snapshot.

When clicking on the bars in the details view the right side panel shows the trace span details of the clicked trace span.

Be aware that the graphs in the example images above show unrealistically low numbers due to the way that request tracing was configured. In a more realistic configuration, the durations are more likely to be in range of a few hundred milliseconds to some seconds.

SQL Page

The *SQL* page gives insight into slow SQL queries for all connection pools configured in Payara Server.

To capture slow SQL queries the *JDBC Connection Pool* configuration's *Slow Query*

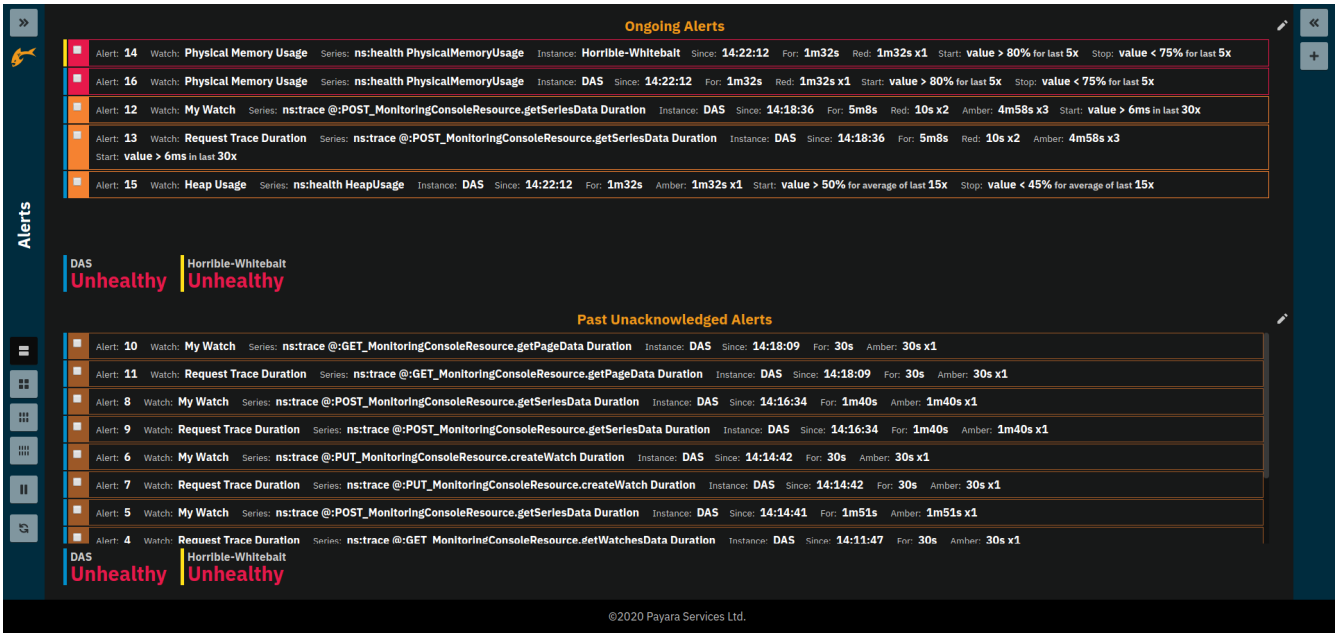
> *Log Threshold* in the *Advanced* tab needs to be set to a positive number.

- *Slow SQL Queries*: Shows SQL details for queries that were too slow. *Value* refers to the duration of the SQL query.
- *Worst SQL Execution Time*: Shows SQL query activity. Each data point gives the duration of the slowest query run during last second. Zero means no SQL query was run.
- *Slow SQL Alerts*: A list of alerts caused by too slow SQL queries in reference to the *Slow Query Log Threshold* given in the pool configuration. Single outliers cause a degraded state (amber alerts), outlier groups cause unhealthy state (red alerts).

Alerts Page

The main use of the *Alerts* page is to check for any server alerts. The page is split into two lists: the upper list containing all ongoing alerts, and the lower list containing past alerts.

As always for alert lists both lists are sorted starting with the most recent severe alert progressing to the oldest least severe alert. Annotations associated with alerts are hidden in this view to make room for more alert entries.



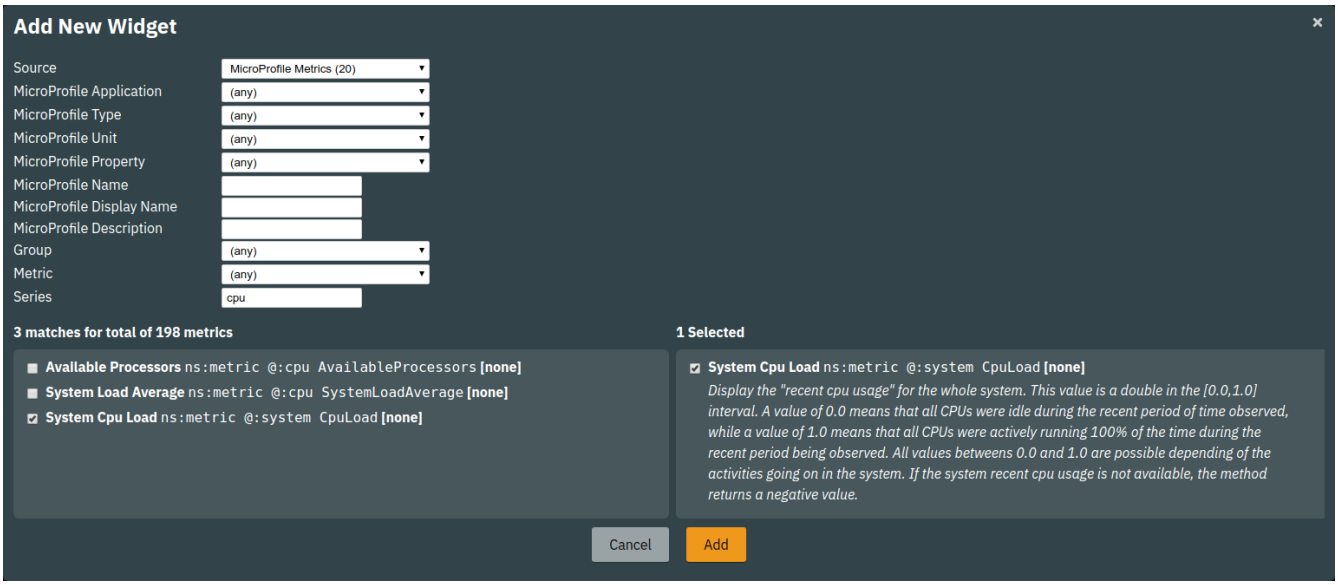
Past alerts can be managed by acknowledging the alerts which makes them disappear from the list.

Application Metrics Page

Payara InSight is build with the intention to make visualising user defined metrics really easy. This includes MicroProfile Metrics and MicroProfile Health checks that as defined by deployed application and server itself.

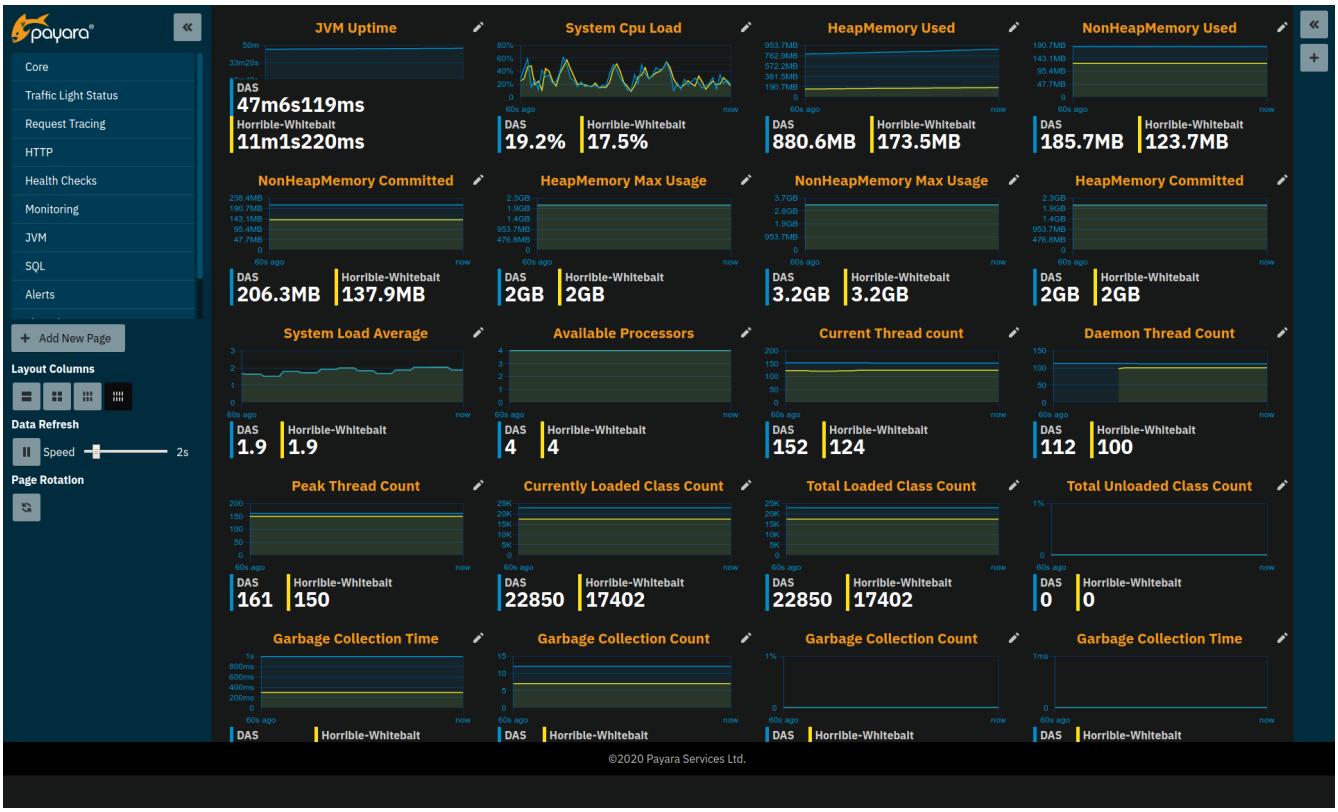
It does not require and further configuration to make them available as metrics within Payara InSight.

In addition, the metrics selection wizard has additional filters specifically filtering on the properties of MicroProfile Metrics.



When MicroProfile Metrics get translated to InSight series the MP tags become the `@` group of the shown series key, the MP *metric* stays the metric name.

The *Application Metrics* page is a page that is automatically populated will MicroProfile Metrics based on a query. This means the metrics shown on the page vary depending on what metrics are defined in applications and the server as MicroProfile metrics.



When populating the page the widgets are configured automatically based on the information available in MicroProfile.

For more details on query pages see Adding Pages and Page Settings.

Experimental Features

This section includes features that aren't fully complete or integrated or which might change drastically or even be removed in future releases.

Pattern Data Series

The term *series* is used for the name or key for a particular metric. Each metric has a unique key or series name.

Usually these names use *tags* for form *key:value* to categorise metrics into groups. For example:

```
ns:jvm MetricName
ns:jvm @:groupName MetricName
```

The series names shown above exemplify conventions used throughout Payara InSight. The first grouping level usually is the `ns` (short for namespace), the second the `@` (short for *group*).

In the example the metrics belong to the `jvm` namespace and the `groupName` group within that namespace.

When metrics are selected using the wizard only fully qualified metric series can be selected. This is a limitation of the selection wizard. On the technical level a series can be either a fully qualified series name or a series pattern.

Patterns contain wild-cards to match not only one specific metric but a set of metrics. Wild-cards can occur in different places. Examples of this can be found in the query page's *Query Series* setting.

For example the *Traffic Light Status* page uses the query `*boldns:health ?:* *`.

A `*bold*` wild-card for the metric name means *any metric name*.

The `*bold?:*` combines a wild-card (tag) value (`*bold*`) with a wild-card tag name (`?`). This means *any tag name* (including none and multiple of them) with *any value*.

So the full `*boldns:health ?:* *` matches any series that is in `ns:health`, weather or not is has more tags, while `*boldns:health *` only would match series in `ns:health` which do not have further tags.

This feature can be used to automatically show all metrics of a certain pattern in a single widget as it is done by the request tracing page.

Diagnostics and Troubleshooting

Diagnostics Tool

Payara Server has a diagnostic tool that on demand collects the following information from the server runtime.

- `domain.xml` configuration file
- Server logs
- Notification logs
- Access logs
- A JVM thread dump.
- A JVM Heap Dump
- JVM Report

The collection of this data can be targeted towards a specific remote or local server instance, deployment group or cluster. By default, everything is collected from the DAS, and each instance, deployment group and cluster configured in the domain.

If the target(s) is(are) offline, only the `domain.xml` configuration file, server, access and notification logs will be collected.

If you are not using the default *domain1*, you must specify the domain to collect diagnostics from.

The diagnostics tool can be manually upgraded to a newer version in case it is needed. To do so, download the latest 2.x JAR release from Nexus using this link

and then replace the older version into your Payara Server installation under the `as-install/glassfish/lib/asadmin` folder.

The tool is also updated at every release of Payara Platform Enterprise.

Usage

The diagnostic tool can be used through the `collect-diagnostics` Asadmin CLI subcommand, which will collect the relevant data and store it locally in a ZIP bundle that can be used for troubleshooting purposes when raising support tickets on the support portal.

Using this command will allow both customers and support staff to work faster on the investigation and analysis of production and development incidents.

The `--obfuscate` parameter will hide sensitive data in the `domain.xml` such as passwords, addresses and hostnames.
Use it if you're afraid of sensitive data being shared along with the domain configuration.

The data collected is stored in a ZIP file in your user home directory, the output directory by default.

The resulting compressed ZIP file will have a directory structure similar to the following:

```
deploymentGroup1
 ├──── instance1
 │     ├──── instance1-domain.xml
 │     ├──── instance1-jvm-report.txt
 │     ├──── instance1-server.log
 │     ├──── instance1-notification.log
 │     ├──── instance1-server_access_log.txt
 │     └──── instance1-thread-dump.txt
 └──── instance2
       ├──── instance2-domain.xml
       ├──── instance2-jvm-report.txt
       ├──── instance2-server.log
       ├──── instance2-notification.log
       ├──── instance2-server_access_log.txt
       └──── instance2-thread-dump.txt
```

Where the data is grouped in sub-folders segregated in all targets (deployment groups, clusters and instances) scanned by the command.

Example

The following example shows how to collect the data of all instances that belong to the `deploymentGroup1` deployment group in the `mydomain` domain:

```
asadmin> collect-diagnostics --target deploymentGroup1 mydomain

Directory selected /home/user/payara/diagnostics/mydomain-2024-04-15T11-42-36Z
Collecting domain.xml from instance2
Attempting to create missing path at /home/user/payara/diagnostics/mydomain-2024-04-
15T11-42-36Z/deploymentGroup1/instance1
Obfuscating /home/user/payara/diagnostics/mydomain-2024-04-15T11-42-
36Z/deploymentGroup1/instance1
Successfully obfuscated /home/user/payara/diagnostics/mydomain-2024-04-15T11-42-
36Z/deploymentGroup1/instance1
Collecting logs from instance2
Collecting jvm report from instance2
Collecting thread dump from instance2
Collecting Heap Dump from instance2
This version of Payara does not support heap dump generation.
Collecting domain.xml from instance1
Attempting to create missing path at /home/user/payara/diagnostics/mydomain-2024-04-
15T11-42-36Z/deploymentGroup1/instance1
Obfuscating /home/user/payara/diagnostics/mydomain-2024-04-15T11-42-
36Z/deploymentGroup1/instance1
Successfully obfuscated /home/user/payara/diagnostics/mydomain-2024-04-15T11-42-
36Z/deploymentGroup1/instance1
Collecting logs from instance1
Collecting jvm report from instance1
Collecting thread dump from instance1
Collecting Heap Dump from instance1

Command collect-diagnostics executed successfully.
```

Collect Diagnostics with an unavailable DAS

Diagnostics can be collected directly from a running instance in case its corresponding DAS it's not available by specifying the admin port of the target instance (see Asadmin Options), like this:

```
asadmin> -p 24848 collect-diagnostics --target deploymentGroup1 mydomain
```

This command must be run locally on the host of the node where this instance is located.

Upgrade Guide

Overview

There are three valid methods of fully upgrading to a newer release of Payara Enterprise. Any of the following methods would work in most circumstances:

If you are migrating from Payara Community edition to Payara Enterprise edition,

you must use the backup and restore method.

1. Backing up and restoring the existing configuration to a new installation. Read Backup and Restore Method
2. Maintaining completely separate domain and node directories and pointing the new version to the existing directories. Read Domain and Node Directories Method
3. Using the Payara Upgrade Tool. Read Payara Upgrade Tool Method

JDK 11: Upgrade Considerations

Applies when upgrading to Payara Server 5.192 and superior releases

The `domain.xml` configuration file contains instructions for handling JDK 11. Without these instructions, Payara Server will not start up on JDK 11 and/or will throw many exceptions during runtime.

If older, pre-5.192, domains are being migrated this has to be taken into account. The following `jvm-options` have to be added to the `java-config` element in `domain.xml`:

```
<jvm-options>[9|]--add-opens=java.base/jdk.internal.loader=ALL-UNNAMED</jvm-options>
<jvm-options>[9|]--add-opens=jdk.management/com.sun.management.internal=ALL-
UNNAMED</jvm-options>
<jvm-options>[9|]--add-exports=java.base/jdk.internal.ref=ALL-UNNAMED</jvm-options>
<jvm-options>[9|]--add-opens=java.base/java.lang=ALL-UNNAMED</jvm-options>
<jvm-options>[9|]--add-opens=java.base/java.nio=ALL-UNNAMED</jvm-options>
<jvm-options>[9|]--add-opens=java.base/sun.nio.ch=ALL-UNNAMED</jvm-options>
<jvm-options>[9|]--add-opens=java.management/sun.management=ALL-UNNAMED</jvm-options>
<jvm-options>[9|]--add-opens=java.base/sun.net.www.protocol.jrt=ALL-UNNAMED</jvm-
options>
<jvm-options>[9|]-Xbootclasspath/a:${com.sun.aas.installRoot}/lib/grizzly-npn-
api.jar</jvm-options>
```

The following `jvm-options` have to be removed:

```
<jvm-options>-
Djava.endorsed.dirs=${com.sun.aas.installRoot}/modules/endorsed${path.separator}${com.
sun.aas.installRoot}/lib/endorsed</jvm-options>
<jvm-options>-
Djava.ext.dirs=${com.sun.aas.javaRoot}/lib/ext${path.separator}${com.sun.aas.javaRoot}
/jre/lib/ext${path.separator}${com.sun.aas.instanceRoot}/lib/ext</jvm-options>
```

JDK 17 and 21: Upgrade Considerations

Applies when upgrading to Payara Enterprise 5.39.0 and superior releases

The `domain.xml` configuration file contains instructions for handling JDKs 17 and 21. Without these instructions, Payara Server will not start up on JDK 17 and/or will throw many exceptions during

runtime.

If older, pre-5.192, domains are being upgraded follow the JDK 11 upgrade considerations steps first, then come back to the JDK 17 & 21 upgrade considerations.

If older, pre-5.39.0, domains are being upgraded to Payara Server 5.39.0 or above, the following `jvm-options` have to be added to the `java-config` element in `domain.xml`:

```
<jvm-options>[17|]--add-exports=java.base/sun.net.www=ALL-UNNAMED</jvm-options>
<jvm-options>[17|]--add-exports=java.base/sun.security.util=ALL-UNNAMED</jvm-options>
<jvm-options>[17|]--add-opens=java.base/java.lang.invoke=ALL-UNNAMED</jvm-options>
<jvm-options>[17|]--add-opens=java.desktop/java.beans=ALL-UNNAMED</jvm-options>
<jvm-options>[17|]--add-opens=java.base/java.io=ALL-UNNAMED</jvm-options>
<jvm-options>[17|]--add-exports=jdk.naming.dns/com.sun.jndi.dns=ALL-UNNAMED</jvm-
options>
<jvm-options>[17|]--add-exports=java.naming/com.sun.jndi.ldap=ALL-UNNAMED</jvm-
options>
```

Payara Server 5 to Payara Server 6 Migration Considerations

Package names for Corba classes have changed from `com.sun` to `org.glassfish`, therefore if you use the `java.naming.factory.initial` system property you should set it to `org.glassfish.jndi.cosnaming.CNCtxFactory` for Payara Server 6.

Upgrade Tool

This tool can be used to upgrade an existing Payara Server installation to a newer version. The Upgrade Tool is bundled in Payara Server by default and is maintained as a separate JAR artifact under the `fish.payara.extras:payara-upgrade-tool` GAV coordinates.

The upgrade tool can be manually upgraded to a newer version in case it is needed. To do so, download the latest 2.x JAR release from Nexus using this link and then replace the older version into your Payara Server installation under the `${PAYARA_SERVER_INSTALL}/glassfish/lib/asadmin` folder.

Upgrading to Payara Server 7

It is possible to upgrade a Payara Server `6.x` domain to version `7.x`. The process should not be any different as to upgrading between different Payara 6 minor versions, though with the following caveats:

1. When performing an upgrade from Payara 6 to Payara 7, make sure that you're using JDK 21 as this is the minimum JDK version required to run Payara Server 7.

It is recommended that users should run the latest version of Payara Server 6.x before attempting to upgrade to version 7.x.

Asadmin CLI Commands

The following are the Asadmin CLI commands available to the upgrade tool.

Upgrade Server Command

Usage

```
asadmin> upgrade-server
```

Aim

This command can be used to upgrade Payara Server to the specified distribution along with all SSH nodes in the `domain.xml` configuration file.

The command will also back up the old version and domains in the default location (`payara7/glassfish/domains`) or the location specified using the `--domaindir` option to allow for rolling back.

Command Options

Option	Type	Description	Default	Mandatory
`--username`	String	The username for the Payara Nexus server.		Yes, unless `--usedownloaded` is specified
`--version`	String	Specifies the version number of the new version of Payara to use.		Yes, unless `--usedownloaded` is specified
`--distribution`	Enum	Specifies the distribution of Payara Server to download. This can payara, payara-web, payara-ml, or payara-web-ml.	payara	No
`--stage`	Boolean	Determines if the upgrade should be installed in-place, or staged into "*x.new*" directories. Scripts are provided that can be used to apply and rollback the staged install. This option is automatically enabled when running the command on Windows.	False on Unix, True on Windows	No
`--domaindir`	String	The directory containing the domains. The domains in this directory are backed up, and their config is used to determine the nodes which will also be upgraded.	`${as-install}/domains`	No

Option	Type	Description	Default	Mandatory
`--usedownloaded`	String	The path to the local Payara Server zip archive to use for upgrading instead of downloading from the Payara Enterprise repository. When this parameter is specified, the `--username`, `--password`, and `--version` parameters are not required.		No
`--nodes`	String	Specifies the nodes to upgrade if you want to selectively upgrade certain nodes. Provide as a comma-separated list of node names.	All nodes in the cluster	No

Example

This example upgrades a Payara Web distribution to version 7.1.0

```
asadmin> upgrade-server --username example-user --distribution web --version 7.1.0
```

To selectively upgrade specific nodes, use the `--nodes` option with a comma-separated list of node names. This example upgrades the domain administration server and one remote node, leaving other nodes to be upgraded later:

```
asadmin> upgrade-server --username example-user --version 7.1.0 --nodes localhost-domain1,remotehost1-node1
```

Rollback Server Command

Usage

`asadmin> rollback-server`

Aim

This command can be used to rollback Payara Server to the point before the upgrade-server command was run, restoring the most recent backup of the domain (expected to be the backup created during execution of the `upgrade-server` command).

This command is not supported on Windows OS, please use the `rollbackUpgrade.bat` script instead.

Command Options

Option	Type	Description	Default	Mandatory
`--domaindir`	String	The directory containing the domains. The domains in this directory are backed up, and their config is used to determine the nodes which will also be upgraded.	`${as-install}/domains`	No
`--nodes`	String	Specifies the nodes to rollback if you want to selectively rollback certain nodes. Provide as a comma-separated list of node names.	All nodes in the cluster	No

Staged Upgrades

When the `upgrade-server` command is either used on Windows or with the `--stage` option enabled, the new server files are installed next to the current installation in various *.new* directories (e.g. `payara7/glassfish/bin.new`). The following helper scripts are available to interact with staged upgrades.

Apply Staged Upgrade Script

Usage

```
> ./payara7/glassfish/bin/applyStagedUpgrade
```

Aim

This script is used to apply an upgrade staged using the `upgrade-server` command. It will move the current installation into *.old* directories, and the staged *.new* installation into the expected "current" location. It will then upgrade the nodes of the domains in the default domain dir, or the domains in the directory provided using `--domaindir`

Command Options

Option	Type	Description	Default	Mandatory
`--domaindir`	String	The directory containing the domains. The config of the domains in this directory are used to determine the nodes which will also be upgraded.	${as-install}/domains	No
`--nodes`	String	Specifies the nodes to upgrade if you want to selectively upgrade certain nodes. Provide as a comma-separated list of node names.	All nodes in the cluster	No

Rollback Upgrade Script

Usage

```
> ./payara7/glassfish/bin/rollbackUpgrade
```

Aim

This script is used to rollback a server upgrade applied using the `applyStagedUpgrade` script. It

will move the *.old* installation back into the expected "current" location, and the applied upgrade back into *.new* directories. It will then rollback the nodes of the domains in the default domain dir, or the domains in the directory provided using `--domaindir`

Command Options

Option	Type	Description	Default	Mandatory
`--domaindir`	String	The directory containing the domains. The config of the domains in this directory are used to determine the nodes which will also be rolled back.	`${as-install}/domains`	No
`--nodes`	String	Specifies the nodes to rollback if you want to selectively rollback certain nodes. Provide as a comma-separated list of node names.	All nodes in the cluster	No

Cleanup Upgrade Script

Usage

```
> ./payara7/glassfish/bin/cleanupUpgrade
```

Aim

This script is used to clean up any leftovers from a staged upgrade: any *.old* folders and any *.new* folders will be deleted.

Use of this script will prevent you from rolling back or applying a staged upgrade.

Configure Logging Levels

The upgrade tool commands and helper scripts will print a set of minimum details of the operations executed (upgrade, staging, rollback). For troubleshooting scenarios, or if wanting to review in detail all executed actions, the following 2 environment variables are available to control the level of logging done by the Upgrade tool:

`AS_DEBUG`

Set to `true` to configure the Upgrade Tool's logging level to `FINER`.

`AS_TRACE`

Set to `true` to configure the Upgrade Tool's logging level to `FINESET`.

These variables can also be configured as system properties in the Asadmin CLI script file located in the `{as-install}/bin` folder like this:

```
AS_INSTALL=`dirname "$0"`/../glassfish
AS_INSTALL_LIB="$AS_INSTALL/lib"
. "${AS_INSTALL}/config/asenv.conf"
JAVA=java
#Depends upon Java from ../config/asenv.conf
```

```
if [ ${AS_JAVA} ]; then
    JAVA=${AS_JAVA}/bin/java
fi

exec "$JAVA" -DAS_DEBUG=true  -XX:+IgnoreUnrecognizedVMOptions -jar
"$AS_INSTALL_LIB/client/appserver-cli.jar" "$@"
```

Remember to turn off these logger level settings after executing a server upgrade, as this setting will affect all future executions of any Asadmin CLI commands, which will cause them to print out more information than usual.

Zero Downtime upgrade

This feature requires payara-upgrade-tool.jar from Payara v5.83.0 or v6.34.0 and above and assumes you are running a minimum of two SSH nodes.

By default, upgrading Payara requires that the domain and all SSH nodes are stopped. This feature allows the upgrading of individual SSH nodes, eliminating downtime. Only upgrades in the same major version are supported 6.x to 6.x, 7.x to 7.x. Zero Downtime upgrades between 6.x and 7.x are not supported however it is possible to achieve if you can avoid restarting any of the 6.x nodes while running 7.x DAS.

Steps to upgrade:

stop the DAS

```
asadmin> stop-domain
```

upgrade the domain

```
asadmin> upgrade-server --username example-user --distribution web --version 7.1.0
--nodes localhost-domain
```

Stop one SSH node to upgrade

```
asadmin> stop-node-ssh node1
```

Upgrade one SSH node

```
asadmin> upgrade-server --username example-user --distribution web --version 7.1.0
--nodes node1
```

Start the upgraded SSH node

```
asadmin> start-node-ssh node1
```

Repeat the last 3 steps with the remaining SSH nodes to upgrade. Start the DAS

```
asadmin> start-domain
```

Use the `_list-node-versions` subcommand to help keep track of the current version of each node, including staged and rollback versions.

the upgrade can cause issues if the nodes are forming a cluster with Hazelcast. When 2 versions of Payara use different versions of Hazelcast, the upgraded node will fail to start as long as nodes using the older versions are running. If the upgraded node/DAS fails to start, you may have to upgrade everything else before restarting the nodes and the DAS. Alternatively, you can avoid these issues by disabling the data grid for every nodes. Below are the known combinations causing issues:

Known upgrade issues

Existing	Upgrade	Result
7.0.0	7.1.0	No issues

Backup and Restore Method

You will need to download the version of Payara Enterprise you are planning to upgrade to before beginning the backup and restore method of upgrading Payara.

Backup a Payara Server Domain

The `backup-domain` command requires the domain is not running, if this method is chosen for a production system, an arranged period of downtime would be required.

To create a backup of a domain, the asadmin `backup-domain` command is used:

```
asadmin backup-domain {domain_name}
```

The resulting ZIP file will be saved in a destination with this structure:

`{backupDir}/{domain_name}/<domain-name>_<YYYY_MM_DD>_v<backup-number>`

Where the backup number is a consecutive integer representing how many backups of the domain have been made.

You can get additional details of the backup operation by using the `--long` argument when running

the command, which will output the following data:

```
asadmin> backup-domain --backupDir /home/james/payarabackup --long domain1

Backed up domain1 at Mon Jul 04 16:25:58 BST 2022.

Description               : domain1 backup created on 2022_07_04 by user james
GlassFish Version         : Payara Server Enterprise  5.39.0 #badassfish (build 529)
Backup User               : james
Backup Date               : Mon Jul 04 16:25:58 BST 2022
Domain Name               : domain1
Backup Type               : full
Backup Config Name        :
Backup Filename (origin)  :
/home/james/payarabackup/domain1/domain1_2022_07_04_v00001.zip
Domain Directory          : /home/james/payara-
5.39.0/payara5/glassfish/domains/domain1

Command backup-domain executed successfully.
```

Read more about the Backup Domain Command

Restore a Payara Server Domain

Since instances are stored separately from a domain, and they may be on remote hosts, the command will have no effect on restoring instance data.

To restore from a backup, the asadmin `restore-domain` command is used:

```
asadmin restore-domain --filename {path_to_backup} {domain_name}
```

You can get additional details of the restore operation by using the `--long` argument when running the command, which will output the following data:

```
asadmin> restore-domain --filename
/home/james/payarabackup/domain1/domain1_2022_07_04_v00001.zip --long domain1

Restored the domain (domain1) to /home/james/PayaraInstalls/payara-
5.40.0/payara5/glassfish/domains/domain1

Description               : domain1 backup created on 2022_07_04 by user james
GlassFish Version         : Payara Server Enterprise  5.39.0 #badassfish (build 529)
Backup User               : james
Backup Date               : Mon Jul 04 16:25:58 BST 2022
Domain Name               : domain1
Backup Type               : full
Backup Config Name        :
Backup Filename (origin)  :
```

```
/home/james/payarabackup/domain1/domain1_2022_07_04_v00001.zip
Domain Directory          : /home/james/PayaraInstalls/payara-
5.39.0/payara5/glassfish/domains/domain1

Command restore-domain executed successfully.
```

Read more about the Restore Domain Command

Restoring an Instance

Since all data in an instance directory is kept in sync with the DAS, there is no added data (besides logs, caches and some MQ data when a file-based store is used) so an instance can be completely restored simply by making sure there is an empty directory with the name of the instance inside a node folder of the correct name.

For example: `payara5/glassfish/nodes/localhost-example/myInstance`

Running the `start-local-instance` command with the `sync` property set to `full` sync, will restore the instance completely:

```
asadmin> start-local-instance --sync=full myInstance
```

Read more about the Start Local Instance Command

Considerations for OpenMQ

If OpenMQ (Payara Server's JMS broker) is being used, the default configuration is to use EMBEDDED mode, meaning that Payara Server will fully manage the JMS broker within the same JVM as the server instance and a file-based store is used for persistent messages.

The alternative option of LOCAL allows for the use of an "enhanced" broker cluster, whereby the JMS broker instances are started as separate JVMs and use a database connection for storage. Assuming the database is highly available, this completely avoids any danger when needing to use --sync=full on the instance.

Domain and Node Directories Method

You can also upgrade Payara Enterprise by creating the domain and node directories in a directory that is separate from the installation. For example, if you downloaded *Payara Server 5.35.0*, created a domain, and then wanted to use *Payara Server 5.40.0*, you would use the following process:

```
/opt/payara/payara-5.35.0/payara5 bin/asadmin create-domain --domaindir /tmp
myTempDomain
/opt/payara/payara-5.35.0/payara5 cd ../../payara-5.40.0/payara5
/opt/payara/payara-5.40.0/payara5 bin/asadmin start-domain --domaindir /tmp
myTempDomain
```

This will use the *5.35.0* installation to create a new domain, and then run it with the *5.40.0*

installation.

Nodes can also be created in a separate directory by using the `--nodedir` property when creating a node.

```
/opt/payara/payara-5.35.0/payara5 bin/asadmin create-node --nodedir /tmp myLocalNode
```

By using this method, the user configuration is always kept separate to the installation, and rollback is as simple as using the previous installation directory.

If you are using Payara Server on **Linux**, you could take advantage of symbolic links. When your domain directory is in a non-standard location, you need to specify its location with each `start`/`stop`/`restart` command. If you were to create a symbolic link to the domain directory inside the default domains directory, then all of your existing scripts will carry on as normal.

This means that any rollback is as simple as stopping the server, updating a symbolic link and starting it again.

If you choose not to use symbolic links, the asadmin `start-domain` command has a `--domaindir` option which allows you to specify the location of a domain directory. So you could have a directory structure like the following:

```
/opt/payara/5.35.0/payara5/...
/opt/payara/5.38.0/payara5/...
/opt/payara/5.40.0/payara5/...
/opt/payara/domains/myDomain
/opt/payara/nodes/myLocalNode
```

Then you could start your domain with whatever version of Payara Server you wanted, by running the start-domain command from the corresponding Payara installation directory.

```
/opt/payara/5.35.0/payara5/bin/asadmin start-domain --domaindir /opt/payara/domains
myDomain
/opt/payara/5.38.0/payara5/bin/asadmin start-domain --domaindir /opt/payara/domains
myDomain
/opt/payara/5.40.0/payara5/bin/asadmin start-domain --domaindir /opt/payara/domains
myDomain
```

The `--domaindir` option specifies the parent directory for your domain, and where you would store all of your domains if needed.

Just as you can create nodes by using the `--domaindir` property, you can also start nodes in the same way.

```
/opt/payara/5.40.0/payara5/bin/asadmin start-local-instance --nodedir
```

```
/opt/payara/nodes myLocalNode
```

Payara Micro Documentation

Overview

This section covers how to use Payara Micro.

Payara Micro is an embedded release of Payara built from the Payara Embedded Web release. It allows you to deploy and run WAR files from the command line with a single command, and also features automatic, dynamic clustering with Hazelcast.

Documentation Conventions

1. Any commands listed will be written assuming they are being run from the same directory as the Payara Micro JAR file.
2. Any commands listed will also be written assuming that the system environment variables have been set up to have Java on the system Path.
3. Any paths listed throughout the documentation will use the Unix/Linux file path structure (forward slashes).
4. The owning class of an API method will not be explicitly stated unless it is not clear if an instance has been started or not; methods that operate on Payara Micro instances before they have been bootstrapped (instances that have not yet been started) are contained in the `PayaraMicro` class, whereas methods that operate on bootstrapped instances (running instances) are contained within the `PayaraMicroRuntime` class.

Docker Images

Payara Services Limited provides official Payara Micro Docker Images which are updated every release.

These images are hosted on Docker hub in the following locations:

- Payara Micro Docker Image

Payara Enterprise customers have access to a private Docker repository containing Payara Enterprise Edition equivalent images, which are also released and updated every month.

Maven Support

This section describes Apache Maven support for Payara Micro.

Maven Central Artifacts

Payara Micro is available in Maven Central, allowing you to include it as a dependency in your project's POM. This allows you to easily add the required Payara Micro classes and methods to your

application to use Payara Micro programmatically.

To do this, use the following GAV coordinates:

```
<dependency>
    <groupId>fish.payara.extras</groupId>
    <artifactId>payara-micro</artifactId>
    <version>main-7</version>
</dependency>
```

The link:/Technical Documentation/Public API/Overview.adoc[Public API,role=unresolved] dependency must be also added to the project's POM when developing applications that use proprietary features (`@Clustered` or `@NamedCache` for example).

Run Payara Micro using the Maven Plugin

There is a maven plugin built specifically for use with Payara Micro. It has goals to `bundle` the application into an Uber JAR, `start` and `stop` Payara Micro. This plugin is link:Technical Documentation/Ecosystem/Project Management Tools/Maven Plugin.adoc[fully documented in the Ecosystem section,role=unresolved].

Run Payara Micro using the NetBeans IDE

There is a Payara Platform tools plugin built for the Apache NetBeans IDE, specifically designed for Payara Micro to create and manage application actions (e.g., run, reload, and debug).

This plugin is fully documented in the link:/Technical Documentation/Ecosystem/IDE Integration/Apache NetBeans IDE/Payara Micro.adoc[Payara Micro Apache NetBeans IDE,role=unresolved] integration.

Payara Micro Configuration and Management

Micro Management

Stopping and Starting Instances

Starting Instance

This section details the very basics of starting a Payara Micro instance.

Starting an Instance from the Command Line

To start an instance of Payara Micro from the command line, you simply run the JAR:

```
java -jar payara-micro.jar
```

This single command is all you need to run Payara Micro instances; additional configuration

options are all part of this command.

Starting an Instance from Persistent Configuration Directory

When using link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Jar Structure and Configuration/Root Directory.adoc[persistent root configuration directory,role=unresolved], it is possible to generate a launcher bound to that directory using the command:

```
java -jar payara-micro.jar --outputlauncher --rootdir $rootDirectory
```

This will create file `$rootDirectory/launch-micro.jar` and exit immediately. After that, it is possible to launch Payara Micro with plain

```
java -jar $rootDirectory/launch-micro.jar
```

This makes configuration directory self-sufficient and the distribution file (`payara-micro.jar`) is no longer needed.

Starting an Instance Programmatically

You need to import two classes from the `fish.payara.micro` package (contained in the Payara Micro JAR, see section link:/Technical Documentation/Payara Micro Documentation/Maven Support.adoc[Maven Support,role=unresolved] for instructions on importing this JAR with **Maven**):

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;
```

You can then start an instance with default settings by calling the `bootstrap()` method from the `PayaraMicro` class. This initialization will throw a `BootstrapException` exception, so you will need to surround it with a **try-catch**, or have the parent method throw the exception.

A simple example is as follows:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{

    public static void main(String[] args) throws BootstrapException{
        PayaraMicro.bootstrap();
    }
}
```

To start an instance with non-default settings (configuration changes or deploying applications upon startup), you have to call the `getInstance()` method before using `bootstrap()`. More details on

this can be found in the link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Configuring An Instance.adoc[Configuring an Instance Programmatically,role=unresolved] section. The use of the `getInstance()` method does not exclude you from using the default settings however; calling the `bootstrap()` method on its own (as shown in the example above) is functionally equivalent to calling the `bootstrap()` method directly after the `getInstance()` method, such as in the example below:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{

    public static void main(String[] args) throws BootstrapException{
        PayaraMicro.getInstance().bootStrap();
    }
}
```

The `bootStrap()` method returns a `PayaraMicroRuntime` object instance, which is comes with various methods that afford you control over the instance and its cluster after you have bootstrapped it. To take advantage of this, you have to initialize a `PayaraMicroRuntime` object from the `bootStrap` method, like so:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.PayaraMicroRuntime;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
        PayaraMicroRuntime instance = PayaraMicro.bootStrap();
    }
}
```

Stopping Instance

This section describes how to shut down a Payara Micro instance.

Stopping an Instance from the Command Line

Payara Micro instances can be stopped by either:

- Using `CTRL-C` on the terminal in which Payara Micro is running.
- Sending a kill signal to the process ID of Payara Micro

Stopping an Instance Programmatically

To shut down a Payara Micro instance programmatically, you will need to use the `shutdown()` method of the `PayaraMicro` or `PayaraMicroRuntime` class.

The `shutdown()` method of the `PayaraMicro` class must be called on the instance of Payara Micro that you want to shut down, so will realistically only be used on a `PayaraMicro` instance variable:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{

    public static void main(String[] args) throws BootstrapException{

        PayaraMicro micro = PayaraMicro.getInstance();
        micro.bootStrap();
        micro.shutdown();
    }
}
```

The `shutdown()` method of the `PayaraMicroRuntime` class is tied to an instance variable, so is used in much the same way:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicroRuntime;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{

        PayaraMicroRuntime instance = PayaraMicro.bootstrap();
        instance.shutdown();
    }
}
```

Configuring An Instance

This section details how to configure a Payara Micro instance.

Configuring an Instance from the Command Line

As described in link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Deploying Applications/Deploy Applications.adoc[Deploying From the Command Line,role=unresolved], the starting and configuration of an instance can be done in its entirety on one line.

The options available can be seen by running the JAR with the `--help` option, or by consulting the link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Command Line Options/Command Line Options.adoc[Payara Micro Command Line Options,role=unresolved] section.

The general structure of starting, configuring, and deploying an application to an instance is as

follows:

```
java -jar payara-micro.jar _--option1_ _--option2_ ...
```

As an example, see below for starting an instance with a non-default HTTP port:

```
java -jar payara-micro.jar --port 2468
```

Separating Configuration from Production Run

An instance can be configured separately, but only when link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Jar Structure and Configuration/Root Directory.adoc[persistent root configuration directory,role=unresolved] is specified by means of command line argument `--rootDir`.

When switch `--warmup` is supplied all configuration and deployment command line parameters are applied to configuration directory and the instance immediately shuts down:

```
java -jar payara-micro.jar --option1 --option2 deployment.war --warmup
```

Another use case for --warmup is to collect profiling information for e.g. Class Data Sharing feature of JDK:

```
# Open JDK; launcher needs to be used because of simpler classpath
java -XX:DumpLoadedClassList=classes.lst -jar rootidr/launch-micro.jar  --warmup

# OpenJ9
java -Xshareclasses:name=payara-micro -jar payara-micro.jar --warmup
```

Read configuration from a file

With `--domainConfig` option, it is possible to define multiple options in a configuration file. This option would override the default Payara Micro configuration completely. The provided file must conform to the same structure as the `domain.xml` file in a Payara Server domain.

The `--rootDir` option sets the root configuration directory and saves the configuration across restarts. If empty, this directory will be filled by the default configuration, including the `domain.xml` file.

Precedence

If specifying multiple options at once, the following precedence is followed:

```
rootDir < domainConfig < autoBindHttp | autoBindSsl < port | sslPort
```

In human language:

- The *domain.xml* in the directory specified by the *rootDir* option (if one exists) is overridden by the *domain.xml* specified with the `domainConfig` option
- The HTTP and HTTPS port numbers specified in either of these *domain.xml* files are overridden to be the default values of **8080** and **8081** when the `autoBindHttp` or `autoBindSsl` options are enabled respectively.
- These default port values are then overridden in turn by the port numbers specified with the `port` or `sslPort` options.

Configuring an Instance Programmatically

There are various methods available for configuring a Payara Micro instance programmatically. You can only configure an instance before it is bootstrapped however.

The configuration methods available to you should be detected by your IDE, allowing you to view them using the auto-complete feature common to most popular IDEs. Alternatively, you can consult the link:/Technical Documentation/Payara Micro Documentation/API/Payara Micro API/Using the Payara Micro API.adoc[Payara Micro Configuration Methods,role=unresolved] section.

As noted in the link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Deploying Applications/Deploy Applications Programmatically.adoc[Deploying an Application Programmatically,role=unresolved] section, you can either call the desired configuration commands on one line during instance initialization, or on separate lines after creating a `PayaraMicro` variable.

As an example of configuring an instance to use a different HTTP and Cluster start port on one line, see here:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{

PayaraMicro.getInstance().setHttpPort(2468).setClusterStartPort(5902).bootStrap();
    }
}
```

For the example of the same, but done across multiple lines, see here:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
        PayaraMicro micro = PayaraMicro.getInstance();
        micro.setHttpPort(2468);
```

```
        micro.setClusterStartPort(5902);
        micro.bootStrap();
    }
}
```

It is also possible to configure an instance programmatically by specifying a `domain.xml` file that is packaged within your application by passing a resource string to the `setApplicationDomainXML` method. The path in the string will be resolved using the `getResource` method of the thread context class loader:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{

PayaraMicro.getInstance().setApplicationDomainXML("config/domain.xml").bootStrap();
    }
}
```

Packaging a Configured Instance as an Uber Jar

Sometimes it is preferable to package the application (or applications), configuration and dependencies into a single executable jar. To do this with Payara Micro use the `--outputUberJar` command line option as in this example:

```
java -jar payara-micro.jar --deploy test.war --outputUberJar test.jar
```

This will package up the `payara-micro.jar` and the WAR application into a single JAR. The resulting file can be executed like this:

```
java -jar test.jar
```

Any additional command line options you specify when creating an Uber JAR are recorded, so the Payara Micro instance is configured later when executing the packaged JAR:

```
java -jar payara-micro.jar --deploy test.war --port 9080 --lite --clusterName test-
cluster --clusterPassword test-password --outputUberJar test2.jar
```

All specified command line option will be retained when the Uber JAR is executed.

Uber JAR Context Root

When creating an Uber JAR, the context root of the packaged application will **always** be the name of the application WAR that is deployed. For example, the `test.war` that was packaged into the

`test2.jar` on port **9080** would be accessible on the following path:

```
http://localhost:9080/test
```

Currently, this is **always** the case; including when a context root is specified in a `payara-web.xml` /`glassfish-web.xml` deployment descriptor.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

If the WAR file is renamed to `ROOT.war` and packaged as an Uber JAR, it will be deployed to the root context:

```
java -jar payara-micro.jar --deploy ROOT.war --port 9080 --outputUberJar test3.jar
java -jar test3.jar
```

The application will now be accessible on:

```
http://localhost:9080/
```

Package Additional Files

It's also possible to package additional files into an Uber JAR, by using a custom root directory. You can run a Payara Micro instance first by generating the domain directory first using the `--rootDir` option first:

```
java -jar payara-micro.jar --rootDir /tmp/micro-dir/
```

You can then add files to the root directory like this:

```
> cd /tmp/micro-dir/
> ls -lsarth

total 784K
   0 drwxr-xr-x 1 root 197609    0 Mar 24 18:16 docroot
160K -rw-r--r-- 1 root 197609 158K Mar 24 18:16 __ds_jdbc_ra.rar
   0 drwxr-xr-x 1 root 197609    0 Mar 24 18:16 META-INF
160K -rw-r--r-- 1 root 197609 159K Mar 24 18:16 __cp_jdbc_ra.rar
160K -rw-r--r-- 1 root 197609 159K Mar 24 18:16 __xa_jdbc_ra.rar
160K -rw-r--r-- 1 root 197609 160K Mar 24 18:16 __dm_jdbc_ra.rar
   0 drwxr-xr-x 1 root 197609    0 Mar 24 18:17 autodeploy
   0 drwxr-xr-x 1 root 197609    0 Mar 24 18:20 lib
4.0K drwxr-xr-x 1 root 197609    0 Mar 30 19:22 config
128K drwxr-xr-x 1 root 197609    0 Mar 30 19:23 runtime
```

```
> cp ~/test-properties /tmp/micro-dir/config/.
```

And then, generate the Uber JAR using the modified root directory:

```
java -jar payara-micro.jar --rootDir /tmp/micro-dir/ --outputUberJar custom-micro.jar
```

You can verify that the files are located in the MICRO-INF/ directory:

```
> unzip -d custom-micro custom-micro.jar
> ls -lsarth custom-micro/** | grep

MICRO-INF/domain:
total 304K
1.0K -rw-r--r-- 1 fabio 197609   24 Apr  3 20:26 test.properties
```

Additional JAR files that are placed in the `${PAYARA_INSTALL_DIR}/lib` directory will be ignored when being packaged to the Uber JAR. To package additional JAR files into an Uber JAR, check the Adding Third Party JARs section

Configuring Payara Micro via System Properties and Environment Variables

Payara Micro can also be configured via system properties. These can either be set on the command line or passed into Payara Micro using the `--systemProperties` command line option which will load the properties from the specified file.

Payara Micro can also be configured using Environment variables. The environment variables supported are the same as the system properties below just replace the `.` with `_` for example `payaramicro.port` should be `payaramicro_port` when used as a system property.

Payara Micro supports the following system properties:

System Property	Equivalent Command Line Flag
payaramicro.domainConfig	`--domainConfig`
payaramicro.hzConfigFile	`--hzConfigFile`
payaramicro.publicaddress	`--hzPublicAddress`
payaramicro.autoBindHttp	`--autoBindHttp`
payaramicro.autoBindRange	`--autoBindrange`
payaramicro.autoBindSsl	`--autoBindSsl`
payaramicro.logo	`--logo`
payaramicro.logToFile	`--logToFile`
payaramicro.enableAccessLog	`--accessLog`

System Property	Equivalent Command Line Flag
payaramicro.logPropertiesFile	`--logProperties`
payaramicro.enableDynamicLogging	`--enableDynamicLogging`
payaramicro.enableHealthCheck	`--enableHealthCheck`
payaramicro.port	`--port`
payaramicro.sslPort	`--sslport`
payaramicro.sslCert	`--sslcert`
payaramicro.mcAddress	`--mcAddress`
payaramicro.mcPort	`--mcPort`
payaramicro.hostAware	`--hostaware`
payaramicro.startPort	`--startport`
payaramicro.clusterName	`--clusterName`
payaramicro.clusterPassword	`--clusterPassword`
payaramicro.lite	`--lite`
payaramicro.maxHttpThreads	`--maxHttpThreads`
payaramicro.minHttpThreads	`--minHttpThreads`
payaramicro.noCluster	`--noCluster`
payaramicro.noHazelcast	`--noHazelcast`
payaramicro.disablePhoneHome	`--disablePhoneHome`
payaramicro.enableRequestTracing	`--enableRequestTracing`
payaramicro.requestTracingThresholdUnit	`--requesttracingthresholdunit`
payaramicro.requestTracingThresholdValue	`--requesttracingthresholdvalue`
payaramicro.rootDir	`--rootDir`
payaramicro.name	`--name`
payaramicro.instanceGroup	`--instancegroup`
payaramicro.initialJoinWait	`--hzinitialjoinwait`

Configuring Alternate KeyStores for SSL

Payara Micro comes with Keystore files directly embedded within the JAR file.

These can be overridden using the following standard Java SSL system properties:

- `javax.net.ssl.trustStore`
- `javax.net.ssl.keyStore`
- `javax.net.ssl.trustStorePassword`
- `javax.net.ssl.keyStorePassword`

When packaging applications into an Uber Jar any keystores specified via system properties will be copied into the uberjar to replace the default internal keystores. However the uber jar will not contain the passwords and these must still be specified via the system properties.

asadmin commands like `add-pkcs8` and `add-to-keystore` are NOT supported in pre-boot and post-boot commands with Payara Micro and Java SSL system properties need to be used to point to the correct stores.

Setting the Key-Pair at Runtime

The key-pair to use as Payara Micro's SSL certificate can also be specified using the `--sslCert` command line option like this:

```
java -jar payara-micro.jar -sslCert my-custom-alias
```

The default key-pair name is `s1as` if not overridden via the command line switch.

Payara Micro Instance Names

Payara Micro instances are automatically assigned a name on boot. These names are generated from a dictionary of adjectives and fish names as `adjective-fish`. For example: `Magnanimous-Payara`, `Disgruntled-Goldfish`, and `Bamboozled-Tetra`.

Setting a Custom Instance Name

Instance names can be overridden with the `--name` command-line argument on start-up. Manually entered instances names are non-unique.

As an example, see below:

```
java -jar payara-micro.jar --name MicroInstance1
```

Payara Micro IPv4 and IPv6

Payara Micro instances automatically configure `java.net.preferIPv4Stack` to true shortly after launching unless configured otherwise on the command line. This is to match the default Hazelcast configuration of preferring IPv4, configured via `hazelcast.prefer.ipv4.stack`.

There may be situations where Payara Micro doesn't configure the `java.net.preferIPv4Stack` early enough, in which case it may be beneficial to define the JVM option on the command line yourself:

```
java -Djava.net.preferIPv4Stack=true -jar payara-micro.jar
```

If you wish Payara Micro and Hazelcast to prefer IPv6 addresses and an IPv6 stack, you can configure this using:

```
java -Djava.net.preferIPv4Stack=false -Djava.net.preferIPv6Addresses=true
-Dhazelcast.prefer.ipv4.stack=false -jar payara-micro.jar
```

Alternatively to return everything to the Java default (which isn't the Hazelcast default) of preferring an IPv6 stack and IPv4 address, you can configure Payara Micro and Hazelcast using:

```
java -Djava.net.preferIPv4Stack=false -Dhazelcast.prefer.ipv4.stack=false -jar payara-
micro.jar
```

Deploying Applications

Deploy Applications

Deploying an Application From the Command Line

If you wish to deploy multiple packages, you must specify the `--deploy` again, or point to a `--deploymentDir` with multiple applications.

Deploying an Application Package

All Payara Micro actions are run for the Payara Micro JAR, all in one command.

To deploy a WAR file to an instance, you need to use the `--deploy` option, followed by the path to the application to deploy. See below for an example of starting a Payara Micro instance and deploying a WAR file:

```
java -jar payara-micro.jar --deploy /home/user/example.war
```

The `--deploy` option is optional if your deployment file ends with `.jar`, `.rar` or `.war` therefore the command line below can also be used

```
java -jar payara-micro.jar /home/user/example.war
```

Deploying an Exploded War

An exploded WAR can be deployed to a Payara Micro instance just by specifying the path to the exploded WAR root directory on the `--deploy` command line or programmatically via the API. The exploded WAR can be redeployed by creating an empty `.reload` file in the root directory and updating its timestamp.

On a Linux OS host, a simple `touch .reload` command can update the timestamp of the file.

Deploying Applications from a Maven repository

You can deploy an application directly from a Maven repository using the `--deployFromGAV` option. This option accepts a comma separated string denoting a Maven artefact's `groupId`, `artifactId`, and `version` attributes.

```
java -jar payara-micro.jar --deployFromGAV "fish.payara.examples,test,1.0-SNAPSHOT"
```

This option can be used multiple times, and in conjunction with the standard `--deploy` options.

By default, Payara Micro will only search for artefacts in the Maven Central repository. If you wish to search additional repositories, you can add them to the list of repositories to search with the `--additionalRepository` option:

```
java -jar payara-micro.jar --deployFromGAV "fish.payara.examples,test,1.0-SNAPSHOT"
--additionalRepository https://maven.java.net/content/repositories/promoted/
```

To search through multiple additional repositories, you can use the option multiple times:

```
java -jar payara-micro.jar --deployFromGAV "fish.payara.examples,test,1.0-SNAPSHOT"
--additionalRepository https://maven.java.net/content/repositories/promoted/
--additionalRepository https://nexus.payara.fish/repository/payara-artifacts
```

Define context root

The context root of an application can be specified using the option `--contextroot` or by appending the path to the war-file name given with the `--deploy` option.

A context root set using `--contextroot <context-path>` option applies to the application of the first `--deploy` use that does not already specify a context root. Let's take the following example:

```
java -jar payara-micro.jar --deploy /home/user/example.war --contextroot hello-world
```

The root context of the `example.war` application is now set to `/hello-world`.

Alternatively the context root can be included in the value of the `--deploy` option. It follows the path to the war file separated by `File.pathSeparator`:

- `--deploy <war-file>:<context-path>` (Linux uses `:`)
- `--deploy <war-file>;<context-path>` (Windows uses `;`)

```
java -jar payara-micro.jar --deploy /home/user/example.war:hello-world
```

The above command again results in the effective root context `/hello-world`.

The two alternative mechanisms can also be used together:

```
java -jar payara-micro.jar --contextroot bar
    --deploy /home/user/example.war:foo
    --deploy /home/user/test.war
```

Here `example.war` is deployed in `/foo` while `test.war` is deployed in `/bar`.

`--deploy example.war:` is identical to `--deploy example.war:/` and deploys to the effective context root `/` while `--deploy example.war` deploys to `/example`.

It follows that leading `/` can be given but is not required. However, tailing `/` must not be given. Using `--deploy example.war:/foo/` will render the `<host>/foo/` endpoint inaccessible.

Define global context root

The global context root for all applications can be specified using the option `--globalcontextroot`.

Let's take the following example:

```
java -jar payara-micro.jar --deploy /home/user/example.war --contextroot hello-world
--globalcontextroot api
```

The complete context of the `example.war` application is now set to `/api/hello-world`.

It follows that leading `/` can be given but is not required. However, tailing `/` must not be given.

Using Root Configuration Directory

When a configuration root directory is reused across restarts (i.e. not running in a container), it is recommended not to set up a deployment each time a Payara Micro instance is started using that directory.

Doing so will cause the application to be deployed twice: Once at startup and second time when deployment section of the command line is processed.

The best approach is to use a warmup run for deployment the first time the root directory is created:

```
# Perform deployments and configuration the first time
java -jar payara-micro.jar --rootdir micro-root --warmup application.war

# All further invocations do not setup deployment
java -jar payara-micro.jar --rootdir micro-root
```

Alternatively a launcher can be generated from a configuration root directory as well:

```
# Perform deployments and configuration the first time
java -jar payara-micro.jar --rootdir micro-root --warmup application.war
java -jar payara-micro.jar --rootdir micro-root --outputlauncher

# All further invocations use the launcher JAR in the configuration directory
java -jar micro-root/launch-micro.jar
```

Payara Micro Post Boot Output

The following information about the output made by Payara Micro after its booting has completed will be available for examination:

Deployed Apps

After Payara Micro has booted, the log output will list data about the instance and all deployed applications, which includes:

- The name of the host machine
- The HTTP port(s) in use by the instance
- The HTTPS port(s) in use by the instance
- The generated instance name
- The instance's group name
- The Hazelcast member UUID
- A list of all deployed application names and their entry-point URLs

Here is an example of this output:

```
[DATE:TIME+TIMEZONE] [] [INFO] [] [PayaraMicro] [tid: _ThreadID=1 _ThreadName=main]
[timeMillis: EPOCHTIME] [levelValue: 800] [[[DATE:TIME+TIMEZONE] [] [INFO] []
[PayaraMicro] [tid: _ThreadID=1 _ThreadName=main] [timeMillis: EPOCHTIME] [levelValue:
800] [[
Instance Configuration
Host: Example-Host
HTTP Port(s): 8080
HTTPS Port(s):
Instance Name: Adjective-Fish
Instance Group: MicroShoal

https://example:port/exampleappendpoint1
http://example:port/exampleappendpoint2
https://example:port/exampleappendpoint2
]]
```

Deploy Applications Programmatically

You can deploy applications onto Payara Micro programmatically via its API.

Deploying Applications Using an asadmin Command

Applications can be deployed using the equivalent administration (`asadmin`) commands present on Payara Server.

Deploying on a Local Instance

It's possible to use the `run(Collection<InstanceDescriptor> members, String command, String… args )` method to run the `deploy` asadmin command. To deploy to a single instance, you must create a `members Collection` object only containing a single instance like in the following example:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicroRuntime;
import fish.payara.micro.services.data.InstanceDescriptor;
import java.util.ArrayList;
import java.util.Collection;

public class EmbeddedPayara {
    public static void main(String[] args) throws BootstrapException {
        PayaraMicroRuntime runtime =
PayaraMicro.getInstance().setHttpAutoBind(true).bootstrap();

        // Get a Collection with all running instances in the local runtimes cluster
        Collection<InstanceDescriptor> allInstances = runtime.getClusteredPayaras();

        // Create a Collection to use as a subset
        Collection<InstanceDescriptor> subset = new ArrayList<>();

        // Loop through all instances
        for (InstanceDescriptor instance : allInstances){
            // Only add the local instance
            if (instance == runtime.getLocalDescriptor()){
                subset.add(instance);
                break;
            }
        }
```

```
        // Run the deploy asadmin command on the subset Collection
        runtime.run(subset, "deploy", "/home/user/test.war");
    }
}
```

Deploying on Multiple Running Instances

You can use the `run` method to run the `deploy` asadmin command on multiple Payara Micro instances that belong to the same cluster. There are two `run` method variants available for running administration commands: One which runs an `asadmin` command on a subset of instances in a cluster, and another than runs an `asadmin` command on ALL instances in a cluster.

Here is an example of deploying an application to ALL instances in a cluster:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicroRuntime;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
        PayaraMicroRuntime runtime =
PayaraMicro.getInstance().setHttpAutoBind(true).bootstrap();

        // Run the deploy asadmin command on all instances in the runtimes cluster
        runtime.run("deploy", "/home/user/test.war");
    }
}
```

See the example for deploying on local instance on how to use the `run` method on a subset of instances in a cluster.

Deploying an Application Programmatically during Bootstrap

There are two methods you can use to deploy an application during Payara Micro's bootstrap process:

- `addDeployment(String pathToWar)`
- `addDeploymentFile(File file)`

The first, `addDeployment(String pathToWar)`, accepts a String that points to the path of the artefact to be deployed. For example:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
```

```
        PayaraMicro.getInstance().addDeployment("/home/user/example.war").bootStrap();
    }
}
```

The second method, `addDeploymentFile(File file)`, functions in the same way, but takes a `File` object instead:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;
import java.io.File;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
        File file = new File("/home/user/example.war");
        PayaraMicro.getInstance().addDeploymentFile(file).bootStrap();
    }
}
```

Unlike when controlling Payara Micro from the command line, you can split the instance initialization and configuration across multiple method invocations. For example, to deploy an application and start the instance on separate method calls, you can run the following code:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicro;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
        PayaraMicro micro = PayaraMicro.getInstance();
        micro.addDeployment("/home/user/example.war");
        micro.bootStrap();
    }
}
```

You can use this strategy to deploy multiple deployments by calling `addDeployment` multiple times, or use `setDeploymentDir` to point to a deployment directory that contains the applications to deploy.

Deploying an Application Programmatically After Bootstrap

There are three methods available for deploying an application to a running instance:

- `deploy(File war)`
- `deploy(String name, InputStream is)`
- `deploy(String name, String contextRoot, InputStream is)`

`deploy(File war)`

The first method works in the exact same way as the `addDeploymentFile` method described in the Deploying Programmatically during Bootstrap section.

`deploy(String name, InputStream is)`

This method allows you to deploy WAR files using an `InputStream`:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicroRuntime;
import java.io.FileInputStream;
import java.io.IOException;
import java.io.InputStream;
import java.util.logging.Level;
import java.util.logging.Logger;

public class EmbeddedPayara {
    public static void main(String[] args) throws BootstrapException{
        PayaraMicroRuntime instance = PayaraMicro.bootstrap();

        try (InputStream is = new FileInputStream("/home/user/test.war")){
            instance.deploy("test", is);
        }
        catch (IOException ex){
            Logger.getLogger(EmbeddedPayara.class.getName()).log(Level.SEVERE, null,
ex);
        }
    }
}
```

`deploy(String name, String contextRoot, InputStream is)`

This method works in the same way as the previous one, but allows you to specify the context root of the application at the same time. The following example would deploy the `test` application to a context root of `/app`:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;
import fish.payara.micro.PayaraMicroRuntime;
import java.io.FileInputStream;
import java.io.IOException;
import java.io.InputStream;
import java.util.logging.Level;
import java.util.logging.Logger;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
        PayaraMicroRuntime instance = PayaraMicro.bootstrap();
```

```
        try (InputStream is = new FileInputStream("/home/user/test.war")){
            instance.deploy("test", "app", is);
        }
        catch (IOException ex){
            Logger.getLogger(EmbeddedPayara.class.getName()).log(Level.SEVERE, null,
ex);
        }
    }
}
```

Deploying an Application Programmatically from a Maven Repository

Payara Micro supports the deployment of an application's artefact that is hosted in a Maven repository.

Deploying an Artefact Using Maven Coordinates

To deploy an application directly from a Maven repository, you will need to add a Maven GAV coordinate. This can be done using `addDeployFromGAV()` method. This method accepts a comma separated string denoting a maven artefact's `groupId`, `artifactId`, and `version` attributes.

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
       PayaraMicro.getInstance().addDeployFromGAV("fish.payara.testing,clusterjsp,
1.1").bootStrap();
    }
}
```

Specifying Additional Maven Repositories

By default, Payara Micro will only search for artefacts in the Maven Central repository. If you wish to search additional repositories, you can add them to the list of repositories to search with the `addRepoUrl()` method:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{

PayaraMicro.getInstance().addRepoUrl("https://nexus.payara.fish/repository/payara-
artifacts");

PayaraMicro.getInstance().addDeployFromGAV("fish.payara.testing,clusterjsp,1.1").bootS
trap();
```

```
    }
}
```

To search through multiple additional repositories, you can simply call the `addRepoUrl` method, and specify a comma-separated list of the URLs of each repository:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
       PayaraMicro micro = PayaraMicro.getInstance();
       micro.addRepoUrl("https://nexus.payara.fish/repository/payara-artifacts",
"https://maven.java.net/content/repositories/promoted/");
       micro.addDeployFromGAV("fish.payara.testing,clusterjsp,1.1");
       micro.bootStrap();
    }
}
```

Deploying Multiple Applications from a Maven Repository

To deploy multiple applications hosted in a Maven repository, you must call the `addDeployFromGAV` method for each application.For example, to deploy two applications:

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{
       PayaraMicro micro = PayaraMicro.getInstance();
       micro.addDeployFromGAV("fish.payara.testing,clusterjsp,1.1");
       micro.addDeployFromGAV("fish.payara.testing,demo,1.0");
       micro.bootStrap();
    }
}
```

Jar Structure and Configuration

Payara Micro Jar Structure

This page details the structure of the currents Payara Micro JAR file.

Payara Micro JAR folder structure

The following is an overview of the file structure for a Payara Micro JAR file:

```
payara-micro.jar
 ├─── fish
```

```
│   └── payara/micro/
├── META-INF
│   ├── MANIFEST.MF
│   └── maven/fish.payara.micro/payara-micro-boot/pom.xml
└── MICRO-INF
    ├── classes
    ├── deploy
    ├── domain
    ├── lib
    ├── payara-boot.properties
    ├── post-boot-commands.txt
    ├── pre-boot-commands.txt
    └── runtime
```

Structure Descriptions

Here's a brief summary of the folders and files that belong to the structure shown earlier:

File	Description
`fish/payara`	Payara Micro's class files.
`META-INF`	Contains the **Manifest** and **POM** files.
`MICRO-INF/classes`	Contains classes which are added to the class path before those in the `/runtime` folder.
`MICRO-INF/deploy`	Contains WAR, EAR, and EJB-JAR files for deployment.
`MICRO-INF/domain`	Contains the *domain.xml*, *default-web.xml*, keystores, *login.conf*, *logging.properties* files, and other files that are written to the temporary file directory.
`MICRO-INF/lib`	Contains additional third party dependency jars which will be automatically added to the instance's classpath.
`MICRO-INF/runtime`	Contains the core runtime jars.
`MICRO-INF/payara-boot.properties`	The System properties file containing Payara Micro runtime flags. This will override runtime flags and can be overridden by command-line arguments.
`MICRO-INF/<command-files>.txt`	**.txt** files containing asadmin commands to execute post boot can also be stored within MICRO-INF. This includes `pre-boot-commands`, `post-boot-commands`, and `post-deploy-commands`.

Nested JAR

Payara Micro has two options for unpacking classes:

Unpacking to File System (`--unpack`)

By default, Payara Micro will unpack the nested JARs into a temporary directory within the directory specified by either the system property `java.io.tmpdir` or the command line argument `--unpackdir`, and then load them as classes.

Unpacking to Memory (`--nested`)

The `--nested` argument will load the classes directly from the nested JARs to the memory without unpacking the JARs into a folder, but may slow the booting process.

To start Payara Micro as a nested JAR, use the `--nested` option as shown:

```
java -jar payara-micro.jar --nested
```

Adding Jars

There are multiple scenarios when it's needed to add a third-party library to the class path of a Payara Micro instance:

- Deploying applications that use JDBC resources, which have a need to access the respective JDBC driver JAR.
- Shared libraries used by multiple applications deployed on the same instance.
- Avoiding the creation of fat application WARs with lots of bundled libraries to simplify a build-integration pipeline.

Such scenarios are easily solved on Payara Server by adding these JAR files at the domain or modules of the application server library directories. On Payara Micro, this can be done on multiple ways.

From the command line

In order to add a third-party jar to a new Payara Micro instance, use the `--addLibs` argument when starting the instance like this:

```
java -jar payara-micro.jar --addLibs third-party.jar
```

You can specify a directory instead of a simple JAR to add all the JARs that are located in that directory:

```
java -jar payara-micro.jar --addLibs /home/payara-libs/
```

Finally, in order to add third-party libraries from multiple sources, specify each source (either a file or directory path) separating them using the colon character (`:`). Here's a simple example to add 3 sources for libraries:

```
java -jar payara-micro.jar --addLibs third-party.jar:/opt/application/jars:~/v/mysql-
jdbc-driver.jar
```

You may notice that this syntax is similar to the syntax used to specify the classpath using the `-cp` argument when running the JVM.

If you don't like using the previous syntax and prefer a simpler option, you can repeat the `--addLibs` argument as many times as you want per each JAR source, like in the following example:

```
java -jar payara-micro.jar --addLibs third-party.jar --addLibs /opt/application/jars
--addLibs ~/v/mysql-jdbc-driver.jar
```

This argument cannot be used when instance is started via link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Stopping and Starting Instances/Starting Instance.adoc[root directory launcher,role=unresolved].

It is however accepted when creating a launcher via `--outputlauncher` and provided libraries will be added to launcher's classpath.

Programmatically using the API

In order to add third-party libraries to a new Payara Micro instance programmatically, use the `PayaraMicro.addLibrary` method to properly add either JAR files or a directory of JAR files. You can call the method multiple times to each multiple sources.

For example, to add both a JAR file and a new directory of JAR files to a new instance use the following code:

```
public static void main(String[] args) throws BootstrapException {
    PayaraMicro instance = PayaraMicro.getInstance();
    instance.addLibrary(new File("~/my-library"));
    instance.addLibrary(new File("~/my-libs/"));
    instance.bootStrap();
}
```

Unlike other configuration methods of the `PayaraMicro` class, the `addLibrary` method **DOES NOT RETURN** a reference to the `PayaraMicro` object, which means that this method cannot be used for method-chaining style configuration. This is an issue which will be solved on a future release.

Packaging Libraries in an Uber JAR

When creating an Uber JAR using the `--outputUberJar` argument from the command line, all specified third-party libraries will be packaged on the resulting JAR. All added JARS will be located on the `MICRO-INF/lib` directory.

Here is an example to package 2 JDBC drivers (for MySQL and PostgreSQL) into an Uber JAR called `my-micro.jar`:

```
java -jar payara-micro.jar --addLibs postgresql.jar:mysql-connector-java.jar
--outputUberJar my-micro.jar
```

We can inspect this Uber JAR to verify that the third-party JAR files were packaged successfully:

```
> jar -tf my-micro.jar | grep "MICRO-INF/lib"

MICRO-INF/lib/
MICRO-INF/lib/postgresql.jar
MICRO-INF/lib/mysql-connector-java.jar
```

Root Directory

Payara Micro is distributed as a single JAR file. However, at runtime, it creates and depends on a folder structure that is referred to as Root Configuration Directory or `rootdir`.

This directory stores all of the instance configuration, deployed applications, as well as implementation JAR files needed for running the instance.

Temporary Root Configuration Directory

By default, Payara Micro will create a folder in the system's temporary directory and prepares a root configuration directory there. This makes instances' configuration stateless, but also has two potentially undesirable effects:

- Temporary directory may be deleted by system cleanup procedure. It is therefore important not to use a temporary directory in production scenarios. If files are removed by a third party process, the application will not behave correctly anymore.
- Preparing the directory has an impact on startup time

Persistent Root Configuration Directory

Root configuration directory can be explicitly specified with the command line parameter `--rootDir <directory>`. In such case, the directory is created only once, and instance configuration is preserved across restarts of the instance.

Following configuration is preserved:

- Deployed applications
- Effects of preboot, postboot and post-deploy commands
- Logging configuration

Clustering

A Payara Micro cluster is based on Hazelcast, similarly to how Hazelcast clustering works in Payara Server. Each node in a Payara Micro cluster is effectively a Hazelcast node.

This makes it easy to dynamically scale infrastructure setup, without any complex configuration or downtime required.

Lite Cluster Members

You may configure a Payara Micro instance as a Hazelcast *lite* node, meaning that the instance will join an existing cluster but will not store any data; like web session data or JCache data, for example.

To do this, use the `--lite` option when launching the instance through the command line.

You can create a cluster topology whereby a web application is hosted in a number of Payara Micro instances and the garbage collection ergonomics for these instances are tuned for throughput. In addition, a number of Payara Micro instances can be in the cluster with no applications deployed and these instances can be tuned for long-lived web session data. In this case, the web application instances could be designated as lite cluster members to make sure no web session data is stored within their JVMs.

Lite members can also be used purely if you want a clustered Payara Micro instance to join the same cluster and receive CDI events or clustered events, but without storing any data.

Automatic Clustering

Payara Micro has the ability to auto-cluster, since by default it uses the Multicast discovery mode.

Discovery Modes

Like in Payara Server, the following discovery modes are supported in Payara Micro:

Multicast Discovery Mode

The integration of Hazelcast into Payara Micro allows instances to automatically and dynamically cluster together when two instances or more instances are pointed at the same multicast address and port.

Example

Start two Payara Micro instances (with different HTTP port configurations or use `--autobindhttp`), and you should see the following output:

```
Members [2] {
Member [192.168.174.130]:5900 this
Member [192.168.174.130]:5901
```

The `--startPort` option is used to determine which clustering port the Payara Micro instance will **first** try to bind to. If the port is already bound to then the Payara Micro instance will simply increment the *startPort* value and try again until it finds a port it can bind to.

Preventing Multicast Cluster Cross Talk

By default Payara Micro clusters automatically discover other cluster members via multicast. This can lead to the situation whereby different development environments that are used by different teams may unintentionally cluster together as they are using the same multicast address and multicast port.

If you wish to separate multiple clusters, then you can use the `--mcAddress` and `` `--mcPort `` options to define a different multicast address and port; assign a different address and port to each set of instances you wish to run in a separate cluster and they will automatically make their own cluster on the new multicast address and port.

You can also use `--clusterName` and `--clusterPassword` to separate clusters. If all other multicast settings are similar, instances will only cluster together if all the instances have the same cluster name and cluster password.

Domain Discovery Mode

Domain Discovery Mode enables a Payara Micro instance to join an existing Domain Data Grid managed by a Payara Server DAS. To join a Domain Data Grid start the Micro instance in domain cluster mode:

```
java -jar payara-micro.jar --clustermode domain:192.168.0.64:4900
```

The format of the domain cluster mode is `domain:ip:port` where `ip` is the IP network address that the Hazelcast instance is bound to in the DAS.

Hazelcast is very particular about the IP address used to join a cluster. The IP Address should be exactly as reported by the details

When the DAS starts it will log output similar to this one:

```
Data Grid Status
Payara Data Grid State: DG Version: 35 DG Size: 2
Instances: {
Address: /192.168.0.104:4900 UUID: 7c1bd6ca-1574-4e38-9189-effcd4ccafd2 Lite: false
This: true Name: server Group: server-config
Address: /192.168.0.104:5900 UUID: 0f6887b2-9932-4085-a6f8-e40751269023 Lite: false
This: false
}
```

This shows the IP address and ports that can be used as input into the domain cluster mode.

If you accidentally choose the DAS admin port (by default 4848) as the cluster port you will get a warning like the following:

```
[2018-03-08T13:51:46.446+0000] [] [WARNING] []
[fish.payara.nucleus.hazelcast.DomainDiscoveryService] [tid: _ThreadID=1
_ThreadName=main] [timeMillis: 1520517106446] [levelValue: 900] You have specified
4848 as the datagrid domain port however this is the default DAS admin port, the
default domain datagrid port is 4900
```

TCPIP Discovery Mode

The TCPIP Discovery Mode can be used to cluster Payara Micro instances when multicast is not available on the network. This is especially useful in Cloud environments or in containerized deployments like Docker and Kubernetes. For the TCPIP discovery mode you specify a comma separated list of `ip:port` addresses where you believe other instances will be listening.

Hazelcast is very particular about the IP address used to join a cluster. The IP Address should be exactly as reported by the details

For example the following command will cluster two Payara Micros together when multicast is not available:

```
java -jar payara-micro.jar --autobindhttp --clustermode
tcpip:192.168.0.104:6900,192.168.0.104:6901
java -jar payara-micro.jar --autobindhttp --clustermode
tcpip:192.168.0.104:6900,192.168.0.104:6901
```

A range of IP addresses can be specified in the list of members for example: `192.168.1.0-7:6900`. This is especially useful if you have a cloud VPC and you have a number of Payara Micro instances running across a number of Cloud VMs. Using a range is also useful in Docker environments where the range of IP Addresses is known but dynamic for example `172.17.0.2-8:6900`.

During discovery Payara Micro will test each `IP:Port` combination until it finds another Payara Micro instance. As long as one instance exists then it will join the existing cluster. If no Payara Micro instances are contactable the instance will create a new cluster with itself as the single member.

TCPIP cluster mode can also be used to join an existing Payara Server Domain Data Grid by specifying the `ip:port` of the DAS Hazelcast's instance.

DNS Discovery Mode

The DNS Discovery mode can be used to cluster Payara Micro instances by specifying a DNS name. Similar to the TCPIP discovery mode, this discovery mode takes a comma separated list of DNS **A** /**AAAA** record names and ports to determine where to look for instances to cluster with, like this:

```
java -jar payara-micro.jar --autobindhttp --clustermode
dns:localhost:6900,ubuntu:6900,suse:6900
```

If there are multiple IP addresses associated with a DNS name, Payara Micro will attempt to cluster with all of them.

Kubernetes Discovery Mode

The Kubernetes discovery mode can be used to cluster Payara Micro instances running in a Kubernetes cluster, which can be useful due to the variable networking inherent to the technology. When using this discovery mode, the default settings will make Payara Micro attempt to cluster with instances present on Pods within the default namespace:

```
java -jar payara-micro.jar --autobindhttp --clustermode kubernetes
```

Optionally, you can provide a Kubernetes namespace and service name separated by a comma. Payara Micro will then attempt to cluster with instances present on pods within the specified namespace and service. If using the latter option, you must provide BOTH a namespace and service name, as these options cannot be used individually.

```
java -jar payara-micro.jar --autobindhttp --clustermode kubernetes:default,service1
```

This discovery mode internally uses the Hazelcast Kubernetes plugin, and so you will need to grant specific permissions to query the Kubernetes master node. As per the plugin documentation, you will need to apply the following permissions using the `kubectl apply` command:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: default-cluster
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: view
subjects:
- kind: ServiceAccount
  name: default
  namespace: default
```

Network Interfaces

If Hazelcast chooses the incorrect IP Address to bind to (for example a docker interface) the `--interfaces` command line option can be used to force Hazelcast to use the specified network interface and prevent second-guesses:

```
java -jar payara-micro.jar --autobindhttp --clustermode
tcpip:192.168.0.104:6900,192.168.0.104:6901 --interfaces 192.168.0.104
```

HTTP(S) Auto-Binding

Payara Micro supports an auto-binding feature for its HTTP and HTTPS port, allowing Payara Micro to dynamically find a free HTTP or HTTPS port as required during startup.

This feature is controlled through these three options:

`--autoBindHttp`
: Enables auto-bind functionality for the HTTP port

`--autoBindSsl`
: Enables auto-bind functionality for the HTTPS port

`--autoBindRange`
: Sets the range for the auto-bind feature

When auto-binding is enabled, Payara Micro will attempt to connect to the port specified with the `--port` or `--sslPort` option (or, if these options are not specified, to port **8080** and **8181** respectively), and if that port is busy, it will instead try to bind on the next port up, repeating this process until it finds a free port, or the `--autoBindRange` limiter is reached.

For example, if ports **8080** and **8081** were busy, and ports **8082** and **8182** were free, then starting Payara Micro with the following command would have the HTTP port bind to **8082** and the HTTPS port bind to **8182**:

```
java -jar payara-micro.jar --autoBindHttp --sslPort 8181 --autoBindSsl
```

Whereas the following would fail to start in the same situation because `--autoBindRange` is not large enough (no free port within the range of **8080-8081**):

```
java -jar payara-micro.jar --port 8080 --autoBindHttp --sslPort 8181 --autoBindSsl
--autoBindRange 1
```

Be aware that the auto-bind feature does not currently read port values from domain.xml files; if the `--port` and `--sslPort` options are not used, then the `--autoBindHttp` and `--autoBindSsl` options will assume that the HTTP and HTTPS ports will be at the default values of 8080 and 8181 respectively.

Command Line Options

All of the options listed below are case-insensitive starting from release `4.1.1.171`; prior versions need the option to be set with camelCase notation

Configuration Option	Description	Default Value
`--accesslog <directory-path>`	Sets user defined directory path for the access log.	
`--accesslogformat`	Sets user defined log format for the access log.	"%client.name% %auth-user-name% %datetime% %request% %status% %response.length%"
`--accessloginterval`	Sets user defined access log write interval.	300
`--accesslogsuffix`	Sets user defined simple date time suffix for access log filenames.	`yyyy-MM-dd`
`--accesslogprefix`	Sets user defined prefix for access log filenames.	
`--additionalrepository <repo-url>`	Specifies an additional repository to search for deployable artefacts in. Supports BASIC authentication. For example https://USER:PASSWORD@example.payara.fish/repositories/repo/. You may also use aliases https://USER:{ALIAS=ALIAS_NAME}@example.payara.fish/repositories/repo/	
`--addjars <jar-path>`	*Deprecated.* Use `--addlibs` instead	
`--addlibs <file or directory path>`	<file-or-directory-path> add specified jar files into classloader, or packaged into an Uber JAR. Multiple files can be specified as colon separated values.	
`--autobindhttp`	Enables auto-binding for the HTTP port.	*false*

Configuration Option	Description	Default Value
`--autobindrange <number-of-ports>`	Sets the range for HTTP and HTTPS port auto-binding.	5
`--autobindssl`	Enables auto-binding for the HTTPS port.	*false*
`--clustermode`	Modifies the cluster discovery mode of Payara Micro when finding members of the cluster. Options are: • `multicast:group:port` • `tcpip:host:port` • `domain:dashost:port`	multicast
`--clustername <cluster-name>`	Sets the cluster group name.	
`--clusterpassword <cluster-password>`	Sets the cluster group password.	
`--contextroot <context-path>`	Sets the context root of the application originating from the `--deploy` option given first that does not specify a context root itself. See link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Deploying Applications/Deploy Applications.adoc#define-context-root[Define context root,role=unresolved] for more details.	
`--copytouberjar <directory-path`	<directory-path> copy a directory into the root of an uber JAR	
`--deploy <file-path>[:<context-path]`	Specifies a WAR file to deploy and optionally the context path to use for that application.	If not set, has no value and is not used.
`--deploydir <directory-path>`	Sets a directory which will be scanned for EAR, WAR, and RAR files for auto-deployment.	If not set, has no value and is not used.

Configuration Option	Description	Default Value
`--deployfromgav <list-of-artefacts>`	Specifies a comma separated `groupId`, `artifactId`, `versionNumber` of an artefact to deploy from a repository.	
`--deploymentdir <directory-path>`	See `--deploydir`.	
`--disablephonehome`	Disables the *Phone Home* service for this instance.	If not set, the *Phone Home* service is active.
`--domainconfig <file-path>`	Overrides the server configuration with an alternative *domain.xml* file.	If not set, the domain.xml contained in the Payara Micro JAR is used.
`--enableDynamicLogging`	Watch the logging properties file for changes, and apply them dynamically	
`--enablehealthcheck <boolean>`	enables/disables the HealthCheck Service.	*false*
`--enablerequesttracing`	Enables the Request Tracing Service and optionally sets the threshold unit and/or value.	
`--enablerequesttracingadaptive sampling <boolean>`	<boolean> Enables the adaptive sampling. Can also be enabled by configuring any one of the adaptive sampling configuration options	
`--globalcontextroot <context-path>`	Sets the global context root of any deployed application. This will prepend the context root. See link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Deploying Applications/Deploy Applications.adoc#define-global-context-root[Define global context root,role=unresolved] for more details.	
`--group <group-name>`	Sets the instance's group.	
`--help`	Displays the configuration options and then exits.	If not set, this option is not used.

Configuration Option	Description	Default Value
`--hostaware`	Enable Host Aware Partitioning. When enabled cluster backups will not be stored on members with the same IP Address.	*false*
`--hzconfigfile <file-path>`	Sets the Hazelcast configuration file to use for overriding the built-in Hazelcast cluster configuration.	If not set, the built-in Hazelcast configuration file is used.
`--hzinitialjoinwait <time in seconds>`	Sets the time in seconds for Payara Micro to wait before attempting to join the data grid.	1
`--hzPublicAddress <host-name or ip>`	The Public Address to use for this Data Grid Node. Used when the node is behind a NAT	
`--instancegroup <group-name>`	See `--group`	
`--interfaces`	Specifies the Interfaces that the data grid discovery mode should use to listen. Can be comma separated, e.g. 127.0.0.1,192.168.0.*	
`--lite`	Sets the micro container to lite mode, which means it clusters with other Payara Micro instances but does not store clustered data.	*false*
`--logo`	Reveals either the **#BadAssFish** or a custom logo on boot.	
`--logproperties <file-path>`	Allows user to set their own logging properties file.	
`--logtofile <file-path>`	Outputs all the Log entries to a user defined file.	
`--maxhttpthreads <max-thread-count>`	Sets the maximum number of threads in the HTTP thread pool.	10
`--mcaddress <multicast-address>`	Sets the cluster multicast group if multicast cluster mode is selected. See `--clustermode`.	
`--mcport <multicast-port>`	Sets the cluster multicast port if multicast cluster mode is selected. See `--clustermode`.	2904

Configuration Option	Description	Default Value
`--minhttpthreads <min-thread-count>`	Sets the minimum number of threads in the HTTP thread pool.	10
`--name <instance-name>`	Sets the instance name.	Generated Universally Unique Identifier *(Adjective-Fish)*.
`--nested`	Do not unpack the Nested Jars when booting the server. This is generally slower than unpacking the runtime.	*false*
`--nocluster`	Disables clustering for this instance.	*false*
`--noHazelcast`	Disables Hazelcast and clustering for this instance.	*false*
`--nohostaware`	Disables Host Aware Partitioning. See `--hostaware`	
`--outputuberjar <file-path>`	Packages up an Uber JAR at the specified path based on the provided command line arguments and exit.	
`--outputlauncher`	Create launcher `launch-micro.jar` into the root directory that is specified by `--rootdir` and exit.	
`--port <http-port-number>`	Sets the HTTP port that the instance will bind to.	8080
`--postbootcommandfile <file-path>`	Provides a file of asadmin commands to run **after booting the server**.	
`--postdeploycommandfile <file-path>`	Provides a file of asadmin commands to run **after all deployments have completed**.	
`--prebootcommandfile <file-path>`	Provides a file of asadmin commands to run **before booting the server**.	
`--requesttracingadaptivesamplingtargetcount`	The target number of traces to sample per the configured time window	6

Configuration Option	Description	Default Value
`--requesttracingadaptivesamplingtimeunit`	The time unit for the adaptive sample time; a `java.util.concurrent.TimeUnit` value (also in singular) or one of the short forms: `ns`, `us`/`µs`, `ms`, `s`, `m`/`min`/`mins`, `h` or `d`.	MINUTES
`--requesttracingadaptivesamplingtimevalue`	The period of time to attempt to hit the adaptive sample target count in	1
`--requesttracingthresholdunit <threshold-unit-notation>`	Sets the time unit for the requestTracingThresholdValue option, i.e. `SECONDS`, `ms`, `days` etc.	
`--requesttracingthresholdvalue <threshold-unit-value>`	Sets the threshold time before a request is traced.	
`--rootdir <directory-path>`	Sets the root configuration directory and saves the configuration across restarts.	Defaults to `java.io.tmpdir`.
`--secretsdir`	Directory to read configuration from key-value files using the Microprofile config api.	
`--shutdowngrace <duration-ms>`	After server shutdown is initiated the server waits this period of time to finish ongoing requests before terminating. Currently, new requests are still accepted during this grace period.	0
`--sslport <ssl-port-number>`	Sets the HTTPs port that the instance will bind to.	If not set, has no value and HTTPS is disabled.
`--sslcert <certificate-name>`	Sets the SSL certificate name to be used from the keystore for SSL	`s1as`
`--startport <cluster-start-port-number>`	Sets the cluster start port number.	5900
`--systemproperties <file-path>`	Reads system properties from a file.	
`--unpackdir <directory-path>`	Unpack the Nested Jar runtime jars to the specified directory.	Unpack to `java.io.tmpdir`.
`--version`	Displays the version information	

Configuration Option	Description	Default Value
`--warmup`	Exit the server immediately after configuration is done, applications are deployed and it's ready to serve requests.	

Disable Phone Home

Payara Micro, like Payara Server, has the Phone Home functionality enabled by default. It can be easily disabled in Payara Micro.

Disable Phone Home for Payara Micro

When starting Payara Micro, the Phone Home Service can be disabled with the command-line argument `--disablephonehome`:

```
java -jar payara-micro.jar --disablephonehome
```

See Also

- Phone Home in Payara Server

Asadmin Commands

Pre and Post Boot Commands

Administration commands can also be run against a Payara Micro instance at specific moments in its lifecycle. To do this, you must provide the commands you wish to execute in special scripts via a command line option.

Structure of a Boot Script

Boot scripts are simple text files that contain the *asadmin* subcommands used to configure the instance. These scripts will follow these set of rules:

1. Each *asadmin* command must be represented in one line of text in the script. No line breaks are allowed.
2. Each *asadmin* command must be formatted on the syntax `subcommand [options] [operands]`, as if you were running the commands in a multimode session from the command line.
3. Empty lines and comment lines (starting with the `#` character) are ignored.
4. Each *asadmin* command may contain variable references (e.g. to environment variables or system properties) as described in Using variables

asadmin commands that contain spaces in the value should be surrounded with quotations marks and nested quotation marks must be escaped with the `\` character.

Here's a sample of a post boot script used to configure an instance for production uses:

```
#Disable dynamic reloading of applications
set configs.config.server-config.admin-service.das-config.dynamic-reload-enabled=false

# Set a system property which contains spaces and quotation marks in the property
value
create-system-properties "property.name=This is a \"property\" value"
#Disable auto deployment
set configs.config.server-config.admin-service.das-config.autodeploy-enabled=false

#Optimizing Heap size
delete-jvm-options -client:-Xmx1024:-Xms512
create-jvm-options -server:-Xmx2048:-Xms2048

#Configuring Hazelcast cluster
set-hazelcast-configuration --clusterName=my-production-cluster --target=server-config

#Using a reference to a system property payara.deployed-app-name
set configs.config.server-config.http-service.virtual-server.server.default-web-
module=${payara.deployed-app-name}

#Using a reference to an environment variable security-enabled
set configs.config.server-config.network-config.protocols.protocol.http-listener-
1.security-enabled=${ENV=security-enabled}
```

Configuring Boot Scripts

When running Payara Micro from the command line, use appropriate command file options to specify the script file locations and the moment in the boot lifecycle when they should be executed:

`--prebootcommandfile`
: provides a file of asadmin commands to run before booting the server (only some commands work at this point)

`--postbootcommandfile`
: provides a file of asadmin commands to run after booting the server

`--postdeploycommandfile`
: provides a file of asadmin commands to run after all deployments have completed

For example:

```
java -jar payara-micro.jar --prebootcommandfile prepare-resources.txt
--postbootcommandfile ready-production-use.txt --postdeploycommandfile post-process-
apps.txt
```

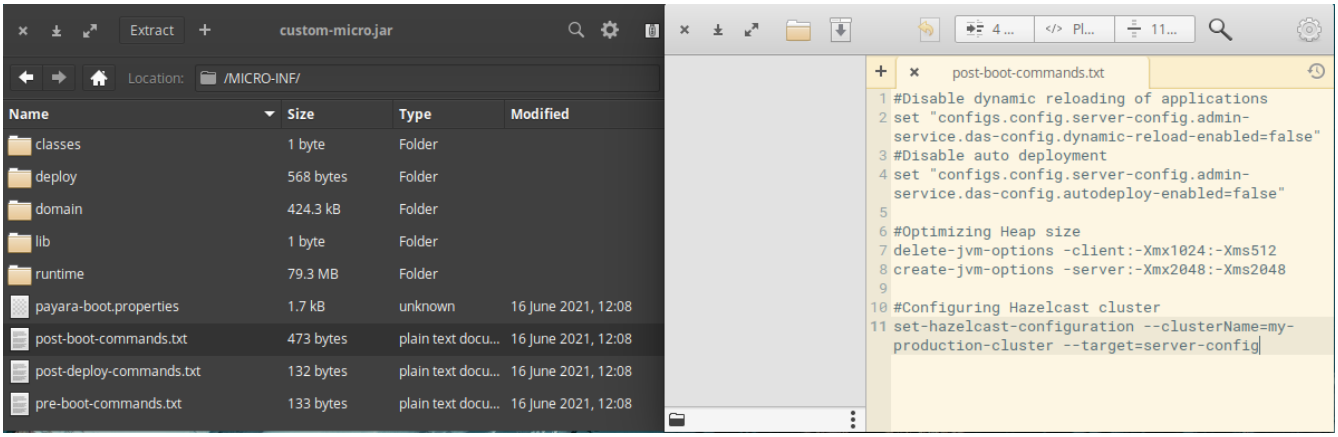
When creating an Uber JAR using the `--outputUberJAR` option, the scripts are transferred into the

`MICRO-INF/` directory of the resulting JAR artifact as the `pre-boot-commands.txt`, `post-boot-commands.txt` and `post-deploy-commands.txt` files.

For example, when generating the Uber JAR like this:

```
java -jar payara-micro.jar --prebootcommandfile prepare-resources.txt
--postbootcommandfile ready-production-use.txt --outputUberJar custom-micro.jar
```

Examining the JAR structure will confirm that the scripts have been transferred correctly:



Boot Scripts with Persistent Root Directory

A command in a boot script usually results in change of configuration in `config/domain.xml`. When persistent root directory is reused between restarts, it may cause some commands to fail, particularly those that create new resources, like for example `create-jdbc-connection-pool`. However, failure of a script command is not critical for server startup, just a warning is logged in such case.

By utilizing `--warmup`, these commands can be run as part of preparation of root directory rather than run on every startup. That also spares startup time for productive instance.

When a command uses variable references, the values for variables are determined during execution of the script, before executing the command and changing the configuration. If a variable value should be evaluated each time Payara Micro starts, then executing a script in `--warmup` mode will not suffice and the script needs to be passed as argument also for productive runs.

Restrictions on Pre-boot Scripts

Keep in mind when writing a **pre-boot** command script, that the commands prepared will be running before the server has booted, which means not all available asadmin subcommands will yield results (for example deploying or listing applications).

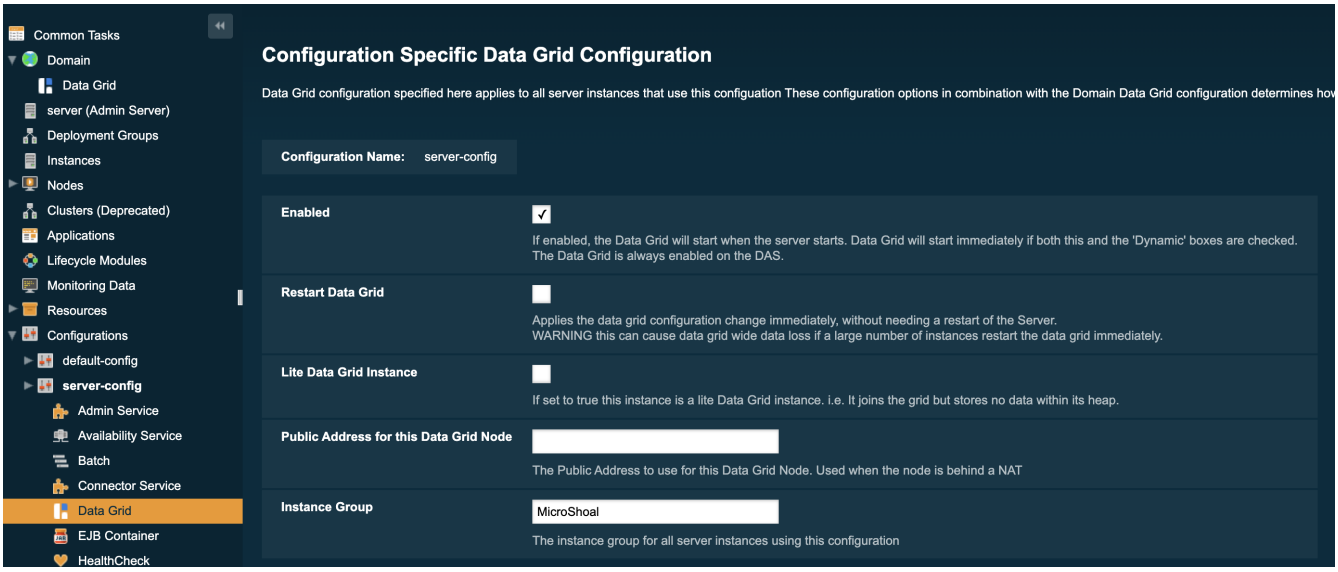
It's recommended to create *preboot* scripts that use simple set commands to change the configuration of existing resources (adding new resources might not work in all cases) like network listeners, standard domain configuration and such.

Send Asadmin Commands from Admin Console

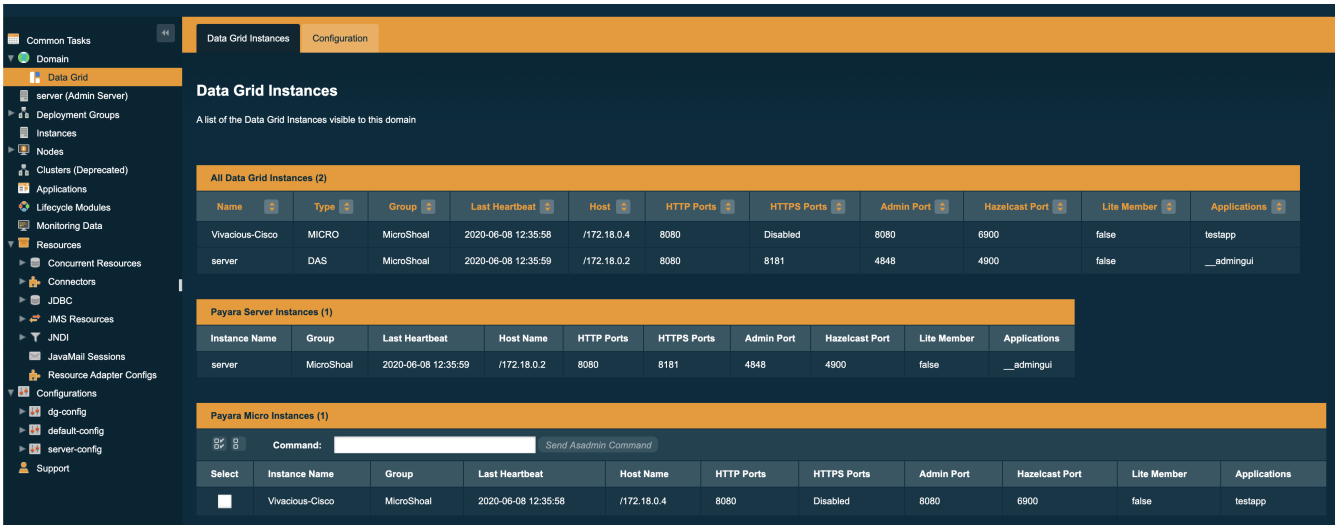
Asadmin commands can be sent from the Domain Administration Server (DAS) to Payara Micro instances that are running within the same data grid as the DAS.

How to Send Asadmin Commands To Payara Micro using the Admin Console

Sending an Asadmin command is performed through the Domain Data Grid. This Data Grid is powered by Hazelcast and is enabled by default. You can verify if it actived by looking under the *server-config* configuration under the *Data Grid* item.

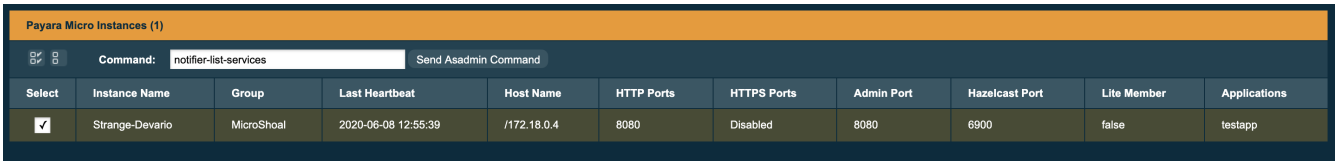


All the members can be seen under the *Data Grid* entry of the Domain item on the left menu. At the bottom of the page, you will find a table filled with the Payara Micro instances:



To send an administration command:

1. Select the recipient nodes
2. Enter the asadmin command in the textbox
3. Press **Send Asadmin Command**



Sending Asadmin Commands from the Command Line

To send administration commands using the command line there is a new `asadmin` command for the Domain Administration Server - `send-asadmin-command`. The asadmin command is entered using the `--command` option, which only accepts a single command as an input (including said commands own arguments).

As an example of sending a command from the command line:

```
asadmin send-asadmin-command --command deploy /home/user/application
--contextRoot=/example
```

Database Management

Log JDBC Calls

Payara Micro supports SQL Tracing which brings powerful operational diagnostics to your microservices platform.

Enabling Logging JDBC Calls

To enable SQL Tracing of JDBC on applications deployed on Payara Micro, use can use the annotation or deployment descriptor methods described below.

Application Deployment

In Java EE 7+ applications, a JDBC data source can be deployed by adding the `@DataSourceDefinition` annotation to a managed component (like and `@Stateless` EJB bean for example). The **Log JDBC Calls** setting can be configured using this annotation as well:

```
@DataSourceDefinition(
    name = "java:app/MyApp/MyDS",
    className = "org.h2.jdbcx.JdbcDataSource",
    url = "jdbc:h2:mem:test",
    properties = {"fish.payara.log-jdbc-calls=true"})
```

The Data source definition can also be added to a deployment descriptor of an application, for example in the *web.xml* standard deployment descriptor:

```
<data-source>
   <name>java:global/ExampleDataSource</name>
   <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
   <server-name>localhost</server-name>
```

```
    <port-number>3306</port-number>
    <database-name>mysql</database-name>
    <user>test</user>
    <password>test</password>
    <!-- Example of how to use a Payara specific custom connection pool setting -->
    <property>
        <name>fish.payara.log-jdbc-calls</name>
        <value>true</value>
    </property>
</data-source>
```

or in the definition of a `jdbc-connection-pool` in a *payara-resources.xml* file:

```
<jdbc-connection-pool name="examplePool"
        res-type="javax.sql.DataSource"
        datasource-classname="org.h2.jdbcx.JdbcDataSource" log-jdbc-calls="true">
    <property name="user" value="test"/>
    <property name="password" value="test"/>
    <property name="url" value="java:global/ExampleDataSource"/>
</jdbc-connection-pool>
```

This can also be done in the creation of a JDBC Connection Pool with the `--logjdbccalls` option.

```
asadmin create jdbc-connection-pool --datasourceclassname org.h2.jdbcx.JdbcDataSource
--restype javax.sql.XADataSource --logjdbccalls=true examplePool
```

- SQL Trace Listeners in Payara Micro
- SQL in Payara Server

SQL Trace Listeners

Payara Micro also supports SQL Trace Listeners which brings powerful operational diagnostics to your microservices platform.

Adding a SQL Trace Listener

To add a SQL Trace Listener to your data source used by applications deployed on Payara Micro, you can use the annotation or deployment descriptor methods described below.

Application Deployment

In Java EE 7+ applications, a JDBC data source can be deployed by adding the `@DataSourceDefinition` annotation to a managed component (like and `@Stateless` EJB bean for example). SQL Trace Listener classes can be configured using this annotation, like in the following example:

```
@DataSourceDefinition(
    name = "java:app/MyApp/MyDS",
    className = "org.h2.jdbcx.JdbcDataSource",
    url = "jdbc:h2:mem:test",
    properties = {"fish.payara.sql-trace-
listeners=fish.payara.examples.payaramicro.datasource.example.CustomSQLTracer"})
```

The Data source definition can also be added to a deployment descriptor of an application, for example in the *web.xml* standard deployment descriptor:

```
<data-source>
    <name>java:global/ExampleDataSource</name>
    <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
    <server-name>localhost</server-name>
    <port-number>3306</port-number>
    <database-name>mysql</database-name>
    <user>test</user>
    <password>test</password>
    <!-- Example of how to use a Payara specific custom connection pool setting -->
    <property>
       <name>fish.payara.sql-trace-listeners</name>

<value>fish.payara.examples.payaramicro.datasource.example.CustomSQLTracer</value>
    </property>
</data-source>
```

- SQL in Payara Server

Slow SQL Logger

Payara Micro supports slow logging of SQL queries which brings powerful operational diagnostics to your microservices platform.

Enabling Slow SQL Logging

To enable it on applications deployed on Payara Micro, you can use the annotation or deployment descriptor methods described below.

Application Deployment

In Java EE 7+ applications, a JDBC data source can be deployed by adding the `@DataSourceDefinition` annotation to a managed component (like and `@Stateless` EJB bean for example). The **Slow Query Log Threshold** time can be configured using this annotation, like in the following example:

```
@DataSourceDefinition(
    name = "java:app/MyApp/MyDS",
    className = "org.h2.jdbcx.JdbcDataSource",
    url = "jdbc:h2:mem:test",
    properties = {"fish.payara.slow-query-threshold-in-seconds=5"})
```

The Data source definition can also be added to a deployment descriptor of an application, for example in the *web.xml* standard deployment descriptor:

```
<data-source>
    <name>java:global/ExampleDataSource</name>
    <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
    <server-name>localhost</server-name>
    <port-number>3306</port-number>
    <database-name>mysql</database-name>
    <user>test</user>
    <password>test</password>
    <!-- Example of how to use a Payara specific custom connection pool setting -->
    <property>
       <name>fish.payara.slow-query-threshold-in-seconds</name>
       <value>5</value>
    </property>
</data-source>
```

Logging and Monitoring

Logging

Logging to File

This section describes how to print all the Payara Micro log messages into a file.

Logging to a file from the Command Line

To print all of the Payara Micro log messages into a file from the command line, you will need to use the `--logToFile` option, followed by either a path to where you want to put the log file or by giving the name of a file you want to print the logs into. If a file name is not given, a default file called *payara-server.log* is generated.

```
java -jar payara-micro.jar --logToFile /home/user/PayaraMicro.log
```

Logging to a file Programmatically

To print all the Payara Micro log messages into a file programmatically, you will need to use `setUserLogFile(String filePath)` method.

```
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.BootstrapException;

public class EmbeddedPayara{
    public static void main(String[] args) throws BootstrapException{

PayaraMicro.getInstance().setUserLogFile("/home/user/PayaraMicro.log").bootStrap();
    }
}
```

Configuration

You can specify a `Logging Properties File` to configure the JUL logger for Payara Micro.

Options	Type	Description	Default	Mandatory
`--logProperties`	`String`	File with logging configuration		No
`--enableDynamicLogging`	`Boolean`	Enable dynamic reloading of configuration	False	No

Example

You can provide a logging configuration file that uses the standard JUL notation RDP Logging Config

```
java -jar payara-micro.jar --logProperties micro-logging.properties
--enableDynamicLogging --deploy myapplication.war
```

Config Access Log

Payara Micro supports a number of commands to help you configure access logging. It is easiest to configure access logging before it is bootstrapped, however you can edit `domain.xml` also, as Payara Micro can reload that dynamically.

Configuration Option	Description	Default Value
`--accesslog <directory-path>`	Sets user defined directory path for the access log	
`--accesslogformat`	Sets user defined log format for the access log	`%client.name% %auth-user-name% %datetime% %request% %status% %response.length%`

Configuration Option	Description	Default Value
`--accessloginterval`	Sets user defined access log write interval	300
`--accesslogsuffix`	Sets user defined simple date time suffix for access log filenames	`yyyy-MM-dd`
`--accesslogprefix`	Sets user defined prefix for access log filenames	

All options available for configuring Payara Micro can be seen by running the JAR with the `--help` option, or by consulting link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Command Line Options/Command Line Options.adoc[Payara Micro Command Line Options,role=unresolved]

Usage Examples

Configuration Option	Usage	Result
`--accesslog`	`java -jar payara-micro --accesslog ~/logs/accesslogs`	Access logging is enabled
`--accesslogformat`	`java -jar payara-micro --accesslog ~/logs/accesslogs --accesslogformat %u %t %s %b`	Payara [22/11/2019:09:24:36 00] 200 532
`--accessloginterval`	`java -jar payara-micro --accesslog ~/logs/accesslogs --accessloginterval 0`	Access log write interval is set to write its buffer to file immediately
`--accesslogsuffix`	`java -jar payara-micro --accesslog ~/logs/accesslogs --accesslogsuffix %hh%mm%a`	server_access_log.%09%30%AM .txt
`--accesslogprefix`	`java -jar payara-micro --accesslog ~/logs/accesslogs --accesslogprefix Production`	Production.2019-11-22.txt

Request Tracing

The Request Tracing service works the same on Payara Micro and will trace the same events described in its documentation.

Usage

Payara Micro exposes a number of command line options to configure request tracing. These options cover the most frequent use cases for Payara Micro, but you can also configure the Request Tracing Service using a **post**-boot command file, giving you access to the asadmin commands and the full range of options they provide.

Configuration Options

Parameter	Summary
`enableRequestTracing`	Enables the service when present. A supplementary parameter can be provided with this option to encapsulate the value and unit options, for example, the following will enable the service with a threshold of `4ms`: ``` java -jar payara-micro.jar --enableRequestTracing 4ms ```
`requestTracingThresholdUnit`	Accepts a String value determining the time unit, defaulting to seconds if no value is given. The accepted strings are (case-insensitive): • `NANOSECONDS` • `MICROSECONDS` • `MILLISECONDS` • `SECONDS` • `MINUTES` • `HOURS` • `DAYS` This is combined with the `requestTracingThresholdValue` setting to determine the threshold time period.
`requestTracingThresholdValue`	Accepts an integer value to determine the threshold value before a request is traced, defaulting to 30 if no value is entered. This is combined with the `requestTracingThresholdUnit` setting to determine the threshold time period.
`enablerequesttracingadaptivesampling`	Enables the *Adaptive Sampling* option when present. When enabled, this allows the sample rate to change to attempt to meet a target count of traces over a specified period of time.
`requesttracingadaptivesamplingtargetcount`	Accepts an integer value to determine the threshold value before a request is traced, defaulting to 6 if no value is entered. Only used if adaptive sampling is enabled.

Parameter	Summary
`requesttracingadaptivesamplingtimevalue`	Accepts an integer value to determine the threshold value before a request is traced, defaulting to 1 if no value is entered. Only used if adaptive sampling is enabled. This is combined with the `requesttracingadaptivesamplingtimeunit` setting to determine the adaptive sampling time period.
`requesttracingadaptivesamplingtimeunit`	Accepts a String value determining the time unit, defaulting to minutes if no value is given. The accepted strings are (case-insensitive): • `NANOSECONDS` • `MICROSECONDS` • `MILLISECONDS` • `SECONDS` • `MINUTES` • `HOURS` • `DAYS` This is combined with the `requesttracingadaptivesamplingtimevalue` setting to determine the adaptive sampling time period. Only used if adaptive sampling is enabled.

Shorthand Notation

To enable and configure request tracing with a single command, the `--enableRequestTracing` option allows you to provide **one** string following it to set the threshold unit and/or value.

In other words, the value and unit need to be a single string with no spaces, so `500ms` would be allowed, but `500 ms` would not. In the second case, the unit is ignored and the default `SECONDS` is kept.

Notation for units is as follows:

Unit	Acceptable notation
`NANOSECONDS`	• `Nanoseconds` (case-insensitive) • `Nanosecond` (case-insensitive) • `ns`
`MICROSECONDS`	• `Microseconds` (case-insensitive) • `Microsecond` (case-insensitive) • `us` • `µs`

Unit	Acceptable notation
`MILLISECONDS`	• `Milliseconds` (case-insensitive) • `Millisecond` (case-insensitive) • `ms`
`SECONDS`	• `Seconds` (case-insensitive) • `Second` (case-insensitive) • `s`
`MINUTES`	• `Minutes` (case-insensitive) • `Minute` (case-insensitive) • `Mins` (case-insensitive) • `Min` (case-insensitive) • `m`
`HOURS`	• `Hours` (case-insensitive) • `Hour` (case-insensitive) • `h`
`DAYS`	• `Days` (case-insensitive) • `Day` (case-insensitive) • `d`

Example usages

`java -jar payara-micro.jar --enableRequestTracing`

Enable request tracing

`java -jar payara-micro.jar --enableRequestTracing ns`

Enable request tracing and set threshold unit to nanoseconds (`value` *defaults to* `30`)

`java -jar payara-micro.jar --enableRequestTracing 2`

Enable request tracing and set threshold value to 2 (`unit` *defaults to* `SECONDS`)

`java -jar payara-micro.jar --enableRequestTracing 4ms`

Enable request tracing and set threshold to 4 microseconds

Exercise caution when using the shorthand notation together with other parameters. Due to the way the parser works, the last parameter entered will override the previous. For example:

```
java -jar payara-micro.jar --requestTracingThresholdUnit DAYS
--enableRequestTracing 1ns
```

Will enable request tracing, and set the threshold to `1 NANOSECOND`, while

```
java -jar payara-micro.jar --enableRequestTracing 1ns
--requestTracingThresholdUnit DAYS
```

Will enable request tracing, and set the threshold to `1 Day`

API

JCache in Payara Micro

Payara Micro provides JCache functionality and the documentation for using JCache in Payara Server also applies to it.

Payara Micro API

Overview

This section details documentation on the Payara Micro API. The Javadoc for the most recent version of the Payara Micro API can be found here.

`PayaraMicro.class` methods are used during the bootstrap process, whereas `PayaraMicroRuntime.class` methods are used on running instances.

Configuration Methods

Configuration Methods of `PayaraMicro.class` are detailed here.

Configuration Operand	Description	Get Method	Set Method	Default Value	Command Line Equivalent
Alternate Domain XML	Gets or sets the domain.xml used to override the default server configuration.	`File getAlternateDomainXML()`	`PayaraMicro setAlternateDomainXML(File alternateDomainXML)`	`null`	`--domainConfig`
Cluster Multicast Group	Gets or sets the cluster multicast group for the instance.	`String getClusterMulticastGroup()`	`PayaraMicro setClusterMulticastGroup(String hzMulticastGroup)`	`null` (Default value of 224.2.2.4 set in default domain.xml is not read into instance variable)	`--mcAddress`

Configuration Operand	Description	Get Method	Set Method	Default Value	Command Line Equivalent
Cluster Port	Gets or sets the multicast cluster port.	`int getClusterPort()`	`PayaraMicro setClusterPort(int hzPort)`	-2147483648 (MIN_VALUE) (Default value of 2904 set in default domain.xml is not read into instance variable)	`--mcPort`
Cluster Start Port	Gets or sets the start port number for the Payara Micro instance to listen on for cluster communications.	`int getClusterStartPort()`	`PayaraMicro setClusterStartPort(int hzStartPort)`	-2147483648 (MIN_VALUE) (Default value of 5900 set in default configuration files is not read into instance variable)	`--startPort`
Deployment Directory	Gets or sets the directory to be scanned for archives to deploy.	`File getDeploymentDir()`	`PayaraMicro setDeploymentDir(File deploymentRoot)`	`null`	`--deploymentDir`
HTTP Port	Gets or sets the HTTP port for the instance to bind to.	`int getHttpPort()`	`PayaraMicro setHttpPort(int httpPort)`	-2147483648 (MIN_VALUE) (Default value of 8080 set in default domain.xml is not read into instance variable)	`--port`
Instance Name	Gets or sets the name of the instance.	`String getInstanceName()`	`PayaraMicro setInstanceName(String instanceName)`	Generated Universally Unique Identifier.	`--name`

Configuration Operand	Description	Get Method	Set Method	Default Value	Command Line Equivalent
Maximum HTTP Threads	Gets or sets the maximum number of threads in the HTTP thread pool.	`int getMaxHttpThreads()`	`PayaraMicro setMaxHttpThreads(int maxHttpThreads)`	-2147483648 (MIN_VALUE) (Default value of 10 set in default domain.xml is not read into instance variable)	`--maxHttpThreads`
Minimum HTTP Threads	Gets or sets the minimum number of threads in the HTTP thread pool.	`int getMinHttpThreads()`	`PayaraMicro setMinHttpThreads(int minHttpThreads)`	-2147483648 (MIN_VALUE) (Default value of 10 set in default domain.xml is not read into instance variable)	`--minHttpThreads`
Root Directory	Gets or sets the root configuration directory.	`File getRootDir()`	`PayaraMicro setRootDir(File rootDir)`	`null`	`--rootDir`
HTTPS Port	Gets or sets the HTTPS port for the instance to bind to. An HTTPS port is not bound unless this value is manually set.	`int getSslPort()`	`PayaraMicro setSslPort(int sslPort)`	-2147483648 (MIN_VALUE) (Default value of 8443 set in default domain.xml is not read into instance variable)	`--sslPort`
No Clustering	Gets or sets whether clustering is enabled or disabled for an instance.	`boolean isNoCluster()`	`PayaraMicro setNoCluster(boolean noCluster)`	*false*	`--noCluster`
HTTP Auto-Binding	Enables or Disables auto-binding of the HTTP port for an instance.	`boolean getHttpAutoBind()`	`PayaraMicro setHttpAutoBind(boolean httpAutoBind)`	*false*	`--autoBindHttp`

Configuration Operand	Description	Get Method	Set Method	Default Value	Command Line Equivalent
HTTPS Auto-Binding	Enables or Disables auto-binding of the HTTPS port for an instance.	`boolean getSslAutoBind()`	`PayaraMicro setSslAutoBind(boolean sslAutoBind)`	*false*	`--autoBindSsl`
Auto-Bind Range	Sets the range for HTTP and HTTPS port auto-binding.	`int getAutoBindRange()`	`PayaraMicro setAutoBindRange(int autoBindRange)`	5	`--autoBindRange`

Operation Methods

The other methods of the Payara Micro API that operate Payara Micro instances are detailed here.

The list of methods in the API:

- Deployment Methods
- Setup and Shutdown Methods
- CDI Methods
- Run Methods
- Get Methods
- Library Methods

Deployment Methods

Deployment methods are used for the deployment of applications to Payara Micro instances.

`PayaraMicro.class` Methods

Method	Description	Command Line Equivalent
`PayaraMicro addDeployment(String pathToWar)`	Adds the file found at the location of the `pathToWar` parameter to the list of files to be deployed upon starting the instance.	`--deploy`
`PayaraMicro addDeploymentFile(File file)`	Adds the file associated with the `file` parameter to the list of files to be deployed upon starting the instance.	`--deploy`

`PayaraMicroRuntime.class` Methods

Method	Description
`boolean deploy(String name, InputStream is)`	Deploys an application from an `InputStream` with the name specified.
`boolean deploy(String name, String contextRoot, InputStream is)`	Deploys an application from an `InputStream`, with the specified name and context root.
`boolean deploy(File war)`	Deploys the application located at the *war* parameter path.
`boolean undeploy(String name)`	Un-deploys the specified application.

Setup and Shutdown Methods

These methods are required for setting up and cleaning Payara Micro instances.

`PayaraMicro.class` Methods

Method	Description
`PayaraMicroRuntime bootStrap() throws BootstrapException`	Checks the supplied configuration parameters and starts a Payara Micro instance.
`PayaraMicro getInstance()`	Obtains the static singleton instance of the Payara Micro server. If one does not exist, one will be created and returned.
`PayaraMicro getInstance(boolean create)`	Obtains the static singleton instance of the Payara Micro server. If one does not exist and `create` is set to true, one will be created and returned, otherwise returns *null*.
`void shutdown() throws BootstrapException`	Stops and shuts down the Payara Micro instance.

`PayaraMicroRuntime.class` Methods

Method	Description
`void shutdown() throws BootstrapException`	Stops and shuts down the Payara Micro instance.

CDI Methods

These methods are used for firing CDI Events across running instances.

Method	Description
`void addCDIEventListener(CDIEventListener listener)`	Adds a CDI Event Listener.
`void removeCDIEventListener(CDIEventListener listener)`	Removes a CDI Event Listener.
`void addClusterListener(PayaraClusterListener listener)`	Adds a Cluster Listener.

Method	Description
`void removeClusterListener(PayaraClusterListener listener)`	Removes a Cluster Listener.
`void publishCDIEvent(PayaraClusteredCDIEvent event)`	Publishes a CDI Event.

Run Methods

These methods are used for running `asadmin` commands or `Callable` objects on bootstrapped instances.

Method	Description
`Map<InstanceDescriptor, Future<ClusterCommandResult>> run (String command, String… args )`	Runs an asadmin command on all members of a Payara Micro Cluster.
`Map<InstanceDescriptor, Future<ClusterCommandResult>> run (Collection<InstanceDescriptor> members, String command, String… args )`	Runs an asadmin command on specified members of a Payara Micro Cluster.
`<T extends Serializable> Map<InstanceDescriptor, Future<T>> run (Callable<T> callable)`	Runs a Callable object on all members of a Payara Micro Cluster.
`<T extends Serializable> Map<InstanceDescriptor, Future<T>> run (Collection<InstanceDescriptor> members, Callable<T> callable)`	Runs a Callable object on specified members of a Payara Micro Cluster.

Get Methods

These methods are used for getting information on running Payara Micro instances. For information on the `Get` methods of a non-bootstrapped instance, see the [Technical Documentation-Payara Micro Documentation-API-Payara Micro API-Overview:::configuration-methods] section.

Method	Description
`Collection<InstanceDescriptor> getClusteredPayaras()`	Returns a collection of instance descriptors for all the Payara Micros instances in a cluster.
`Collection<String> getDeployedApplicationNames()`	Returns the names of the deployed applications.
`String getInstanceName()`	Returns the instance name.
`InstanceDescriptor getLocalDescriptor()`	Returns the instance descriptor of the instance the method is run on.

Library Methods

These methods are used for configuring additional libraries to the instance's classpath.

Method	Description
`void addLibrary(File)`	Adds a new library source (a JAR file or a directory with multiple JAR files) to be considered for the instance's classpath

Using the Payara Micro API

It is possible to execute administration commands programmatically using the link:/Technical Documentation/Payara Micro Documentation/API/Payara Micro API/Overview.adoc[Payara Micro API,role=unresolved], using the `PayaraMicroRuntime.run` method.

There are two overloaded forms that can be used:

`run(String command, String… args )`

This method executes the specified *asadmin* command on all instances in the runtime's cluster. It returns a `Map<InstanceDescriptor, Future<ClusterCommandResult>>`, which can be used to inspect the results of the execution on each instance the command was executed.

`run(Collection<InstanceDescriptor> members, String command, String… args )`

This method executes the specified *asadmin* command on all instances contained in the `Collection` supplied. As with the previous method, it returns a `Map<InstanceDescriptor, Future<ClusterCommandResult>>`, which can be used to inspect the results of the command execution.

For both methods, it's recommended to use the `getClusteredPayaras()` method exposed by the `PayaraMicroRuntime` class to retrieve a list of all the instances in the cluster and determine which command executions should be filtered.

Here's an example of how to use the first form of the method that executes the `deploy` subcommand to deploy an application and parses the results to check out if the application was successfully deployed on all instances of the cluster:

```
import fish.payara.micro.BootstrapException;
import fish.payara.micro.ClusterCommandResult;
import fish.payara.micro.PayaraMicro;
import fish.payara.micro.PayaraMicroRuntime;
import fish.payara.micro.data.InstanceDescriptor;
import java.util.Map;
import java.util.concurrent.Future;
import java.util.logging.Logger;

public class EmbeddedPayara {

    private static final Logger LOG = Logger.getLogger(EmbeddedPayara
.class.getName());

    public static void main(String[] args) throws BootstrapException {
```

```
        PayaraMicro instance = PayaraMicro.getInstance();
        PayaraMicroRuntime runtime = instance.bootStrap();

        Map<InstanceDescriptor, Future<? extends ClusterCommandResult>> results =
runtime.run("deploy", "application.war");
        for(InstanceDescriptor descriptor : results.keySet()){
            ClusterCommandResult commandResult =
(ClusterCommandResult)results.get(descriptor);
            if(commandResult.getExitStatus() ==
ClusterCommandResult.ExitStatus.SUCCESS){
                LOG.info("Application was successfully deployed on cluster instance "
+ descriptor.getInstanceName());
            }
        }
    }
}
```

Extensions

JCA Support

Payara Micro supports the deployment of Java EE Connector Architecture (JCA) adapters which can enable communication with external services not natively supported by Payara Micro.

These can include JMS brokers, cloud messaging providers like Amazon SQS or existing legacy systems. In the case of JMS, for example, Payara Micro can be used for both inbound and outbound messaging to a JMS broker using a standard Message Driven Bean (MDB) and can therefore take advantage of pooling behaviour available to all types of EJB.

Installing a JCA Adapter

A JCA Resource Archive (RAR) is installed by deploying it to Payara Micro in the same way as an application archive (e.g. a WAR) is deployed. The following shows an example using an ActiveMQ (JMS 1.1) RAR:

```
java -jar payara-micro.jar --deploy activemq-rar-5.14.5.rar
```

The connector is subsequently available to all other applications deployed to Payara Micro. An application using a connector and the connector itself can be deployed simultaneously:

```
java -jar payara-micro.jar --deploy activemq-rar-5.14.5.rar --deploy myapp.war
```

When deploying multiple files to Payara Micro, the order of `--deploy` options is respected so, in the above example, the ActiveMQ RAR will be deployed before the `myapp.war` application.

Persistent EJB Timers

Payara Micro supports persistent EJB timers which are stored across Payara Micro instances within the cluster, backed by distributed Hazelcast cache.

The timers are persisted as long as the cluster is running, even when the member that created the timer goes down.

In order to make use of a persistent timer in Payara Micro, an application must declare a timer to be persistent, as defined by the EJB specification. This is actually the default behavior, unless timers are specified as **non-persistent**.

The second requirement is to specify a name for every Payara Micro instance which runs an application with persistent timers. Each such instance has to have its own unique name.

Persistent timers are **NOT** coordinated across a Payara Micro cluster. They are always executed on an instance with the same name that created the timers.

Requirements to setup a persistent timer

1. The timer has to be persistent, i.e. the value of `persistent` attribute is not forcibly set to `false`
2. A Payara Micro instance is given a unique name using `--name` argument
3. A Payara Micro instance is a member of a Hazelcast cluster

The Hazelcast cluster can be formed by other Payara Micro instances, Payara Server instances with Hazelcast turned on, or by standalone Hazelcast instances.

How EJB timers are persisted

Once timers are scheduled, either by the `@Schedule` annotation or using the `TimerService`, the schedule is stored into the Hazelcast distributed cache. The schedule is given a key, which is the name of the Payara Micro instance that created the timer. If that instance goes down, the timer will be recreated on another instance with the same name once it joins the cluster. Until that time, the timer becomes inactive.

The timer would not be recreated on other members of the cluster or any new members of the cluster with a different name.

Remote CDI Events

Payara Micro can listen to and fire CDI events across the cluster of Payara Micro instances, and also across Payara Server instances within the same cluster. Payara Micro supports the same functionality for link:/Technical Documentation/Payara Micro Documentation/Extensions/Remote CDI Events.adoc[remote CDI events,role=unresolved] as provided by Payara Server.

Payara Micro also provides additional methods to fire events and register listeners programmatically.

These methods are used for firing CDI Events across running instances.

Method	Description
`void addCDIEventListener(CDIEventListener listener)`	Adds a CDI Event Listener.
`void removeCDIEventListener(CDIEventListener listener)`	Removes a CDI Event Listener.
`void addClusterListener(PayaraClusterListener listener)`	Adds a Cluster Listener.
`void removeClusterListener(PayaraClusterListener listener)`	Removes a Cluster Listener.
`void publishCDIEvent(PayaraClusteredCDIEvent event)`	Publishes a CDI Event.

This feature has been available in Payara Micro long before it was available in Payara Server.

Manual initialization of the Event Bus

On prior releases, it was necessary to initialize the event bus using `ClusteredCDIEventBus.initialize()` manually upon startup. Although this method is still available in the API, it is not necessary anymore, since the event bus is automatically initialized after an application is started.

Running Callable Objects

Like with running asadmin commands, there are two methods available for running `Callable` objects, both also named `run`.

The two methods also work in a similar way to the two asadmin run methods:

`run(Callable<T> callable)`
: runs the specified Callable on all instances in a runtime's cluster.

`run(Collection<InstanceDescriptor>`
: members, Callable<T> callable)` runs the Callable on a subset of the instances in a runtime's cluster.

Both methods return a `Map` object with a key/value type of `<InstanceDescriptor, Future<T>>`, where the type variable *T* is Serializable.

Payara Micro Docker Image

Overview of the usage and details of the official Payara Micro Enterprise Docker image.

Quick start

Launch a new Payara Micro instance running in a container listening in port `8080` with the following command:

```
docker run -p 8080:8080 nexus.payara.fish:5000/payara/micro
```

Keep in mind the following:

- The instance will start with no deployed applications.
- Accessing the default HTTP endpoint will yield a `404 - Not Found` response.
- The instance's JVM process runs under the `payara` user.

It is recommended to specify the tag name of the Docker image that you plan to use, to guarantee that the correct Payara Enterprise version is used on your environment for guaranteed long-term stability

Using a specific version

```
docker run -p 8080:8080 nexus.payara.fish:5000/payara/micro:main-7
```

AMD64 & ARM64 compatible images are provided. The Docker client should automatically download the appropriate image for your architecture.

Exposed ports

The default ports that are exposed by this image are:

- 8080 - HTTP listener
- 6900 - Datagrid's Hazelcast port

Installation Details

The Payara Micro JAR file is located in the `/opt/payara/` directory (identified by the `HOME_DIR` environment variable), which also is the default work directory of the image.

The directory name is deliberately free of any versioning so that any scripts written to work with one version can be seamlessly migrated to the latest docker image.

Application Deployment

Payara Micro will deploy applications at startup time, depending on how you prefer to instruct the instance to execute the deployments. However, you have to make sure that the container has access to your application artefacts.

You can instruct the container to deploy applications using the following mechanisms:

- Mount a deployment directory (local or in the network) as a Docker volume
- Prepare a custom Docker image that includes your application artefacts.
- Deploy your applications from a remote Maven repository.

Deploy Applications from a Directory

You can instruct the container to deploy all application artefacts that belong to a directory that is mounted as Docker volume mapped to the `/opt/payara/deployments` (which is defined as the value of the `$DEPLOY_DIR` environment variable) local directory.

The following command will start a new Payara Micro instance container and deploy all artefacts located in the `~/payara-micro/applications` directory:

```
docker run -p 8080:8080 -v ~/payara-micro/applications:/opt/payara/deployments
nexus.payara.fish:5000/payara/micro:main-7
```

To only deploy a specific artefact within the directory, simply pass the `--deploy` argument to the container's run command and specify which application to deploy:

```
docker run -p 8080:8080 -v ~/payara-micro/applications:/opt/payara/deployments
nexus.payara.fish:5000/payara/micro:main-7 --deploy
/opt/payara/deployments/myapplication.war
```

Make sure to prefix the artefact names with the absolute path to the local deployment directory.

Deploy Applications using a Custom Image

You can also prepare a custom image based on the official Payara Micro Docker image and copy all application artefacts to the `$DEPLOY_DIR` directory. This way, you can re-package your applications in a simple distributable unit.

The following sample *Dockerfile* can be used to prepare a custom Payara Micro image that deploys the `myapplication.war` artefact at runtime:

```
FROM nexus.payara.fish:5000/payara/micro:main-7
COPY myapplication.war $DEPLOY_DIR
```

Deploy Applications from a Maven Repository

If your application's artefact is already available in a Maven repository, you can instruct the container to download and deploy it directly. To do this, you'll have to pass the `--deployFromGAV` argument with the GAV coordinates of your artefact to the run command used to launch the container.

Here's an example of how to deploy a sample application located in a local Maven repository:

```
docker run -p 8080:8080 nexus.payara.fish:5000/payara/micro:main-7 --deployFromGAV
"fish.payara.examples:my-application:1.0-SNAPSHOT" --additionalRepository
https://172.17.0.10/content/repositories/snapshots
```

Notice that the example also uses the `--additionalRepository` argument to specify the URL of the repository where the artefact lives since by default, Payara Micro will only look for artefacts in the Maven Central repository.

Configuration

Context Root Configuration

By default, the context root of each deployed application corresponds to the artefact's file name. You can override this setting by using the `--contextroot` startup argument.

To deploy an application using the default context root (`/`), set its value to `ROOT`

Here are some basic examples:

One application deployed, uses the `myRoot` context root

```
docker run -p 8080:8080 -v ~/payara-micro/applications:/opt/payara/deployments
nexus.payara.fish:5000/payara/micro:main-7 --deploymentDir /opt/payara/deployments
--contextroot myRoot
```

First application in the directory uses the `/` context root

```
docker run -p 8080:8080 \
 -v ~/payara-micro/applications:/opt/payara/deployments
nexus.payara.fish:5000/payara/micro:main-7 --deploy
/opt/payara/deployments/myapplication.war --contextroot ROOT
```

You can also prepare a custom Docker image that overrides the default `CMD` instruction to specify the context root like this:

```
FROM nexus.payara.fish:5000/payara/micro:main-7
COPY myapplication.war $DEPLOY_DIR
CMD ["--deploymentDir", "/opt/payara/deployments", "--contextroot", "my"]
```

Disable the Data Grid

Payara Micro will start in "clustering" mode by booting up the Data Grid, allowing other instances reachable in the network to join the grid automatically.

The Data Grid initialization and maintenance consumes extra resources, so in cases where clustering is not needed, it is recommended to disable the Data Grid completely.

To disable the Data Grid, you can pass the `--noHazelcast` argument to the entry point of the run command:

```
docker run -p 8080:8080 -v ~/payara-micro/applications:/opt/payara/deployments
nexus.payara.fish:5000/payara/micro:main-7 --noHazelcast
```

Disable Clustering

By default, Payara Micro will start with hazelcast enabled, allowing other instances reachable in the network to join the datagrid automatically and cluster.

Disabling Hazelcast with the --noHazelcast option will also disable all features that depend on Hazelcast, including JCache. The `--noCluster` option allows you to keep Hazelcast and therefore all features depending on Hazelcast, but disable clustering. This will significantly improve performance and is the recommended option if you require Hazelcast dependant features, but do not intend to use clustering.

To disable clustering, you can pass the `--noCluster` argument to the entry point of the run command:

```
docker run -p 8080:8080 -v ~/payara-micro/applications:/opt/payara/deployments
nexus.payara.fish:5000/payara/micro:main-7 --noCluster
```

Using Environment Variables

The following environment variables can be used to configure multiple settings of the Payara Micro instance. They can be either specified in a custom image's `Dockerfile` or passed to the `docker run` command via the `--env` or `--env-file` arguments:

Name	Description	Default Value
`MEM_MAX_RAM_PERCENTAGE`	Value for the JVM argument `-XX:MaxRAMPercentage` which indicates the percentage of memory assigned to the container that can be used by the Java process	`70`
`MEM_XSS`	Value for the JVM argument `-Xss` which controls the stack size	`512K`
`JVM_ARGS`	Additional JVM arguments which will be used to configure the Payara Servers DAS JVM settings	`-Djdk.util.zip.disableZip64ExtraFieldValidation=true`

The following is a list of variables used by the Docker image to set up the Payara Micro instance startup, so it is not recommended to alter their values:

Variable name	Description	Value
`HOME_DIR`	The directory containing the Payara Micro JAR binary and the scripts used to run the instance.	`/opt/payara`

Read Only Support Considerations

The Payara Micro Docker image requires write access to the `HOME_DIR`, and `/tmp` directories to function. If you wish to use `--read-only` Docker containers (or the equivalent `--readOnlyRootFilesystem` property in Kubernetes), you must mount volumes at these directories which the `payara` user has write access to. This can be done using anonymous or tmpfs volumes if you do not wish to persist the data outside the life of the container. Named volumes or bind mounts may be used if you wish the data to persist outside the life of the container.

Here is an example `run` command for a read-only Docker container which will delete itself and its anonymous volumes when stopped, deploying all artefacts located in the `~/payara-micro/applications` directory:

```
docker run -p 8080:8080 --read-only --rm -v /opt/payara -v /tmp -v ~/payara-
micro/applications:/opt/payara/deployments nexus.payara.fish:5000/payara/micro:main-7
```

Payara Embedded Documentation

Overview

This guide explains how to run applications in embedded Payara Server and to develop applications in which Payara Server is embedded.

Payara Server Embedded Guide

This document explains how to run applications in embedded Payara Server and to develop applications in which Payara Server is embedded.

This document is for software developers who are developing applications to run in an embedded instance of Payara Server.

Introduction to Embedded Payara Server

Embedded Payara Server enables you to use Payara Server as a library. Embedded Payara Server also enables you to run Payara Server inside any Virtual Machine for the Java platform (Java Virtual Machine or JVM).

No installation or configuration of embedded Payara Server is required. The ability to run Payara Server inside applications without installation or configuration simplifies the process of bundling Payara Server with applications.

You can use embedded Payara Server in the following ways:

- With the Embedded Server API (see Including the Payara Server Embedded Server API in Applications)
- With the EJB Embeddable API (see Using the EJB Embeddable API with Embedded Payara Server

Embedded Payara Server File System

The following Embedded Payara Server directories and files are important if you are referencing a non-embedded installation of Payara Server:

- Installation Root Directory
- Instance Root Directory
- The `domain.xml` File

Installation Root Directory

The installation root directory, represented as `as-install`, is the parent of the directory that embedded Payara Server uses for configuration files. This directory corresponds to the base directory for an installation of Payara Server. Configuration files are contained in the following directories in the base directory for an installation of Payara Server:

- `domains`
- `lib`

Instance Root Directory

The instance root directory, represented as `domain-dir`, is the parent directory of a server instance directory. Embedded Payara Server uses the server instance directory for domain configuration files.

If you have valid non-embedded Payara Server `as-install` and `domain-dir` directories, specify both in the `BootstrapProperties` and `GlassFishProperties` classes respectively as described in Creating and Configuring an Embedded Payara Server.

If domain-dir is not specified, Payara Server creates a directory named `gfembed random-number tmp` in a temporary directory, where random-number is a randomly generated 19-digit number. Payara Server then copies configuration files into this directory. The temporary directory is the value of the system property `java.io.tmpdir`. You can override this value by specifying the `glassfish.embedded.tmpdir` property in the `GlassFishProperties` class or as a system property.

The `domain.xml` File

Using an existing `domain.xml` file avoids the need to configure embedded Payara Server programmatically in your application. Your application obtains domain configuration data from an existing `domain.xml` file. You can create this file by using the administrative interfaces of an existing Payara Server installation.

To specify an existing `domain.xml` file, invoke the `setConfigFileURI` method of the `GlassFishProperties` class as described in Creating and Configuring an Embedded Payara Server.

Including the Payara Server Embedded Server API in Applications

Payara Server provides an application programming interface (API) for developing applications in

which Payara Server is embedded.

Setting the Class Path

Payara Embedded has two distribution variants, `payara-embedded-all` and `payara-embedded-web`, functionally these are the same as their standalone counterparts, Payara Server Full Profile and Payara Server Web Profile respectively.

To enable your applications to locate the class libraries for embedded Payara Server, add one of the following JAR files to your class path:

`payara-embedded-all.jar`
: Contains classes needed for deploying all Jakarta EE application types. Can be setup as a Maven dependency with the following GAV coordinates:

```
<dependency>
    <groupId>fish.payara.extras</groupId>
    <artifactId>payara-embedded-all</artifactId>
    <version>main-7</version>
    <type>jar</type>
</dependency>
```

`payara-embedded-web.jar`
: Contains classes needed for deploying strictly Jakarta EE web applications. Can be setup as a Maven dependency with the following GAV coordinates:

```
<dependency>
    <groupId>fish.payara.extras</groupId>
    <artifactId>payara-embedded-web</artifactId>
    <version>main-7</version>
    <type>jar</type>
</dependency>
```

In addition, add to the class path any other JAR files or classes upon which your applications depend.

For example, if an application uses a database other than H2, include the JDBC driver JAR files in the class path accordingly.

Creating, Starting, and Stopping Embedded Payara Server

Before you can run applications, you must set up and run the embedded Payara Server.

Creating and Configuring an Embedded Payara Server

To create and configure an embedded Payara Server, perform these tasks:

1. Instantiate the `org.glassfish.embeddable.BootstrapProperties` class.

2. Invoke any methods for configuration settings that you require. This is optional.
3. Invoke the `GlassFishRuntime.bootstrap()` or `GlassFishRuntime.bootstrap(BootstrapProperties)` method to create a `GlassFishRuntime` object.
4. Instantiate the `org.glassfish.embeddable.GlassFishProperties` class.
5. Invoke any methods for configuration settings that you require. This is optional.
6. Invoke the `glassfishRuntime.newGlassFish(GlassFishProperties)` method to create a `GlassFish` object.

The methods of the `BootstrapProperties` class for setting the server configuration are listed in the following table. The default value of each configuration setting is also listed.

Table 175. Methods of the `BootstrapProperties` Class

Purpose	Method	Default Value
References an existing Installation Root Directory, also called `as-install`	`setInstallRoot(String as-install)`	None.

The methods of the `GlassFishProperties` class for setting the server configuration are listed in the following table. The default value of each configuration setting is also listed.

Table 176. Methods of the `GlassFishProperties` Class

Purpose	Method	Default Value
References an existing Instance Root Directory, also called `domain-dir`	`setInstanceRoot(String domain-dir)`	In order of precedence: • `glassfish.embedded.tmpdir` property value specified in `GlassFishProperties` object • `glassfish.embedded.tmpdir` system property value • `java.io.tmp` system property value • `as-install/domains/domain1` if a non-embedded installation is referenced
Creates a new configuration file or references an existing configuration file	`setConfigFileURI(String configFileURI)`	In order of precedence: • `domain-dir/config/domain.xml` if domain-dir was set using `setInstanceRoot` • built-in embedded `domain.xml`
Specifies whether the configuration file is read-only	`setConfigFileReadOnly(boolean readOnly)`	`true`

Purpose	Method	Default Value
Sets the port on which Embedded Payara Server listens.	`setPort`(String networkListener, int port)	None

Do not use `setPort` if you are using the `setInstanceRoot` or `setConfigFileURI` methods.

Creating an Embedded Payara Server

This example shows code for creating an Embedded Payara Server.

```
import org.glassfish.embeddable.*;

public class EmbeddedRunner{

    public static void main(String... args){
        var server = GlassFishRuntime.bootstrap().newGlassFish();
        server.start();
    }
}
```

Creating an Embedded Payara Server with configuration customizations

This example shows code for creating an Embedded Payara Server using the existing domain-dir `C:\samples\test\applicationserver\domains\domain1`:

```
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){

        var bootstrapProperties = new BootstrapProperties();
        bootstrapProperties.setInstallRoot("C:\\samples\\test\\applicationserver");
        GlassFishRuntime glassfishRuntime =
GlassFishRuntime.bootstrap(bootstrapProperties);

        var glassfishProperties = new GlassFishProperties();

glassfishProperties.setInstanceRoot("C:\\samples\\test\\applicationserver\\domains\\do
main1");
        var server = glassfishRuntime.newGlassFish(glassfishProperties);

        server.start();
    }
}
```

Running an Embedded Payara Server

After you create an embedded Payara Server as described in Creating and Configuring an Embedded Payara Server, you can perform operations such as:

- Setting the Port of an Embedded Payara Server From an Application
- Starting an Embedded Payara Server From an Application
- Stopping an Embedded Payara Server From an Application

[[Technical Documentation-Payara Embedded Documentation-Payara Server Embedded Guide:::setting-the-port-of-an-embedded-payara-server-from-an-application]#Technical Documentation-Payara Embedded Documentation-Payara Server Embedded Guide:::setting-the-port-of-an-embedded-payara-server-from-an-application] **Setting the Port of an Embedded Payara Server From an Application**

You must set the server's HTTP or HTTPS port. If you do not set the port, your application fails to start and throws an exception. You can set the port directly or indirectly.

Do not use `setPort` if you are using `setInstanceRoot` or `setConfigFileURI`. These methods set the port indirectly.

- To set the port directly, invoke the `setPort` method of the `GlassFishProperties` object.
- To set the port indirectly, use a `domain.xml` file that sets the port. For more information, see The `domain.xml` File.

This example shows code for setting the port of an embedded Payara Server.

```
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        var glassfishProperties = new GlassFishProperties();
        glassfishProperties.setPort("http-listener", 8080);
        glassfishProperties.setPort("https-listener", 8181);
    }
}
```

[[Technical Documentation-Payara Embedded Documentation-Payara Server Embedded Guide:::starting-an-embedded-payara-server-from-an-application]#Technical Documentation-Payara Embedded Documentation-Payara Server Embedded Guide:::starting-an-embedded-payara-server-from-an-application] **Starting an Embedded Payara Server From an Application**

To start an embedded Payara Server, invoke the `start` method of the corresponding server object.

This example shows code for setting the port and starting an embedded Payara Server:

```
import org.glassfish.embeddable.*;
```

```
public class EmbeddedRunner{
    public static void main(String... args){
        var glassfishProperties = new GlassFishProperties();
        glassfishProperties.setPort("http-listener", 8080);
        glassfishProperties.setPort("https-listener", 8181);

        var server = GlassFishRuntime.bootstrap().newGlassFish(glassfishProperties);
        server.start();
    }
}
```

[[Technical Documentation-Payara Embedded Documentation-Payara Server Embedded Guide:::stopping-an-embedded-payara-server-from-an-application]#Technical Documentation-Payara Embedded Documentation-Payara Server Embedded Guide:::stopping-an-embedded-payara-server-from-an-application] **Stopping an Embedded Payara Server From an Application**

The API for an embedded Payara Server provides a method for stopping an embedded server. Using this method enables your application to stop the server in an orderly fashion by performing any necessary cleanup steps before stopping the server, for example:

- Un-deploying deployed applications
- Releasing any resources that your application uses

To stop an embedded Payara Server, invoke the `stop` method of an existing server object.

This example shows code for prompting the user to press the Enter key to stop an embedded Payara Server:

```
import java.io.BufferedReader;

import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        System.out.println("Press Enter to stop server");
        // wait for Enter
        server.stop();
    }
}
```

As an alternative, you can use the `dispose` method to stop an embedded Payara Server and dispose of the temporary file system.

Deploying and Un-deploying an Application in an Embedded Payara Server

Deploying an application installs the files that comprise the application into Embedded Payara Server and makes the application ready to run. By default, an application is enabled when it is deployed.

To Deploy an Application From an Archive File or a Directory

An archive file contains the resources, deployment descriptor, and classes of an application. The content of the file must be organized in the directory structure that the Jakarta EE specifications define for the type of archive that the file contains. For more information, see Deploying Applications in the Payara Server Application Deployment section.

Deploying an application from a directory enables you to deploy an application without the need to package the application in an archive file. The contents of the directory must match the contents of the expanded Jakarta EE archive file as laid out by the Payara Server. The directory must be accessible to the machine on which the deploying application runs. For more information about the requirements for deploying an application from a directory, see To Deploy an Application or Module in a Directory Format in the Payara Server Application Deployment section.

If some resources needed by an application are not under the application's directory, see Creating a Scattered Archive.

1. Instantiate the `java.io.File` class to represent the archive file or directory.
2. Invoke the `getDeployer` method of the server object to get an instance of the `org.glassfish.embeddable.Deployer` class.
3. Invoke the `deploy(File, archive,params)` method of the instance of the `Deployer` object.

   Specify the `java.io.File` class instance you created previously as the first method parameter.

   For information about optional parameters you can set, see the descriptions of the `deploy` subcommand parameters. Simply quote each parameter in the method, for example `"--force=true"`.

This example shows code for deploying an application from the archive file `c:\samples\simple.war` and setting the name, context root, and force parameters.

```
import java.io.File;
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        var glassfishProperties = new GlassFishProperties();
        glassfishProperties.setPort("http-listener", 8080);
        glassfishProperties.setPort("https-listener", 8181);

        var server = GlassFishRuntime.bootstrap().newGlassFish(glassfishProperties);
        server.start();

        var war = new File("c:\\samples\\simple.war");
        var deployer = server.getDeployer();
        deployer.deploy(war, "--name=simple", "--contextroot=simple", "--force=true");
        // deployer.deploy(war) can be invoked instead. Other parameters are optional.
    }
}
```

Un-deploying an Application

Undeploy an application when the application is no longer required to run in Payara Server. For example, before stopping Payara Server, undeploy all applications that are running in Payara Server.

To undeploy an application, invoke the `undeploy` method of an existing `Deployer` object. In the method invocation, pass the name of the application as a parameter. This name is specified when the application is deployed.

For information about optional parameters you can set, see the descriptions of the `deploy` command parameters. Simply quote each parameter in the method, for example `"--cascade=true"`.

To undeploy all deployed applications, invoke the `undeployAll` method of an existing `EmbeddedDeployer` object. This method takes no parameters.

This example shows code for un-deploying the application that was deployed in the previous example:

```
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        deployer.undeploy(war, "--droptables=true", "--cascade=true");
    }
}
```

Creating a Scattered Archive

Deploying a module from a scattered archive (WAR or JAR) enables you to deploy an un-packaged module whose resources, deployment descriptor, and classes are in any location. Deploying a module from a scattered archive simplifies the testing of a module during development, especially if all the items that the module requires are not available to be packaged.

In a scattered archive, these items are not required to be organized in a specific directory structure. Therefore, you must specify the location of the module's resources, deployment descriptor, and classes when deploying the module.

To create a scattered archive, perform these tasks:

1. Instantiate the `org.glassfish.embeddable.archive.ScatteredArchive` class.
2. Invoke the `addClassPath` and `addMetadata` methods if you require them.
3. Invoke the `toURI` method to deploy the scattered archive.

The methods of this class for setting the scattered archive configuration are listed in the following table. The default value of each configuration setting is also listed.

Table 177. Constructors and Methods of the `ScatteredArchive` Class

Purpose	Method	Default Value
Creates and names a scattered archive	`ScatteredArchive(String name, ScatteredArchive.Type type)`	None
Creates and names a scattered archive based on a top-level directory. If the entire module is organized under the topDir, this is the only method necessary. The `topDir` argument can be null if other methods specify the remaining parts of the module.	`ScatteredArchive(String name, ScatteredArchive.Type type, File topDir)`	None
Adds a directory to the classes classpath	`addClassPath(File path)`	None
Adds a metadata locator	`addMetaData(File path)`	None
Adds and names a metadata locator	`addMetaData(File path, String name)`	None
Gets the deployable URI for this scattered archive	`toURI()`	None

This example shows code for creating a WAR file and using the `addClassPath` and `addMetadata` methods. This example also includes the code from the previous example that showcases deploying an application from an archive file.

```
import java.io.File;
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        var glassfishProperties = new GlassFishProperties();
        glassfishProperties.setPort("http-listener", 9090);

        var server = GlassFishRuntime.bootstrap().newGlassFish(glassfishProperties);
        server.start();

        var deployer = glassfish.getDeployer();
        var archive = new ScatteredArchive("testapp", ScatteredArchive.Type.WAR);
        // target/classes directory contains complied servlets
        archive.addClassPath(new File("target", "classes"));
        // resources/payara-web.xml is the WEB-INF/payara-web.xml
        archive.addMetadata(new File("resources", "payara-web.xml"));
        // resources/web.xml is the WEB-INF/web.xml
        archive.addMetadata(new File("resources", "web.xml"));
```

```
        // Deploy the scattered web archive.
        var appName = deployer.deploy(archive.toURI(), "--contextroot=hello");

        deployer.undeploy(appName);
        server.stop();
        server.dispose();
    }
}
```

Creating a Scattered Enterprise Archive

Deploying an application from a scattered enterprise archive (EAR) enables you to deploy an unpackaged application whose resources, deployment descriptor, and classes are in any location. Deploying an application from a scattered archive simplifies the testing of an application during development, especially if all the items that the application requires are not available to be packaged.

In a scattered archive, these items are not required to be organized in a specific directory structure. Therefore, you must specify the location of the application's resources, deployment descriptor, and classes when deploying the application.

To create a scattered enterprise archive, perform these tasks:

1. Instantiate the `org.glassfish.embeddable.archive.ScatteredEnterpriseArchive` class.
2. Invoke the `addArchive` and `addMetadata` methods if you require them.
3. Invoke the `toURI` method to deploy the scattered enterprise archive.

The methods of this class for setting the scattered enterprise archive configuration are listed in the following table. The default value of each configuration setting is also listed.

Table 178. Constructors and Methods of the `ScatteredEnterpriseArchive` Class

Purpose	Method	Default Value
Creates and names a scattered enterprise archive	`ScatteredEnterpriseArchive(String name)`	None
Adds a module or library	`addArchive(File archive)`	None
Adds a module or library	`addArchive(File archive, String name)`	None
Adds a module or library	`addArchive(URI URI)`	None
Adds a module or library	`addArchive(URI URI, String name)`	None

Purpose	Method	Default Value
Adds a metadata locator	`addMetaData(File path)`	None
Adds and names a metadata locator	`addMetaData(File path, String name)`	None
Gets the deployable URI for this scattered archive	`toURI()`	None

This example shows code for creating an EAR file and using the `addArchive` and `addMetadata` methods.

```
import java.io.File;
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        var glassfishProperties = new GlassFishProperties();
        glassfishProperties.setPort("http-listener", 9090);

        var server = GlassFishRuntime.bootstrap().newGlassFish(glassfishProperties);
        server.start();

        var deployer = glassfish.getDeployer();

        // Create a scattered web application.
        var webmodule = new ScatteredArchive("testweb", ScatteredArchive.Type.WAR);
        // target/classes directory contains my complied servlets
        webmodule.addClassPath(new File("target", "classes"));
        // resources/payara-web.xml is my WEB-INF/payara-web.xml
        webmodule.addMetadata(new File("resources", "payara-web.xml"));

        // Create a scattered enterprise archive.
        var archive = new ScatteredEnterpriseArchive("testapp");
        // src/application.xml is my META-INF/application.xml
        archive.addMetadata(new File("src", "application.xml"));
        // Add scattered web module to the scattered enterprise archive.
        // src/application.xml references Web module as "scattered.war".
        //Hence specify the name while adding the archive.
        archive.addArchive(webmodule.toURI(), "scattered.war");
        // lib/mylibrary.jar is a library JAR file.
        archive.addArchive(new File("lib", "mylibrary.jar"));
        // target/ejbclasses contain my compiled EJB module.
        // src/application.xml references EJB module as "ejb.jar".
        //Hence specify the name while adding the archive.
        archive.addArchive(new File("target", "ejbclasses"), "ejb.jar");
```

```
        // Deploy the scattered enterprise archive.
        var appName = deployer.deploy(archive.toURI());

        deployer.undeploy(appName);
        server.stop();
        server.dispose();
    }
}
```

Running `asadmin` Commands Using the Payara Server Embedded Server API

Running commands from an application enables the application to configure the embedded Payara Server to suit the application's requirements. For example, an application can run the required `asadmin` commands to create a JDBC technology connection to a database.

Ensure that your application has started an embedded Payara Server before the application attempts to run any `asadmin` commands. For more information, see Running an Embedded Payara Server.

The `org.glassfish.embeddable` package contains classes that you can use to run `asadmin` commands. Use the following code examples as templates and change the command name, parameter names, and parameter values as needed.

This example shows code for running an `asadmin create-jdbc-resource` command:

```
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        var command = "create-jdbc-resource";
        var poolId = "--connectionpoolid=DerbyPool";
        var dbname = "jdbc/DerbyPool";
        var commandRunner = glassfish.getCommandRunner();
        var commandResult = commandRunner.run(command, poolId, dbname);
    }
}
```

This example shows code for running an `asadmin set-log-level` command:

```
import org.glassfish.embeddable.*;

public class EmbeddedRunner{
    public static void main(String... args){
        var command = "set-log-level";
        var level = "javax.enterprise.system.container.web=FINE";
        var commandRunner = glassfish.getCommandRunner();
        var commandResult = commandRunner.run(command, level);
    }
```

```
}
```

Sample Applications

This example shows code for the following:

- Using the existing file `c:\myapp\embeddedserver\domains\domain1\config\domain.xml` and preserving this file when the application is stopped.
- Deploying an application from the archive file `c:\samples\simple.war`.

```
import java.io.File;
import java.io.BufferedReader;
import java.io.InputStreamReader;
import org.glassfish.embeddable.*;

public class EmbeddedRunner {
    public static void main(String[] args) {
        var configFile = new File
("c:\\myapp\\embeddedserver\\domains\\domain1\\config\\domain.xml");
        var war = new File("c:\\samples\\simple.war");
        try {
            var glassfishRuntime = GlassFishRuntime.bootstrap();
            var glassfishProperties = new GlassFishProperties();
            glassfishProperties.setConfigFileURI(configFile.toURI());
            glassfishProperties.setConfigFileReadOnly(false);

            var server = glassfishRuntime.newGlassFish(glassfishProperties);
            server.start();

            var deployer = server.getDeployer();
            deployer.deploy(war, "--force=true");
        }
        catch (Exception ex) {
            ex.printStackTrace();
        }

        System.out.println("Press Enter to stop the server");
        try(var reader = new BufferedReader(new
InputStreamReader(System.in)).readLine()) {
            server.dispose();
            server.shutdown();
        }
        catch (Exception ex) {
            ex.printStackTrace();
        }
    }
}
```

Using the EJB Embeddable API with Embedded Payara Server

Payara Server Embedded is not related to the EJB Embeddable API, but you can use these APIs together in some form. The EJB Embeddable API supports all EJB Lite features with addition of the EJB timer service and testing of EJB modules packaged in a WAR file.

For EJB modules in a WAR file (or an exploded directory), if a web application has one EJB module, and there are no other EJB modules in the classpath, those entries (libraries) are ignored. If there are other EJB modules, a temporary EAR file is created. For EJB modules in a WAR file to be tested, the client code must use EJB modules with interfaces or without annotations. Those EJB modules are not part of the classpath and can't be loaded by the client class loader.

To Use the EJB Embeddable API with Embedded Payara Server

1. To specify Payara Server as the Container Provider, include the `payara-embedded-all.jar` dependency in the class path of your embeddable EJB application.

   See Setting the Class Path and section 17.2 of the Jakarta Enterprise Beans specification.

2. Configure any required resources.

   The `jdbc/__default` H2 database is preconfigured in all distributions of the Payara Platform.

   If your embeddable EJB application uses Java Persistence, you do not need to specify a JDBC resource.

   See Default Jakarta Persistence Data Source for Embedded Payara Server.

3. Invoke one of the `createEJBContainer` methods.

   Do not deploy your embeddable EJB application or any of its dependent Jakarta EE modules before invoking one of the `createEJBContainer` methods. These methods perform deployment in the background and do not load previously deployed applications or modules.

4. To change the Instance Root Directory, set the `org.glassfish.ejb.embedded.glassfish.instance.root` system property value by using the `createEJBContainer(Map<?, ?> properties)` method.

   The default root directory location is `as-install/domains/domain1` if a non-embedded installation is referenced. This system property applies only to embeddable EJB applications used in Payara Server.

5. Close the EJB container properly to release all acquired resources and threads.

EJB Embeddable API Properties

Properties that can be passed to the `EJBContainer#createEJBContainer(Properties)` method are summarized in the following table.

All properties use the `org.glassfish.ejb.embedded.glassfish` prefix.
For example, the full name of the `installation.root` property is `org.glassfish.ejb.embedded.glassfish.installation.root`.

Table 179. EJB Embeddable API Properties

Property	Default	Description
`installation.root`	Payara Server installation location	The Installation Root Directory.
`instance.root`	In order of precedence: • `glassfish.embedded.tmpdir` property value specified in `GlassFishProperties` object • `glassfish.embedded.tmpdir` system property value • `java.io.tmp` system property value • `as-install/domains/domain1` if a non-embedded installation is referenced	The Instance Root Directory.
`configuration.file`	`domain-dir/config/domain.xml`	The server's configuration file.
`keep-temporary-files`	`false`	If `true`, keeps temporary files (exploded EAR file and configuration file) created by the embedded EJB container when Embedded Payara Server is stopped.
`web.http.port`	None	Enables the web container if set. Needed for testing web services in a WAR file. The value is ignored and can be an empty string.

Property	Default	Description
`instance.reuse`	`false`	If `true`, no changes are made to the existing configuration file, and a temporary server instance is not created for the embedded run. Instead, execution happens against the existing server instance. Do not use this option if the reused server instance could be in use by the running non-embedded Payara Server.
`skip-client-modules`	`false`	If `true`, omits modules from the classpath if they are not specified using `EJBContainer.MODULES` and have a manifest file with a `Main-Class` attribute.

Changing Log Levels in Payara Server Embedded

To change the JUL (Java Util Logging) log levels in Payara Server Embedded, you can follow the steps in this section, or you can use the Embedded Server API as shown in the previous examples.

For more information about Payara Server logging, see Administering the Logging Service in the Payara Server General Administration section.

You can change log levels in Payara Embedded Server in either of the following ways:

- Using the Payara Server Embedded Server API
- Creating a custom logging configuration file

Both these ways require logger names. For a list of logger names, use the `list-log-levels` subcommand.

This example shows how to set log levels using the `getLogger` method in the API:

```
import org.glassfish.embeddable.*;

public class EmbeddedRunner{

    public static void main(String[] args){
        // Create Embedded server
        var server = GlassFishRuntime.bootstrap().newGlassFish();

        // Set the log levels. For example, set 'deployment' log levels to FINEST

Logger.getLogger("javax.enterprise.system.tools.deployment").setLevel(Level.FINEST);
```

```
        // Start Embedded server and deploy an application.
        // You will see all the FINEST logs printed on the console.
        server.start();
        server.getDeployer().deploy(new File("sample.war"));

        // Dispose Embedded server
        server.dispose();
    }
}
```

This example shows the contents of a custom logging configuration file, `custom-logging.properties`.

```
handlers = java.util.logging.ConsoleHandler
java.util.logging.ConsoleHandler.level = FINEST
javax.enterprise.system.tools.deployment.level = FINEST
javax.enterprise.system.level = FINEST
```

Pass the name of this custom logging configuration file to the `java` command when you invoke the application starts the embedded server. For example:

```
java -Djava.util.logging.config.file=custom-logging.properties
fish.payara.embedded.ServerRunner
```

Default Jakarta Persistence Data Source for Embedded Payara Server

The `jdbc/__default` H2 database is preconfigured in any Embedded Payara Server. It is used when an application is deployed in Embedded Payara Server that uses Jakarta Persistence but doesn't specify a data source.

Embedded Payara Server uses an embedded H2 database created in a temporary domain that is destroyed when an embedded Payara Server is stopped. You can use an H2 database configured with non-embedded Payara Server if you explicitly specify the instance root directory or through its configuration file.

Restrictions for Payara Server Embedded Web Profile

The web profile variant of the Embedded API (`payara-embedded-web.jar`) only supports the following Payara Server features:

- The following web technologies of the Jakarta EE platform:
  - Jakarta Servlet
  - Jakarta Server Pages (JSP) technology
  - Jakarta Faces technology
- JDBC-technology connection pooling

- Jakarta Persistence
- Jakarta Transactions

The full profile variant of the Embedded API (`payara-embedded-all.jar`) support all features of Payara Server with the following exceptions:

- Administration Console
- Upgrade Tool (Enterprise-edition only)
- Apache Felix OSGi framework

Since an Embedded Payara Server requires no installation or configuration, the following files and directories are absent from the file system until the server is properly started:

- `default-web.xml` file
- `domain.xml` file
- Applications directory
- Instance root directory

When embedded Payara Server is started, the base installation directory that Payara Server uses depends on the options with which Payara Server is started. If necessary, an embedded Payara Server creates a base installation directory and then copies the following directories and their contents from the Java archive (JAR) file in which embedded Payara Server is distributed:

- `domains`
- `lib`

If necessary, Payara Server also creates an instance root directory.

Payara Server Embedded Use Cases

Overview of some expected use cases of Payara Server Embedded.

Bundle your Application

Where the installation of Payara Server and the deployment of the applications can't be done on a central infrastructure, you may opt to use Payara Embedded. In this case, you can bundle Payara Server with the application within a single application, which makes it easier for installing it.

Instead of having the three steps, installing Payara Server, configuring the environment, and deploying the application, you can do all those steps within the application containing Payara Embedded. You only need to start the application and the system is ready to respond to user requests.

Integration Testing

While performing integration testing, you may need to deploy the application to Payara in order to verify the behaviour of the code you have written. While you could use a standalone installation of Payara Server, cleanup is not always done correctly and can cause other tests to behave incorrectly.

Integration testing can be done easier and more consistently with Payara Embedded, you can start Payara up as the beginning of the test, verify the functionality and then use a clean instance for each test, therefore eliminating the possibility of an unexpected state in the environment.

Starting Payara Embedded for testing can also be done using the Arquillian connector. In that case, the setup and teardown of Payara is managed for you.

JDK 17 Considerations

When running Payara Embedded on JDK 17, you must update your client side run configuration with all the necessary opens and exports for Payara to work as expected. The following JVM options should be added within your run configuration:

```
--add-opens=java.base/jdk.internal.loader=ALL-UNNAMED --add
-opens=jdk.management/com.sun.management.internal=ALL-UNNAMED --add
-exports=java.base/jdk.internal.ref=ALL-UNNAMED --add-opens=java.base/java.lang=ALL
-UNNAMED --add-opens=java.base/java.nio=ALL-UNNAMED --add
-opens=java.base/sun.nio.ch=ALL-UNNAMED --add-opens=java.management/sun.management=ALL
-UNNAMED --add-opens=java.base/sun.net.www.protocol.jrt=ALL-UNNAMED
-Xbootclasspath/a:${com.sun.aas.installRoot}/lib/grizzly-npn-api.jar --add
-exports=java.base/sun.net.www=ALL-UNNAMED --add
-exports=java.base/sun.security.util=ALL-UNNAMED --add
-opens=java.base/java.lang.invoke=ALL-UNNAMED --add-opens=java.desktop/java.beans=ALL
-UNNAMED --add-exports=jdk.naming.dns/com.sun.jndi.dns=ALL-UNNAMED --add
-opens=java.base/sun.net.www.protocol.jar=ALL-UNNAMED
```

Application Development

Overview

This chapter describes how to create and run Jakarta EE applications in compatible Payara Platform distributions. Topics for this guide include developer tools, security, debugging and specific features for Jakarta EE specification implementations. This document is intended for use by software developers who create, assemble, and deploy Jakarta EE applications using the Payara Platform.

Related Documentation

The following tutorials explain how to develop Jakarta EE applications:

- Your First Cup: An Introduction to the Jakarta EE Platform. This is a recommended tutorial for programmers with no experience or knowledge about Jakarta EE, and it explains the entire process for developing a simple enterprise application using Eclipse Glassfish.
- The Jakarta EE Tutorial. This comprehensive tutorial explains how to use Jakarta EE platform

technologies and APIs to develop enterprise applications. This guide heavily references the contents of this tutorial to guide users in understanding the basic concepts of application development.

The Jakarta EE tutorial uses Eclipse Glassfish as its Jakarta EE runtime. Most of the concepts and instructions used in the tutorial should be directly equivalent to the Payara Platform given its similarities to Eclipse Glassfish.

The Jakarta EE specifications Javadoc documentation is listed within its specification resources under each corresponding specification site at https://jakarta.ee/specifications/.

The Jakarta EE Examples project is a collection of sample applications that demonstrate a broad range of Jakarta EE technologies. They are available to download in their own online repository.

Class Loaders

This section strictly applies to Payara Server.

Payara Server extends the default JVM classloading and provides additional classes, which are loaded by the class loaders included by default on this distribution. Understanding Payara Server class loaders can help you determine where to place supporting JAR and resource files for your modules and applications.

Understanding Payara Server class loaders can help you determine where to place supporting JAR and resource files for your modules and applications.

In a JVM implementation, the class loaders dynamically load a specific Java class file needed for resolving a dependency. For example, when an instance of `java.util.Enumeration` needs to be created, one of the class loaders loads the relevant class into the environment.

For information about class loader debugging, see Class Loader Debugging.

Standard Classloading

In a JVM implementation, the class loaders dynamically load a specific Java class file needed for resolving a dependency. For example, when an instance of `java.util.Enumeration` needs to be created, one of the class loaders loads the relevant class into the environment.

For information about class loader debugging, see Class Loader Debugging.

Class loaders in Payara Server follow a delegation hierarchy by default.

The Class Loader Hierarchy

Class loaders in the Payara Server runtime follow a delegation hierarchy that is illustrated in the following table:

Class Loader	Description
Bootstrap	The Bootstrap class loader loads the basic runtime classes provided by the JVM.
Extension	The Extension class loader loads classes from JAR files present in the system extensions directory, `domain-dir/lib/ext` (that is, libraries of type `ext`). It's parent to the Public API class loader. The Extension classloader no longer works using the Java Optional Package mechanism (see http://docs.oracle.com/javase/8/docs/technotes/guides/extensions/extensions.html) since this mechanism is no longer supported in Java 11+. Instead, this classloader is designed to "trick" the server in handling delegation much sooner.
Public API	The Public API class loader makes available all classes specifically exported by the Payara Server runtime for use by deployed applications. This includes, but is not limited to, Jakarta EE API, Eclipse MicroProfile and the Payara Platform Public API. Parents the Common class loader.
Common	The Common class loader loads JAR files in the`as-install/lib` directory, followed by JAR files in the `domain-dir/lib` directory. Using `domain-dir/lib` is recommended whenever possible, and required for custom login modules and security realms. Parents the Connector class loader.
Connector	The Connector class loader is a single class loader instance that loads individually deployed connector modules, which are shared across all applications. Parents the **Applib** class loader.
Applib	The `Applib` class loader loads the library classes (specifically, libraries of the `app` type), specified during deployment, for a specific enabled module or Jakarta EE application; One instance of this class loader is present in each class loader universe; Parents the Archive class loader. When multiple deployed applications use the same library, they share the same instance of the library. One library cannot reference classes from another library.

Class Loader	Description
Archive	The Archive class loader loads classes from the WAR, EAR, and JAR files or directories (for directory deployment) of applications or modules deployed in Payara Server. This class loader also loads any application-specific classes generated by the Payara Server runtime, such as stub classes or servlets generated by JSP pages.

Classloaders that are lower in the hierarchy will first delegate searching for a class to a classloader higher in the hierarchy.

If none of the classloaders higher in the hierarchy finds the class, the classloader will attempt to find the class itself.

Here, you can see that:

- Classes provided by Payara Server have higher priority than classes provided by an application
- Classes provided by Payara Server have higher priority than installed libraries of type `common` and `app`.
- Classes in installed libraries have higher priority than classes provided by an application
- To install a library with a higher priority than classes provided by Payara Server, it should be installed with the `ext` type.

Configuring Delegation

The Jakarta Servlet specification recommends that a web module's class loader look in the local class loader before delegating to its parent.

You can make this class loader follow the delegation inversion model in the Servlet specification by setting `delegate="false"` in the `class-loader` element of the `payara-web.xml` file. It is safe to do this only for a web module that does not interact with any other modules.

For more details, see "class-loader" in the Payara Server Application Deployment section. An example of how to use this element is given in the disabling classloading delegation on web application section.

The default value is `delegate="true"`, which causes a web module's class loader to delegate in the same manner as the other class loaders. You must use `delegate="true"` for a web application that accesses EJB components or that acts as a web service client or endpoint.

For a number of packages, including `java.*` and `jakarta.\*`, symbol resolution is always delegated to the parent class loader regardless of the `delegate` setting. This prevents applications from overriding core Java runtime classes or changing the API versions of specifications that are part of the Jakarta EE platform.

The delegation hierarchy can also be tweaked using the enhanced classloading features. For example, it's possible to give the classes provided by an application the highest priority (by disabling classloading delegation), or completely hide (isolate) classes provided by Payara Server

from a deployed application.

Class Loader Universes

Access to components within applications and modules installed on the server occurs within the context of isolated class loader universes, each of which has its own *Applib* and *Archive* classloaders.

Application Universe

Each application has its own class loader universe, which loads the classes in all the modules in the application.

Individually Deployed Module Universe

Each individually deployed EJB JAR or web WAR has its own class loader universe, which loads the classes in the module.

A resource such as a file that is accessed by a Jakarta EE application component must be in one of the following locations:

- A directory pointed to by the Libraries field or `--libraries` option used during deployment
- A directory pointed to by the `library-directory` element in the `application.xml` deployment descriptor
- A directory pointed to by the application or module's classpath; for example, a web module's classpath includes these directories:

```
module-name/WEB-INF/classes
module-name/WEB-INF/lib
```

Installing Libraries in a Domain

Since each application or individually deployed module class loader universe is isolated, an application or module cannot load classes from another application or module. *This prevents two similarly named classes in different applications or modules from interfering with each other.*

To circumvent this limitation for libraries, utility classes, or individually deployed modules accessed by more than one application, you can include the relevant path to the required classes by installing a library with those classes into the server domain. This is useful if you'd like to build an application for flexible deployments and configure it with classes dropped on the classpath, or if you'd like multiple deployed applications to share the same library.

If an internal server resource, such as a JDBC connection pool, requires an additional library, you can install it directly into the Payara Server domain too.

To install a library into a server domain, use the asadmin add-library command.

This command accepts the `--type` argument, which accepts the following options:

`common`

The library is installed as a common library into the `lib` directory in the Payara Server domain

`ext`

The library is installed as an "extension" library into the `lib/ext` directory in the Payara Server domain

`app`

the library is installed as an application library into the `lib/applibs` directory in the Payara Server domain

Common Libraries

Common libraries are available to all applications or modules deployed on servers with the same configuration. There are several levels of common libraries:

- Shared by all applications deployed on the same Payara Server installation - located in the `glassfish/lib` directory in the Payara Server installation
- Shared by all applications deployed in the same Payara Server domain - located in the `lib` directory in that Payara Server domain directory
- Shared by all applications deployed on instances that share the same configuration - located in the `config/<config-name>/lib` directory in the particular Payara Server domain directory

Only libraries shared by applications in the same domain can be installed by the `add-library` asadmin command. All other types have to be installed manually by copying the libraries into the particular locations.

Extension Libraries

Application developers can use libraries installed as extension libraries to extend the functionality of the core Payara Server platform. For example, an Oracle Database JDBC driver should be installed as an extension library if it's going to be used via JPA to use Oracle-specific JPA features.

Or a Java agent library should be installed as an extension library if the Java agent instruments classes in Payara Server to use classes from the agent library itself.

Classes in extension libraries will be available to all deployed applications. If you need that classes from an extension library are available also to Payara Server's internal classes (and OSGi bundles in general) as is often the case with Java agents, you also need to add the packages exported by the library into OSGi boot delegation.

This is done by modifying the `as-install/config/osgi.properties` configuration file in the Payara Server installation and adding the packages to the list in the `org.osgi.framework.bootdelegation` property.

Packages exported by Oracle JDBC drivers are already added by default.

Extension libraries are added to the system classpath at the beginning of the classpath, so that they have higher priority than all other classes and libraries on the classpath. This is because the Java extension mechanism isn't supported in Java 11 and newer and the official recommend way to replace it is to add the libraries to the classpath directly.

Since defining the `java.ext.dirs` on Java 11+ leads to an error, this JVM option cannot be used with Java 11+ and extension libraries are automatically added as classpath elements.

Application Specific Libraries

You can specify module or application-specific library classes in one of the following ways:

- Use the Administration Console. Open the *Applications* component, then go to the page for the type of application or module. Select the *Deploy* button. Type the comma-separated paths in the *Libraries* field.
- Use the `asadmin deploy` command with the `--libraries` option and specify comma-separated paths. For more details, see the Payara Server Reference Manual.
- Use the `asadmin add-library` command with the `--type app` option. For details, see the add-library.

None of these alternatives apply to application clients. For more information, see Using Libraries with Application Clients.

You can update a library JAR file using dynamic reloading or by restarting (disabling and re-enabling) a module or application. To add or remove library JAR files, you can redeploy the module or application. Application libraries are included in the *Applib* class loader. Paths to libraries can be relative or absolute.

A relative path is relative to `domain-dir/lib/applibs`. If the path is absolute, the path must be accessible to the domain administration server (DAS). Payara Server automatically synchronizes these libraries to all remote instances when a cluster or deployment group is restarted. However, libraries specified by absolute paths are not guaranteed to be synchronized.

You can also use application-specific class loading to access different versions of a library from different applications.

If multiple applications or modules refer to the same libraries, classes in those libraries are automatically shared. This can reduce the memory footprint and allow sharing of static information. However, applications or modules using application-specific libraries are not portable.

If you see an access control error message when you try to use a library, you may need to grant permission to the library in the `server.policy` file. For more information, see Changing Permissions for an Application.

Packaging the Client JAR for One Application in Another Application

By packaging the client JAR for one application in a second application, you allow a Jakarta EE component in the second application to call an EJB component in the first (dependent) application,

without making either of them accessible to any other application or module.

As an alternative for a production environment, you can have the Common class loader load the client JAR of the dependent application as described in the previous section.

To do this follow these steps:

1. Deploy the dependent application.
2. Add the dependent application's client JAR file to the calling application.
   - For a calling EJB component, add the client JAR file at the same level as the EJB component. Then add a `Class-Path` entry to the `MANIFEST.MF` file of the calling EJB component.
   - For a calling web component, add the client JAR file under the `WEB-INF/lib` directory.

     If you need to package the client JAR with both the EJB and web components, set `delegate="true"` attribute in the `class-loader` element of the `payara-web.xml` file.

     This changes the Web class loader so that it follows the standard class loader delegation model and delegates to its parent before attempting to load a class itself.

     For most applications, packaging the client JAR file with the calling EJB component is sufficient. You do not need to package the client JAR file with both the EJB and web components unless the web component is directly calling the EJB component in the dependent application.
3. Deploy the "client" application. The calling EJB or web component must specify in its `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` or `payara-web.xml` file the JNDI name of the EJB component in the dependent application. Using an `ejb-link` mapping does not work when the EJB component being called resides in another application.

Enhanced Classloading

This sections below cover the enhanced class loading functionality provided by the Payara Platform.

Default Class and Library Loading

Payara Server has included many standard Java libraries and packages, for example **Jackson**, **Nimbus JOSE**, **Logback**, and others to use. These libraries are located on the `as-install/modules` directory.

The default class loading mechanism of Payara Server works like this: When loading classes that belong to a library or framework that is included in the server, the server **will always** load those classes even if the application itself includes different versions.

In some cases, application developers will want to include a different version of the libraries that are already included on the server. Common use cases for this are:

1. Use a newer version of a library that is included in the server. For example, Payara Server

includes the Jackson library, and you might need to use a newer version that includes a specific feature you want to use.

2. Use an older version of a library included within the server in order to support legacy applications. For example, you are using an older version of **Icefaces** that depends on an older version of Jakarta Faces.

Unfortunately, due to the way the default class loading hierarchy works, this will not be possible, and all libraries included with the server libraries will take precedence.

Disable Classloading delegation

As detailed in Configuring Delegation, it is possible to invert/disable the way that delegation works as per the requirements of the Jakarta Servlet specification. The Payara Platform introducers greater delegation disabling mechanisms, detailed in the following sections.

Disable Classloading delegation globally

To disable class loading delegation globally, you can set the system property `fish.payara.classloading.delegate` to `false`.

Disable Classloading delegation locally

It's possible to disable class loading delegation directly at the application level. This can be done for both WAR and EAR applications.

[[Technical Documentation-Application Development-Class Loaders:::disabling-classloading-delegation-on-webapps]#Technical Documentation-Application Development-Class Loaders:::disabling-classloading-delegation-on-webapps] For **Web** applications, you can include `<class-loader delegate="false"/>` element in the `payara-web.xml`/`glassfish-web.xml` deployment descriptor.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

Here's an example:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app error-url="">
  <class-loader delegate="false"/>
</payara-web-app>
```

[[Technical Documentation-Application Development-Class Loaders:::disabling-classloading-delegation-on-ears]#Technical Documentation-Application Development-Class Loaders:::disabling-classloading-delegation-on-ears] For **EAR** applications, you can include the `<classloading-delegate>false</classloading-delegate>` element in the `payara-application.xml` deployment descriptor.

Here is an example:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-application PUBLIC "-//Payara.fish//DTD Payara Application Server 7
Jakarta EE Application 11//EN" "https://raw.githubusercontent.com/payara/Payara-
Documentation/main-7/docs/modules/ROOT/pages/Appendix/Schemas/payara-application_11-
0.dtd">
<payara-application>
    <classloading-delegate>false</classloading-delegate>
</payara-application>
```

Extreme Classloading Isolation

It's possible to configure an extreme isolation level on the class loading delegation for deployed applications. With this extreme isolation behavior, a deployed application can force the server to load only classes and resources from libraries included on the server that belong to **whitelisted packages** defined on its deployment descriptors.

To configure whitelist packaging you can use the `<whitelist-package>` element on the `payara-web.xml` / `glassfish-web.xml` (for WAR artifacts) or the `glassfish-application.xml`/`payara-application.xml` (for EAR artifacts) deployment descriptors. This element can be included multiple times to whitelist multiple packages.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

Here is an example of whitelisting both the **Google Guava**, **Jackson** and **Faces Config** packages for a WAR application:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app error-url="">
  <whitelist-package>com.google.guava</whitelist-package>
  <whitelist-package>com.fasterxml.jackson</whitelist-package>
  <whitelist-package>com.sun.faces.spi.FacesConfigResourceProvider</whitelist-package>
</payara-web-app>
```

The whitelist syntax is simple: Define the name of the package which contains the classes or resources in question. For example writing `com.google` would whitelist all Google libraries included on the server, while writing `com.google.guava` would only whitelist the Google Guava library instead.

To enable this extreme isolation behavior, at least one `whitelist-package` element must be defined in the appropriate descriptor.

Default Whitelisted Classes

Certain classes are whitelisted automatically, meaning they will always be loaded from the server libraries and follow the default classloading hierarchy, even if this feature is turned on.

This is because these packages are required by the server and therefore cannot be loaded from application modules:

- `java`
- `javax`
- `com.sun`
- `org.glassfish`
- `org.apache.jasper`
- `fish.payara`
- `com.ibm.jbatch`
- `org.hibernate.validator`
- `org.jboss.weld`
- `com.ctc.wstx`

Likewise, the default whitelisted resources are:

- `META-INF/services/jakarta.`
- `META-INF/services/org.glassfish.`
- `META-INF/services/java.`

Debugging Applications

This chapter gives guidelines for debugging applications deployed in Payara Server or Payara Micro.

Debugging in Payara Server

Enabling Debugging

When you enable debugging, you enable both local and remote debugging. To start the server in debug mode, use the `--debug` option as follows:

```
asadmin start-domain --debug [domain-name]
```

You can then attach to the server from the Java Debugger (`jdb`) at its default Java Platform Debugger Architecture (JPDA) port, which is `9009`.

For example, in UNIX systems:

```
jdb -attach 9009
```

And for Windows OS:

```
jdb -connect com.sun.jdi.SocketAttach:port=9009
```

For more information about the `jdb` debugger, see the following official Java SE 11 documentation links:

- Java Platform Debugger Architecture: https://docs.oracle.com/en/java/javase/11/docs/specs/jpda/jpda.html
- Java SE `jdb` command: https://docs.oracle.com/en/java/javase/11/tools/jdb.html

Payara Server debugging is based on JPDA. For more information, see JPDA Options.

You can attach any JPDA compliant debugger to Payara Server, including that of all major Java IDE environments like IntelliJ, Apache Netbeans, Eclipse and Visual Studio Code.

You can enable debugging even when Payara Server is started without the `--debug` option. This is useful in development environments where you want to make sure that debugging is always turned on.

To Set the Server to Automatically Start Up in Debug Mode

1. Use the Administration Console. Select the *JVM Settings* component under the relevant configuration.
2. Check the *Debug Enabled* box.
3. To specify a different port (from `9009`, the default) to use when attaching the JVM software to a debugger, specify `address=` port-number in the *Debug Options* field.
4. To add JPDA options, add any desired JPDA debugging options in Debug Options. See JPDA Options.

JPDA Options

The default JPDA options in Payara Server are as follows:

```
-Xdebug -agentlib:transport=dt_socket,server=y,suspend=n,address=9009
```

In Windows OS, you can change `dt_socket` to `dt_shmem` to connect via a shared memory transport protocol.

If you specify `suspend=y`, the JVM software starts in suspended mode and stays suspended until a debugger attaches to it. This is helpful if you want to start debugging as soon as the JVM process starts.

To specify a different port (from `9009`, the default) to use when attaching the JVM software to a debugger, specify `address=<port-number>`.

You can include any additional options if needed.

Generating a Stack Trace for Debugging

To generate a Java stack trace for debugging purposes, use the `asadmin generate-jvm-report --type=thread` command. The generated stack trace goes to the `domain-dir/logs/server.log` file and also appears on the command prompt screen.

For more information about the `asadmin generate-jvm-report` command, see `generate-jvm-report`.

Application Client Debugging

When the `appclient` script executes the `java` command to run the Application Client Container (ACC), which in turn runs the client itself, it includes on the command line the value of the `VMARGS` environment variable. You can set this variable to any suitable value. For example:

```
VMARGS=-agentlib:transport=dt_socket,server=y,suspend=y,address=8118
```

For debugging an application client, you must set the suspend option to `y` so you can connect the debugger to the client before any code has actually executed. Otherwise, the client may start running and execute past the point you want to examine.

You should use different ports for the server and client if you are debugging both concurrently. For details about setting the port, see JPDA Options.

You can also include JVM options in the `appclient` script directly. For information about the `appclient` script, see `appclient`.

The Application Client Container is supported only in the Full Profile, not in the Web Profile. See Developing Java Clients.

Open Message Queue Debugging

Open Message Queue has a broker logger, which can be useful for debugging Java Message Service (JMS) applications, including message-driven bean applications.

You can adjust the logger's verbosity, and you can send the logger output to the broker's console using the broker's `-tty` option.

JMS resources are supported only in the Full Profile, not in the Web Profile. See Using Jakarta Messaging.

Enabling Verbose Mode

To have the server logs and messages printed to `System.out` on your command prompt screen, you

can start the server in **verbose mode**. This makes it easy to do simple debugging using print statements, without having to check the `server.log` file every time.

To start the domain in verbose mode, use the `--verbose` option as follows:

```
asadmin start-domain --verbose [domain-name]
```

When the server is in verbose mode, messages are logged to the console or terminal window in addition to the log file. In addition, pressing `Ctrl-C` stops the server and pressing `Ctrl-\` (on UNIX platforms) or `Ctrl-Break` (on Windows OS) prints a thread dump.

On UNIX platforms, you can also print a thread dump using the `jstack` command or the command `kill -QUIT <process_id>`.

Class Loader Debugging

To generate class loading messages you can use the `-Xlog` JVM argument by running the following `asadmin create-jvm-options` command:

```
asadmin create-jvm-options -Xlog\:class+load
```

As classloading debugging messages will heavily populate the standard output, it is recommended to log these entries on a special log file. The `-Xlog` argument can be appended with the `file:[file-path]` option to store the information on a separate log file like this:

```
asadmin create-jvm-options -Xlog\:class+load\:file=classloading.log
```

It is recommended that this log is located in the standard logs directory output like so:

```
asadmin create-jvm-options
-Xlog\:class+load\:file=${com.sun.aas.instanceRoot}/logs/classloading.log
```

More information about how to configure the log levels of events to filter and other useful tags available to the `-Xlog` JVM argument cane be read on its command help output by running `java -Xlog:help`

Debugging in Payara Micro

As Payara Micro server instance is a standalone Java process that runs without an administration interface, debugging applications that run in it is as simple as configuring the debugging options when launching a new server instance from the command line:

```
java -agentlib:jdwp=transport=dt_socket,server=y,address=9011,suspend=y -jar payara-
micro.jar --deploy myapp.war
```

Then you can attach a new debugger session from within your preferred IDE.

Profiling Tools

You can use a profiler to perform remote profiling on Payara Server to discover bottlenecks in server-side performance. Profilers are extremely useful (either **Instrumental** or **Sampling** profiles) in analysing the CPU cycles of an application's specific components, finding bottlenecks on long-spanning operations, track the runtime of specific methods, etc.

Most profiling tools in the market can be integrated with Payara Server running on Java 11. The following "free-to_use" tools are recommended to be used due to their simplicity and ease to integrate with Payara Server:

Apache NetBeans Profiler

Comes bundled with Apache Netbeans, which has native support for running, debugging and profiling applications in Payara Server. For more information read Introduction to Profiling Java Applications in NetBeans IDE

Async Profiler

A powerful lightweight profiler that can run locally or remotely and trace CPU cycles, hardware and software performance and do Java Heap allocation analysis. This profiler is currently maintained as an open source project.

If using IntelliJ IDEA Ultimate, Async profiler is bundled by default and requires no extra installation.

Securing Applications

This chapter describes how to write secure Jakarta EE applications, which contain components that perform user authentication and access authorization for the business logic of Jakarta EE components.

For general information about Jakarta EE security, see Security in The Jakarta EE Tutorial.

Payara Server's Web Profile supports the EJB 4.0+ specification, which allows enterprise beans within web applications, among other features. The Full Profile supports the entire EJB 4.0+ specification. For details, see Jakarta Enterprise Beans.

Security Goals

In an enterprise computing environment, there are many security risks. The goal of Payara Server is to provide highly secure, interoperable, and distributed component computing based on the Jakarta EE security model. Security goals include:

- Full compliance with the Jakarta EE security model. This includes EJB and servlet role-based authorization.
- Full compliance with Eclipse MicroProfile JWT Propagation API.
- Support for single sign-on across all Payara Server applications within a single security domain.

- Support for web services message security.
- Security support for application clients.
- Support for the Jakarta Authentication API.
- Support for the Jakarta Authorization API.
- Support for Web Services Interoperability Technologies (WSIT) as described in the Metro Users Guide.
- Support for the Jakarta Security API
- Support for several underlying security realms, such as simple file, JDBC and Lightweight Directory Access Protocol (LDAP) configurable realms.

  Certificate authentication is also supported for Secure Socket Layer (SSL) client authentication.

  For Solaris, OS platform authentication is supported in addition to these.

- Support for declarative security through Payara Server specific XML-based role mapping.
- Support for OpenID Connect compatible security features (such as OAuth2).

Payara Server Specific Security Features

Payara Server supports the Jakarta EE Platform's security model (and added features courtesy of Eclipse MicroProfile APIs), as well as the following features which are specific to it:

- Message security; see Configuring Message Security for Web Services
- Single sign-on across all Payara Server applications within a single security domain; see User Authentication for Single Sign-on
- Programmatic login; see Programmatic Login Using the ProgrammaticLogin Class
- OAuth2 integration support.

Container Security

The component containers are responsible for providing Jakarta EE application security. The container provides two security forms:

- Declarative Security
- Programmatic Security

Annotations (also called metadata) enable a declarative style of programming, and so encompass both the declarative and programmatic security concepts. Users can specify information about security within a class file using annotations.

When an application is deployed, this information can either be used by or overridden by the application or module deployment descriptors.

Declarative Security

Declarative security means that the security mechanism for an application is declared and handled

externally to the application.

Deployment descriptors describe the Jakarta EE application's security structure, including security roles, access control, and authentication requirements.

Payara Server supports the deployment descriptors specified by Jakarta EE and has additional security elements included in its own deployment descriptors. Declarative security is the application deployer's responsibility.

There are two levels of declarative security, as follows:

- Application Level Security
- Component Level Security

Application Level Security

For an application, roles used by any application must be defined in `@DeclareRoles` annotations in the code or `role-name` elements in the application deployment descriptor (`application.xml`).

These role names are scoped to the EJB XML deployment descriptors (`ejb-jar.xml` and `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` files) and to the servlet XML deployment descriptors (`web.xml` and `payara-web.xml` files).

For an individually deployed web or EJB module, you define roles using `@DeclareRoles` annotations or `role-name` elements in the Jakarta EE deployment descriptor files `web.xml` or `ejb-jar.xml`.

To map roles to principals and groups, define matching `security-role-mapping` elements in the `glassfish-application.xml`/`payara-application.xml`, `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml`, or `glassfish-web.xml`/`payara-web.xml` file for each `role-name` used by the application.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

By default, group principal names are mapped to roles of the same name. Accordingly, the **Default Principal To Role Mapping** setting is enabled by default on the *Security* page of the Payara Server Administration Console.

This default role mapping definition is in effect if you do not define your own mapping in the deployment descriptor for your application as described in this section.

Component Level Security

Component level security encompasses web components and EJB components.

A secure web container authenticates users and authorizes access to a servlet or JSP by using the security policy laid out in the servlet XML deployment descriptors (`web.xml`, `glassfish-web.xml` and `payara-web.xml` files).

glassfish-web.xml is deprecated and support will be removed in a future release. It

> is recommended to use payara-web.xml instead.

The EJB container is responsible for authorizing access to a bean method by using the security policy laid out in the EJB XML deployment descriptors (`ejb-jar.xml` and `glassfish-ejb-jar.xml` /`payara-ejb-jar.xml` files).

Programmatic Security

Programmatic security involves an EJB component or servlet using method calls to the security API, as specified by the Jakarta EE security model, to make business logic decisions based on the caller or remote user's security role.

Programmatic security should only be used when declarative security alone is insufficient to meet the application's security model.

The API for programmatic security consists of methods of the Jakarta Security API `SecurityContext` interface, and methods of the EJB `EJBContext` interface and the servlet `HttpServletRequest` interface.

Payara Server supports these interfaces as specified in the Jakarta EE specification.

There is also a proprietary Payara API for programmatic login. See Programmatic Login Using the ProgrammaticLogin Class.

For more information about programmatic security in web applications, see Using Programmatic Security with Web Applications in the Jakarta EE Tutorial.

Roles, Principals, and Principal to Role Mapping

By default, any groups that an authenticated user belongs to will be mapped to roles with the same names.

Therefore, the **Default Principal To Role Mapping** setting is enabled by default on the *Security* page of the Payara Administration Console. To change the default mapping you can clear this setting.

For applications, you define roles in `@DeclareRoles` annotations or the Jakarta EE deployment descriptor file `application.xml`. You define the corresponding role mappings in the Payara Server deployment descriptor file `glassfish-application.xml`/`payara-application.xml`.

For individually deployed web or EJB modules, you define roles in `@DeclareRoles` annotations or the Jakarta EE deployment descriptor files `web.xml` or `ejb-jar.xml`. You define the corresponding role mappings in the Payara Server deployment descriptor files `glassfish-web.xml`/`payara-web.xml` or `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml`.

For more information regarding Jakarta EE deployment descriptors, see the Jakarta EE Specification. For more information regarding Payara Server deployment descriptors, see "Elements of the Payara Server Deployment Descriptors" in the Application Deployment section.

Each `security-role-mapping` element in the `glassfish-application.xml`/`payara-application.xml`, `glassfish-web.xml`/`payara-web.xml`, or `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` file maps a role name permitted by the application or module to principals and groups.

For example, a `payara-web.xml` file for an individually deployed web module might contain the following:

```
<payara-web-app>
    <security-role-mapping>
        <role-name>manager</role-name>
        <principal-name>jgarcia</principal-name>
        <principal-name>mwebster</principal-name>
        <group-name>team-leads</group-name>
    </security-role-mapping>
    <security-role-mapping>
        <role-name>administrator</role-name>
        <principal-name>dsmith</principal-name>
    </security-role-mapping>
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

A role can be mapped to either specific principals or to groups (or both). The principal or group names used must be valid principals or groups in the realm for the application or module.

Note that the `role-name` in this example must match the `@DeclareRoles` annotations or the `role-name` in the `security-role` element of the corresponding `web.xml` file.

You can also specify a custom principal implementation class. This provides more flexibility in how principals can be assigned to roles.

A user's Jakarta Authentication login module now can authenticate its custom principal, and the authenticated custom principal can further participate in the Payara Server's authorization process. For example:

```
<security-role-mapping>
    <role-name>administrator</role-name>
    <principal-name class-name="CustomPrincipalImplClass">dsmith</principal-name>
</security-role-mapping>
```

You can specify a default principal and a default principal to role mapping, each of which applies to the entire Payara Server instance. The default principal to role-mapping maps group principals to the same named roles.

Web modules that omit the `run-as` element in `web.xml` use the default principal. Applications and modules that omit the `security-role-mapping` element use the default principal to role mapping. These defaults settings are part of the *Security Service*, which you can access in the following ways:

- In the Administration Console, select the *Security* component under the relevant configuration.
- Use the `asadmin set` command. For example, you can set the default principal as follows:

```
asadmin set server-config.security-service.default-principal=dsmith
asadmin set server-config.security-service.default-principal-password=secret
```

You can set the default principal to role mapping as follows.

```
asadmin set server-config.security-service.activate-default-principal-to-role-
mapping=true
asadmin set server-config.security-service.mapped-principal-
class=CustomPrincipalImplClass
```

Default principal to role mapping is enabled by default. To disable it, set the default principal to role mapping property to `false`.

Realm Configuration

Supported Security Realms

The following security realms are supported:

- `file` - Stores user information in a file. This is the default realm.
- `ldap` - Stores user information in an LDAP directory.
- `jdbc` - Stores user information in a database.

  In the JDBC realm, the server gets user credentials from a database Payara Server uses the database information and the enabled JDBC realm option in the configuration file.

  For digest authentication, a JDBC realm should be created with `jdbcDigestRealm` as the JAAS context.

- `certificate` - Sets up the user identity in the Payara Server's security context, and populates it with user data obtained from cryptographically verified client certificates.
- `solaris` - Allows authentication using Solaris `username+password` data.

This realm is only supported on the Solaris operating system, version 9 and above

How to Configure a Security Realm

You can configure a realm in one of these ways:

- In the Administration Console, open the *Security* component under the relevant configuration and go to the *Realms* page.
- Use the `asadmin create-auth-realm` command to create a new security realms.

How to Set a Realm for an Application or Module

The following deployment descriptor elements have optional `realm` or `realm-name` data sub-elements

or attributes that override the domain's default realm:

- `glassfish-application`/`payara-application` element in `glassfish-application.xml`/`payara-application.xml`
- `web-app` element in `web.xml`
- `as-context` element in `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml`
- `client-container` element in `sun-acc.xml`
- `client-credential` element in `sun-acc.xml`

If modules within an application specify realms, these are ignored. If present, the realm defined in `glassfish-application.xml`/`payara-application.xml` is used, otherwise the domain's default realm is used.

For example, a realm is specified in `payara-application.xml` as follows:

```
<payara-application>
    ...
    <realm>ldap</realm>
</payara-application>
```

For more information about the deployment descriptor files and elements, see "Elements of the Payara Server Deployment Descriptors" in the Payara Server Application Deployment section.

Creating a Custom Realm

You can create a custom security realm by providing a custom Jakarta Authentication login module class and a custom security realm class.

Client-side login modules are not suitable for use with Payara Server.

To activate custom login modules and security realms, place their corresponding JAR files in the `domain-dir/lib` directory or the class files in the `domain-dir/lib/classes` directory.

For more information about class loading in the Payara Server, see Class Loaders.

Jakarta Authentication is a set of APIs that enable services to authenticate and enforce access controls upon users. They provide a pluggable and extensible framework for programmatic user authentication and authorization.

For Javadoc tool pages relevant to custom realms, see the `com.sun.appserv.security` package.

Custom login modules must extend the `com.sun.appserv.security.AppservPasswordLoginModule` class. This class implements `jakarta.security.auth.spi.LoginModule`.

Custom login modules must not implement the `LoginModule` interface directly.

Custom login modules must provide an implementation for one `abstract` method defined in the

`AppservPasswordLoginModule` class:

```
public abstract class AppservPasswordLoginModule extends BasePasswordLoginModule {
    abstract protected void authenticateUser() throws LoginException;
}
```

This method performs the actual authentication. The custom login module must not implement any of the other methods, such as `login`, `logout`, `abort`, `commit`, or `initialize`.

Default implementations are provided in `AppservPasswordLoginModule` which hook into the Payara Server infrastructure.

The custom login module can access the following protected object fields, which it inherits from `AppservPasswordLoginModule`. These contain the username and password credentials of the user to be authenticated:

```
public abstract class AppservPasswordLoginModule extends BasePasswordLoginModule {
    protected String _username;
    protected String _password;
}
```

The `authenticateUser` method must end with the following code sequence:

```
public abstract class AppservPasswordLoginModule extends BasePasswordLoginModule {

    protected void authenticateUser() throws LoginException{
        String[] grpList;
        // populate grpList with the set of groups to which
        // _username belongs in this realm, if any
        commitUserAuthentication(grpList);
    }
}
```

Custom security realms must extend the `com.sun.appserv.security.AppservRealm` class and implement the following methods:

```
public abstract class AppservRealm extends BaseRealm {
    public void init(Properties props) throws BadRealmException, NoSuchRealmException;
}
```

This method is invoked during server startup when the realm is initially loaded. The `props` argument contains the configuration properties defined for this realm. The realm can do any initialization it needs in this method.

If the method returns without throwing an exception, Payara Server assumes that the realm is

ready to service authentication requests. If an exception is thrown, the realm is disabled.

```
public abstract class AppservRealm extends BaseRealm {
    public String getAuthType();
}
```

This method returns a descriptive string representing the type of authentication done by this realm.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract Enumeration getGroupNames(String username) throws
InvalidOperationException, NoSuchUserException;
}
```

This method returns an `Enumeration` (of `String` objects) enumerating the groups (if any) to which the given `username` belongs in this realm.

Custom realms that manage users must implement the following additional methods:

```
public abstract class AppservRealm extends BaseRealm {
    public abstract boolean supportsUserManagement();
}
```

This method returns `true` if the realm supports user management.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract Enumeration getGroupNames() throws BadRealmException;
}
```

This method returns an `Enumeration` of all group names.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract Enumeration getUserNames() throws BadRealmException;
}
```

This method returns an `Enumeration` of all usernames.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract void refresh() throws BadRealmException;
}
```

This method refreshes the realm data so that new users and groups are visible.

```
public abstract class AppservRealm extends BaseRealm {
```

```
    public abstract void persist() throws BadRealmException;
}
```

This method persists the realm data to permanent storage.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract User getUser(String name) throws
NoSuchUserException,BadRealmException;
}
```

This method returns the information recorded about a particular named user.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract void addUser(String name, String password, String[] groupList)
throws BadRealmException, IASSecurityException;
}
```

This method adds a new user, who cannot already exist in the realm's storage.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract void removeUser(String name) throws NoSuchUserException,
BadRealmException;
}
```

This method removes a user, who must exist in the realm's storage.

```
public abstract class AppservRealm extends BaseRealm {
    public abstract void updateUser(String name, String newName, String password,
String[] groups) throws NoSuchUserException, BadRealmException, IASSecurityException;
}
```

This method updates data for a user, who must exist.

The array passed to the `commitUseAuthentication` method should be newly created and otherwise unreferenced. This is because the group name array elements are set to null after authentication as part of cleanup.

So the second time your custom realm executes it returns an array with `null` elements.

Ideally, your custom realm should not return member variables from the `authenticate` method. It should return local variables Your custom realm can create a local `String` array in its `authenticate` method, copy the values from the member variables, and return the `String` array.

The `server.policy` File

Each Payara Server domain has its own global Java policy file, located in `domain-dir/config`. The file is named `server.policy`.

Payara Server is a Jakarta EE compliant application server. As such, it follows the requirements of the Jakarta EE specification, including the ability to run application components in the presence of a security manager (the internal Java component that enforces the policy) and a limited permission set for Jakarta EE application code.

Default Permissions

Internal server code is granted all permissions. These are covered by the `AllPermission` grant blocks to various parts of the server infrastructure code.

Application permissions are granted in the default `grant` block. These permissions apply to all code not part of the internal server code listed previously.Payara Server does not distinguish between EJB and web module permissions.

All code is granted the minimal set of web component permissions (which is a superset of the EJB minimal set).

A few permissions above the minimal set are also granted in the default `server.policy` file. These are necessary due to various internal dependencies of the server implementation. Jakarta EE application developers must not rely on these additional permissions.

In some cases, deleting these permissions might be appropriate. For example, one additional permission is granted specifically for using connectors. If connectors are not used in a particular domain, you should remove this permission, because it is not otherwise necessary.

Unless strictly required, do not modify the entries for the default permissions under any circumstance.

System Properties

The following predefined system properties, also called system variables, are available for use in the `server.policy` file.

The system property most frequently used in the `server.policy` file is `${com.sun.aas.instanceRoot}`.

Table 180. Predefined System Properties

Property	Default	Description
`com.sun.aas.installRoot`	Depends on operating system	Specifies the directory where Payara Server is installed.
`com.sun.aas.instanceRoot`	Depends on operating system	Specifies the top level directory for a server instance.
`com.sun.aas.hostName`	`none`	Specifies the name of the host (machine).

Property	Default	Description
com.sun.aas.javaRoot	Depends on operating system	Specifies the installation directory for the Java runtime.
com.sun.aas.imqLib	Depends on operating system	Specifies the library directory for the Open Message Queue software.
com.sun.aas.configName	server-config	Specifies the name of the configuration used by a server instance.
com.sun.aas.instanceName	server1	Specifies the name of the server instance.
com.sun.aas.clusterName	cluster1	Specifies the name of the cluster. This property is only set on clustered server instances. This property is not supported for **deployment groups**.
com.sun.aas.domainName	domain1	Specifies the name of the domain.

The com.sun.aas.instanceName, com.sun.aas.clusterName and com.sun.aas.domainName properties are not used in the default configuration, but can be used to customize configuration.

Changing Permissions for an Application

The default policy for each domain limits the permissions of Jakarta EE deployed applications to the minimal set of permissions required for these applications to operate correctly.

Do not add extra permissions to the default set (the grant block with no codebase, which applies to all code). Instead, add a new grant block with a codebase specific to the applications requiring the extra permissions, and only add the minimally necessary permissions in that block.

If you develop multiple applications that require more than this default set of permissions, you can add the custom permissions that your applications need. The com.sun.aas.instanceRoot variable refers to the domain directory. For example:

```
grant codeBase "file:${com.sun.aas.instanceRoot}/applications/-" {
...
}
```

You can add permissions to stub code with the following grant block:

```
grant codeBase "file:${com.sun.aas.instanceRoot}/generated/-" {
...
```

```
}
```

In general, you should add extra permissions only to the applications or modules that require them, not to all applications deployed to a domain. To apply permissions for a specific application, for example:

```
grant codeBase "file:${com.sun.aas.instanceRoot}/applications/MyApp/-" {
...
}
```

And for a specific module:

```
grant codeBase "file:${com.sun.aas.instanceRoot}/applications/MyModule/-" {
...
}
```

An alternative way to add permissions to a specific application or module is to edit the `granted.policy` file for that application or module. The `granted.policy` file is located in the `domain-dir/generated/policy/<app-or-module-name>` directory. In this case, you add permissions to the default `grant` block.

Do not delete permissions from this file.

When the Payara Server policy subsystem determines that a permission should not be granted, it logs a `server.policy` message specifying the permission that was not granted and the protection domains, with indicated code source and principals that failed the protection check.

For example, here is a similar entry:

```
[#|INFO|jakarta.enterprise.system.core.security|_ThreadID=14;_ThreadName=Thread-
31;|JACC Policy Provider: PolicyProviderImpl.implies, context(null)-
permission((java.util.PropertyPermission java.security.manager write)) domain that
failed(ProtectionDomain(file:/glassfish/domains/domain1/applications/sample/ ... )
```

Granting the following permission eliminates the message:

```
grant codeBase "file:${com.sun.aas.instanceRoot}/applications/sample/-" {
    permission java.util.PropertyPermission "java.security.manager", "write";
}
```

Do not add `java.security.AllPermission` to the `server.policy` file for application code. Doing so completely defeats the purpose of the security manager, yet you still get the performance overhead associated with it.

As a last resort, you can iteratively determine the permission set an application needs by observing `AccessControlException` occurrences in the server's log.

If this is not sufficient, you can add the `-Djava.security.debug=failure` JVM option to the domain. Use the following `asadmin create-jvm-options` command, then restart the server:

```
asadmin create-jvm-options -Djava.security.debug=failure
```

Enabling and Disabling the Security Manager

The security manager is disabled by default.

In a production environment, you may be able to safely disable the security manager if all the following conditions are true:

- Performance is critical
- Deployment to the production server is carefully controlled
- Only trusted applications are deployed
- Applications don't need a strict policy enforcement

Disabling the security manager may improve performance significantly for some types of applications.

To enable the security manager, do one of the following:

- To use the Administration Console, open the *Security* component under the relevant configuration, and check the *Security Manager Enabled* box. Then restart the server instance.
- Use the following `asadmin create-jvm-options` command, then restart the server:

  ```
  asadmin create-jvm-options -Djava.security.manager
  ```

To disable the security manager, uncheck the *Security Manager Enabled* box or use the corresponding `asadmin delete-jvm-options` command.

You must grant additional permissions to CDI-enabled Jakarta EE applications that are deployed in a Payara Server domain, cluster or deployment group for which the security manager is enabled. These additional permissions are not required when it is disabled.

To deploy CDI-enabled Jakarta EE applications in this scenario in which security manager is enabled, add the following permissions to the corresponding applications:

```
grant codeBase "file:${com.sun.aas.instanceRoot}/applications/[ApplicationName]" {
    permission java.lang.reflect.ReflectPermission "suppressAccessChecks";
};
```

For example, for a CDI application named `foo.war`, add the following permissions to the `server.policy` file, restart the domain, cluster or deployment group, and then deploy and use the application.

```
grant codeBase "file:${com.sun.aas.instanceRoot}/applications/foo" {
    permission java.lang.reflect.ReflectPermission "suppressAccessChecks";
};
```

Configuring Message Security for Web Services

In message security, security information is applied at the message layer and travels along with the web services message. Web Services Security (WSS) is the use of XML Encryption and XML Digital Signatures to secure messages.

WSS profiles the use of various security tokens including X.509 certificates, Security Assertion Markup Language (SAML) assertions, and username/password tokens to achieve this.

Message layer security differs from transport layer security in that it can be used to decouple message protection from message transport so that messages remain protected after transmission, regardless of how many hops they travel.

Message layer annotations are not currently supported.

For more information about web services, see Developing Web Services.

For more information about message security, see the following:

- Introduction to Security in the Jakarta EE Platform in The Jakarta EE Tutorial
- Jakarta Authorization
- The Oasis Web Services Security (WSS) specification
- The Web Services Interoperability Organization (WS-I) Basic Security Profile (BSP) specification
- The Metro User's guide WSIT Security documentation.

Message Security Providers

By default, the `XWS_ClientProvider` and `XWS_ServerProvider` security message providers are configured but disabled. You can enable them in one of the following ways:

- To enable the message security providers using the Administration Console, open the *Security* component under the relevant configuration, select the *Message Security* component, and select *SOAP*. Then select `XWS_ServerProvider` from the *Default Provider* list and `XWS_ClientProvider` from the *Default Client Provider* list.
- You can enable the message security providers using the following Asadmin CLI commands:

```
asadmin set
server-config.security-service.message-security-
```

```
config.SOAP.default_provider=XWS_ServerProvider
asadmin set
server-config.security-service.message-security-
config.SOAP.default_client_provider=XWS_ClientProvider
```

You can create new message security providers in one of the following ways:

- To create a message security provider using the Administration Console, open the *Security* component under the relevant configuration, and select the *Message Security* component.
- You can use the `asadmin create-message-security-provider` command to create a message security provider.

In addition, you can set a few optional provider properties using the `asadmin set` command. For example:

```
asadmin set server-config.security-service.message-security-config.provider-
config.property.debug=true
```

The following table describes these message security provider properties.

Table 181. Message Security Provider Properties

Property	Default	Description
`security.config`	`domain-dir/config/wss-server-config-1.0.xml`	Specifies the location of the message security configuration file. To point to a configuration file in the `domain-dir/config` directory, use the system property like this: `${com.sun.aas.instanceRoot}/config/wss-server-config-1.0.xml`
`debug`	`false`	If `true`, enables dumping of server provider debug messages to the server log.
`dynamic.username.password`	`false`	If `true`, signals the provider runtime to collect the username and password from the `CallbackHandler` for each request. If `false`, the username and password for `wsse:UsernameToken(s)` is collected once, during module initialization. This property is only applicable for a `ClientAuthModule`.

Property	Default	Description
`encryption.key.alias`	`s1as`	Specifies the encryption key used by the provider. The key is identified by its `keystore` alias.
`signature.key.alias`	`s1as`	Specifies the signature key used by the provider. The key is identified by its `keystore` alias.

Message Security Responsibilities

In Payara Server, the system administrator and application deployer roles are expected to take primary responsibility for configuring message security.

In some situations, the application developer may also contribute, although in the typical case either of the other roles may secure an existing application without changing its implementation and without involving the developer.

Application Developer Responsibilities

The application developer can turn on message security, but is not responsible for doing so. Message security can be set up by the system administrator so that all web services are secured, or set up by the application deployer when the provider or protection policy bound to the application must be different from that bound to the container.

The application developer is responsible for the following:

- Determining if an application-specific message protection policy is required by the application. If so, ensuring that the required policy is specified at application assembly which may be accomplished by communicating with the application deployer.
- Determining if message security is necessary at the server's level. If so, ensuring that this need is communicated to the system administrator, or taking care of implementing message security at the server's level.

Application Deployer Responsibilities

The application deployer is responsible for the following:

- Specifying (at application assembly) any required application-specific message protection policies if such policies have not already been specified by upstream roles (the developer or assembler).
- Modifying Payara Server deployment descriptors to specify application-specific message protection policies information (message-security-binding elements) to web service endpoint and service references

These security tasks are discussed in Application-Specific Message Protection.

System Administrator Responsibilities

The system administrator is responsible for the following:

- Configuring message security providers on Payara Server.
- Managing user databases.
- Managing keystore and truststore files.

A system administrator uses the Administration Console to manage server security settings and uses a command line tool to manage certificate databases. Certificates and private keys are stored in key stores and are managed with the `keytool` utility (and in the case of Payara Server Enterprise with its Integrated Certificate Management enhancements).

Application-Specific Message Protection

When the Payara Server provided configuration is insufficient for your security needs, and you want to override the default protection, you can apply application-specific message security to a web service.

Application-specific security is implemented by adding the message security binding to the web service endpoint, whether it is an EJB or servlet web service endpoint. Modify the corresponding XML deployment descriptor files to add the message binding information.

Message security can also be specified using a WSIT security policy in the WSDL file.

For more information about message security providers, see Message Security Providers.

For more details on message security binding for EJB web services,servlet web services, and clients, see the XML file descriptions in "Elements of the Payara Server Deployment Descriptors" in the Payara Server Application Deployment section.

Using a Signature to Enable Message Protection for All Methods

To enable message protection for all methods using digital signature, update the `message-security-binding` element for the EJB web service endpoint in the application's `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` file.

To apply the same protection mechanisms for all methods, leave the method-name element blank. Configuring Message Protection for a Specific Method Based on Digital Signatures discusses listing specific methods or using wildcard characters.

To Enable Message Protection for All Methods Using Digital Signature

Follow this procedure:

1. Modify the `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` file by adding the `message-security-binding` element as shown:

```
<payara-ejb-jar>
  <enterprise-beans>
    <unique-id>1</unique-id>
    <ejb>
      <ejb-name>HelloWorld</ejb-name>
      <jndi-name>HelloWorld</jndi-name>
```

```
      <webservice-endpoint>
        <port-component-name>HelloIF</port-component-name>
        <endpoint-address-uri>service/HelloWorld</endpoint-address-uri>
        <message-security-binding auth-layer="SOAP">
          <message-security>
            <request-protection auth-source="content" />
            <response-protection auth-source="content"/>
          </message-security>
        </message-security-binding>
      </webservice-endpoint>
    </ejb>
  </enterprise-beans>
</payara-ejb-jar>
```

2. Compile and deploy the corresponding application.

Configuring Message Protection for a Specific Method Based on Digital Signatures

To enable message protection for a specific method, or for a set of methods that can be identified using a wildcard value, follow these steps.

As in the example discussed in Using a Signature to Enable Message Protection for All Methods, to enable message protection for a specific method, update the `message-security-binding` element for the EJB web service endpoint in the application's `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` file.

Add the `request-protection` and `response-protection` elements, which are analogous to the `request-policy` and `response-policy` elements discussed in the Payara Platform Security Guide.

The administration guide includes a table listing the set and order of security operations for different request and response policy configurations.

To Enable Message Protection for a Particular Method or Set of Methods Using Digital Signature

Follow this procedure.

1. Modify the `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` file by adding the `message-security-binding` element as shown:

```
<payara-ejb-jar>
  <enterprise-beans>
  <unique-id>1</unique-id>
    <ejb>
      <ejb-name>HelloWorld</ejb-name>
      <jndi-name>HelloWorld</jndi-name>
      <webservice-endpoint>
        <port-component-name>HelloIF</port-component-name>
        <endpoint-address-uri>service/HelloWorld</endpoint-address-uri>
        <message-security-binding auth-layer="SOAP">
          <message-security>
            <message>
```

```
            <java-method>
              <method-name>ejbCreate</method-name>
            </java-method>
          </message>
          <message>
            <java-method>
              <method-name>sayHello</method-name>
            </java-method>
          </message>
          <request-protection auth-source="content" />
          <response-protection auth-source="content"/>
        </message-security>
      </message-security-binding>
    </webservice-endpoint>
  </ejb>
 </enterprise-beans>
</payara-ejb-jar>
```

2. Compile and deploy the corresponding application.

Programmatic Login Using the ProgrammaticLogin Class

Programmatic login allows a deployed Jakarta EE application or module to invoke a **login** method. If the login is successful, a `SecurityContext` is established as if the client had authenticated using any of the conventional Jakarta EE mechanisms.

Programmatic login is supported for servlet and EJB components on the server side, and for stand-alone or application clients on the client side.

Programmatic login is useful for an application having special needs that cannot be accommodated by any of the Jakarta EE standard authentication mechanisms.

This section describes a proprietary Payara mechanism, but see also the standard security APIs in the Jakarta EE tutorial.

The `com.sun.enterprise.security.ee.auth.login.ProgrammaticLogin` class present in Payara Server is not part of any Jakarta EE APIs; therefore, it is not portable to other application servers.

Programmatic Login Precautions

Payara Server is not involved in how the login information (`user`, `password`) is obtained by the deployed application. Programmatic login places the burden on the application developer with respect to assuring that the resulting system meets security requirements. If the application code reads the authentication information across the network, the application determines whether to trust the user.

Programmatic login allows the application developer to bypass the Payara Server-supported authentication mechanisms and feed authentication data directly to the security service.

While flexible, this capability should not be used without some understanding of security issues.
Since this mechanism bypasses the container-managed authentication process and sequence, the application developer must be very careful in making sure that authentication is established before accessing any restricted resources or methods.

It is also the application developer's responsibility to verify the status of the login attempt and to alter the behavior of the application accordingly.

The programmatic login state does not necessarily persist in sessions or participate in single sign-on.

Lazy authentication is not supported for programmatic login. If an access check is reached and the deployed application has not properly authenticated using the programmatic login method, access is denied immediately and the application might fail if not coded to account for this occurrence.

One way to account for this occurrence is to catch the access control or security exception, perform a programmatic login, and repeat the request.

Granting Programmatic Login Permission

The `ProgrammaticLoginPermission` permission is required to invoke the programmatic login mechanism for an application if the security manager is enabled. For information about the security manager, see The `server.policy` File.

This permission is not granted by default to deployed applications because this is not a standard Jakarta EE mechanism.

To grant the required permission to the application, add the following to the `domain-dir/config/server.policy` file:

```
grant codeBase "file:${jar-file-path}" {
    permission com.sun.appserv.security.ProgrammaticLoginPermission "login";
};
```

`jar-file-path` is the path to the application's JAR file.

The `ProgrammaticLogin` Class

The `com.sun.enterprise.security.ee.auth.login.ProgrammaticLogin` class enables a user to perform login programmatically and in addition, logout of the existing security context when required.

The `ProgrammaticLogin` class has eight overloaded `login` methods: four variants to be used by Web components and four variants to be used by EJB components.

The login methods for web components have the following signatures:

```
public class ProgrammaticLogin {
```

```
    public Boolean login(String user, String password, HttpServletRequest request,
HttpServletResponse response);

    //Same as above, but uses a char[] for the password credential
    public Boolean login(String user, char[] password, HttpServletRequest request,
HttpServletResponse response);

    public Boolean login(String user, String password, String realm,
HttpServletRequest request, HttpServletResponse response, boolean errors) throws
Exception;

    //Same as above, but uses a char[] for the password credential
    public Boolean login(String user, char[] password, String realm,
HttpServletRequest request, HttpServletResponse response, boolean errors) throws
Exception;
}
```

The login methods for EJB components have the following signatures:

```
public class ProgrammaticLogin {
    public Boolean login(String user, String password);
    //Same as above, but uses a char[] for the password credential
    public Boolean login(String user, char[] password);
    public Boolean login(String user, String password, String realm, boolean errors)
throws Exception;
    //Same as above, but uses a char[] for the password credential
    public Boolean login(String user, char[] password, String realm, boolean errors);
}
```

All method variants accomplish the following:

- Perform the authentication
- Return `true` if login succeeded, `false` if the login has failed

The login occurs on the realm specified unless it is `null`, in which case the domain's default realm is used. The variants with no `realm` parameter will use the domain's default security realm.

If the `errors` parameter is set to `true`, any exceptions encountered during the login process are propagated to the caller. If set to `false`, exceptions will be thrown.

On the client side, the `realm` and `errors` parameters are ignored and the actual login does not occur until a resource requiring a login is accessed. A `java.rmi.AccessException` with a `COBRA NO_PERMISSION` occurs if the actual login fails.

The `logout` method has 4 overloaded variants: 2 used by Web components, 2 used by EJB components. Here are the variants used by web components:

```
public class ProgrammaticLogin {
```

```
    public Boolean logout(HttpServletRequest request, HttpServletResponse response);
    public Boolean logout(HttpServletRequest request, HttpServletResponse response,
boolean errors) throws Exception;
}
```

The variants used for EJB components have the following signatures:

```
public class ProgrammaticLogin {
    public Boolean logout();
    public Boolean logout(boolean errors) throws Exception;
}
```

All `logout` method variants return `true` if the logout process succeeded, `false` if it failed.

If the `errors` parameter is set to `true`, any exceptions encountered during the logout process are propagated to the caller. If set to `false`, exceptions will be thrown.

User Authentication for Single Sign-on

The single sign-on feature of the Payara Server allows multiple web applications deployed to the same virtual server to share the user authentication state.

With single sign-on enabled, users who log in to one web application become **implicitly logged** into other web applications on the same virtual server that require the same authentication information. Otherwise, users would have to log in separately to each web application whose protected resources they tried to access.

A sample application using the single sign-on scenario could be a consolidated airline booking service that searches all airlines and provides links to different airline websites. After the user signs on to the consolidated booking service, the user information can be used by each individual airline site without requiring another sign-on.

Single sign-on operates according to the following rules:

- Single sign-on applies to web applications configured for the same security realm and virtual server. The realm is defined by the `realm-name` element in the `web.xml` file. For information about virtual servers, see "Administering Internet Connectivity" in the Payara Server General Administration section.
- As long as users access only unprotected resources in any of the web applications on a virtual server, they are not challenged to authenticate themselves.
- As soon as a user accesses a protected resource in any web application associated with a virtual server, the user is challenged to authenticate himself or herself, using the login method defined for the web application currently being accessed.
- After authentication, the roles associated with this user are used for access control decisions across all associated web applications, without challenging the user to authenticate to each application individually.
- When the user logs out of one web application (for example, by invalidating the corresponding

web session), the user's sessions in all web applications are automatically invalidated. Any subsequent attempt to access a protected resource in any application requires the user to authenticate again.

The single sign-on feature utilizes HTTP cookies to transmit a token that associates each request with the saved user identity, so it can only be used in client environments that support cookies.

To configure single sign-on, set the following configuration properties for a **virtual server**:

`sso-enabled`

If `false`, single sign-on is disabled for this virtual server, and users must authenticate separately to every application on the virtual server. The default value is `false`.

`sso-max-inactive-seconds`

Specifies the time after which a user's single sign-on record becomes eligible for purging if no client activity is received. Since single sign-on applies across several applications on the same virtual server, access to any of the applications keeps the single sign-on record active. The default value is *5 minutes* (`300` seconds).

Higher values provide longer single sign-on persistence for the users at the expense of more memory use on the server.

`sso-reap-interval-seconds`

Specifies the interval between purges of expired single sign-on records. The default value is `60`.

Here are example `asadmin set` commands on a virtual server named `vsrv1` using the default values mentioned above:

```
asadmin set server-config.http-service.virtual-server.vsrv1.property.sso-
enabled="true"
asadmin set server-config.http-service.virtual-server.vsrv1.property.sso-max-inactive-
seconds="300"
asadmin set server-config.http-service.virtual-server.vsrv1.property.sso-reap-
interval-seconds="60"
```

Jakarta Security Support

Jakarta Security defines several authentication-related plugin SPIs, such as the `HttpAuthenticationMechanism` and `IdentityStore` interfaces:

`HttpAuthenticationMechanism`

An interface for modules that authenticate callers to a web application. An application can supply its own `HttpAuthenticationMechanism`, or use one of the default implementations provided by the container.

`IdentityStore`

This interface defines methods for validating a caller's credentials (such as username and password) and returning group membership information. An application can provide its own `IdentityStore`, or use the builtin LDAP or Database stores.

In addition to these authentication plugin SPIs, the Jakarta Security specification defines the `SecurityContext` API for use by application code to query and interact with the current security context.

The `SecurityContext` interface defines methods that allow an application to access security information about a caller, authenticate a caller, and authorize a caller. These methods include `getCallerPrincipal()`, `getPrincipalsByType()`, `isCallerInRole()`, `authenticate()`, and `hasAccessToWebResource()`.

Payara Platform and Jakarta Security

Payara Server and Micro implement Jakarta Security to provide built-in support for the following authentication mechanisms:

- BASIC
- FORM
- Custom FORM
- OpenID Connect

A significant advantage of using `HttpAuthenticationMechanism` and `IdentityStore` over the declarative mechanisms defined by the Servlet specification is that it allows an application to control the identity stores that it authenticates against, in a standard, portable way. You can use the built-in implementations of these APIs, or define custom implementations as suggested by the specification.

Jakarta Security defines several annotations, with names that end with the `Definition` suffix, which when used makes the corresponding built-in mechanism available as a CDI bean.

Jakarta Security also supports the use of Jakarta Expression Language in these annotations to allow dynamic configuration.

Built-in Authentication Mechanisms and Identity Stores

An application packages its own `HttpAuthenticationMechanism` by including in a bean archive that is a part of the application. Alternatively, it may select and configure one of the built-in mechanisms using the corresponding annotation, as listed below:

`BasicAuthenticationMechanismDefinition`

Implements HTTP BASIC authentication that conforms to the behavior of the servlet container when BASIC <auth-method> is declared in the `web.xml` deployment descriptor.

`FormAuthenticationMechanismDefinition`

Implements HTTP FORM authentication that conforms to the behavior of the servlet container

when the FORM <auth-method> is declared in the `web.xml` deployment descriptor.

`CustomFormAuthenticationMechanismDefinition`

Implements a modified version of HTTP FORM authentication in which custom handling replaces the POST action to the `j_security_check` servlet.

`OpenIdAuthenticationMechanismDefinition`

Implements an OpenID Connect authentication workflow using the metadata configured in the annotation attributes.

All built-in authentication mechanisms need to be authenticated using an identity store. The `IdentityStore` interface, included in the Jakarta Security API, defines an SPI for interacting with identity stores, which are repositories (like databases or naming directories) containing user account information.

The `IdentityStore` interface has four methods: `validate(Credential)`, `getCallerGroups(CredentialValidationResult)`, `validationTypes()` and `priority()`. Developers can provide their own implementation of this interface, or use one of the built-in identity stores.

The `RememberMeIdentityStore` interface, which is a variation on the `IdentityStore` interface, can be used when an application wants to "remember" a user's authenticated session for an extended period, so that the caller can return to the application periodically without needing to present primary authentication credentials each time.

There are two built-in implementations of `IdentityStore`:

`LdapIdentityStoreDefinition`

Used to configure an LDAP naming directory as the identity store of an application.

`DatabaseIdentityStoreDefinition`

Used to configure a set of relational database tables as the identity store.

The following snippet shows the usage of the `DatabaseIdentityStoreDefinition` annotation, which makes it available as a CDI bean.

```
@DatabaseIdentityStoreDefinition(
    callerQuery = "#{'select password from caller where name = ?'}",
    groupsQuery = "select group_name from caller_groups where caller_name = ?",
    hashAlgorithm = Pbkdf2PasswordHash.class,
    priorityExpression = "#{100}",
    hashAlgorithmParameters = {
        "Pbkdf2PasswordHash.Iterations=3072",
        "${applicationConfig.dynamic}"
    }
)
public class MyComponent{
}
```

Since the Jakarta Security API provides support for Jakarta Expression Language, regular expressions can be used to set value of annotation attributes.

Payara Server provides out of the box implementation of the `Pbkdf2PasswordHash` interface that supports PBKDF2 password hashing.

It is suggested that you use `Pbkdf2PasswordHash` for generating and validating passwords, unless there are specific requirements which cannot be met in any other way.

Custom Authentication Mechanism

An application provider can choose to provide its own custom authentication mechanism, apart from built-in authentication mechanisms.

A custom authentication mechanism implements the `HttpAuthenticationMechanism` interface, introduced in Jakarta Security. This interface defines the following three methods.

```
public interface HttpAuthenticationMechanism{
    AuthenticationStatus validateRequest(HttpServletRequest request,
HttpServletResponse response, HttpMessageContext httpMessageContext) throws
AuthenticationException;

    AuthenticationStatus secureResponse(HttpServletRequest request,
HttpServletResponse response, HttpMessageContext httpMessageContext) throws
AuthenticationException;

    void cleanSubject(HttpServletRequest request, HttpServletResponse response,
HttpMessageContext httpMessageContext);
}
```

A custom authentication mechanism must return an `AuthenticationStatus` to indicate the status of its current authentication request. Internally, it gets translated to a corresponding Jakarta Authentication `AuthStatus` instance as shown below:

- `AuthenticationStatus.NOT_DONE` → `AuthStatus.SUCCESS`
- `AuthenticationStatus.SEND_CONTINUE` → `AuthStatus.SEND_CONTINUE`
- `AuthenticationStatus.SUCCESS` → `AuthStatus.SUCCESS`
- `AuthenticationStatus.SEND_FAILURE` → `AuthStatus.SEND_FAILURE`

Each method of the `HttpAuthenticationMechanism` interface performs the same function as the corresponding `ServerAuth` methods.

Unlike Jakarta Authentication, `HttpAuthenticationMechanism` is specified for the servlet container only. Only the `validateRequest()` must be implemented, for other two methods, default behaviors are specified.

`validateRequest` allows a caller to authenticate. The request gets inspected inside `validateRequest` to read credential or any other information, or it can write to standard response with status of the

authentication request or redirect the caller to an OAuth provider. Once the credential is validated, the result of the validation is communicated to the container using the `HttpMessageContext` parameter.

Here's an example of a custom authentication mechanism:

Only the `validateRequest` method has been implemented, since Jakarta Security provides default implementation of the other two methods. An application provider may choose to override the default implementation depending on the business context.

```
import jakarta.enterprise.context.RequestScoped;
import jakarta.inject.Inject;
import jakarta.security.enterprise.AuthenticationException;
import jakarta.security.enterprise.AuthenticationStatus;
import
jakarta.security.enterprise.authentication.mechanism.http.HttpAuthenticationMechanism;
import jakarta.security.enterprise.authentication.mechanism.http.HttpMessageContext;
import jakarta.security.enterprise.credential.UsernamePasswordCredential;
import jakarta.security.enterprise.identitystore.CredentialValidationResult;
import jakarta.security.enterprise.identitystore.IdentityStoreHandler;
import jakarta.servlet.http.HttpServletRequest;
import jakarta.servlet.http.HttpServletResponse;

import static
jakarta.security.enterprise.identitystore.CredentialValidationResult.Status.VALID;

@RequestScoped
public class MyAuthenticationMechanism implements HttpAuthenticationMechanism {

    @Inject
    private IdentityStoreHandler identityStoreHandler;

    @Override
    public AuthenticationStatus validateRequest(HttpServletRequest request,
HttpServletResponse response, HttpMessageContext httpMessageContext) throws
AuthenticationException {

        // Get the (caller) name and password from the request
        // NOTE: This is for the smallest possible example only. In practice
        // putting the password in a request query parameter is highly
        // insecure and is discouraged.
        var name = request.getParameter("name");
        var password = request.getParameter("password");

        if (name != null && password != null) {
            // Delegate the {credentials in -> identity data out} function to the
Identity Store
            var result = identityStoreHandler.validate(new
UsernamePasswordCredential(name, password));
```

```
            if (result.getStatus() == VALID) {
                // Communicate the details of the authenticated user to the container.
                response.addHeader("Authentication Mechanism",
"MyAuthenticationMechanism");
                return
httpMessageContext.notifyContainerAboutLogin(result.getCallerPrincipal(),
result.getCallerGroups());
            } else {
                return httpMessageContext.responseUnauthorized();
            }
        }
        return httpMessageContext.doNothing();
    }
}
```

Multiple HttpAuthenticationMechanisms in EAR Application

Within the Security API specification, an `HttpAuthenticationMechanism` can be defined to retrieve the user credentials from the HTTP Request. These credentials are then used by any configured identity stores to validate the user.

However, a restriction of the Security API specification is that only one `HttpAuthenticationMechanism` can be defined per application.

This restriction is also in place for EAR applications file where it's possible to have multiple web modules.

Payara Server allows to circumvent this restriction so that multiple authentication mechanisms are used in an EAR application that hosts more than one Web module. To this effect, each web module must configure its own authentication mechanism separately.

In order to use this feature, there must not be any custom `HttpAuthenticationMechanism` implementations bundled in any of the modules hosted in the EAR artifact. If this is the case, the feature will not work as intended.

This behaviour is specific to the Payara Platform and not compatible with the Jakarta Security specification.

How to Configure

In order to configure a specific `HttpAuthenticationMechanism` for a Web application, define the `fish.payara.security.mechanism` parameter in the `web.xml` deployment descriptor like in the following case:

```
<context-param>
    <param-name>fish.payara.security.mechanism</param-name>
    <param-value>JWT</param-value>
```

```
</context-param>
```

The following mechanisms can be used:

Value	Description
`Basic`	Use *BasicAuthenticationMechanism* as mechanism.
`Form`	Use *FormAuthenticationMechanism* as mechanism.
`CustomForm`	Use *CustomFormAuthenticationMechanism* as mechanism.
`JWT`	Use the custom Payara *JWTAuthenticationMechanism* as mechanism.
`Certificate`	Use the custom Payara *CertificateAuthenticationMechanism* as mechanism.
`Azure`	Use the custom Payara *AzureOpenIdAuthenticationMechanism* as mechanism.
`Google`	Use the custom Payara *GoogleOpenIdAuthenticationMechanism* as mechanism.
`OAuth2`	Use the custom Payara *OAuth2AuthenticationMechanism* as mechanism.
<any Fully Qualified Class Name>	Use the `HttpAuthenticationMechanism` indicated by the class name.

When no parameter is specified, the standard rules of Jakarta Security are active (only 1 mechanism allowed per application/module).

Jakarta Authentication Support

Jakarta Authentication is part of the Jakarta EE specification and defined by its own specification.

Jakarta Authentication defines an interface for pluggable authorization providers. Specifically, it is used to plug in the Java policy provider used by the container to perform Jakarta EE caller access decisions. The Java policy provider performs Java policy decisions during application execution.

This provides third parties with a mechanism to develop and plug in modules that are responsible for answering authorization decisions during a Jakarta EE application execution. The interfaces and rules used for developing authentication providers are defined in the specification document.

Payara Server provides a simple file-based Jakarta Authentication engine as a default **JACC provider** (JACC stands for the previous name of the specification before its transition to Jakarta EE), named `default`.

To configure an alternate provider using the Administration Console, open the *Security* component under the relevant configuration, and select the *JACC Providers* component.

Payara Server and Jakarta Authentication

The Jakarta Authentication specification defines profiles that establish contracts for the use of the SPI in specific contexts.

Jakarta Authentication's Servlet Container Profile defines the use of the SPI by a Servlet container

such that:

- The resulting container can be configured with new authentication mechanisms.
- The container employs the configured mechanisms in its enforcement of the declarative servlet security model (declared in a `web.xml` deployment descriptor file using `security-constraint` elements or by specific annotations in the servlet implementation classes).

Jakarta Authentication defines a simple message processing model composed of four interaction points when processing an authentication request:

1. `secureRequest` on the client
2. `validateRequest` on the server
3. `secureResponse` on the server
4. `validateResponse` on the client

A message processing runtime uses the SPI at these interaction points to delegate the corresponding message security processing to authentication providers, also called authentication modules, integrated into the runtime by way of the SPI.

A compatible server-side message processing runtime, such as the Payara Server servlet container, supports the `validateRequest` and `secureResponse` interaction points of the message processing model.

The servlet container uses the SPI at these interaction points to delegate the corresponding message security processing to a **server authentication module (SAM)**, integrated by the SPI into the container.

Adding Authentication Modules to the Servlet Container

You can use Jakarta Authentication in the web tier to facilitate the injection of pluggable authentication modules within the servlet constraint processing engine. Payara Server includes implementations of a number of HTTP layer authentication mechanisms such as `basic`, `form`, and `digest` authentication.

You can add alternative implementations of the included mechanisms or implementations of new mechanisms such as Kerberos/SPNEGO or CAS for example.

Writing a Server Authentication Module

A key step in adding an authentication mechanism to a compatible server-side message processing runtime such as the servlet container is acquiring a SAM that implements the desired authentication mechanism. One way to do that is to write the SAM yourself.

A SAM implements the `jakarta.security.auth.message.module.ServerAuthModule` interface as defined by the specification. A SAM is invoked indirectly by the message processing runtime at the `validateRequest` and `secureResponse` interaction points. A SAM must implement the five methods of the `ServerAuthModule` interface:

`getSupportedMessageTypes`

Returns an array of `Class` objects where each element defines a message type supported by the SAM.

For a SAM to be compatible with the Servlet Container Profile, the returned array must include the `HttpServletRequest.class` and `HttpServletResponse.class` objects.

`initialize(MessagePolicy requestPolicy, MessagePolicy responsePolicy, CallbackHandler cbh, Map options)`

The container calls this method to provide the SAM with configuration values and with a `CallbackHandler`.

The configuration values are returned in the policy arguments and in the options `Map`. The SAM uses `CallbackHandler` to access services, such as password validation, provided by the container.

`AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)`

The container calls this method to process each `HttpServletRequest` received. The request and its associated `HttpServletResponse` are passed by the container to the SAM in the `messageInfo` argument. The SAM processes the request and may establish the response to be returned by the container.

The SAM uses the provided `Subject` arguments to convey its authentication results. The SAM returns different status values to control the container's invocation processing. The status values and the circumstances under which they are returned are as follows:

- `AuthStatus.SUCCESS` is returned when the application request message is successfully validated. The container responds to this status value by using the returned client `Subject` to invoke the target of the request. When this value is returned, the SAM (provided a custom `AuthConfigProvider` is not being used) must use its `CallbackHandler` to handle a `CallerPrincipalCallback` using the `clientSubject` as an argument to the callback.
- `AuthStatus.SEND_CONTINUE` indicates that message validation is incomplete and that the SAM has established a preliminary response as the response message in `messageInfo`. The container responds to this status value by sending the response to the client.
- `AuthStatus.SEND_FAILURE` indicates that message validation failed and that the SAM has established an appropriate failure response message in `messageInfo`. The container responds to this status value by sending the response to the client.
- `AuthStatus.SEND_SUCCESS` is not typically returned. This status value indicates the end of a multi-message security dialog originating after the service interaction and during the processing of the application response. The container responds to this status value by sending the response to the client.

  The `validateRequest` method may also throw an `AuthException` to indicate that the message processing by the SAM failed without establishing a failure response message in `messageInfo`.

`secureResponse(MessageInfo messageInfo, Subject serviceSubject)`

The container calls this method before sending a response, resulting from an application invocation, to the client. The response is passed to the SAM in the `messageInfo` argument. In most cases, this method should just return the `SEND_SUCCESS` status.

`cleanSubject(MessageInfo messageInfo, Subject subject)`

This method removes the mechanism-specific principals, credentials, or both from the subject. This method is not currently called by the container. A legitimate implementation could remove all the principals from the argument subject.

Sample Server Authentication Module

The class `MySam.java` is a sample SAM implementation. Notice that the sample implements the five methods of the ServerAuthModule interface. This SAM implements an emulation of HTTP basic authentication for demonstration purposes.

```
package fish.payara.samples.security;

import java.io.IOException;
import java.util.Map;
import jakarta.security.auth.Subject;
import jakarta.security.auth.callback.Callback;
import jakarta.security.auth.callback.CallbackHandler;
import jakarta.security.auth.callback.UnsupportedCallbackException;
import jakarta.security.auth.message.AuthException;
import jakarta.security.auth.message.AuthStatus;
import jakarta.security.auth.message.MessageInfo;
import jakarta.security.auth.message.MessagePolicy;
import jakarta.security.auth.message.callback.CallerPrincipalCallback;
import jakarta.security.auth.message.callback.GroupPrincipalCallback;
import jakarta.security.auth.message.callback.PasswordValidationCallback;
import jakarta.security.auth.message.module.ServerAuthModule;
import jakarta.servlet.http.HttpServletRequest;
import jakarta.servlet.http.HttpServletResponse;
import org.apache.catalina.util.Base64;

public class MySam implements ServerAuthModule {

    protected static final Class[] supportedMessageTypes = new Class[]{
            HttpServletRequest.class, HttpServletResponse.class
    };

    private MessagePolicy requestPolicy;
    private MessagePolicy responsePolicy;
    private CallbackHandler handler;
    private Map options;
    private String realmName = null;
    private String defaultGroup[] = null;

    private static final String REALM_PROPERTY_NAME = "realm.name";
```

```
    private static final String GROUP_PROPERTY_NAME = "group.name";
    private static final String BASIC = "Basic";
    private static final String AUTH_TYPE_INFO_KEY = "jakarta.servlet.http.authType";

    static final String AUTHORIZATION_HEADER = "authorization";
    static final String AUTHENTICATION_HEADER = "WWW-Authenticate";

    public void initialize(MessagePolicy requestPolicy, MessagePolicy responsePolicy,
CallbackHandler handler, Map options) throws AuthException {
        if (options != null) {
            realmName = (String) options.get(REALM_PROPERTY_NAME);
            if (options.containsKey(GROUP_PROPERTY_NAME)) {
              defaultGroup = new String[]{(String) options.get(GROUP_PROPERTY_NAME)};
            }
        }
    }

    public Class[] getSupportedMessageTypes() {
      return supportedMessageTypes;
    }

    public AuthStatus validateRequest(MessageInfo msgInfo, Subject client, Subject
server) throws AuthException {
        try {
          var username = processAuthorizationToken(msgInfo, client);
          if (username == null && requestPolicy.isMandatory()) {
              return sendAuthenticateChallenge(msgInfo);
          }
          setAuthenticationResult(username, client, msgInfo);
          return AuthStatus.SUCCESS;
        } catch (Exception e) {
          var ae = new AuthException();
          ae.initCause(e);
          throw ae;
        }
    }

    private String processAuthorizationToken(MessageInfo msgInfo, Subject s) throws
AuthException {

        var request = (HttpServletRequest) msgInfo.getRequestMessage();
        var token = request.getHeader(AUTHORIZATION_HEADER);

        if (token != null && token.startsWith(BASIC + " ")) {
            token = token.substring(6).trim();

            // Decode and parse the authorization token
            var decoded = new String(Base64.decode(token.getBytes()));
            int colon = decoded.indexOf(':');
            if (colon <= 0 || colon == decoded.length() - 1) {
                return null;
```

```
            }

            var username = decoded.substring(0, colon);
            // use the callback to ask the container to validate the password
            var pVC = new PasswordValidationCallback(s, username,
decoded.substring(colon + 1).toCharArray());
            try {
                handler.handle(new Callback[]{pVC});
                pVC.clearPassword();
            } catch (Exception e) {
                var ae = new AuthException();
                ae.initCause(e);
                throw ae;
            }

            if (pVC.getResult()) {
                return username;
            }
        }
        return null;
    }

    private AuthStatus sendAuthenticateChallenge(MessageInfo msgInfo) {

        var realm = realmName;

        // if the realm property is set use it, otherwise use the name of the server
as the realm name.
        if (realm == null) {
            var request = (HttpServletRequest) msgInfo.getRequestMessage();
            realm = request.getServerName();
        }

        var response = (HttpServletResponse) msgInfo.getResponseMessage();

        response.setHeader(AUTHENTICATION_HEADER, BASIC + " realm=\"" + realm + "\"");
        response.setStatus(HttpServletResponse.SC_UNAUTHORIZED);
        return AuthStatus.SEND_CONTINUE;
    }

    public AuthStatus secureResponse(MessageInfo msgInfo, Subject service) throws
AuthException {
        return AuthStatus.SEND_SUCCESS;
    }

    public void cleanSubject(MessageInfo msgInfo, Subject subject) throws
AuthException {
        if (subject != null) {
            subject.getPrincipals().clear();
        }
    }
```

```
    // distinguish the caller principal and assign default groups
    private void setAuthenticationResult(String name, Subject s, MessageInfo m) throws
IOException, UnsupportedCallbackException {
        handler.handle(new Callback[]{
           new CallerPrincipalCallback(s, name)
        });
        if (name != null) {
           // add the default group if the property is set
           if (defaultGroup != null) {
               handler.handle(new Callback[]{
                   new GroupPrincipalCallback(s, defaultGroup)
               });
           }
           m.getMap().put(AUTH_TYPE_INFO_KEY, "MySAM");
        }
    }
}
```

The `initialize` method looks for the `group.name` and `realm.name` properties. The `group.name` property configures the default group assigned as a result of any successful authentication.
The `realm.name` property defines the realm value sent back to the browser in the `WWW-Authenticate` challenge.

Compiling and Installing a Server Authentication Module

Before you can use the sample SAM, you need to compile, install, and configure it. Then you can bind it to an application.

To compile the SAM, include the SPI in your classpath. After you compile the SAM, install it by copying a JAR file containing the compiled SAM to the `$as-install/glassfish/lib` directory.

Configuring a Server Authentication Module

You can configure a SAM in one of these ways:

- In the Administration Console, open the *Security* component under the relevant configuration and go to the *Message Security* page. Set the following options:
  - **Authentication Layer**: `HttpServlet`
  - **Provider Type**: `server` or `client-server`
  - **Provider ID**: Specify a unique name for the SAM, for example `MySAM`
  - **Class Name**: Specify the fully qualified class name, for example `fish.payara.samples.security.MySam`
  - **Additional Property**:
    - Name: `group-name`
    - Value: `user`

- **Additional Property**:
  - Name: `realm-name`
  - Value: `Sam`

- Use the `asadmin create-message-security-provider` command to configure a SAM. Set the following options:
  - `--layer HttpServlet`
  - `--providertype server` or `--providertype client-server`
  - `--classname fish.payara.samples.security.MySam`
  - `--property group-name=user:realm-name=Sam`
  - Provider name operand — Specify a unique name for the SAM, for example `MySAM`

Binding a Server Authentication Module to Your Application

After you install and configure the SAM, you can bind it for use by the container on behalf of one or more of your applications. You have two options in how you bind the SAM, depending on whether you are willing to repackage and redeploy your application:

- If you are willing to repackage and redeploy, you can bind the SAM using the `glassfish-web.xml` or `payara-web.xml` deployment descriptor file. Set the value of the `httpservlet-security-provider` attribute of the `glassfish-web-app`/`payara-web-app` element to the SAM's configured provider ID, for example, `MySAM`. This option leverages the native `AuthConfigProvider` implementation that ships with Payara Server.
- Another approach is to develop your own `AuthConfigProvider` and register it with the server's `AuthConfigFactory` for use on behalf of your applications. For example, a simple `AuthConfigProvider` can obtain, through its initialization properties, the classname of a SAM to configure on behalf of the applications for which the provider is registered.

You can find a description of the functionality of an `AuthConfigProvider` and of the registration facilities provided by an `AuthConfigFactory` in the Jakarta Authentication specification.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

Advanced Groups Configuration

Payara Server allows the advanced configuration mapping of a client certificate's distinguished name (DN) to specific realm groups, which allows the realm to automatically assign groups based on the values of each DN part to all principals registered in the realm.

This feature can be configured by using the `dn-parts-used-for-groups` property of any security realm of type `com.sun.enterprise.security.auth.realm.certificate.CertificateRealm`. It must define a comma separated list of identifiers of DN parts, i.e. `EMAILADDRESS,DC,OU`, and it is empty by default.

The default empty value means that only content of the `assign-groups` property

value will be used as the list of assigned groups.

If both properties are set, a principal who completed the certificate validation will have all groups from both `assign-groups` settings.

Not all DN parts are supported. The following is the list of all parts that are supported, categorized by their OIDs:

Table 182. Supported OIDs

DN Part	Description	Object ID
CN	Common Name	2.5.4.3
SURNAME	Surname	2.5.4.4
SERIALNUMBER	Serial Number of the certificate	2.5.4.5
C	Country	2.5.4.6
L	Locality	2.5.4.7
ST	State	2.5.4.8
STREET	Street	2.5.4.9
O	Organisation	2.5.4.10
OU	Organisation Unit	2.5.4.11
T	Title	2.5.4.12
GIVENNAME	Given Name	2.5.4.42
INITIALS	Initials	2.5.4.43
GENERATION	Generation	2.5.4.44
DNQUALIFIER	DN Qualifier	2.5.4.46
UID	User ID	0.9.2342.19200300.100.1.1
DC	Domain Component	0.9.2342.19200300.100.1.25
EMAILADDRESS	E-Mail address	1.2.840.113549.1.9.1
IP	IP Address	1.3.6.1.4.1.42.2.11.2.1

Configuration using the Admin Console

This feature can be configured on the default certificate realm with the following steps:

1. Navigate to the applicable configuration page for your use (e.g. `server-config`) under the `Configurations` option in the side menu
2. Head to `Security` → `Realms` and select the `certificate` realm
3. Click the `Add Property` button
4. Set the property *Name* to be `dn-parts-used-for-groups` and set the *Value* to a comma separated

list of OID names.

Configuration using the Asadmin CLI

You can also use the following asadmin command to set the value of the property in the security realm:

```
asadmin set configs.config.${YOUR_INSTANCE_CONFIG}.security-service.auth-
realm.certificate.property.dn-parts-used-for-groups=EMAILADDRESS,DC,OU
```

After setting the value of the property, make sure that you **restart the server instance** for the changes to take effect.

Keep in mind that the set of DN parts used to configure the realm groups must be predictable to be useful, so be careful to use DN parts that do not create group name collisions.

Mapping Groups to Security Roles in Applications

After configuring the realm groups, you can map these groups to application roles as you'd do by using the Payara Server specific deployment descriptors. You can even map these roles to principals that are configured as documented in the advanced Principal Name configuration section.

Here's a quick summary of the authentication and authorization process would work in this scenario:

- The principal receives principal name as configured (whole DN or only CN part)
- The principal receives all groups from realm's `assign-groups` list
- The principal receives all groups from certificate's DN parts listed in `dn-parts-used-for-groups` realm property (limited to those listed in table)
- The server allows the principal to access the application
- The client receives all roles from application's security role mapping, where at least one of his principal names or groups matches their respective element.
- The security roles are then used for authorization to access application resources

For example, if user roles were mapped like this in the `payara-web.xml` deployment descriptor of an application, and we enabled using `CN` as a principal name and set the `dn-parts-used-for-groups` to `OU`:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app error-url="">
  <context-root>/health-services</context-root>
  <security-role-mapping>
```

```
    <role-name>role1</role-name>
    <principal-name>C=UK, S=lak, L=zak, OU=unitA, CN=foo1</principal-name>
    <principal-name>C=UK, S=lak, L=zak, OU=unitA, CN=foo2</principal-name>
    <principal-name>C=UK, S=lak, L=zak, OU=unitC, CN=foo4</principal-name>
    <principal-name>C=UK, S=lak, L=zak, OU=unitD, CN=foo-director</principal-name>
  </security-role-mapping>
  <security-role-mapping>
    <role-name>role2</role-name>
    <principal-name>C=UK, S=lak, L=zak, OU=unitB, CN=foo3</principal-name>
    <principal-name>C=UK, S=lak, L=zak, OU=unitD, CN=foo-director</principal-name>
  </security-role-mapping>
</payara-web-app>
```

Then the role mapping can be based on organizational unit in this case. But you can still use the principal name as in any normal case:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app error-url="">
  <context-root>/health-services</context-root>
  <security-role-mapping>
    <role-name>role1</role-name>
    <group-name>unitA</group-name>
    <group-name>unitC</group-name>
    <group-name>unitD</group-name>
  </security-role-mapping>
  <security-role-mapping>
    <role-name>role2</role-name>
    <group-name>unitB</group-name>
    <principal-name>foo-director</principal-name>
  </security-role-mapping>
</payara-web-app>
```

Advanced Principal Name Configuration

Payara Server allows the use of the Common-Name (`CN`) attribute of a client certificate's DN to be used as the full principal's name when the certificated is authenticated in an application. This simplifies the authentication process, as the common name will replace the full name in the validation process of the certificate's authentication.

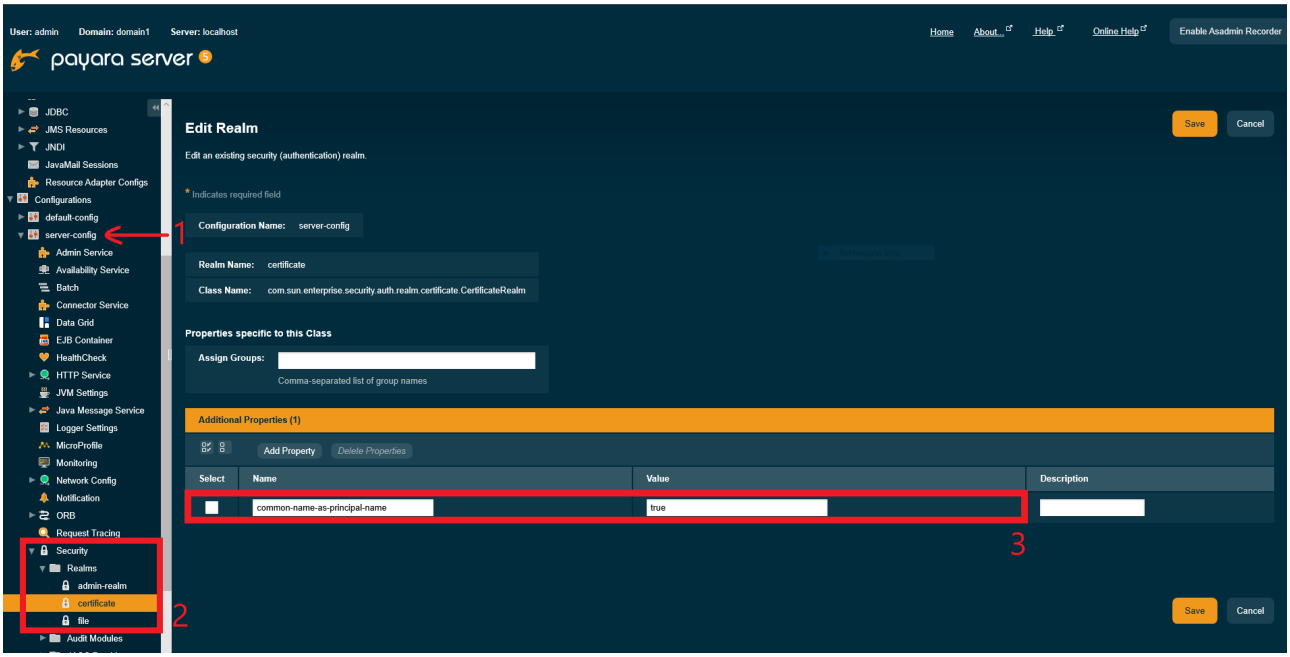
To configure this behaviour, the `common-name-as-principal-name` property can be used in any security realm of type `com.sun.enterprise.security.auth.realm.certificate.CertificateRealm`.

The `common-name-as-principal-name` property is set to false by default if no configuration is provided.

Configuration using the Admin Console

This feature can be configured on the default certificate realm as follows on the Admin Console:

1. Navigate to the applicable configuration page for your use (e.g. `server-config`) under the `Configurations` option in the side menu
2. Head to `Security` → `Realms` and select the `certificate` realm
3. Click the `Add Property` button
4. Set the property *Name* to be `common-name-as-principal-name` and set the *Value* to `true`



Configuration using the Asadmin CLI

You can also use the following asadmin command to set the value of the property:

```
asadmin set configs.config.${YOUR_INSTANCE_CONFIG}.security-service.auth-
realm.certificate.property.common-name-as-principal-name=true
```

After setting the value of the property, make sure that you **restart the server instance** for the changes to take effect.

Using `CN` as Subject in Applications

Once this feature is enabled, users can be authenticated when a valid certificate uses the common name instead of the full domain name. It is also possible to map users to roles in this directly.

For example, if user authorization roles were mapped like this in the `payara-web.xml` deployment descriptor:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
```

```
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app error-url="">
  <context-root>/health-services</context-root>
  <security-role-mapping>
    <role-name>gl</role-name>
    <principal-name>C=UK, S=lak, L=zak, O=kaz, CN=foo</principal-name>
  </security-role-mapping>
</payara-web-app>
```

Then the `principal-name` can be simplified by using only the common name like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app error-url="">
  <context-root>/health-services</context-root>
  <security-role-mapping>
    <role-name>gl</role-name>
    <principal-name>foo</principal-name>
  </security-role-mapping>
</payara-web-app>
```

Client Certificate Custom Validations

By default, the Payara Server runtime checks only if the submitted Client Certificate is present in the trust store and that it hasn't expired already. If these conditions are met, it is accepted without any additional checks.

Custom Client Certificate Validation allows you to perform extra checks in addition to checking for the presence of the certificate in the trust store.

You can perform a check on the validity date, and use the Online Certificate Status Protocol (OCSP) to validate the certificate when it has a Certificate Revocation List entry (CRL), or lookup the DN name in a database for example, and determine based on this information if the certificate is still accepted.

Creating a Custom Validator

When you want to implement custom validation, implement the `fish.payara.security.client.ClientCertificateValidator` interface and define your class through the `ServiceLoader` mechanism.

To have the `ClientCertificateValidator` interface available in your application, add the `payara-api` artifact to your application with the provided scope. When using maven, add the following snippet if not already defined.

```
<dependency>
```

```
    <groupId>fish.payara.api</groupId>
    <artifactId>payara-api</artifactId>
    <version>{page-version}</version>
    <scope>provided</scope>
</dependency>
```

Now that you have the interface available, you can implement it in your application.

```
public class MyCertificateValidator implements ClientCertificateValidator {

    @Override
    public boolean isValid(Subject subject, X500Principal principal, X509Certificate
certificate) {
          var isValid = true;
          //Determine if the subject is valid
          return isValid;
    }
}
```

The most important parameter here is the `principal` parameter which contains the user information contained in the Client Certificate presented in the request. The Certificate itself is in the last parameter and in the case you like to have access already to the `Subject` for this validation, it is passed in as the first parameter.

When you return `true` as the method result, the processing of the request continues. In the case false is returned, a `LoginException` is thrown resulting in a status `401` for the request.

This class is loaded through the Java ServiceLoader mechanism. Make sure you have the following file. `META-INF/services/fish.payara.security.client.ClientCertificateValidator` containing the fully qualified name of your implementation.

```
com.company.certificate.MyCertificateValidator
```

You can @Inject CDI and EJB beans in your validator implementation, however since the validator itself is not a Jakarta EE bean, `@PostConstruct` and `@PreDestroy` -annotated methods will not be called on the validator instance.

Certificate Expiration Validation

By default, certificate expiration validation is enabled. This validation checks if the certificates in the trust store haven't expired yet. If the client certificate has expired or is not valid yet, a warning message will be printed in the server logs.

Configuration using the Asadmin CLI

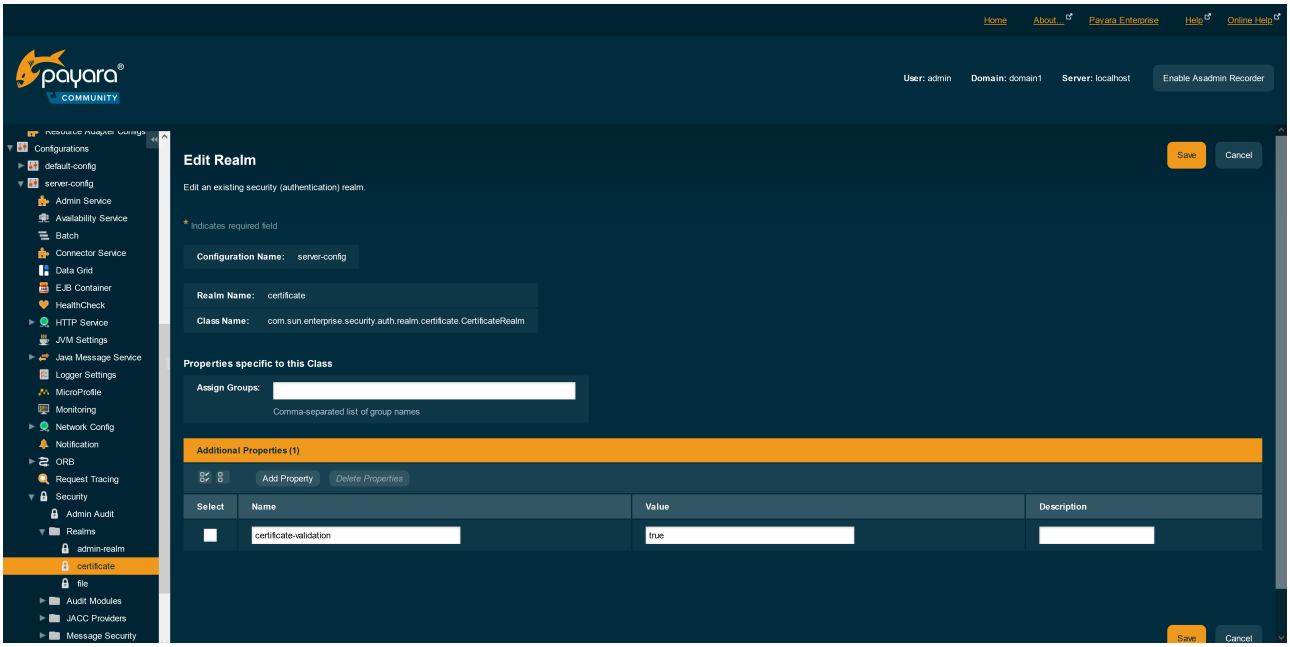
You can use the following asadmin command to set the value of the property through:

```
asadmin> set configs.config.${YOUR_INSTANCE_CONFIG}.security-service.auth-
realm.certificate.property.certificate-validation=[true/false]
```

Configuration using the Admin Console

This feature can be configured on the default certificate realm as follows on the Admin Console:

1. Navigate to the applicable configuration page for your use (e.g. `server-config`) under the `Configurations` option in the side menu
2. Head to `Security` → `Realms` and select the `certificate` realm
3. Set the property `certificate-validation` *value* to `[true/false]`



After setting the value of the property, make sure that you **restart the server instance** for the changes to take effect.

JCE Provider Support

Payara Server supports using the JCE framework to configure custom security providers. Custom providers can be installed statically in the JDK, via the service loader mechanism, or via the programmatic API.

Although the provider can be changed while the server is running, this can influence other processes that already use the previous preferred provider.

Example

The example below uses an existing provider (Bouncy Castle), to which a custom service is added programmatically. As suggested above, this is not the suggested way to do this since it is being changed dynamically. Rather, this example is here for an idea of how it *could* be used.

Custom Certificate Factory

```
public class MyJCECertificateFactory extends CertificateFactory {

    @Override
    public Certificate engineGenerateCertificate(InputStream in) throws
CertificateException {
        Certificate certificate = super.engineGenerateCertificate(in);

        if (certificate instanceof X509Certificate == false) {
            return certificate;
        }

        return new MyJCEX509Certificate((X509Certificate) certificate);
    }

}
```

This factory is based on the CertificateFactory SPI type, but instead of implementing it fully the Bouncy Castle's CertificateFactory is used.

The returned Certificate is then wrapped in our own. A custom certificate type might then look as follows:

Custom Certificate Type

```
public class MyJCEX509Certificate extends X509Certificate {

    private final X509Certificate certificate;

    public MyJCEX509Certificate(X509Certificate certificate) {
        this.certificate = certificate;
    }

    @Override
    public X500Principal getSubjectX500Principal() {

        var principal = certificate.getSubjectX500Principal();
        if ("C=UK,ST=lak,L=zak,O=kaz,OU=bar,CN=lfoo".equals(principal.getName())) {
            return new X500Principal("CN=u1");
        }
        return principal;
    }

    @Override
    public Principal getSubjectDN() {

        va principal = certificate.getSubjectDN();
        if ("CN=lfoo,OU=bar,O=kaz,L=zak,ST=lak,C=UK".equals(principal.getName())) {
            return new X500Principal("CN=u1");
```

```
        }
        return principal;
    }

    // Other methods omitted for brevity
}
```

This custom certificate is where the "principal mapping" is performed. For the example only `CN=lfoo,OU=bar,O=kaz,L=zak,ST=lak,C=UK` to `CN=u1` is mapped though.

The example above overrides two methods. The `getSubjectDN()` method is actually deprecated (or denigrated as in the Certificate's terminology), but it's still being used. `getSubjectX500Principal()` is the preferred method to use.

Finally, the factory can be installed for example via a Servlet that we can easily ping (as mentioned, this would not normally be the advisory way to do this):

Custom Factory Installation

```
@WebServlet(urlPatterns = { "/BouncyServlet" })
public class BouncyServlet extends HttpServlet {

    private static final long serialVersionUID = 1L;

    @Override
    protected void doGet(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException {

        var provider = new BouncyCastleProvider();
        provider.put("CertificateFactory.X.509",
MyJCECertificateFactory.class.getName());

        int pos = Security.insertProviderAt(provider, 1);
        response.getWriter().print("pos:" + pos);
    }
}
```

The above code instantiates the bouncy castle provider, and registers the previous custom certificate factory with it. In this example you can see the type and algorithm being combined into the single key for registering our factory class.

The modified provider is then inserted at provider position 1 (the first, there's no 0), using a static method of the Security class.

After pinging this Servlet, and requesting another Servlet over HTTPS that's protected with the client-cert authentication mechanism, a principal with name `CN=lfoo,OU=bar,O=kaz,L=zak,ST=lak,C=UK` will be replaced at nearly the lowest level in the system with `CN=u1`, and the server runtime will only see this principal name. We can use this principal name for instance to map groups and roles to it:

```
<payara-web-app>
    <security-role-mapping>
        <role-name>g1</role-name>
        <group-name>g1</group-name>
        <principal-name>CN=u1</principal-name>
    </security-role-mapping>
</payara-web-app>
```

A fully working sample demonstrating exactly this can be found in the Java EE 7 samples repo.

Developing CDI Components

This section lists additional available enhancements to the CDI implementation shipped in the Payara Platform.

Concurrent CDI Bean Loading

It is possible to concurrently load CDI beans and potentially speed up an application's load time by enabling Weld's Multi-Threaded Bean Loading feature.

By default, this feature is disabled for all applications on Payara Server, and enabled for all applications on Payara Micro.

Enable Concurrent CDI Bean Loading

Concurrent CDI bean loading is configured on a per-configuration basis using the `set` on the `cdi-service.enable-concurrent-deployment` property like this:

```
asadmin set configs.config.server-config.cdi-service.enable-concurrent-deployment=true
```

It is possible to configure the number of pre-loader threads like this:

```
asadmin set configs.config.server-config.cdi-service.pre-loader-thread-pool-size=4
```

When configuring the number of the pre-loader threads, use a sensible value that is consistent with the number of CPU cores available for the server instance, otherwise this setting may introduce performance degradation on the deployment times.

Concurrent deployment of CDI Beans is enabled by default with 2 pre-loader threads in Payara Micro.

There are no equivalent configuration views for these commands in the Web admin console. They'll be reserved for a future release.

Legacy mode of empty beans.xml

Starting with CDI 4.0, bean archives with empty beans.xml have discovery mode `annotated`. It is possible to activate the legacy mode option to switch this back to `all` discovery mode.

Enable legacy mode of empty beans.xml

The legacy mode of empty beans.xml can be enabled using the following mechanisms:

Via asadmin CLI

Using the asadmin CLI it is possible to enable legacy mode for a single application or for ALL deployed applications.

Enabling for a single application

The legacy mode can be enabled for a single application with the `deploy` command. Add the `emptyBeansXmlModeALL=true` property to the `--properties` argument's value of the `deploy` command.

Here's an example of enabling development mode for an application named `application.war`:

```
asadmin deploy --properties emptyBeansXmlModeALL=true myapplication.war
```

Legacy mode is configured on a per-configuration basis using the `create-system-properties` on the `fish.payara.deployment.emptyBeansXmlModeALL` property like this:

```
asadmin create-system-properties fish.payara.deployment.emptyBeansXmlModeALL=true
```

The legacy mode is enabled by default for any transformed Jakarta EE 8 applications that are converted via the Eclipse Transformer.

Developing SOAP Webservices

This chapter describes Payara Server's support for SOAP-compatible web services. "Building with Jakarta XML Web Services" in The Jakarta EE Tutorial shows more details on creating dedicated SOAP Web Services for any Jakarta EE runtime.

For additional information about JAXB (Jakarta XML Binding), see its corresponding specification and The Databinding Provider.

For additional information about Jakarta XML Web Services, see its corresponding specification.

For information about web services security, see Configuring Message Security for Web Services.

The Fast Infoset standard specifies a binary format based on the XML Information Set. This format is an efficient alternative to XML. For more information about using Fast Infoset, see the following links:

- Fast Infoset Project

- XML Information Set

Deploying a Web Service

You deploy a web service endpoint to Payara Server just as you would any servlet, stateless session bean (SLSB), or application.

For complex services with dependent classes, user specified WSDL files, or other advanced features, auto-deployment of an annotated file is not sufficient.

The Payara Server deployment descriptor files `glassfish-web.xml`/`payara-web.xml` and `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` provide optional web service enhancements in the `webservice-endpoint` and `webservice-description` elements, including a `debugging-enabled` sub-element that enables the creation of a test page.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

The test page feature is enabled by default and described in The Web Service URI, WSDL File, and Test Page.

The Web Service URI, WSDL File, and Test Page

Clients can run a deployed web service by accessing its service endpoint address URI, which has the following format:

```
http://${host}:${port}/${context-root}/${servlet-mapping-url-pattern}
```

The context-root is defined in the `application.xml` or `web.xml` file, and can be overridden in the `glassfish-application.xml`/`payara-application.xml` or `glassfish-web.xml`/`payara-web.xml` file. The servlet-mapping-url-pattern is defined in the `web.xml` file.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

In the following example, the context-root is `my-ws` and the servlet-mapping-url-pattern is `/simple` for local deployment in the default port:

```
http://localhost:8080/my-ws/simple
```

You can view the WSDL file of the deployed service in a browser by adding `?WSDL` to the end of the URI. For example:

```
http://localhost:8080/my-ws/simple?WSDL
```

For debugging, you can run a test page for the deployed service in a browser by adding `?Tester` to

the end of the URL. For example:

```
http://localhost:8080/my-ws/simple?Tester
```

This URL will show the SOAP Web Service Tester in the corresponding browser allowing users to quickly test their web services after deployment.

You can also test a service using the Administration Console. Open the *Web Services* component for the corresponding deployed application, select the web service in the listing on the *General* tab, and select *Test*.

The tester webpage works only for WS-I compliant web services. This means that the tester servlet does not work for services with WSDL files that use RPC/encoded binding.

The Web Service tester application is enabled by default. You can disable the test page for a web service by setting the value of the `debugging-enabled` element in the `glassfish-web.xml`/`payara-web.xml` and `glassfish-ejb-jar.xml`/payara-ejb-jar.xml` deployment descriptor to `false`.

The Databinding Provider

To specify the Jakarta XML Binding provider implementation for the server runtime, set the `com.sun.xml.ws.spi.db.BindingContextFactory` JVM property to one of the following values:

- `com.sun.xml.ws.db.glassfish.JAXBRIContextFactory`: Specifies the JAXB reference implementation in Payara Server (bundled within Metro). This is the default setting.
- `org.eclipse.persistence.jaxb.JAXBContextFactory`: Specifies Eclipselink MOXy Jakarta XML bindings.

  For example:

  ```
  asadmin create-jvm-options
  -Dcom.sun.xml.ws.spi.db.BindingContextFactory=org.eclipse.persistence.jaxb.JAXBCont
  extFactory
  ```

To specify the Jakarta XML Binding provider for a **specific** web service endpoint, you have the following options:

- Set the `com.oracle.webservices.api.databinding.DatabindingModeFeature` feature during `WebServiceFeature` initialization or using the `add` method.

  Allowed values are as follows:

  - `com.oracle.webservices.api.databinding.DatabindingModeFeature.GLASSFISH_JAXB`: Specifies the JAXB reference implementation (bundled within Metro). This is the default setting.
  - `org.eclipse.persistence.jaxb.JAXBContextFactory.ECLIPSELINK_JAXB`: Specifies Eclipselink MOXy JAXB binding.

For example:

```
import jakarta.xml.ws.WebServiceFeature;
import com.oracle.webservices.api.databinding.DatabindingModeFeature;
import org.eclipse.persistence.jaxb.JAXBContextFactory;

WebServiceFeature[] features = {new
DatabindingModeFeature(JAXBContextFactory.ECLIPSELINK_JAXB)};
```

- Set the `com.oracle.webservices.api.databinding.DatabindingModeFeature` feature using the `@DatabindingMode` annotation. For example:

```
import jakarta.jws.WebService;
import com.oracle.webservices.api.databinding.DatabindingMode;
import org.eclipse.persistence.jaxb.JAXBContextFactory;

@WebService
@DatabindingMode(JAXBContextFactory.ECLIPSELINK_JAXB)
public class MyWebService{
}
```

To configure these features in your application at compile time you'll have to configure explicit dependencies to the Eclipse EE4J Metro and EclipseLink's projects.

Additional Scanning Locations

Payara Server scans for specific JAX-WS files in locations further to those specified in the **JAX-WS** specification.

Additional directories and sources are scanned are documented here.

`jax-ws-catalog.xml`

The Jakarta XML Web Services specification states that the `jax-ws-catalog.xml` file should be searched for in the `META-INF` directory of a deployed `WAR` file relative to the classpath.

Since the classpath of a WAR can be found in `/WEB-INF/classes/`, this means that this file is expected at `/WEB-INF/classes/META-INF/jax-ws-catalog.xml` (from the root of the `WAR` artifact).

Payara Server also searches for this file at `/WEB-INF/jax-ws-catalog.xml`.

Configuring the Java Persistence Provider

This chapter describes EclipseLink, the default persistence provider in Payara Server, and introduces how to use it.

This chapter also tells how to set the default persistence provider in Payara Server and how to use

persistence-related features specific to the Payara Platform such as automatic schema generation.

EclipseLink Overview

EclipseLink is the default persistence provider in the Payara Platform. It is a comprehensive standards-based object-persistence and object-transformation framework that provides APIs, schemas, and run-time services for the persistence layer of an application.

EclipseLink implements the following specifications, plus value-added extensions:

Jakarta Persistence (JPA) 3.0+

JPA is part of the Jakarta EE specification. It includes improvements and enhancements to domain modeling, object/relational mapping, `EntityManager` and `Query` interfaces, and the Jakarta Persistence Query Language (JPQL). It includes an API for criteria queries, a metamodel API, and support for validation. The Jakarta Persistence API can be used with non-EJB components outside the EJB container.

For more information, see the Jakarta Persistence specification. For basic information about the Jakarta Persistence API, see "Persistence" in The Jakarta EE Tutorial.

Jakarta XML Binding (JAXB)

The EclipseLink JAXB implementation, plus EclipseLink extensions, is called **MOXy**. The `org.eclipse.persistence.moxy.jar` file is bundled as a module in Payara Server.

For more information about MOXy support in Payara Server, see The Databinding Provider.

For the JAXB specification, see the Jakarta XML Binding specification.

- EclipseLink binary utilities are not included but can be used with Payara Server. To use them, download the EclipseLink zip file at `http://www.eclipse.org/eclipselink/downloads/` and unzip it. The utility files are located in the `bin` folder and are the following:
  - `jaxb-compiler`: Used to compile Java binding source files.
  - `sdo-compiler`: Used to compile SDO files.
  - `sdo-jaxb-compiler`: Used to compile Java binding source files for SDO components.

All utilities are available as both a CMD and BASH shell script.

For information about developing, deploying, and configuring EclipseLink, and applications, see the following resources:

- EclipseLink Project Home
- EclipseLink Documentation Center
- EclipseLink JPA Examples

Using EclipseLink in Payara Server

To run EclipseLink JPA applications in Payara Server, you must configure the server and coordinate certain server and application settings. These are described in the following steps:

1. Set up the datasource. See "Administering Database Connectivity" in Payara Server General Administration section.
2. Create the application. For guidance in writing your application, see "Persistence" in The Jakarta EE Tutorial.
3. Create the `persistence.xml` file. See Specifying the Database for an Application for considerations specific to Payara Server.

   If you are using the Jakarta Persistence API by calling `Persistence.createEMF()`, see Specifying the Persistence Provider for an Application.
4. If the security manager is enabled, and you are using the Jakarta Persistence API by calling `Persistence.createEMF()`, see Enabling and Disabling the Security Manager.
5. Deploy the application.
6. Run the application.
7. Monitor the application. See "Administering the Monitoring Service" in the Payara Server General Administration section.

Specifying the Database for an Application

Payara Server uses an embedded H2 database to provision its default datasource, named `jdbc/__default`. If the `transaction-type` element is omitted or specified as `JTA` and both the `jta-data-source` and `non-jta-data-source` elements are omitted in the `persistence.xml` file, the default datasource is used as a JTA data source.

If `transaction-type` is specified as `RESOURCE_LOCAL` and both `jta-data-source` and `non-jta-data-source` are omitted, the default datasource is used as a non-JTA data source.

To use a non-default database, either specify a value for the `jta-data-source` element, or set the `transaction-type` element to `RESOURCE_LOCAL` and specify a value for the `non-jta-data-source` element.

When using EclipseLink, it attempts to automatically detect the database type based on the connection metadata. This database type is used to issue SQL statements specific to the detected database type's SQL dialect.

You can specify the optional `eclipselink.target-database` property to guarantee that the database type is correct. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence version="3.0" xmlns="https://jakarta.ee/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:schemaLocation="https://jakarta.ee/xml/ns/persistence
https://jakarta.ee/xml/ns/persistence/persistence_3_0.xsd">
    <persistence-unit name ="em1">
        <jta-data-source>jdbc/MyDB2DB</jta-data-source>
        <properties>
            <property name="eclipselink.target-database"  value="DB2"/>
```

```
        </properties>
    </persistence-unit>
</persistence>
```

The following `eclipselink.target-database` property values are allowed. Supported platforms have been tested in Payara Server and are found to be Jakarta EE compatible.

```
//Supported platforms
Attunity
Cloudscape
DB2
DB2Mainframe
DBase
Derby
HSQL
H2
Informix
JavaDB
MaxDB
MySQL
MySQL4
Oracle
Oracle10
Oracle11
Oracle8
Oracle9
PointBase
PostgreSQL
SQLAnywhere
SQLServer
Sybase
Symfoware
TimesTen
```

For more information about the `eclipselink.target-database` property, see EclipseLink JPA Extensions - Target Database.

If you are using the Java Persistence API by calling `Persistence.createEMF()`, do not specify the `jta-data-source` or `non-jta-data-source` elements. Instead, specify the `provider` element and any additional properties required by the JDBC driver or the database. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence version="3.0" xmlns="https://jakarta.ee/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:schemaLocation="https://jakarta.ee/xml/ns/persistence
https://jakarta.ee/xml/ns/persistence/persistence_3_0.xsd">
    <persistence-unit name ="em2">
        <provider>org.eclipse.persistence.jpa.PersistenceProvider</provider>
```

```
        <class>fish.payara.jpa.JpaBean</class>
        <properties>
            <property name="eclipselink.target-database" value="H2"/>
            <!-- JDBC connection properties -->
            <property name="eclipselink.jdbc.driver" value="org.h2.Driver"/>
            <property name="eclipselink.jdbc.url"
value="jdbc:h2://localhost:1527/~/testdb"/>
            <property name="eclipselink.jdbc.user" value="APP"/>
            <property name="eclipselink.jdbc.password" value="APP"/>
        </properties>
    </persistence-unit>
</persistence>
```

For configurations of supported and other drivers, see "Configuration Specifics for JDBC Drivers" in the Payara Server General Administration section.

Specifying the Persistence Provider for an Application

If you are using the default persistence provider in an application that uses the Jakarta Persistence API by injecting or looking up an entity manager or entity manager factory, you do not need to specify the provider explicitly.

If you are using the Jakarta Persistence API by calling `Persistence.createEMF()`, you should always specify the persistence provider for specification compliance. To specify the default provider, set the `provider` element of the `persistence.xml` file to `org.eclipse.persistence.jpa.PersistenceProvider`.

You can specify a non-default persistence provider for an application in the manner described in the Jakarta Persistence API Specification:

1. Install the provider. Copy the provider JAR files to the `domain-dir/lib` directory, and restart the Payara Server domain.

   The new persistence provider is now available to all modules and applications deployed on servers that share the same configuration.

   EclipseLink will remain as the default persistence provider.

2. In your persistence unit, specify the provider and any properties the provider requires in the `persistence.xml` file. For example:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <persistence xmlns="http://java.sun.com/xml/ns/persistence">
       <persistence-unit name ="em3">
           <provider>com.company.persistence.PersistenceProviderImpl</provider>
           <properties>
               <property name="company.database.name" value="MyDB"/>
           </properties>
       </persistence-unit>
   ```

```
</persistence>
```

Primary Key Generation Defaults

In the descriptions of the `@GeneratedValue`, `@SequenceGenerator`, and `@TableGenerator` annotations in the Jakarta Persistence Specification, certain defaults are noted as specific to the persistence provider. The default persistence provider's primary key generation defaults are listed here.

`@GeneratedValue` defaults are as follows:

- Using `strategy=AUTO` (or no `strategy`) creates a `@TableGenerator` named `SEQ_GEN` with default settings. Specifying a `generator` has no effect.
- Using `strategy=TABLE` without specifying a `generator` creates a `@TableGenerator` named `SEQ_GEN_TABLE` with default settings.

  Specifying a `generator` but no `@TableGenerator` creates and names a `@TableGenerator` with default settings.

- Using `strategy=IDENTITY` or `strategy=SEQUENCE` produces the same results, which are database-specific.
  - For Oracle databases, not specifying a `generator` creates a `@SequenceGenerator` named `SEQ_GEN_SEQUENCE` with default settings.

    Specifying a `generator` but no `@SequenceGenerator` creates and names a `@SequenceGenerator` with default settings.

  - For PostgreSQL databases, a `SERIAL` column named entity-table`_`pk-column`_SEQ` is created.
  - For MySQL databases, an `AUTO_INCREMENT` column is created.
  - For other supported databases, an `IDENTITY` column is created.

The `@SequenceGenerator` annotation has one default specific to the default provider. The default `sequenceName` is the specified `name`.

`@TableGenerator` defaults are as follows:

- The default `table` is `SEQUENCE`.
- The default `pkColumnName` is `SEQ_NAME`.
- The default `valueColumnName` is `SEQ_COUNT`.
- The default `pkColumnValue` is the specified `name`, or the default `name` if no `name` is specified.

Automatic Schema Generation

The automatic schema generation feature of Payara Server defines database tables based on the fields or properties in entities and the relationships between the fields or properties.

This insulates developers from many of the database related aspects of development, allowing them

to focus on entity development.

The resulting schema is usable as-is or can be given to a database administrator for tuning with respect to performance, security, and so on.

Automatic schema generation is supported on an all-or-none basis: it expects that no tables exist in the database before it is executed. It is not intended to be used as a tool to generate extra tables or constraints.
Deployment won't fail if all tables are not created, and un-deployment won't fail if not all tables are dropped. Instead, an error is written to the server log. This is done to allow you to investigate the problem and fix it manually. You should not rely on the partially created database schema to be correct for running the application.

Annotations

The following annotations are used in automatic schema generation:

- `@AssociationOverride`
- `@AssociationOverrides`
- `@AttributeOverride`
- `@AttributeOverrides`
- `@Column`
- `@DiscriminatorColumn`
- `@DiscriminatorValue`
- `@Embedded`
- `@EmbeddedId`
- `@GeneratedValue`
- `@Id`
- `@IdClass`
- `@JoinColumn`
- `@JoinColumns`
- `@JoinTable`
- `@Lob`
- `@ManyToMany`
- `@ManyToOne`
- `@OneToMany`
- `@OneToOne`
- `@PrimaryKeyJoinColumn`
- `@PrimaryKeyJoinColumns`

- `@SecondaryTable`
- `@SecondaryTables`
- `@SequenceGenerator`
- `@Table`
- `@TableGenerator`
- `@UniqueConstraint`
- `@Version`

For information about these annotations, see the Jakarta Persistence Specification.

For `@Column` annotations, the `insertable` and `updatable` elements are not used in automatic schema generation.

For `@OneToMany` and `@ManyToOne` annotations, no `ForeignKeyConstraint` is created in the resulting DDL files.

Generation Options

Schema generation properties or `asadmin` command line options can control automatic schema generation by the following:

- Creating tables during deployment
- Dropping tables during un-deployment
- Dropping and creating tables during redeployment
- Generating the DDL files

Optional schema generation properties control the automatic creation of database tables. You can specify them in the `persistence.xml` file. For more information, see EclipseLink JPA Extensions for Schema Generation.

The following options of the `asadmin deploy` command control the automatic creation of database tables at deployment.

Table 183. The `asadmin deploy` Generation Options

Option	Default	Description
`--createtables`	none	If `true`, causes database tables to be created for entities that need them. No unique constraints are created. If `false`, does not create tables. If not specified, the value of the `eclipselink.ddl-generation` property in `persistence.xml` is used.

Option	Default	Description
`--dropandcreatetables`	none	If `true`, and if tables were automatically created when this application was last deployed, tables from the earlier deployment are dropped and fresh ones are created. If `true`, and if tables were not automatically created when this application was last deployed, no attempt is made to drop any tables. If tables with the same names as those that would have been automatically created are found, the deployment proceeds, but a warning is thrown to indicate that tables could not be created. If `false`, the `eclipselink.ddl-generation` property setting in `persistence.xml` is overridden.

The following options of the `asadmin undeploy` command control the automatic removal of database tables at un-deployment.

Table 184. The `asadmin undeploy` Generation Options

Option	Default	Description
`--droptables`	none	If `true`, causes database tables that were automatically created when the entities were last deployed to be dropped when the entities are un-deployed. If `false`, does not drop tables. If not specified, tables are dropped only if the `eclipselink.ddl-generation` property setting in `persistence.xml` is `drop-and-create-tables`.

When `asadmin` deployment options and `persistence.xml` options are both specified, the `asadmin` deployment options take precedence.

Restrictions and Optimizations

This section discusses restrictions and performance optimizations that affect using the Java Persistence API.

Extended Persistence Context

The Jakarta Persistence API specification does not specify how the container and persistence provider should work together to serialize an extended persistence context. This also prevents successful serialization of a reference to an extended persistence context in a stateful session bean.

Even in a single-instance environment, if a stateful session bean is passivated, its extended persistence context could be lost when the stateful session bean is activated.

In Payara Server, a stateful session bean with an extended persistence context is never passivated and cannot be failed over.

Using `@OrderBy` with a Shared Session Cache

Setting `@OrderBy` on a `ManyToMany` or `OneToMany` relationship field in which a `List` represents the Many side doesn't work if the session cache is shared. Use one of the following workarounds:

- Have the application maintain the order so the `List` is cached properly.
- Refresh the session cache using `EntityManager.refresh()` if you don't want to maintain the order during creation or modification of the `List`.
- Disable session cache sharing in `persistence.xml` as follows:

```
<property name="eclipselink.cache.shared.default" value="false"/>
```

Database Case Sensitivity

Mapping references to column or table names must be in accordance with the expected column or table name case, and ensuring this is the programmer's responsibility.

If column or table names are not explicitly specified for a field or entity, Payara Server uses upper case column names by default, so any mapping references to the column or table names must be in upper case.

If column or table names are explicitly specified, the case of all mapping references to the column or table names must be in accordance with the case used in the specified names.

The following are examples of how case sensitivity affects mapping elements that refer to columns or tables. Keep case sensitivity in mind when writing these mappings.

Unique Constraints

If column names are not explicitly specified on a field, unique constraints and foreign key mappings must be specified using uppercase references. For example:

```
@Table(name="Department",
    uniqueConstraints= {
        @UniqueConstraint(columnNames= "DEPTNAME")
})
```

The other way to handle this is by specifying explicit column names for each field with the required case. For example:

```
@Table(name="Department",
        uniqueConstraints={ @UniqueConstraint ( columnNames= { "deptName" } ) } )
public class Department{
```

```
    @Column(name="deptName")
    private String deptName;
}
```

Otherwise, the `ALTER TABLE` statement generated by Payara Server uses the incorrect case, and the creation of the unique constraint fails.

Foreign Key Mapping

Use `@OneToMany(mappedBy="COMPANY")` or specify an explicit column name for the `Company` field on the `Many` side of the relationship.

SQL Result Set Mapping

Use the following elements:

```
<sql-result-set-mapping name="SRSMName">
   <entity-result entity-class="entities.someEntity" />
   <column-result name="UPPERCASECOLUMNNAME" />
</sql-result-set-mapping>
```

Or specify an explicit column name for the `upperCaseColumnName` field.

Named Native Queries and JDBC Queries

Column or table names specified in SQL queries must be in accordance with the expected case. For example, MySQL requires column names in the `SELECT` clause of JDBC queries to be uppercase, while PostgreSQL and Sybase require table names to be uppercase in all JDBC queries.

PostgreSQL Case Sensitivity

PostgreSQL stores column and table names in lower case. JDBC queries on PostgreSQL retrieve column or table names in lowercase unless the names are quoted. For example:

```
use aliases Select m.ID AS \"ID\" from Department m
```

Use the backslash as an escape character in the class file, but not in the `persistence.xml` file.

Sybase Finder Limitation

If a finder method with an input greater than 255 characters is executed and the primary key column is mapped to a `VARCHAR` column, Sybase attempts to convert type `VARCHAR` to type `TEXT` and generates the following error:

```
com.sybase.jdbc2.jdbc.SybSQLException: Implicit conversion from datatype 'TEXT' to
'VARCHAR' is not allowed. Use the CONVERT function to run this query.
```

To avoid this error, make sure the finder method input is less than 255 characters.

MySQL Database Restrictions

The following restrictions apply when you use a MySQL database with Payara Server in conjunction with JPA.

- MySQL treats `int1` and `int2` as reserved words. If you want to define `int1` and `int2` as fields in your tables, use `\`int1\`` and `\`int2\`` field names in your SQL file.
- When `VARCHAR` fields get truncated, a warning is displayed instead of an error. To get an error message, start the MySQL database in strict SQL mode.
- The order of fields in a foreign key index must match the order in the explicitly created index on the primary table.
- The `CREATE TABLE` syntax in the SQL file must end with the following line.

  ```
  )  Engine=InnoDB;
  ```

  `InnoDB` provides MySQL with a transaction-safe (ACID compliant) storage engine having commit, rollback, and crash recovery capabilities.

- For a `FLOAT` type field, the correct precision must be defined. By default, MySQL uses four bytes to store a `FLOAT` type that does not have an explicit precision definition. For example, this causes a number such as `12345.67890123` to be rounded off to `12345.7` during an `INSERT`.

  To prevent this, specify `FLOAT(10,2)` in the DDL file, which forces the database to use an eight-byte double-precision column. For more information, see https://dev.mysql.com/doc/refman/8.0/en/numeric-types.html.

- To use `||` as the string concatenation symbol, start the MySQL server with the `--sql-mode="PIPES_AS_CONCAT"` option.
- MySQL always starts a new connection when `autoCommit==true` is set. This ensures that each SQL statement forms a single transaction on its own. If you try to rollback or commit an SQL statement, you get an error message like the following:

  ```
  javax.transaction.SystemException: java.sql.SQLException: Can't call rollback when
  autocommit=true
  javax.transaction.SystemException: java.sql.SQLException: Error open transaction is
  not closed
  ```

  To resolve this issue, add `relaxAutoCommit=true` to the JDBC URL.

- MySQL does not allow a `DELETE` on a row that contains a reference to itself. Here is an example that illustrates the issue:

  ```
  create table EMPLOYEE (
      empId   int         NOT NULL,
  ```

```
    salary  float(25,2) NULL,
    mgrId   int         NULL,
    PRIMARY KEY (empId),
    FOREIGN KEY (mgrId) REFERENCES EMPLOYEE (empId)
) ENGINE=InnoDB;

insert into Employee values (1, 1234.34, 1);
delete from Employee where empId = 1;
```

This example fails with the following error message.

```
ERROR 1217 (23000): Cannot delete or update a parent row: a foreign key constraint
fails
```

To resolve this issue, change the table creation script to the following:

```
create table EMPLOYEE (
    empId   int         NOT NULL,
    salary  float(25,2) NULL,
    mgrId   int         NULL,
    PRIMARY KEY (empId),
    FOREIGN KEY (mgrId) REFERENCES EMPLOYEE (empId)
    ON DELETE SET NULL
) ENGINE=InnoDB;

insert into Employee values (1, 1234.34, 1);
delete from Employee where empId = 1;
```

This can be done only if the foreign key field is allowed to be `null`.

Using the Hazelcast EclipseLink Cache Coordination Protocol

If necessary, your can configure the Data Grid (implemented via Hazelcast) as the coordination mechanism for the application's L2 cache (if enabled). To do so, configure the `persistence.xml` deployment descriptor as follows:

1. Set the `eclipselink.cache.coordination.protocol` property to `fish.payara.persistence.eclipselink.cache.coordination.HazelcastPublishingTransportManager`
2. Set the `eclipselink.cache.coordination.channel` property to a unique value for the coordination channel's name.

The channel property is optional, but is highly recommended if the application has more than one Persistence Unit. A good practice is to name the channel after the persistence unit.

Here is a complete example:

```
<?xml version="1.0" encoding="UTF-8" ?>
```

```
<persistence version="3.0" xmlns="https://jakarta.ee/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:schemaLocation="https://jakarta.ee/xml/ns/persistence
https://jakarta.ee/xml/ns/persistence/persistence_3_0.xsd">
    <persistence-unit name="MyPU" transaction-type="JTA">
        <jta-data-source>jdbc/myDataSource</jta-data-source>
        <shared-cache-mode>DISABLE_SELECTIVE</shared-cache-mode>
        <properties>
            <property name="eclipselink.cache.coordination.protocol"
value="fish.payara.persistence.eclipselink.cache.coordination.HazelcastPublishingTrans
portManager"/>
            <property name="eclipselink.cache.coordination.channel"
value="MyPUChannel"/>
        </properties>
    </persistence-unit>
</persistence>
```

Developing Web Applications

This chapter describes how web applications are supported in the Payara Platform.

For general information about web applications, see "The Web Tier" in The Jakarta EE Tutorial.

Using Servlets

Both Payara Server and Payara Micro supports the Jakarta Servlet specification. For information about using the Jakarta Servlet API, see the specification at https://jakarta.ee/specifications/servlet/.

This section describes how to create effective servlets to control application interactions running on Payara Server or Micro, including standard-based servlets. In addition, this section describes additional features introduced in the Payara Platform.

Caching Servlet Results

Payara Server and Micro can cache the results of invoking a servlet, a JSP, or any URL pattern to make subsequent invocations of the same servlet, JSP, or URL pattern faster. The server runtime caches the request results for a specific amount of time. In this way, if another data call occurs, the server runtime can return the cached data instead of performing the operation again.

For example, if your servlet returns a stock quote that updates every **5 minutes**, you set the cache to expire after **300 seconds**.

Whether to cache results and how to cache them depends on the data involved. For example, it makes no sense to cache the results of a quiz submission, because the input to the servlet is different each time. However, it makes sense to cache a high level report showing demographic data taken from quiz results that is updated once an hour.

To define how a web application handles response caching, you'll have to modify specific attributes in the `glassfish-web.xml` or `payara-web.xml` deployment descriptor file.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

A servlet that uses caching is not portable.

For information about JSP caching, see JSP Caching.

Caching Features

The Payara Platform has the following web application response caching capabilities:

- Caching is configurable based on the servlet name or the URI.
- When caching is based on the URI, this includes user specified parameters in the query string.

  For example, a response from `/garden/catalog?category=roses` is different from a response from `/garden/catalog?category=lilies`. These responses are stored under different keys in the cache.
- Cache size, entry timeout, and other caching behaviors are configurable.
- Entry timeout is measured from the time an entry is created or refreshed. To override this timeout for an individual cache mapping, specify the `cache-mapping` sub-element `timeout`.
- To determine caching criteria programmatically, write a class that implements the `com.sun.appserv.web.cache.CacheHelper` interface. For example, if only a servlet knows when a back end data source was last modified, you can write a helper class to retrieve the last modified timestamp from the data source and decide whether to cache the response based on that timestamp.
- To determine cache key generation programmatically, write a class that implements the `com.sun.appserv.web.cache.CacheKeyGenerator` interface. See The CacheKeyGenerator Interface.
- All non-ASCII request parameter values specified in cache key elements must be URL encoded. The caching subsystem attempts to match the raw parameter values in the request query string.
- Since newly updated classes impact what gets cached, the web container clears the cache during dynamic deployment or reloading of classes.
- The following `HttpServletRequest` request attributes are exposed:
  - `com.sun.appserv.web.cachedServletName`, the cached servlet target
  - `com.sun.appserv.web.cachedURLPattern`, the URL pattern being cached
- Results produced by resources that are the target of a `RequestDispatcher.include()` or `RequestDispatcher.forward()` call are cached if caching has been enabled for those resources. For details, see "cache-mapping" and "dispatcher in the Payara Server Application Deployment section.

Default Cache Configuration

If you enable caching but do not provide any special configuration for a servlet or JSP page, the default cache configuration is as follows:

- The default cache timeout is **30 seconds**.

- Only the HTTP `GET` method is eligible for caching.
- HTTP requests with cookies or sessions automatically disable caching.
- No special consideration is given to `Pragma`, `Cache-control`, or `Vary` HTTP headers.
- The default key consists of the servlet's path (minus `pathInfo` and the query string).
- The "least recently used" list is maintained to evict cache entries if the maximum cache size is exceeded.
- Key generation concatenates the servlet path with key field values, if any are specified.
- Results produced by resources that are the target of a `RequestDispatcher.include()` or `RequestDispatcher.forward()` call are never cached.

Caching Example

Here is an example cache element in the `payara-web.xml` file:

```
<cache max-capacity="8192" timeout="60">
 <cache-helper name="myHelper" class-name="MyCacheHelper"/>
 <cache-mapping>
     <servlet-name>myservlet</servlet-name>
     <timeout name="timefield">120</timeout>
     <http-method>GET</http-method>
     <http-method>POST</http-method>
 </cache-mapping>
 <cache-mapping>
     <url-pattern> /catalog/* </url-pattern>
     <!-- cache the best-selling category; cache the responses to this resource only
when the given parameters exist.
         Cache only when the catalog parameter has 'lilies' or 'roses' but no other
catalog varieties:
         * /orchard/catalog?best&category='lilies'
         * /orchard/catalog?best&category='roses'

         but not the result of
         * /orchard/catalog?best&category='wild'
     -->
     <constraint-field name='best' scope='request.parameter'/>
     <constraint-field name='category' scope='request.parameter'>
         <value> roses </value>
         <value> lilies </value>
     </constraint-field>
      <!-- Specify that a particular field is of given range but the field doesn't
need to be present in all the requests -->
     <constraint-field name='SKUnum' scope='request.parameter'>
         <value match-expr='in-range'> 1000 - 2000 </value>
     </constraint-field>
     <!-- cache when the category matches with any value other than a specific value
-->
     <constraint-field name="category" scope="request.parameter">
         <value match-expr="equals" cache-on-match-failure="true">bogus</value>
```

```
    </constraint-field>
  </cache-mapping>
  <cache-mapping>
    <servlet-name> InfoServlet </servlet-name>
    <cache-helper-ref>myHelper</cache-helper-ref>
  </cache-mapping>
</cache>
```

For more information about the `glassfish-web.xml`/`payara-web.xml` caching settings, see "cache" in the Payara Server Application Deployment section.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

The CacheKeyGenerator Interface

The built-in default `CacheHelper` implementation allows web applications to customize the key generation. An application component (in a servlet or JSP) can set up a custom `CacheKeyGenerator` implementation as an attribute in the `ServletContext`.

The name of the context attribute is configurable as the `value` of the `cacheKeyGeneratorAttrName` property in the `default-helper` element of the `glassfish-web.xml`/`payara-web.xml` deployment descriptor.

For more information, see "default-helper" in the Payara Server Application Deployment section.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

About the Servlet Engine

Servlets exist in and are managed by the servlet engine in Payara Server or Micro. The servlet engine is an internal container that handles all servlet meta functions. These functions include instantiation, initialization, destruction, access from other components, and configuration management.

Instantiating and Removing Servlets

After the servlet engine instantiates the servlet, the servlet engine calls the servlet's `init` method to perform any necessary initialization. You can override this method to perform an initialization function for the servlet's life, such as initializing a counter.

When a servlet is removed from service, the servlet engine calls the `destroy` method in the servlet so that the servlet can perform any final tasks and deallocate resources. You can override this method to write log messages or clean up any lingering connections that won't be caught in garbage collection.

Request Handling

When a request is made, the server runtime hands the incoming data to the servlet engine. The servlet engine processes the request's input data, such as form data, cookies, session information, and URL name-value pairs, into an `HttpServletRequest` request object type.

The servlet engine also creates an `HttpServletResponse` response object type. The engine then passes both as parameters to the servlet's `service` method.

In an HTTP servlet, the default `service` method routes requests to another method based on the HTTP transfer method. For example, HTTP `POST` requests are sent to the `doPost` method, HTTP `GET` requests are sent to the `doGet` method, and so on. This enables the servlet to process request data differently, depending on which transfer method is used.

Since the routing takes place in the `service` method, you generally do not override `service` in an HTTP servlet. Instead, override `doGet`, `doPost`, and so on, depending on the request type you expect.

To perform the tasks to answer a request, override the `service` method for generic servlets, and the `doGet` or `doPost` methods for HTTP servlets. Very often, this means accessing EJB components or CDI beans to perform business operations, then collating the information in the `request` object or in a JDBC `ResultSet` object.

Using Jakarta Server Pages

Payara Server and Micro supports the following features:

- Jakarta Server Pages (JSP) Specification
- Pre-compilation of JSP files, which is especially useful for production servers
- JSP tag libraries and standard portable tags

This section describes how to use Jakarta Server Pages (JSP files) as page templates in a web application.

JSP Tag Libraries and Standard Portable Tags

Payara Server and Micro supports tag libraries and standard portable tags. For more information, see the Jakarta Standard Tag Library (JSTL) specification.

The standard tag libraries are automatically available to all web applications.

JSP Caching

JSP caching lets you cache tag invocation results within the servlet engine. Each view can be cached using different cache criteria. For example, suppose you have invocations to view stock quotes, weather information, and so on. The stock quote result can be cached for 10 minutes, the weather report result for 30 minutes, and so on.

For more information about response caching as it pertains to servlets, see Caching Servlet Results.

Enabling JSP Caching

To globally enable JSP caching, set the `jspCachingEnabled` property to `true`. The default is `false`. For example:

```
asadmin set server-config.web-container.property.jspCachingEnabled=true
```

To enable JSP caching for a single web application, follow these steps:

1. Extract the `/META-INF/jspcachtags.tld` file from the `as-install/glassfish/modules/web-glue.jar` file.
2. Create a new JAR file (for example, `jspcachtags.jar`) containing just the `/META-INF/jspcachtags.tld` file previously extracted.
3. Bundle this new JAR file in the `WEB-INF/lib` directory of your web application.

Web applications that use JSP caching without bundling the tag library are not portable.

Refer to the caching tags in JSP files as follows:

```
<%@ taglib prefix="prefix" uri="http://glassfish.org/taglibs/cache" %>
```

Subsequently, the cache tags are available as `<${prefix}:cache>` and `<${prefix}:flush>`. For example, if your prefix is `mypfx`, the cache tags are available as `<mypfx:cache>` and `<mypfx:flush>`.

Caching Scope

JSP caching is available in three different scopes: `request`, `session`, and `application`. The default is `application`. To use a cache in `request` scope, a web application must configure the `com.sun.appserv.web.taglibs.cache.CacheRequestListener` as a web listener in the application's `web.xml` deployment descriptor, as follows:

```
<listener>
   <listener-class>com.sun.appserv.web.taglibs.cache.CacheRequestListener</listener-
class>
</listener>
```

Likewise, for a web application to utilize a cache in `session` scope, it must configure the `com.sun.appserv.web.taglibs.cache.CacheSessionListener` as a web listener in its `web.xml` deployment descriptor, as follows:

```
<listener>
   <listener-class>com.sun.appserv.web.taglibs.cache.CacheSessionListener</listener-
class>
</listener>
```

To utilize a cache in `application` scope, a web application doesn't need to configure any extra listener. The `com.sun.appserv.web.taglibs.cache.CacheContextListener` is already specified in the `jspcachtags.tld` file.

The `cache` Tag

The `cache` tag caches the body between the beginning and ending tags according to the attributes specified. The first time the tag is encountered, the body content is executed and cached. Each subsequent time it is run, the cached content is checked to see if it needs to be refreshed and if so, it is executed again, and the cached data is refreshed.

Otherwise, the cached data in the page is served.

Attributes of `cache`

The following table describes attributes for the `cache` tag.

Table 185. The `cache` tag attributes

Attribute	Default	Description
`key`	`ServletPath_Suffix`	(optional) The name used by the container to access the cached entry. The cache key is suffixed to the servlet path to generate a key to access the cached entry. If no key is specified, a number is generated according to the position of the tag in the page.
`timeout`	`60s`	(optional) The time in seconds after which the body of the tag is executed and the cache is refreshed. By default, this value is interpreted in seconds. To specify a different unit of time, add a suffix to the timeout value as follows: `s` for seconds, `m` for minutes, `h` for hours, `d` for days. For example, `2h` specifies two hours.
`nocache`	`false`	(optional) If set to `true`, the body content is executed and served as if there were no `cache` tag. This offers a way to programmatically decide whether the cached response is sent or whether the body has to be executed, though the response is not cached.
`refresh`	`false`	(optional) If set to `true`, the body content is executed and the response is cached again. This lets you programmatically refresh the cache immediately regardless of the `timeout` setting.
`scope`	`application`	(optional) The scope of the cache. Can be `request`, `session`, or `application`. See Caching Scope.

Example of `cache` tag annotation usage

The following example represents a cached JSP file:

```
<%@ taglib prefix="mypfx" uri="http://glassfish.org/taglibs/cache" %>
<%@ taglib prefix="c" uri="jakarta.tags.core" %>
<mypfx:cache key="${sessionScope.loginId}" nocache="${param.nocache}"
refresh="${param.refresh}" timeout="10m">
    <c:choose>
        <c:when test="${param.page == 'frontPage'}">
            <%-- get headlines from database --%>
        </c:when>
        <c:otherwise>
            ...
        </c:otherwise>
    </c:choose>
</mypfx:cache>
<mypfx:cache timeout="1h">
    <h2>Local News</h2>
    <%-- get the headline news and cache them --%>
</mypfx:cache>
```

The `flush` Tag

Forces the cache to be flushed. If a `key` is specified, only the entry with that key is flushed. If no key is specified, the entire cache is flushed.

Attributes of `flush`

The following table describes the attributes used for the `flush` tag.

Table 186. The `flush` tag attributes

Attribute	Default	Description
`key`	`ServletPath_Suffix`	(optional) The name used by the container to access the cached entry. The cache key is suffixed to the servlet path to generate a key to access the cached entry. If no key is specified, a number is generated according to the position of the tag in the page.
`scope`	`application`	(optional) The scope of the cache. Can be `request`, `session`, or `application`. See Caching Scope

Examples of `flush`

To flush the entry with `key="foobar"`:

```
<mypfx:flush key="foobar"/>
```

To flush the entire cache:

```
<c:if test="${empty sessionScope.clearCache}">
   <mypfx:flush />
</c:if>
```

Options for Compiling JSP Files

Payara Server provides the following ways of compiling JSP source files into servlets:

- JSP files are automatically compiled at runtime.
- The `asadmin deploy` command has a `--precompilejsp` option.
- The `jspc` command line tool allows you to precompile JSP files at the command line.

Creating and Managing Sessions

This section describes how to create and manage HTTP sessions that allows users and transaction information to persist between interactions.

Configuring Sessions

HTTP Sessions, Cookies, and URL Rewriting

To configure whether and how HTTP sessions use cookies and URL rewriting, edit the `session-properties` and `cookie-properties elements in the `glassfish-web.xml` or `payara-web.xml` file for an individual web application. For more details about the properties you can configure, see "session-properties" "cookie-properties" and in the Payara Server Application Deployment section.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

For information about configuring default session properties for the entire web container, see Using the `default-web.xml` File.

Saving Sessions During Redeployment

Whenever an application redeployment is done, the sessions at that transit time become invalid unless you use the `--keepstate=true` option of the `asadmin redeploy` command. For example:

```
asadmin redeploy --keepstate=true --name hello.war
```

The default for the `--keepstate` is `false`. This option is supported only on the default server instance, named `server`.

This option is not supported and ignored for other targets (clusters and deployment groups included).

For web applications, this feature is applicable only if in the `payara-web.xml` / `glassfish-web.xml` deployment descriptor files when the `persistence-type` attribute of the `session-manager` element is set to `file`.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

If any active web session fails to be preserved or restored, none of the sessions will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.

The new class loader of the redeployed application is used to deserialize any sessions previously saved. The usual restrictions about serialization and deserialization apply. For example, any application-specific class referenced by a session attribute may evolve only in a backward-compatible fashion.

For more information about class loaders, see Class Loaders.

Logging Session Attributes

You can write specific session attribute values to the HTTP service access log. The access log format placeholder `%session.name%` logs one of the following:

- The value of the session attribute with the `${ATTRIBUTE_NAME}-name` format.
- `NULL-SESSION-ATTRIBUTE-name` if the named attribute does not exist in the session.
- `NULL-SESSION` if no session exists.

Distributed Sessions and Persistence

A distributed HTTP session can run in multiple Payara Server/Micro instances, provided the following criteria are met:

- Each server instance has the same distributable web application deployed to it. The `web-app` element of the `web.xml` deployment descriptor file must have the `distributable` sub-element specified.
- The web application uses high-availability session persistence. If a non-distributable web application is configured to use high-availability session persistence, a warning is written to the server log, and the session persistence type reverts to `memory`. See The `memory` persistence Type.
- All objects bound into a distributed session must be of the types listed in the table below.
- The web application must be deployed using the `deploy` command with the `--availabilityenabled` option set to `true`.

Contrary to what is recommended in the Jakarta Servlet specification, Payara Server does not throw an `IllegalArgumentException` if an object type not

supported for failover is bound into a distributed session.

Keep the distributed session size as small as possible. Session size has a direct impact on overall system throughput.

In the event of an instance or hardware failure, another server instance can take over a distributed session, with the following limitations:

- If a distributable web application references a Jakarta EE component or resource, the reference might be lost. See the table below for a list of the types of references that `HTTPSession` failover supports.
- References to open files or network connections are lost.

In the following table, **No** indicates that failover for the object type might not work in all cases and that no failover support is provided. However, failover might work in some cases for that object type. For example, failover might work because the class implementing that type is serializable.

For more information about the `InitialContext`, see Accessing the Naming Context.

For more information about transaction recovery, see Using the Transaction Service. For more information about Administered Objects, see "Administering JMS Physical Destinations" in the Payara Server General Administration section.

Table 187. Object Types Supported for Web Application Session State Failover

Java Object Type	Failover Support
Co-located or distributed stateless session, stateful session, or entity bean references	Yes
JNDI context	Yes, for `InitialContext` and `java:comp/env` namespace references
`UserTransaction`	Yes, but if the instance that fails is never restarted, any prepared global transactions are lost and might not be correctly rolled back or committed.
JDBC DataSource	No
Jakarta Messaging (JMS) ConnectionFactory and Destination	No
Jakarta Mail Session	No
Connection Factory	No
Administered Object	No
SOAP Web Service reference	No
Serializable Java types	Yes
Extended persistence context	No

Session Managers

A session manager automatically creates new session objects whenever a new session starts. In some circumstances, clients do not join the session, for example, if the session manager uses cookies and the client does not accept cookies.

The Payara Platform offers these session management options, determined by the `session-manager` element's `persistence-type` attribute in the `glassfish-web.xml`/`payara-web.xml` file:

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

- The `memory` Persistence Type
- The `file` Persistence Type, which uses a file to store session data
- The `hazelcast` Persistence Type, which uses the Data Grid to store session data

If the session manager configuration contains an error, the error is written to the server log and the default (`memory`) configuration is used.

For more information, see "session-manager" in the Payara Server Application Deployment section.

The `memory` Persistence Type

This persistence type is not designed for a production environment that requires session persistence as it provides no actual session persistence. However, you can configure it so that the session state in memory is written to the file system prior to server shutdown.

To specify the `memory` persistence type for a specific web application, edit the `glassfish-web.xml` or `payara-web.xml` file as in the following example. The `persistence-type` attribute is optional, but must be set to `memory` if included. This overrides the web container availability settings for the web application.

```
<payara-web-app>
 <session-config>
     <session-manager persistence-type="memory">
         <manager-properties>
             <property name="sessionFilename" value="sessionstate" />
         </manager-properties>
     </session-manager>
 </session-config>
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

The only manager property that the `memory` persistence type supports is `sessionFilename`, which is listed under "manager-properties" in the Payara Server Application Deployment section.

The `sessionFilename` property specifies the name of the file where sessions are serialized and persisted if the web application or the server is stopped. To disable this behavior, specify an empty string as the value of `sessionFilename`. The default value is an empty string.

The `file` Persistence Type

This persistence type provides session persistence to the local file system, and allows a single server domain to recover the session state after a failure and restart. The session state is persisted in the background, and the rate at which this occurs is configurable.

The store also provides passivation and activation of the session state to help control the amount of memory used. This option is not supported in a production environment since it is not adequate for any high-availability environments. However, it is useful for a development system with a single server instance.

Make sure the `delete` option is set in the `server.policy` file, or expired file-based sessions might not be deleted properly. For more information about `server.policy`, see The `server.policy` File.

To specify the `file` persistence type for a specific web application, edit the `glassfish-web.xml` or `payara-web.xml` file as in the following example. Note that `persistence-type` must be set to `file`. This overrides the web container availability settings for the web application.

```
<payara-web-app>
  <session-config>
      <session-manager persistence-type="file">
          <store-properties>
              <property name="directory" value="sessiondir" />
          </store-properties>
      </session-manager>
  </session-config>
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

The `file` persistence type supports all the manager properties listed under "manager-properties" in the Payara Server Application Deployment section except `sessionFilename`, and supports the `directory` store property listed under "store-properties" in the same document.

The `hazelcast` Persistence Type

The `hazelcast` persistence type uses Payara Server/Micro Data Grid to store information in the internal distributed memory grid. All server instances that join the data grid (regardless of the deployment groups they belong to) will store partitioned information of the session data courtesy of Hazelcast. This allows sessions to be distributed properly with failover in place. For details, see Distributed Sessions and Persistence. This is the default persistence type for both Payara Server and Micro instances.

Hazelcast and the Data Grid must be enabled for the Payara Server domain or a corresponding Payara Micro instance for this persistence type to work.

Session data will only be stored in non-lite Data Grid members, so for this persistence type to work properly, the Data Grid must be conformed by more than **1 non-lite member**, so that data is stored in the grid in a resilient manner.

To use the `hazelcast` persistence type, you must enable availability first. Select the *Availability Service* component under the relevant configuration in the Administration Console. Check the *Availability Service* box. To enable availability for the web container, select the *Web Container Availability* tab, then check the *Availability Service* box.

All instances in a cluster or deployment group should have the same availability settings to ensure consistent behavior.

Using Comet

This section explains the Comet programming technique and how to create and deploy a Comet-enabled application in Payara Server or Micro.

Introduction to Comet

Comet is a programming technique that allows a web server to send updates to clients without requiring the clients to explicitly request them.

This kind of programming technique is called **server push**, which means that the server pushes data to the client. The opposite style is **client pull**, which means that the client must pull the data from the server, usually through a user-initiated event, such as a button click.

Web applications that use the Comet technique can deliver updates to clients in a more timely manner than those that use the client-pull style while avoiding the latency that results from clients frequently polling the server.

One of the more common use cases for Comet is a chat room application. When the server receives a message from one of the chat clients, it needs to send the message to the other clients without requiring them to ask for it.

With Comet, the server can deliver messages to the clients as they are posted rather than expecting the clients to poll the server for new messages.

To accomplish this scenario, a Comet application establishes a long-lived HTTP connection. This connection is suspended on the server side, waiting for an event to happen before resuming. This kind of connection remains open, allowing an application that uses the Comet technique to send updates to clients when they are available rather than expecting clients to reopen the connection to poll the server for updates.

The Grizzly Implementation of Comet

A limitation of the Comet technique is that you must use it with a web server that supports non-blocking connections to avoid poor performance. Non-blocking connections are those that do not

need to allocate one thread for each request. If the web server were to use blocking connections then it might end up holding many thousands of threads, thereby hindering its scalability.

The Payara Platform includes the Grizzly HTTP Engine, which enables asynchronous request processing (ARP) by avoiding blocking connections. Grizzly's ARP implementation accomplishes this by using the Java NIO API.

With Java NIO, Grizzly enables greater performance and scalability by avoiding the limitations experienced by traditional web servers that must run a thread for each request. Instead, Grizzly's ARP mechanism makes efficient use of a thread pool system and also keeps the state of requests so that it can keep requests alive without holding a single thread for each of them.

Client Technologies to Use With Comet

In addition to creating a web component that uses the Comet APIs, you need to enable your client to accept asynchronous updates from the web component. To accomplish this, you can use Iframes, plain JavaScript, or a robust JavaScript framework, such as the Dojo Toolkit.

The next section explains the two kinds of connections that you can make to the server. While you can use any of the client technologies listed in this section with either kind of connection, it is more challenging to use JavaScript with an HTTP-streaming connection.

Types of Comet Connections

When working with Comet, as implemented in Grizzly, you have two different ways to handle client connections to the server:

HTTP Streaming

The HTTP Streaming technique keeps a connection open indefinitely. It never closes, even after the server pushes data to the client.

In the case of HTTP streaming, the application sends a single request and receives responses as they come, reusing the same connection forever. This technique significantly reduces the network latency because the client and the server don't need to open and close the connection.

The basic life cycle of an application using HTTP-streaming is:

> Request → Suspend → Data available → Write response → Data available → Write response

The client makes an initial request and then suspends the request, meaning that it waits for a response. Whenever new data is available, the server writes it to the response.

Long Polling

The long-polling technique is a combination of server-push and client-pull because the client needs to resume the connection after a certain amount of time or after the server pushes an update to the client.

The basic life cycle of an application using long-polling is:

> Request → Suspend → Data available → Write response → Resume

The client makes an initial request and then suspends the request. When an update is available, the server writes it to the response. The connection closes, and the client optionally resumes the connection.

How to Choose the Type of Connection

If you anticipate that your web application will need to send frequent updates to the client, you should use the HTTP-streaming connection so that the client does not have to frequently reestablish a connection. If you anticipate less frequent updates, you should use the long-polling connection so that the web server does not need to keep a connection open when no updates are occurring.

One caveat to using the HTTP-streaming connection is that if you are streaming through a proxy, the proxy can buffer the response from the server. So, be sure to test your application if you plan to use HTTP-streaming behind a proxy.

Grizzly Comet

For details on using Grizzly Comet including a sample application, refer to the Grizzly Comet documentation on GitHub (`https://javaee.github.io/grizzly/comet.html`).

Grizzly's support for Comet includes a small set of APIs that make it easy to add Comet functionality to your web applications. The Grizzly Comet APIs that developers use most often are the following:

- `CometContext`: A Comet context, which is a shareable space to which applications subscribe to receive updates.
- `CometEngine`: The entry point to any component using Comet. Components can be servlets, JavaServer Pages (JSP), JavaServer Faces components, or pure Java classes.
- `CometEvent`: Contains the state of the `CometContext` object
- `CometHandler`: The interface an application implements to be part of one or more Comet contexts.

The way a developer would use this API in a web component is to perform the following tasks:

1. Register the context path of the application with the `CometContext` object:

```
var cometEngine = CometEngine.getEngine();
var cometContext = cometEngine.register(contextPath)
```

2. Register the `CometHandler` implementation with the `CometContext` object:

```
cometContext.addCometHandler(handler);
```

3. Notify one or more `CometHandler` implementations when an event happens:

```
cometContext.notify(handler);
```

Enabling Comet

Before running a Comet-enabled application, you need to enable Comet in the HTTP listener for your application by setting a special attribute in the associated protocol configuration. The following example shows the `asadmin set` command that adds this attribute:

```
asadmin set server-config.network-config.protocols.protocol.${protocol-
name}.http.comet-support-enabled="true"
```

Advanced Web Application Features

The Server's Default Locale

To set the default locale of the entire server runtime, which determines the locale of the Payara Server Administration Console (In a multi-language distribution variant), text entries in the logs, and so on, use the Administration Console. Select the *domain* component.

Then type a value in the *Locale* field. Values must conform to a valid `java.util.Locale` constant (see the Javadoc for the Locale class for more information).

Servlet Character Encoding

This section explains how the server runtime determines the character encoding for the servlet request and response. Valid encoding formats must conform to the list of Java's supported encodings.

Servlet Request

When processing a servlet request, the server uses the following order of precedence, first to last, to determine the request character encoding:

- The `getCharacterEncoding` method.
- A hidden field in the form, specified by the `form-hint-field` attribute of the `parameter-encoding` element in the `glassfish-web.xml` or `payara-web.xml` deployment descriptor
- The `default-charset` attribute of the `parameter-encoding` element in the `glassfish-web.xml` or `payara-web.xml` deployment descriptor
- The default encoding, which is `ISO-8859-1`

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

For details about the `parameter-encoding` element, see "parameter-encoding" in the Payara Server Application Deployment section.

Servlet Response

When processing a servlet response, the server uses the following order of precedence, first to last, to determine the response character encoding:

- The `setCharacterEncoding` or `setContentType` method
- The `setLocale` method
- The default encoding, which is `ISO-8859-1`

Virtual Server Properties

You can set virtual server properties in the following ways:

- You can define virtual server properties using the `asadmin create-virtual-server` command. For example:

  ```
  asadmin create-virtual-server --hosts localhost --property authRealm=ldap MyVS
  ```

  For more details and a complete list of virtual server properties, see `create-virtual-server`.

- You can define virtual server properties using the `asadmin set` command.

  For example:

  ```
  asadmin set server-config.http-service.virtual-
  server.MyVS.property.authRealm="ldap"
  ```

- You can define virtual server properties using the Administration Console. Select the *HTTP Service* component under the relevant configuration, then select *Virtual Servers*, and select the desired virtual server. Select *Add Property*, enter the property name and value, check the *Enable* box, and save your changes.

Using the `default-web.xml` File

You can use the `default-web.xml` file to define features such as filters and security constraints that apply to all web applications deployed in a Payara Server domain.

For example, directory listings are disabled by default for added security. To enable directory listings, in your domain's `default-web.xml` file, search for the definition of the servlet whose `servlet-name` is equal to `default`, and set the value of the `init-param` named `listings` to `true`.

Then redeploy your web application if it has already been deployed, or restart the server. Here's an excerpt of the file configured as stated:

```
<init-param>
   <param-name>listings</param-name>
   <param-value>true</param-value>
```

```
</init-param>
```

If `listings` is set to `true`, you can also determine how directory listings are sorted. Set the value of the `sortedBy` parameter to `NAME`, `SIZE`, or `LAST_MODIFIED`. Then redeploy your web application if it has already been deployed, or restart the server instance.

Here's an excerpt of the file configured as stated:

```
<init-param>
   <param-name>sortedBy</param-name>
   <param-value>LAST_MODIFIED</param-value>
</init-param>
```

The `mime-mapping` elements in `default-web.xml` are global and inherited by all web applications. You can override these mappings or define your own using `mime-mapping` elements in your web application's `web.xml` file. For more information about `mime-mapping` elements, see the Jakarta Servlet specification.

To Use the `default-web.xml` File

1. Place the JAR file for the filter, security constraint, or any other specific web component features in the `domain-dir/lib` directory.
2. Edit the `domain-dir/config/default-web.xml` file to refer to the JAR file.
3. Restart the domain and any server instances.

Configuring Logging and Monitoring in the Web Container

Select *Logger Settings* under the relevant configuration, or select the *Instances* component, select the instance from the table, and select the *Monitor* tab.

Catalina Specific Features

Catalina is the internal implementation of the Servlet implementation used in the Payara Platform, originated from Apache Tomcat's own implementation.
Catalina will be replaced in future releases and as such the specifics documented here may change or be completely rewritten.

Configuring Valves and Catalina Listeners

You can configure custom valves and **Catalina** listeners for web modules or virtual servers by defining properties. A valve class must implement the `org.glassfish.web.valve.GlassFishValve` interface. A listener class for a virtual server must implement the `org.apache.catalina.ContainerListener` or `org.apache.catalina.LifecycleListener` interfaces.

A listener class for a web module must implement one the following interfaces:

- `org.apache.catalina.ContainerListener`

- `org.apache.catalina.LifecycleListener`
- `org.apache.catalina.InstanceListener`

In the `glassfish-web.xml`/`payara-web.xml` deployment descriptor, valve and listener properties for a web module look like this:

```
<payara-web-app>
   <property name="valve_1" value="org.glassfish.extension.Valve"/>
   <property name="listener_1" value="org.glassfish.extension.MyLifecycleListener"/>
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

You can define these same properties for a virtual server configuration. For more information, see Virtual Server Properties.

Using a `context.xml` File

You can define an Apache Tomcat `context.xml` configuration file for all web applications, for web applications assigned to a specific virtual server, or for a specific web application.

To define a global `context.xml` file, place the file in the `domain-dir/config` directory and name it `context.xml`.

Use the `contextXmlDefault` property to specify the name and the location, relative to the domain directory, of the `context.xml` file for a specific virtual server. Specify this property in one of the following ways:

- In the Administration Console, open the *HTTP Service* component under the relevant configuration. Open the *Virtual Servers* component and scroll down to the bottom of the page.

  Enter `contextXmlDefault` as the property name and the path and file name relative to domain-dir as the property value.

- Use the `asadmin create-virtual-server` command. For example:

  ```
  asadmin create-virtual-server --property contextXmlDefault=config/vs1ctx.xml vs1
  ```

- Use the `asadmin set` command for an existing virtual server. For example:

  ```
  asadmin set server-config.http-service.virtual-
  server.vs1.property.contextXmlDefault=config/myctx.xml
  ```

To define a `context.xml` file for a specific web application, place the file in the `META-INF` directory of the corresponding application and name it `context.xml`.

For more information about virtual server properties, see Virtual Server Properties. For more information about the `context.xml` file, see The Context Container.

Not all context definitions are supported by the Payara Platform.

Enabling WebDav

To enable WebDav in Payara Server, you edit the `web.xml` and `glassfish-web.xml`/`payara-web.xml` files as follows.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

First, enable the WebDav servlet in your `web.xml` file:

```
<servlet>
   <servlet-name>webdav</servlet-name>
   <servlet-class>org.apache.catalina.servlets.WebdavServlet</servlet-class>
   <init-param>
      <param-name>debug</param-name>
      <param-value>0</param-value>
   </init-param>
   <init-param>
      <param-name>listings</param-name>
      <param-value>true</param-value>
   </init-param>
   <init-param>
      <param-name>readonly</param-name>
      <param-value>false</param-value>
   </init-param>
</servlet>
```

Then define the servlet mapping associated with your WebDav servlet in your `web.xml` file:

```
<servlet-mapping>
   <servlet-name>webdav</servlet-name>
   <url-pattern>/webdav/*</url-pattern>
</servlet-mapping>
```

To protect the WebDav servlet so other users can't modify it, you must add a security constraint in your `web.xml` deployment descriptor:

```
<security-constraint>
   <web-resource-collection>
      <web-resource-name>Login Resources</web-resource-name>
      <url-pattern>/webdav/*</url-pattern>
   </web-resource-collection>
```

```
    <auth-constraint>
       <role-name>Admin</role-name>
    </auth-constraint>
    <user-data-constraint>
       <transport-guarantee>NONE</transport-guarantee>
    </user-data-constraint>
    <login-config>
       <auth-method>BASIC</auth-method>
       <realm-name>default</realm-name>
    </login-config>
    <security-role>
       <role-name>Admin</role-name>
    </security-role>
</security-constraint>
```

Then define a security role mapping in your `glassfish-web.xml` or `payara-web.xml` deployment descriptor:

```
<security-role-mapping>
   <role-name>Admin</role-name>
   <group-name>Admin</group-name>
</security-role-mapping>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

Enable the security manager as described in Enabling and Disabling the Security Manager.

You can now use any WebDav client by connecting to the WebDav servlet URL, which has this format:

```
http://${host}:${port}/${context-root}/webdav/file
```

For example:

```
http://localhost:80/myapp-webdav/webdav/index.html
```

You can add the WebDav servlet to your `default-web.xml` file to enable it for all applications, but you can't set up a security role mapping to protect it.

Using SSI

To enable SSI (server-side includes) processing for a specific web module, add the `SSIServlet` to your `web.xml` deployment descriptor as follows:

```
<web-app>
```

```
    <servlet>
       <servlet-name>ssi</servlet-name>
       <servlet-class>org.apache.catalina.ssi.SSIServlet</servlet-class>
    </servlet>
    <servlet-mapping>
       <servlet-name>ssi</servlet-name>
       <url-pattern>*.shtml</url-pattern>
    </servlet-mapping>
    <mime-mapping>
       <extension>shtml</extension>
       <mime-type>text/html</mime-type>
    </mime-mapping>
</web-app>
```

To enable SSI processing for all web modules, un-comment the corresponding sections in the `default-web.xml` file.

If the `mime-mapping` is not specified in `web.xml`, Payara Server attempts to determine the MIME type from `default-web.xml` or the operating system default.

You can configure the following `init-param` values for the `SSIServlet`.

Table 188. `SSIServlet` `init-param` Values

init-param	Type	Default	Description
`buffered`	`boolean`	`false`	Specifies whether the output should be buffered.
`debug`	`int`	`0` (for no debugging)	Specifies the debugging level.
`expires`	`Long`	`Expires` header in HTTP response not set	Specifies the expiration time in seconds.
`inputEncoding`	`String`	OS encoding	Specifies encoding for the SSI input if there is no URL content encoding specified.
`isVirtualWebappRelative`	`boolean`	`false` (relative to the given SSI file)	Specifies whether the virtual path of the `#include` directive is relative to the `content-root`.
`outputEncoding`	`String`	`UTF-8`	Specifies encoding for the SSI output.

For more information about SSI, see `http://httpd.apache.org/docs/2.2/mod/mod_include.html`.

Using CGI

To enable CGI (common gateway interface) processing for a specific web module, add the `CGIServlet` to your `web.xml` file as follows:

```
<web-app>
   <servlet>
      <servlet-name>cgi</servlet-name>
      <servlet-class>org.apache.catalina.servlets.CGIServlet</servlet-class>
```

```
    </servlet>
    <servlet-mapping>
       <servlet-name>cgi</servlet-name>
       <url-pattern>/cgi-bin/*</url-pattern>
    </servlet-mapping>
 </web-app>
```

To enable CGI processing for all web modules, un-comment the corresponding sections in the `default-web.xml` file.

Package the CGI program under the `cgiPathPrefix`. The default `cgiPathPrefix` is `WEB-INF/cgi`. For security, it is highly recommended that the contents and binaries of CGI programs be prohibited from direct viewing or download.

For information about hiding directory listings, see Using the `default-web.xml` File.

Invoke the CGI program using a URL of the following format:

```
http://${host}:${port}/${context-root}/cgi-bin/cgi-name
```

For example:

```
http://localhost:8080/mycontext/cgi-bin/hello
```

You can configure the following `init-param` values for the `CGIServlet`.

Table 189. `CGIServlet` `init-param` Values

Parameter	Type	Default	Description
`cgiPathPrefix`	`String`	`WEB-INF/cgi`	Specifies the subdirectory containing the CGI programs.
`debug`	`int`	`0` (for no debugging)	Specifies the debugging level.
`executable`	`String`	`perl`	Specifies the executable for running the CGI script.
`parameterEncoding`	`String`	`System.getProperty("file.encoding", "UTF-8")`	Specifies the parameter's encoding.
`passShellEnvironment`	`boolean`	`false`	Specifies whether to pass shell environment properties to the CGI program.

To work with a native executable, do the following:

1. Set the value of the `init-param` named executable to an empty `String` in the `web.xml` file.
2. Make sure the executable has its executable bits set correctly.

3. Use directory deployment to deploy the web module. Do not deploy it as a WAR file, because the executable bit information is lost during the process of `jar` and `unjar`.

Alternate Document Roots

An alternate document root (`docroot`) allows a web application to serve requests for certain resources from outside its own document root, based on whether those requests match one (or more) of the URI patterns of the web application's alternate document roots.

To specify an alternate document root for a web application or a virtual server, use the `alternatedocroot_n` property, where n is a positive integer greater than zero that allows specifying more than one.

This property can be a sub-element of a `glassfish-web-app`/`payara-web-app` element in the `glassfish-web.xml`/`payara-web.xml` file or a virtual server property.

For more information about this element, see "payara-web-app" in the Payara Server Application Deployment section.

A virtual server's alternate document roots are considered only if a request does not map to any of the web modules deployed on that virtual server. A web module's alternate document roots are considered only once a request has been mapped to that web module.

If a request matches an alternate document root's URI pattern, it is mapped to the alternate document root by appending the request URI (minus the web application's context root) to the alternate document root's physical location (directory). If a request matches multiple URI patterns, the alternate document root is determined according to the following precedence order:

- Exact match
- Longest path match
- Extension match

For example, the following properties specify three `payara-web.xml` document root configurations. The URI pattern of the first alternate document root uses an exact match, whereas the URI patterns of the second and third alternate document roots use extension and longest path prefix matches, respectively:

```
<payara-web-app>
    <property name="alternatedocroot_1" value="from=/my.jpg dir=/srv/images/jpg"/>
    <property name="alternatedocroot_2" value="from=*.jpg dir=/srv/images/jpg"/>
    <property name="alternatedocroot_3" value="from=/jpg/* dir=/src/images"/>
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

The `value` of each alternate document root has two components: The first component, `from`, specifies the alternate document root's URI pattern, and the second component, `dir`, specifies the alternate

document root's physical location (directory).

Suppose the above examples belong to a web application deployed at `http://examples.payara.fish/myapp`. The first alternate document root maps any requests with this URL:

```
http://examples.payara.fish/myapp/my.jpg
```

To this resource:

```
/svr/images/jpg/my.jpg
```

The second alternate document root maps any requests with a `*.jpg` suffix, such as:

```
http://examples.payara.fish/myapp/*.jpg
```

To this physical location:

```
/svr/images/jpg
```

The third alternate document root maps any requests whose URI starts with `/myapp/jpg/`, such as:

```
http://examples.payara.fish/myapp/jpg/*
```

To the same directory as the second alternate document root.

For example, the second alternate document root maps this request:

```
http://examples.payara.fish/myapp/abc/def/my.jpg
```

To:

```
/srv/images/jpg/abc/def/my.jpg
```

The third alternate document root maps:

```
http://examples.payara.fish/myapp/jpg/abc/resource
```

To:

```
/srv/images/jpg/abc/resource
```

If a request does not match any of the target web application's alternate document roots, or if the target web application does not specify any alternate document roots, the request is served from the web application's standard document root, as usual.

Using Jakarta Faces Technology

This chapter describes how to use the Jakarta Faces (JSF) API.

Introducing Jakarta Faces

Jakarta Faces is a server-side component framework for creating diverse Java technology–based web applications for browser-focused environments.

Jakarta Faces consists of the following:

- An API for representing components and managing their state; handling events, server-side validation, and data conversion; defining page navigation; supporting internationalization and accessibility
- Tag library sets for adding components to web pages and for linking components to server-side objects.

Jakarta Faces provides a well-defined programming model and various **tag libraries**. These tag libraries contain **tag handlers** that implement component tags. These features significantly ease the burden of creating and maintaining web applications with server-side user interfaces.

Jakarta Faces Applications

The functionality provided by a Jakarta Faces application is similar to that of any other Java web-based application. A typical Jakarta Faces application includes the following parts.

- A set of web pages in which components are rendered at runtime.
- A set of tags to add components to the web page.
- A set of managed Java beans, which are lightweight, container-managed objects (POJOs).
    - In a Jakarta Faces application, managed beans usually serve as **backing beans**, which define properties to store data and methods and event handlers for UI components on a page.
- A web deployment descriptor (`web.xml`).
- *(Optional)* One or more application configuration resource files, such as a `faces-config.xml` file, which can be used to define page navigation rules and provide further customization options for the application.
- *(Optional)* A set of custom objects, which can include custom components, validators, converters, or listeners.
- *(Optional)* A set of custom tags for representing custom or complex objects on the page.

Configurable JSF options

This section documents specific configuration settings that are not available in the standard deployment descriptors or configuration files described above as part of the Jakarta Faces API.

Parallel Initialization

It is possible to specify a Payara Platform specific JSF context parameter in the `web.xml` deployment descriptor, named `fish.payara.faces.enableParallelInit` to provide parallel initialization benefits to the application in question.

Usage

When the `fish.payara.faces.enableParallelInit` context parameter is set to `true` some of the internal initialisation of Mojarra (the JSF implementation Payara Server uses) is performed in parallel.

To this effect, this the platform fork/join thread pool is used, which is the same pool used for processing JDK 8 Streams in parallel.

Example

Here's an example that sets the option to `true` in `web.xml`:

```
<context-param>
    <param-name>fish.payara.faces.enableParallelInit</param-name>
    <param-value>true</param-value>
</context-param>
```

The `fish.payara.faces.enableParallelInit` context parameter can also be combined with the `com.sun.faces.enableThreading` parameter:

```
<context-param>
    <param-name>com.sun.faces.enableThreading</param-name>
    <param-value>true</param-value>
</context-param>
```

This is an existing Mojarra-specific parameter to also enable parallel initialisation, but in a slightly earlier stage of the initialisation process.

As a Payara Platform specific implementation this will use the default Platform Concurrency executor if there is one, if not it will create a single use executor with 5 threads.

Using an Alternative Jakarta Faces Implementation

As a special case of how the classloader hierarchy can be modified (see configuring classloading delegation), the Payara Platform allows the use of a Jakarta Faces implementation that is bundled on a web application.

This feature may be useful to switch to a different implementation than the default one included with the server.

To configure this feature, you need to indicate within the `payara-web.xml` / `glassfish-web.xml`

deployment descriptor that the server should use a bundled Jakarta Faces implementation as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-web-app PUBLIC "-//Payara.fish//DTD Payara Server 7 Servlet 6.1//EN"
"https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-web-app_6_1-0.dtd">
<payara-web-app error-url="">
    <class-loader delegate="false"/>
    <property name="useBundledJsf" value="true" />
</payara-web-app>
```

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

By specifying these options, the bundled Jakarta Faces implementation within your web application will be used instead of the default implementation included within the server.

If deploying a EAR application you must bundle the Jakarta Faces implementation library within the embedded WAR component. You cannot add an alternative Jakarta Faces implementation as an EAR library.

Using Jakarta MVC

This chapter describes how to use the Jakarta MVC API, an action-based framework for building web applications using the model view controller architecture pattern.

The model, or the **M**, refers to the underlying application data. In Jakarta EE, this is generally a Jakarta Persistence entity or its projected instance (DTOs etc).

The view or **V**, refers to the presentation of the model data to the user. Depending on the framework, there are different view technologies that can be used. For instance Jakarta Faces uses Facelets as its view technology, while Jakarta MVC supports both Facelets and Jakarta Server Pages (which is the default).

The controller, or **C**, refers to the unit that manages user input, connects that input to the model and returns output to the user. The returned output could be another view, a redirect, a file download, or anything at all, depending on the application. You can think of the controller as the central, coordinating piece of the application that liaises user actions to different parts of the application.

Introducing Jakarta MVC

Jakarta EE has action and component based frameworks for building web applications using the model view controller architecture pattern. Jakarta Faces is a component based framework while Jakarta MVC is an action based one.

An action based web framework is one in which the application code creates an explicit controller

that accepts requests and maps them to actions.

Component based web frameworks on the other hand, have the controllers owned and managed by the framework itself. The controller is transparent to the developer in a component based framework.

What is Jakarta MVC?

Jakarta MVC is an action based web application development framework built on top of Jakarta REST. It is an alternative way to build traditional web applications on the Jakarta EE Platform. Jakarta MVC is an optional standalone specification that is not part of Jakarta EE by default.

As a Jakarta REST based framework, it makes all the features and options for developing REST services available for developing much more traditional web applications.

Action Vs Component Based Frameworks

An action based web framework is one in which the application code creates an explicit controller that accepts requests and maps them to actions.

Component based web frameworks on the hand, have the controllers owned and managed by the framework itself. The controller is transparent to the developer in a component based framework.

Dependencies Setup

To start with Jakarta MVC, you will need to add the specification API to your application dependencies. The current release can be obtained from the Payara API BOM. This setup is shown below.

Jakarta MVC Maven Dependencies

```
<project>
    <dependencyManagement>
        <dependencies>
            <dependency>
                <groupId>fish.payara.api</groupId>
                <artifactId>payara-bom</artifactId>
                <version>main-7</version>
                <type>pom</type>
                <scope>import</scope>
            </dependency>
        </dependencies>
    </dependencyManagement>

    <dependencies>
        <dependency>
            <groupId>jakarta.platform</groupId>
            <artifactId>jakarta.jakartaee-web-api</artifactId>
            <scope>provided</scope>
        </dependency>
        <dependency>
```

```
            <groupId>jakarta.mvc</groupId>
            <artifactId>jakarta.mvc-api</artifactId>
            <scope>provided</scope>
        </dependency>
    </dependencies>
</project>
```

The Controller

A typical Jakarta MVC application has three parts - the view, the controller and a model. The model doesn't have to necessarily be a database entity.

Any data that the UI displays can be considered as the model. With your above setup, a typical "*Hello, World*" will look as follows.

```
@Path("app")
@Controller
public class AppController {

    @Inject
    Models models;

    @GET
    public String sayHello() {
        models.put("greet", "Hello, World! Jakarta MVC");
        models.put("platform", "Jakarta EE 11 on Payara Platform Community 7");
        models.put("date",
LocalDateTime.now(ZoneOffset.UTC).format(DateTimeFormatter.ofPattern("yyyy-MM-dd
HH:mm:ss")));
        models.put("message", "Your Jakarta MVC application is running!");

        return "greet.xhtml";
    }

}
```

The AppController is a Jakarta REST resource class, identified as such by the `@Path` annotation.nThe `@Controller` annotation is from Jakarta MVC, marking all methods in this class as controller methods.

A controller method is one that returns a view in the form of a string, as done by the `sayHello()` method, or a `jakarta.ws.rs.core.Response` object that wraps a string object, resolvable to a view.

The `sayHello()` method creates the models for the UI by using the `jakarta.mvc.Models` map.

The `Models` are injected into the controller and then the method populates it accordingly with data for the UI to display. In this example, the injected `Models` instance, `models`, is populated with a few strings identified by their keys.

`Models` is essentially a map that makes its values available to the UI through its keys. All of this is done automatically on your behalf by the Jakarta MVC runtime.

The last line of the `sayHello()` method returns `greet.xhtml`. This is the UI that will be rendered when the user navigates to the `sayHello()` method.

For the sample application, the full path is `http://localhost:8080/jakarta-mvc/mvc/app/`, where `jakarta-mvc` is the context path, `mvc` is the Jakarta REST root resource path, and `app` is the path to the `sayHello()` method.

```
@ApplicationPath("mvc")
public class RestConfiguration extends Application {

}
```

The `Models` map instance is automatically available to the view and as such it can access all the values we put into it.

The View

There are two view technology options you can use with Jakarta MVC. The first and default is the Jakarta Server Pages, or optionally Jakarta Faces.

As Jakarta Server Pages is no longer a popular technology, this chapter will use the much more popular Jakarta Faces option.

The easiest way to tell Jakarta MVC to use Jakarta Faces as the default view technology is to create an empty `faces-config.xml` in the `WEB-INF` folder.

```
<?xml version='1.0' encoding='UTF-8'?>
<faces-config xmlns="https://jakarta.ee/xml/ns/jakartaee"
              xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
              xsi:schemaLocation="https://jakarta.ee/xml/ns/jakartaee
https://jakarta.ee/xml/ns/jakartaee/web-facesconfig_4_0.xsd"
              version="4.0">
</faces-config>
```

With that done, the `greet.xhtml` facelet is shown next.

This should be created under a `views` directory in the `WEB-INF` folder.

```
<!DOCTYPE html>
<html lang="en" xmlns:h="http://xmlns.jcp.org/jsf/html">

<h:head>
    <title>Jakarta MVC</title>
</h:head>
```

```
<h:body>
    <h1>#{greet}</h1>
    <p>#{message}</p>
    <p>This application is running on #{platform}, deployed on #{date}</p>
</h:body>
</html>
```

The `greet.xhtml` view is a very simple facelet file that is accessing the models to display to the user. The models that were put in the `Models` map instance are being accessed through the `\#{}` expression, using the key of each value.

For instance the `#{greet}` will return "Hello, World! Jakarta MVC", as was put in the map.

Accessing `http://localhost:8080/jakarta-mvc/mvc/app/` gives us the response shown below.

[Hello world example] | *../_images/mvc/mvc-1.png*

Models

So far we have seen how we can pass models, or data to the view for display through the `Models` map.

Another way is through the use of CDI. First let's introduce our model, this time as a Plain Old Java Object (POJO), garnished with two CDI annotations, shown below.

```
@Named
@RequestScoped
public class Salutation {

    private String greet;
    private String platform;
    private String greetingDate;
    private String message;

    public String getGreet() {
        return greet;
    }

    public void setGreet(String greet) {
        this.greet = greet;
    }

    public String getPlatform() {
        return platform;
    }

    public void setPlatform(String platform) {
        this.platform = platform;
    }
```

```
    public String getGreetingDate() {
        return greetingDate;
    }

    public void setGreetingDate(String greetingDate) {
        this.greetingDate = greetingDate;
    }

    public String getMessage() {
        return message;
    }

    public void setMessage(String message) {
        this.message = message;
    }

}
```

Class `Salutation` is a simple Java class with some fields. These are the same fields we passed to the first view through the `Models` map.

`Salutation` is annotated `@Named` and `@RequestScoped`. `@Named` is a CDI qualifier that makes CDI managed instances of the class available in an Expression Language context - as used in the facelet files.

The `@RequestScoped` annotation will cause a new instance of `Salutation` to be created for each injection point.

With the model in place, let's look at the amended controller and how the model is instantiated and populated.

```
@Path("app")
@Controller
public class AppController {

    @Inject
    Salutation salutation;

    @GET
    @Path("salute")
    public String salute() {
        String formattedDate =
LocalDateTime.now(ZoneOffset.UTC).format(DateTimeFormatter.ofPattern("yyyy-MM-dd
HH:mm:ss"));

        salutation.setGreet("Hello, World! Jakarta MVC");
        salutation.setPlatform("Jakarta EE 11 on Payara 7 Community");
        salutation.setGreetingDate(formattedDate);
        salutation.setMessage("Your Jakarta MVC application is running!");
```

```
        return "salute.xhtml";
    }

}
```

The `AppController` controller has a new method, `salute()`, hosted at the path `/salute`, that populates a CDI injected instance of class `Salutation`.

This method returns the `salute.xhtml` view to render the data. As you can see, the `Models` map is not used anywhere at all.

The injected `Salutation` instance is automatically available to the view thanks to the `@Named` annotation.

The `salute.xhtml` is shown next. This should be created under a `views` directory in the `WEB-INF` folder.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE html>
<html xmlns:h="http://xmlns.jcp.org/jsf/html">

<h:head>
    <title>Title</title>
</h:head>

<h:body>
    <h1>#{salutation.greet}</h1>

    <p>#{salutation.message}</p>
    <p>This application is running on #{salutation.platform}, deployed on
#{salutation.greetingDate}</p>
</h:body>

</html>
```

The `salute.xhtml` uses the same `#{}` expression to access the model. This time around it calls the getter methods of the various fields.

The salutation instance is what is CDI makes available automatically. This way, the view has access to the model without explicitly using the `Models` map. The `salute` method is hosted at `http://localhost:8080/jakarta-mvc/mvc/app/salute`, which returns the following.

[Hello world example 2] | *../_images/mvc/mvc-2.png*

- Jakarta MVC Specification

Using Jakarta Enterprise Beans Technology

This chapter describes how Jakarta Enterprise Beans (EJB) technology is supported in the Payara Platform.

For general information about enterprise beans, see "Enterprise Beans" in The Jakarta EE Tutorial.

The Web Profile of the Payara Server supports the EJB 4.0+ Lite specification, which allows enterprise beans within web applications, among other features.
The Full Profile supports the entire EJB 4.0+ specification. For details, see Jakarta Enterprise Beans.

Payara Server is backward compatible with 1.1, 2.0, 2.1, 3.0, 3.1 and 4.0 enterprise beans. However, to take advantage of version 3.1+ features, you should develop new beans as 3.1+ enterprise beans.

Customized EJB-JAR Archive Names

It is possible to instruct the server runtime to override the name of an EJB-JAR module when it is deployed either as a standalone module or as part of an EAR application. It is also possible to instruct Payara Server to override the module and/or application's name.

Overwriting the Module Name

When deploying an EJB-JAR module on Payara Server/Micro, the portable JNDI names for all scanned EJBs will be generated using the name of the module as specified on the *ejb-jar.xml* deployment descriptor:

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar xmlns = "https://jakarta.ee/xml/ns/jakartaee"
         version = "4.0"
         xmlns:xsi = "http://www.w3.org/2001/XMLSchema-instance"
         xsi:schemaLocation = "https://jakarta.ee/xml/ns/jakartaee
https://jakarta.ee/xml/ns/jakartaee/ejb-jar_4_0.xsd">
    <module-name>MODULE_NAME</module-name>
</ejb-jar>
```

If the name's not specified in the deployment descriptor, the specification states that the module name will be the same as the JAR artifact used to deploy it.

However, when deploying a JAR from an IDE (like **NetBeans** or **IntelliJ**), the IDE deploys to Payara Server using the asadmin `deploy` command, with the `--name` option specified. This will force the module to have the specified name over the name defined in *ejb-jar.xml*. This is undesired because the IDE usually infers the module name from the name of the project or the JAR file and doesn't take the correct name of the module into account.

The module name defined in the deployment descriptor will be used even if it tries to be overridden using the `--name` option. This behaviour will **always** take precedence.

In the case you need to overwrite the name of the module when deploying the module, use the `--forceName` command option.

Overwriting the Application Name

In the case of EAR artifacts, the portable JNDI names for all scanned EJBs will use the application name defined in the *application.xml* deployment descriptor:

```
<?xml version="1.0" encoding="UTF-8"?>
<application xmlns="https://jakarta.ee/xml/ns/jakartaee"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="https://jakarta.ee/xml/ns/jakartaee
https://jakarta.ee/xml/ns/jakartaee/application_10.xsd" version="10">
    <display-name>My Application</display-name>
    <application-name>APPLICATION_NAME</application-name>
</application>
```

You can use the `--name` and `--forcename` deployment options to override the application name in a similar manner with what happens with EJB-JAR modules.

Value Added Features

The Payara Platform provides a number of value additions that relate to EJB development. References to more in-depth material are included.

Read-Only Beans

Another feature that Payara Server provides is the read-only bean, an EJB 2.1 entity bean that is never modified by an EJB client. Read-only beans avoid database updates completely.

Read-only beans are specific to the Payara Platform and are not part of the Enterprise JavaBeans Specification, v2.1. Use of this feature for an EJB 2.1 bean results in a non-portable application.
To make an EJB 3.0 entity read-only, use `@Column` annotations to mark its columns `insertable=false` and `updatable=false`.

A read-only bean can be used to cache a database entry that is frequently accessed but rarely updated (externally by other beans).

When the data that is cached by a read-only bean is updated by another bean, the read-only bean can be notified to refresh its cached data.

Payara Server provides a number of ways by which a read-only bean's state can be refreshed. By setting the `refresh-period-in-seconds` element in the `payara-ejb-jar.xml` file and the `trans-attribute` element (or `@TransactionAttribute` annotation) in the `ejb-jar.xml` file, it is easy to configure a read-only bean that is one of the following:

- Always refreshed

- Periodically refreshed
- Never refreshed
- Programmatically refreshed

Read-only beans are best suited for situations where the underlying data never changes, or changes infrequently. For further information and usage guidelines, see Using Read-Only Beans.

The `pass-by-reference` Element

The `pass-by-reference` element in the `payara-ejb-jar.xml` file allows you to specify the parameter passing semantics for co-located remote EJB invocations. This is an opportunity to improve performance.

However, use of this feature results in non-portable applications. See "pass-by-reference" in the Payara Server Application Deployment section.

Pooling and Caching

The EJB container of Payara Server pools anonymous instances (message-driven beans, stateless session beans, and entity beans) to reduce the overhead of creating and destroying objects.

The EJB container maintains the free pool for each bean that is deployed. Bean instances in the free pool have no identity (that is, no primary key associated) and are used to serve method calls. The free beans are also used to serve all methods for stateless session beans.

Bean instances in the free pool transition from a **Pooled** state to a **Cached** state after `ejbCreate` and the business methods run. The size and behavior of each pool is controlled using pool-related properties in the EJB container or the `payara-ejb-jar.xml` file.

In addition, Payara Server supports a number of tunable parameters that can control the number of "stateful" instances (stateful session beans and entity beans) cached as well as the duration they are cached. Multiple bean instances that refer to the same database row in a table can be cached. The EJB container maintains a cache for each bean that is deployed.

To achieve scalability, the container selectively evicts some bean instances from the cache, usually when it overflows. These evicted bean instances return to the free bean pool. The size and behavior of each cache can be controlled using the cache-related properties in the EJB container or the `payara-ejb-jar.xml` file.

Pooling and caching parameters for the `payara-ejb-jar.xml` file are described in "bean-cache" in the Payara Server Application Deployment section.

Pooling Parameters

One of the most important parameters for Payara Server pooling is `steady-pool-size`. When `steady-pool-size` is set to a value greater than `0`, the container not only pre-populates the bean pool with the specified number of beans, but also attempts to ensure that this number of beans is always available in the free pool. This ensures that there are enough beans in the ready-to-serve state to

process user requests.

Note that the `steady-pool-size` and `max-pool-size` parameters only govern the number of instances that are pooled over a long period of time. They do not necessarily guarantee that the number of instances that may exist in the JVM at a given time will not exceed the value specified by `max-pool-size`.

For example, suppose an idle stateless session container has a fully-populated pool with a `steady-pool-size` of `10`. If `20` concurrent requests arrive for the EJB component, the container creates `10` additional instances to satisfy the burst of requests. The advantage of this is that it prevents the container from blocking any of the incoming requests. However, if the activity dies down to `10` or fewer concurrent requests, the additional `10` instances are discarded.

Another parameter, `pool-idle-timeout-in-seconds`, allows the administrator to specify the amount of time a bean instance can be idle in the pool. When `pool-idle-timeout-in-seconds` is set to greater than `0`, the container removes or destroys any bean instance that is idle for this specified duration.

Caching Parameters

Payara Server provides a way that completely avoids caching of entity beans, using commit option `C`. Commit option `C` is particularly useful if beans are accessed in large number but very rarely reused. For additional information, refer to Commit Options.

Payara Server caches can be either bounded or unbounded. Bounded caches have limits on the number of beans that they can hold beyond which beans are passivated. For stateful session beans, there are three ways (LRU, NRU and FIFO) of picking victim beans when cache overflow occurs.

Caches can also passivate beans that are idle (not accessed for a specified duration).

Priority Based Scheduling of Remote Bean Invocations

You can create multiple thread pools, each having its own work queues. An optional element in the `payara-ejb-jar.xml` file, `use-thread-pool-id`, specifies the thread pool that processes the requests for the bean. The bean must have a remote interface, or `use-thread-pool-id` is ignored. You can create different thread pools and specify the appropriate thread pool ID for a bean that requires a quick response time.

If there is no such thread pool configured or if the element is absent, the default thread pool is used.

Immediate Flushing

Normally, all entity bean updates within a transaction are batched and executed at the end of the transaction. The only exception is the database flush that precedes execution of a finder or select query.

Since a transaction often spans many method calls, you might want to find out if the updates made by a method succeeded or failed immediately after method execution. To force a flush at the end of a method's execution, use the `flush-at-end-of-method` element in the `payara-ejb-jar.xml` file. Only non-finder methods in an entity bean can be flush-enabled. (For an EJB 2.1 bean, these methods

must be in the Local, Local Home, Remote, or Remote Home interface). See "flush-at-end-of-method" in the Payara Server Application Deployment section.

Upon completion of the method, the EJB container updates the database. Any exception thrown by the underlying data store is wrapped as follows:

- If the method that triggered the flush is a `create` method, the exception is wrapped with `CreateException`.
- If the method that triggered the flush is a `remove` method, the exception is wrapped with `RemoveException`.
- For all other methods, the exception is wrapped with `EJBException`.

All normal end-of-transaction database synchronization steps occur regardless of whether the database has been flushed during the transaction.

EJB Timer Service

The EJB Timer Service uses a database to store persistent information about EJB timers. The EJB Timer Service in Payara Server is preconfigured to use an embedded version of the H2 database via its `jdbc/__TimerPool` default datasource.

The EJB Timer Service configuration can store persistent timer information in any database supported by Payara Server for persistence. For configurations of supported drivers, see "Configuration Specifics for JDBC Drivers" in the Payara Server General Administration section.

The timer service is automatically enabled when you deploy an application or module that uses it. You can verify that the timer service is running by accessing the following URL in a local context:

```
http://localhost:8080/ejb-timer-service-app/timer
```

To change the database used by the EJB Timer Service, set the EJB Timer Service's Timer DataSource setting to a valid JDBC resource. If the EJB Timer Service has already been started in a server instance, you must also create the timer database table. DDL files to create these tables are located in `as-install/lib/install/databases`.

Using the EJB Timer Service is equivalent to interacting with a single JDBC resource manager. If an EJB component or application accesses a database either directly through JDBC or indirectly (for example, through an entity bean's persistence mechanism), and also interacts with the EJB Timer Service, its data source must be configured with an XA-compatible JDBC driver.

You can change the following EJB Timer Service settings. You must restart the server for these changes to take effect.

Minimum Delivery Interval

Specifies the minimum time in milliseconds before an expiration for a particular timer can occur. This guards against tiny timer increments that can overload the server. The default value is `1000`.

Maximum Redeliveries

Specifies the maximum number of times the EJB timer service attempts to redeliver a timer expiration after an exception or rollback of a container-managed transaction. The default value is `1`.

Redelivery Interval

Specifies how long in milliseconds the EJB timer service waits after a failed `ejbTimeout` delivery before attempting a redelivery. The default is `5000`.

Timer DataSource

Specifies the database used by the EJB Timer Service. The default is `jdbc/__TimerPool`.

Do not use the <code>jdbc/TimerPool</code> resource for timers in clustered Payara Server environments. You must instead use a custom JDBC resource or the <code>jdbc/default</code> resource. See the instructions below, in To Deploy an EJB Timer to a Cluster.
 Also refer to "Enabling the jdbc/default Resource in a Clustered Environment" in the Payara Server General Administration section.

For information about migrating EJB timers, see "Migrating EJB Timers" in the Payara Server High Availability section.

You can use the `--keepstate` option of the `asadmin redeploy` command to retain EJB timers between re-deployments.

The default value for `--keepstate` is `false`. This option is supported only on the default server instance (the DAS), named `server`. It is not supported and ignored for any other deployment target.

When the `--keepstate` is set to `true`, each application that uses an EJB timer is assigned an **ID** in the timer database. The EJB object that is associated with a given application is assigned an ID that is constructed from the application ID and a numerical suffix. To preserve active timer data, Payara Server stores the application ID and the EJB ID in the timer database. To restore the data, the class loader of the newly redeployed application retrieves the EJB timers that correspond to these IDs from the timer database.

Advanced Persistent Timer Configuration

If using an external RDBMS engine for storing persistent timer data is not an option, it is also possible to use the **Domain Data Grid** to function as a replacement in production environments.

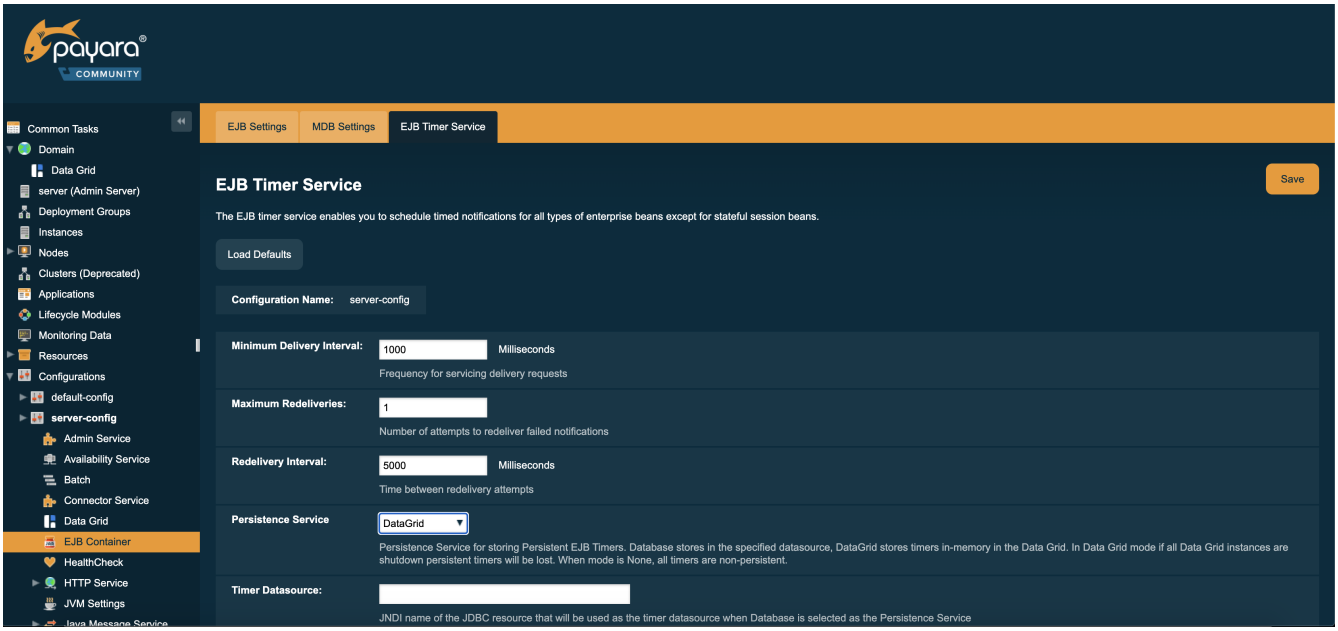
Persisting an EJB Timer to the Domain Data Grid means that the Data Grid itself will store the timer details, preserving it even if the original instance leaves the grid.

All stored timers are lost if the whole domain is stopped.

> In the case of Payara Micro, this will occur if all instances in the Data Grid are stopped as well.

The Persistence service for EJB Timers can be set in the Admin console by navigating to the **EJB Timer Service** tab in the EJB Container node of a configuration.

To use the Data Grid to store EJB Timers set the **Persistence Service** to *DataGrid*



EJB Timers will be coordinated across a single deployment group and if an instance of the deployment group is stopped another instance in the same deployment group will take ownership of the timer and ensure it is fired.

> Clustered Timer Firing Mode is NOT used in this version of Payara Server and is always "One Per Deployment Group"

It is also possible to set the `ejb-timer-service` from the command line. To get the current state, run the following command:

```
asadmin> get configs.config.<your-config>.ejb-container.ejb-timer-service
```

This will return the current state taken from the *domain.xml* configuration file, which by default should be something similar to the following:

```
asadmin> get configs.config.server-config.ejb-container.ejb-timer-service
configs.config.server-config.ejb-container.ejb-timer-service.ejb-timer-
service=Database
configs.config.server-config.ejb-container.ejb-timer-service.max-redeliveries=1
configs.config.server-config.ejb-container.ejb-timer-service.minimum-delivery-
interval-in-millis=1000
configs.config.server-config.ejb-container.ejb-timer-service.redelivery-interval-
internal-in-millis=5000
```

```
Command get executed successfully.
```

To persist to the Data Grid you need only change the value for `configs.config.server-config.ejb-container.ejb-timer-service.ejb-timer-service` to `DataGrid`.

To do this, run the following `set` command:

```
asadmin> set configs.config.server-config.ejb-container.ejb-timer-service.ejb-timer-service=DataGrid
```

You will need to restart your domain to apply the changes.

Timer Migration

EJB Timers stored in the Domain Data Grid support timer migration between instances in the same Deployment Group. You can migrate timers using the Admin console from the **Deployment Group** page.

Timers can also be migrated between instances using asadmin commands like this:

```
asadmin> migrate-timers --target server1 server2
```

Where `server1` is the active instance to migrate timers to and `server2` is the failed instance.

Migration from Live Instances

The `migrate-timers` command can also be used to migrate timers that are scheduled to expire on a live instance. This allows a user to pre-emptively move their timers around without having to resort to failover mechanics.

To Deploy an EJB Timer to a Cluster

This procedure explains how to deploy an EJB timer to a cluster or deployment group.

By default, Payara Server's Timer Service points to the preconfigured `jdbc/__TimerPool` resource, which uses an embedded H2 database configuration that will not work in clustered environments.

The problem is that the embedded H2 database runs in the server's JVM, so when you use the `jdbc/__TimerPool` resource, each DAS and each server instance will have their own, separate, databases.

Because of this, clustered server instances will not be able to find the database table on the DAS, and the DAS will not be able to find the tables on the clustered server instances.

The solution is to use either a custom JDBC resource or the `jdbc/__default` resource that is preconfigured but not enabled by default in Payara Server.

If you intend on creating a new timer data resource, it should be created BEFORE

> deploying applications that will use the timer.

Here are the steps on configuring the Timer Service:

1. Execute the following command:

```
asadmin set configs.config.cluster_name-config.ejb-container.ejb-timer-
service.timer-datasource=jdbc/my-timer-resource
```

2. Restart the DAS and the target cluster(s) or deployment groups.

```
asadmin stop-cluster cluster-name | deployment-group-name
asadmin stop-domain domain-name
asadmin start-domain domain-name
asadmin start-cluster cluster-name | deployment-group-name
```

Troubleshooting

If you inadvertently used the `jdbc/__TimerPool` resource for your EJB timer in a clustered Payara Server environment, the DAS and the server instances will be using separate H2 database instances that are running in individual JVMs.

For timers to work in a clustered environment, the DAS and the clustered server instances must share a common database.

If you attempt to deploy an application with EJB timers without setting the timer resource correctly, the startup will fail, and you will be left with a marker file, named `ejb-timer-service-app`, on the DAS that will prevent the Timer Service from correctly creating the database table.

The solution is to remove the marker file on the DAS, restart the DAS and the clusters or deployment groups, and then redeploy any applications that rely on the offending EJB timer.

The marker file is located on the DAS in `domain-dir/generated/ejb/ejb-timer-service-app`.

Using Session Beans

This section provides guidelines for creating session beans in a Payara Server environment.

Information on session beans is contained in the Jakarta Enterprise Beans specification.

About the Session Bean Containers

Like an entity bean, a session bean can access a database through Java Database Connectivity (JDBC) calls. A session bean can also provide transaction settings. These transaction settings and JDBC calls are referenced by the session bean's container, allowing it to participate in transactions managed by the container.

A container managing stateless session beans has a different charter from a container managing stateful session beans.

Stateless Container

The stateless container manages stateless session beans, which, by definition, do not carry client-specific states. All session beans (of a particular type) are considered equal.

A stateless session bean container uses a bean pool to service requests. The Payara Server specific deployment descriptor file, `payara-ejb-jar.xml`, contains the properties that define the pool:

- `steady-pool-size`
- `resize-quantity`
- `max-pool-size`
- `pool-idle-timeout-in-seconds`

For more information about `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml`, see "The payara-ejb-jar.xml File" in the Payara Server Application Deployment section.

Payara Server provides the `wscompile` and `wsdeploy` tools to help you implement a web service endpoint as a stateless session bean.

It is possible to limit the number of concurrent Stateless EJB instances that are dispatched, allowing fine-grained control of resources, limiting surface area for DDOS attacks and making applications run more smoothly and efficiently.

This is done regardless of the maximum number of instances available in a bean's pool. Using these boundaries, it is possible to instruct the EJB container so that the maximum number of threads is not exceeded at runtime.

The system property `fish.payara.ejb-container.max-wait-time-in-millis` can be set to change the default global value of `<max-wait-time-in-millis>` for ***ALL*** Stateless EJB bean pools.

Example

The following is a sample `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` deployment descriptor that configures 2 EJBs with the settings mentioned beforehand.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE payara-ejb-jar PUBLIC "-//Payara.fish//DTD Payara Application Server 7 EJB
4.0//EN" "https://raw.githubusercontent.com/payara/Payara-Documentation/main-
7/docs/modules/ROOT/pages/Appendix/Schemas/payara-ejb-jar_4_0-0.dtd">
<payara-ejb-jar>
  <enterprise-beans>
    <ejb>
      <ejb-name>PooledStatelessBean</ejb-name>
      <bean-pool>
          <max-pool-size>1</max-pool-size>
          <steady-pool-size>1</steady-pool-size>
      </bean-pool>
    </ejb>
```

```
    <ejb>
      <ejb-name>PooledMDB</ejb-name>
      <bean-pool>
          <max-pool-size>1</max-pool-size>
          <resize-quantity>1</resize-quantity>
      </bean-pool>
    </ejb>
  </enterprise-beans>
</payara-ejb-jar>
```

Stateful Container

The stateful container manages the stateful session beans, which, by definition, carry the client-specific state. There is a one-to-one relationship between the client and the stateful session beans. At creation, each stateful session bean (SFSB) is given a unique session ID that is used to access the session bean so that an instance of a stateful session bean is accessed by a single client only.

Stateful session beans are managed using an internal cache. The size and behavior of stateful session beans cache are controlled by specifying the following `payara-ejb-jar.xml` parameters:

- `max-cache-size`
- `resize-quantity`
- `cache-idle-timeout-in-seconds`
- `removal-timeout-in-seconds`
- `victim-selection-policy`

The `max-cache-size` element specifies the maximum number of session beans that are held in cache. If the cache overflows (when the number of beans exceeds `max-cache-size`), the container then passivates some beans or writes out the serialized state of the bean into a file. The directory in which the file is created is obtained from the EJB container using the configuration APIs.

For more information about `payara-ejb-jar.xml`, see "The payara-ejb-jar.xml File" in the Payara Server Application Deployment section.

The passivated beans are stored on the file system. The Session Store Location setting in the EJB container allows an administrator to specify the directory where passivated beans are stored. By default, passivated stateful session beans are stored in application-specific subdirectories created under `${domain-dir}/session-store`.

Make sure the `delete` option is set in the `server.policy` file, or expired file-based sessions might not be deleted properly. For more information about `server.policy`, see The `server.policy` File.

The Session Store Location setting also determines where the session state is persisted if it is in a High Availability environment; see Choosing a Persistence Store.

Stateful Session Bean Failover

A stateful session bean's state can be saved in a persistent store in case a server instance fails. The state of an SFSB is saved to the persistent store at predefined points in its life cycle. This is called **checkpointing**. If SFSB checkpointing is enabled, checkpointing generally occurs after any transaction involving the SFSB is completed, even if the transaction rolls back.

However, if an SFSB participates in a bean-managed transaction, the transaction might be committed in the middle of the execution of a bean method. Since the bean's state might be undergoing transition as a result of the method invocation, this is not an appropriate instant to checkpoint the bean's state.

In this case, the EJB container checkpoints the bean's state at the end of the corresponding method, provided the bean is not in the scope of another transaction when that method ends. If a bean-managed transaction spans across multiple methods, checkpointing is delayed until there is no active transaction at the end of a subsequent method.

The state of an SFSB is not necessarily transactional and might be significantly modified as a result of non-transactional business methods. If this is the case for an SFSB, you can specify a list of checkpointed methods. If SFSB checkpointing is enabled, checkpointing occurs after any checkpointed methods are completed.

The following table lists the types of references that SFSB failover supports. All objects bound into an SFSB must be one of the supported types. In the table, `No` indicates that failover for the object type might not work in all cases and that no failover support is provided. However, failover might work in some cases for that specific object type. For example, failover might work because the class implementing that type is **serializable**.

Java Object Type	Failover Support
Co-located or distributed stateless session, stateful session, or entity bean reference	Yes
JNDI context	Yes, `InitialContext` and `java:comp/env`
`UserTransaction`	Yes, but if the instance that fails is never restarted, any prepared global transactions are lost and might not be correctly rolled back or committed.
JDBC DataSource	No
Java Message Service (JMS) ConnectionFactory, Destination	No
JavaMail Session	No
Connection Factory	No
Administered Object	No
Web service reference	No
Serializable Java types	Yes
Extended persistence context	No

For more information about the `InitialContext`, see Accessing the Naming Context. For more information about transaction recovery, see Using the Transaction Service. For more information about Administered Objects, see "Administering JMS Physical Destinations" in the Payara Server General Administration section.

If a server instance to which an RMI-IIOP client request is sent crashes during the request processing (before the response is prepared and sent back to the client), an error is sent to the client.

The client must retry the request explicitly. When the client retries the request, the request is sent to another server instance in the cluster, which retrieves session state information for this client.

HTTP sessions can also be saved in a persistent store in case a server instance fails. In addition, if a distributable web application references an SFSB, and the web application's session fails over, the EJB reference is also failed over. For more information, see Distributed Sessions and Persistence.

If an SFSB that uses session persistence is un-deployed while the Payara Server instance is stopped, the session data in the persistence store might not be cleared. To prevent this, undeploy the SFSB while the Payara Server instance is running.

Configure SFSB failover by:

1. Choosing a Persistence Store
2. Enabling Checkpointing
3. Specifying Methods to Be Checkpointed

Choosing a Persistence Store

The following types of persistent storage are supported for passivation and checkpointing of the SFSB state:

The local file system

Allows a single server instance to recover the SFSB state after a failure and restart. This store also provides passivation and activation of the state to help control the amount of memory used. This option is not supported in a production environment that requires SFSB state persistence.

This is the default storage mechanism if availability is not enabled.

Other servers

Uses other server instances in the cluster for session persistence. Clustered server instances replicate session state. Each backup instance stores the replicated data in memory. This is the default storage mechanism if availability is enabled.

Choose the persistence store in one of the following ways:

- To use the local file system, first disable availability. Select the *Availability Service* component under the relevant configuration in the Administration Console. Uncheck the *Availability Service* box. Then select the EJB Container component and edit the Session Store Location value. The default is `${domain-dir}/session-store`.

- To use other servers, select the *Availability Service* component under the relevant configuration in the Administration Console. Check the *Availability Service* box. To enable availability for the EJB container, select the EJB Container Availability tab, then check the Availability Service box.

All instances in a Payara Server cluster or deployment group must have the same availability settings to ensure consistent behavior.

Using the `--keepstate` Option

If you are using the file system for persistence, you can use the `--keepstate` option of the `asadmin redeploy` command to retain the SFSB state between re-deployments.

The default value for `--keepstate` is `false`. This option is supported only on the default server instance (the DAS), named `server`. It is not supported and ignored for any other deployment target.

Some changes to an application between re-deployments prevent this feature from working properly. For example, do not change the set of instance variables in the SFSB bean class.

If any active SFSB instance fails to be preserved or restored, none of the SFSB instances will be available when the redeployment is complete. However, the redeployment continues and a warning is logged.

To preserve active state data, Payara Server serializes the data and saves it in memory. To restore the data, the class loader of the newly redeployed application deserializes the data that was previously saved.

Using the `--asyncreplication` Option

If you are using replication on other servers for persistence, you can use the `--asyncreplication` option of the `asadmin deploy` command to specify that SFSB states are first buffered and then replicated using a separate asynchronous thread.

If `--asyncreplication` is set to `true` (the default), performance is improved but availability is reduced. If the instance where states are buffered but not yet replicated fails, the states will be lost.

If set to `false`, performance is reduced but availability is guaranteed. States are not buffered but immediately transmitted to other instances in the cluster or deployment group.

Enabling Checkpointing

Server Instance and EJB Container Levels

To enable SFSB checkpointing at the server instance or EJB container level, see Choosing a Persistence Store.

Application and EJB Module Levels

To enable SFSB checkpointing at the application or EJB module level during deployment, use the `asadmin deploy` command with the `--availabilityenabled` option set to `true`.

SFSB Level

To enable SFSB checkpointing at the bean level, set `availability-enabled="true"` in the `ejb` element of the bean definition in the `payara-ejb-jar.xml` file as follows:

```
<payara-ejb-jar>
   ...
   <enterprise-beans>
      ...
      <ejb availability-enabled="true">
         <ejb-name>MySFSB</ejb-name>
      </ejb>
   ...
   </enterprise-beans>
</payara-ejb-jar>
```

Specifying Methods to Be Checkpointed

If SFSB checkpointing is enabled, checkpointing generally occurs after any transaction involving the SFSB is completed, even if the transaction rolls back.

To specify additional optional checkpointing of SFSBs at the end of non-transactional business methods that cause important modifications to the bean's state, use the `checkpoint-at-end-of-method` element within the `ejb` element in `payara-ejb-jar.xml`.

For example:

```
<payara-ejb-jar>
   ...
   <enterprise-beans>
      ...
      <ejb availability-enabled="true">
         <ejb-name>ShoppingCartEJB</ejb-name>
         <checkpoint-at-end-of-method>
            <method>
               <method-name>addToCart</method-name>
            </method>
         </checkpoint-at-end-of-method>
      </ejb>
      ...
   </enterprise-beans>
</payara-ejb-jar>
```

For details, see "checkpoint-at-end-of-method" in the Payara Server Application Deployment section.

The non-transactional methods in the `checkpoint-at-end-of-method` element can be the following:

- `create` methods defined in the home or business interface of the SFSB, if you want to checkpoint

the initial state of the SFSB immediately after creation.

- For SFSBs using container managed transactions only, methods in the remote interface of the bean marked with the transaction attribute `TX_NOT_SUPPORTED` or `TX_NEVER`.
- For SFSBs using bean managed transactions only, methods in which a bean managed transaction is neither started nor committed.

Any other methods mentioned in this list are ignored. At the end of invocation of each of these methods, the EJB container saves the state of the SFSB to the persistent store.

If an SFSB does not participate in any transaction, and if none of its methods are explicitly specified in the `checkpoint-at-end-of-method` element, the bean's state is not checkpointed at all even if `availability-enabled="true"` for this bean.

For better performance, specify a small subset of methods. The methods chosen should accomplish a significant amount of work in the context of the Jakarta EE application or should result in some important modification to the bean's state.

Session Bean Restrictions and Optimizations

This section discusses restrictions on developing session beans and provides some optimization guidelines.

Optimizing Session Bean Performance

For stateful session beans, co-locating the stateful beans with their clients so that the client and bean are executing in the same process address space improves performance.

Restricting Transactions

The following restrictions on transactions are enforced by the container and must be observed as session beans are developed:

- A session bean can participate in, at most, a single transaction at a time.
- If a session bean is participating in a transaction, a client cannot invoke a method on the bean such that the `trans-attribute` element (or `@TransactionAttribute` annotation) in the `ejb-jar.xml` file would cause the container to execute the method in a different or unspecified transaction context or an exception is thrown.
- If a session bean instance is participating in a transaction, a client cannot invoke the `remove` method on the session object's home or business interface object, or an exception is thrown.

EJB Singletons

EJB Singletons are created for each server instance in a cluster, and not once per cluster.

Using Read-Only Beans

A read-only bean is an EJB 2.1 entity bean that is never modified by an EJB client. The data that a read-only bean represents can be updated externally by other enterprise beans, or by other means, such as direct database updates.

Read-only beans are specific to Payara Server and are not part of the Jakarta Enterprise Beans Specification. Use of this feature for an EJB 2.1 bean results in a non-portable application.

To make an EJB 3.0+ entity bean read-only, use `@Column` annotations to mark its columns `insertable=false` and `updatable=false`.

Read-only beans are best suited for situations where the underlying data never changes, or changes infrequently.

Read-Only Bean Characteristics and Life Cycle

Read-only beans are best suited for situations where the underlying data never changes, or changes infrequently. For example, a read-only bean can be used to represent a stock quote for a particular company, which is updated externally. In such a case, using a regular entity bean might incur the burden of calling `ejbStore`, which can be avoided by using a read-only bean.

Read-only beans have the following characteristics:

- Only entity beans can be read-only beans.
- Only container-managed transactions are allowed; read-only beans cannot start their own transactions.
- Read-only beans don't update any bean state.
- `ejbStore` is never called by the container.
- `ejbLoad` is called only when a transactional method is called or when the bean is initially created (in the cache), or at regular intervals controlled by the bean's `refresh-period-in-seconds` element in the `payara-ejb-jar.xml` file.
- The home interface can have any number of find methods. The return type of the find methods must be the primary key for the same bean type (or a collection of primary keys).
- If the data that the bean represents can change, then `refresh-period-in-seconds` must be set to refresh the beans at regular intervals. `ejbLoad` is called at this regular interval.

A read-only bean comes into existence using the appropriate find methods.

Read-only beans are cached and have the same cache properties as entity beans. When a read-only bean is selected as a "victim" to make room in the cache, `ejbPassivate` is called and the bean is returned to the free pool. When in the free pool, the bean has no identity and is used only to serve any finder requests.

Read-only beans are bound to the naming service like regular read-write entity beans, and clients can look up read-only beans the same way read-write entity beans are looked up.

Read-Only Bean Good Practices

For best results, follow these guidelines when developing read-only beans:

- Avoid having any `create` or `remove` methods in the home interface.

- Use any of the valid EJB 2.1 transaction attributes for the `trans-attribute` element.

  The reason for having `TX_SUPPORTED` is to allow reading uncommitted data in the same transaction. Also, the transaction attributes can be used to force `ejbLoad`.

Refreshing Read-Only Beans

There are several ways of refreshing read-only beans, as addressed in the following sections:

Invoking a Transactional Method

Invoking any transactional method invokes `ejbLoad`.

Refreshing Periodically

Use the `refresh-period-in-seconds` element in the `payara-ejb-jar.xml` file to refresh a read-only bean periodically.

- If the value specified in `refresh-period-in-seconds` is zero or not specified, which is the default, the bean is never refreshed (unless a transactional method is accessed).
- If the value is greater than zero, the bean is refreshed at the rate specified.

This is the only way to refresh the bean state if the data can be modified external to Payara Server.

By default, a single timer is used for all instances of a read-only bean. When that timer fires, all bean instances are marked as expired and are refreshed from the database the next time they are used.

Use the `-Dcom.sun.ejb.containers.readonly.relative.refresh.mode=true` flag to refresh each bean instance independently upon access if its refresh period has expired. Its default value is `false`. Note that each instance still has the same refresh period.This additional level of granularity can improve the performance of read-only beans that do not need to be refreshed at the same time.

To set this flag, use the `asadmin create-jvm-options` command. For example:

```
asadmin create-jvm-options
-Dcom.sun.ejb.containers.readonly.relative.refresh.mode=true
```

Deploying Read-Only Beans

Read-only beans are deployed in the same manner as other entity beans. However, in the entry for the bean in the `payara-ejb-jar.xml` file, the `is-read-only-bean` element must be set to `true`. That is:

```
<is-read-only-bean>true</is-read-only-bean>
```

Also, the `refresh-period-in-seconds` element in the `payara-ejb-jar.xml` file can be set to some value that specifies the rate at which the bean is refreshed. If this element is missing, no refresh occurs.

All requests in the same transaction context are routed to the same read-only bean instance. Set the `allow-concurrent-access` element to either `true` (to allow concurrent accesses) or `false` (to serialize concurrent access to the same read-only bean). The default is `false`.

For further information on these elements, refer to "The payara-ejb-jar.xml File" in the Payara Server Application Deployment section.

Using Message-Driven Beans

This section describes message-driven beans and explains the requirements for creating them in a Payara Server environment.

Message-Driven Bean Configuration

For information about setting up load balancing for message-driven beans, see Load-Balanced Message Inflow.

Connection Factory and Destination

A message-driven bean is a client to a Connector inbound resource adapter. The message-driven bean container uses the JMS service integrated into Payara Server for message-driven beans that are JMS clients. JMS clients use JMS Connection Factory- and Destination-administered objects. A JMS Connection Factory administered object is a resource manager Connection Factory object that is used to create connections to the JMS provider.

The `mdb-connection-factory` element in the `payara-ejb-jar.xml` file for a message-driven bean specifies the connection factory that creates the container connection to the JMS provider.

The `jndi-name` element of the `ejb` element in the `payara-ejb-jar.xml` file specifies the JNDI name of the administered object for the JMS Queue or Topic destination that is associated with the message-driven bean.

Message-Driven Bean Pool

The container manages a pool of message-driven beans for the concurrent processing of a stream of messages. The `payara-ejb-jar.xml` file contains the elements that define the pool (that is, the `bean-pool` element):

- `steady-pool-size`
- `resize-quantity`
- `max-pool-size`
- `pool-idle-timeout-in-seconds`

For more information about `payara-ejb-jar.xml`, see "The payara-ejb-jar.xml File" in the Payara Server Application Deployment section.

Domain-Level Settings

You can control the following domain-level message-driven bean settings in the EJB container:

Initial and Minimum Pool Size

Specifies the initial and minimum number of beans maintained in the pool. The default is `0`.

Maximum Pool Size

Specifies the maximum number of beans that can be created to satisfy client requests. The default is `32`.

Pool Resize Quantity

Specifies the number of beans to be created if a request arrives when the pool is empty (subject to the **Initial** and **Minimum Pool Size**), or the number of beans to remove if idle for more than the Idle Timeout. The default is `8`.

Idle Timeout

Specifies the maximum time in seconds that a bean can remain idle in the pool. After this amount of time, the bean is destroyed. The default is `600` (10 minutes). A value of `0` means a bean can remain idle indefinitely.

Select the *Instances* component, select the instance from the table, and select the Monitor tab.

Running monitoring when it is not needed might impact performance, so you might choose to turn monitoring off when it is not in use. For details, see "Administering the Monitoring Service" in the Payara Server General Administration section.

Message-Driven Bean Restrictions and Optimizations

This section discusses the following restrictions and performance optimizations that pertain to developing message-driven beans:

Pool Tuning and Monitoring

The message-driven bean pool is also a pool of threads, with each message-driven bean instance in the pool associating with a server session, and each server session associating with a thread.

Therefore, a large pool size also means a high number of threads, which impacts performance and server resources.

When configuring message-driven bean pool properties, make sure to consider factors such as message arrival rate and pattern, `onMessage` method processing time, overall server resources (threads, memory, and so on), and any concurrency requirements and limitations from other resources that the message-driven bean accesses.

When tuning performance and resource usage, make sure to consider potential JMS provider properties for the connection factory used by the container (the `mdb-connection-factory` element in the `payara-ejb-jar.xml` file). For example, you can tune the Open Message Queue flow control related properties for connection factory in situations where the message incoming rate is much higher than `max-pool-size` can handle.

Refer to "Administering the Monitoring Service" in the Payara Server General Administration

section for information on how to get message-driven bean pool statistics.

Fine-tuning with the ActivationConfigProperty annotation

It is also possible to configure the MDB bean pool size with the `ActivationConfigProperty` annotation. Any bean annotated with `@MessageDriven` can use `@ActivationConfigProperty` to set property names and property values. For example:

```
@ActivationConfigProperty(propertyName = "MaxPoolSize", propertyValue = "100")
public class CustomerListener implements MessageListener{
}
```

The `MaxPoolSize`, `MaxWaitTimeInMillis`, `PoolResizeQuantity`, `SteadyPoolSize` and `PoolIdleTimeoutInSeconds` are all MDB pool properties that can configured using the `@ActivationConfigProperty` annotation.

The `onMessage` Runtime Exception

Message-driven beans, like other well-behaved `MessageListener` implementations, should not, in general, throw runtime exceptions. If a message-driven bean's `onMessage` method encounters a system-level exception or error that does not allow the method to successfully complete, the Jakarta Enterprise Beans Specification provides the following guidelines:

- If the bean method encounters a system exception or error, it should simply propagate the error from the bean method to the container (i.e., the bean method does not have to catch the exception).
- If the bean method performs an operation that results in a checked exception that the bean method cannot recover, the bean method should throw the `jakarta.ejb.EJBException` that wraps the original exception.
- Any other unexpected error conditions should be reported using the `jakarta.ejb.EJBException`.

Under container-managed transaction demarcation, upon receiving a runtime exception from a message-driven bean's `onMessage` method, the container rolls back the container-started transaction and the message is redelivered. This is because the message delivery itself is part of the container-started transaction.

By default, the Payara Server container closes the container's connection to the JMS provider when the first runtime exception is received from a message-driven bean instance's `onMessage` method.

This avoids potential message redelivery looping and protects server resources if the message-driven bean's `onMessage` method continues misbehaving. To change this default container behavior, use the `cmt-max-runtime-exceptions` property of the MDB container.

Here is an example `asadmin set` command that sets this property:

```
asadmin set server-config.mdb-container.property.cmt-max-runtime-exceptions="5"
```

The `cmt-max-runtime-exceptions` property specifies the maximum number of runtime exceptions allowed from a message-driven bean's `onMessage` method before the container starts to close the container's connection to the message source. By default, this value is set to `1`; `-1` disables this container protection.

A message-driven bean's `onMessage` method can use the `jakarta.jms.Message.getJMSRedelivered` method to check whether a received message is a redelivered message.

The `cmt-max-runtime-exceptions` property is deprecated and support for this feature may be removed in the future.

EJB Timers in Deployment Groups

This section only applies to Payara Server environments.

Timer facilities provided by the EJB APIs `TimerService` and `@Scheduled` need special configuration in order to work intuitively for applications targeting a deployment group. It is important to understand how EJB timers run (or expire) when configured on deployment group scenarios.

Before stating the specifics, keep in mind that there are four types of timers distinguished by their lifecycle (**persistent**, **non-persistent**) and the means of their definition (**declarative**, **programmatic**).

- Declarative timers are defined in EJB deployment descriptors or with the `@Scheduled` annotation.
- Programmatic timers are created via calls to the `TimerService.createTimer` method and its equivalents.

Non-Persistent Timers

Non-Persistent timers exist in memory only for the duration in which the application runs on the instances that belong to a deployment group.

Declarative non-persistent timers run/expire on every instance, whereas **programmatic ones only run/expire on the instance that created them**. When the instance shuts down, the timer will stop its expiration.

Standalone instances do not see each other's non-persistent timers, so calling `TimerService.getTimers()` only returns local non-persistent timers.

Non-Persistent timers have a simpler lifecycle but are not the default option. To explicitly define a non-persistent timer, the `@Schedule` annotation needs the `persistent=false` attribute, or the `TimerConfig` objects need to have their property `persistent` set to `false` explicitly.

Persistent Timers

Persistent timers exist in the persistent store for the entire time for which application is deployed to its corresponding domain.

Contrary to non-persistent ones, each persistent timer is **only executed on a single instance of a deployment group**. When the instance shuts down, each persistent timer migrates to another

instance in the application's deployment group and continues firing there.

Since persistent timers are shared, the `TimerService.getTimers()` method returns all persistent timers in the deployment group, regardless of which instance created them.

EJB Timers are persistent by default.

Preconditions for using Persistent Timers in Deployment Groups

Because deployment groups do not need to share configurations amongst their instances, there are several configuration and operational constraints that are not enforced by the server.

To ensure correct behaviour of persistent timers within a deployment group, the following conditions need to be met:

- The EJB Timer Service needs to use shared storage --an external database-- or the DataGrid.
- All instances of a deployment group, and the Domain Administration Server MUST share the same configuration settings for the EJB Timer Service (see here for more information).
- Applications with persistent timers are deployed to a deployment group and not managed on instance level afterward.
- Instances are members of only a single deployment group

EJB Timers may behave in unexpected ways if these conditions are not met.

Tracing Remote EJBs

Remote calls to an EJB from a Java SE client will have their active OpenTelemetry span context automatically propagated to the server, with the server-side span being created as a child of this client call. This will allow users to trace EJB calls that are originated externally from the server, and the span context will be propagated internally to any traceable components.

Java SE Client Tracing

No additional setup is required on the client side over what is to be expected for making regular un-traced remote EJB calls - the requirements are the same: usage of `payara-embedded-all` or the application client facilities of a Payara Server instance.

No additional properties need to be specified when performing the initial context lookup either:

```
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.util.Properties;

public class MainClass{
    public static void main(String[] args){
        var contextProperties = new Properties();
        contextProperties.setProperty(Context.INITIAL_CONTEXT_FACTORY,
"com.sun.enterprise.naming.SerialInitContextFactory");
```

```
        try {
            Context context = new InitialContext(contextProperties);
            EjbRemote ejb = (EjbRemote) context.lookup("java:global/myRemoteEjb/Ejb");
        } catch (NamingException ne) {
            logger.warning("Failed performing lookup:\n" + ne.getMessage());
        }
    }
}
```

Getting a Tracer Instance

Injection of an OpenTracing tracer is not supported on Java SE clients, so you must create an instance yourself and register it to a `GlobalTracer` instance.

Manual registration of a tracer instance is only required if using a third-party tracer such as ZipKin or Jaeger - if using the built-in Payara Platform Request Tracing service the registration will automatically happen during creation of the initial context.

The built-in Payara Request Tracing service does not support tracing of Java SE clients (though will still propagate the active span context to the server)

```
import io.opentracing.Tracer;
import io.opentracing.util.GlobalTracer;

import javax.naming.Context;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.util.Properties;

public class MainClass{

    public static void main(String[] args){
        var contextProperties = new Properties();
        contextProperties.setProperty(Context.INITIAL_CONTEXT_FACTORY,
"com.sun.enterprise.naming.SerialInitContextFactory");

        try {
            Context context = new InitialContext(contextProperties);
            EjbRemote ejb = (EjbRemote) context.lookup("java:global/myRemoteEjb/Ejb");

            Tracer tracer = GlobalTracer.get();
        } catch (NamingException ne) {
            logger.warning("Failed performing lookup:\n" + ne.getMessage());
        }
    }
}
```

Extra information on creating a Tracer instance and registering it to the `GlobalTracer` can be found here, but in short it can be done like so (replacing `CustomTracer` with your desired implementation):

```
public class MainClass{

    public static void main(String[] args){
        Tracer tracerImpl = new CustomTracer();
        GlobalTracer.register(tracerImpl);
    }
}
```

Starting a Span

The `@Traced` annotation is not supported on Java SE client methods, so spans must be started and finished manually. Note that the Span Context of the **active** span will be propagated to the server, so it is recommended that you use a try-with-resources clause to help ensure your span scope is the one you expect.

```
import io.opentracing.Scope;
import io.opentracing.Span;
import io.opentracing.Tracer;
import io.opentracing.util.GlobalTracer;

import javax.naming.Context;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.util.Properties;

public class TracerClass{

    public static void main(String[] args){
        var contextProperties = new Properties();
        contextProperties.setProperty(Context.INITIAL_CONTEXT_FACTORY,
"com.sun.enterprise.naming.SerialInitContextFactory");

        try {
            Context context = new InitialContext(contextProperties);
            EjbRemote ejb = (EjbRemote) context.lookup("java:global/myRemoteEjb/Ejb");

            Tracer tracer = GlobalTracer.get();

            try (Scope scope = tracer.buildSpan("ExecuteEjb").startActive(true)) {
                ejb.doTheThing();
            }
        } catch (NamingException ne) {
            logger.warning("Failed performing lookup:\n" + ne.getMessage());
        }
    }
```

```
}
```

Once your span has been started, you can attach any desired baggage items (String key:value pairs), and these will be propagated to the server along with the span context. These can then be retrieved within the EJB implementation hosted on Payara Server like so:

```
import io.opentracing.Span;
import io.opentracing.Tracer;

import jakarta.ejb.Stateless;
import jakarta.inject.Inject;

@Stateless
public class Ejb implements EjbRemote {

    @Inject
    Tracer tracer;

    public void businessMethod(){
        Span activeSpan = tracer.activeSpan();
        if (activeSpan != null) {
            String myBaggageItem = activeSpan.getBaggageItem("myBaggageItem");
        }
    }
}
```

Baggage items are attached to the Span you invoke `setBaggageItem` on, as well as any child spans, so you are not prevented from starting additional child spans on your EJB methods manually or via the `@Traced` annotation.

JDK 17+ Support Considerations

The following considerations must be taken into account when using EJB Features on JDK 17+:

- If using a Java SE client for remote EJB lookups, add the `--add-opens=java.base/java.lang=ALL-UNNAMED` JVM argument to the list of startup arguments of the client.

Using Lite Remote EJB Technology

For scenarios when communication with remote EJBs is needed across a complex network topology or when a server architecture is deployed on a cloud provider, there's a new feature for the EJB server and client applications: A lite and thin client that can be used to communicate via HTTP(S) instead of IIOP-RMI.

Payara Server has support for classic remote EJB since its inception. Classic remote EJB uses the **IIOP-RMI** (Internet Inter-ORB Protocol Remote Method Invocation) protocol for transport communication and the CSIv2 (Common Secure Interoperability Protocol Version 2) protocol for security.

While feature rich, these protocols were not designed with firewalls, NAT, (private) clouds, Docker and generally the Internet in mind. For these environments the requirements of the protocol, such as establishing independent connections back from the server to the client, are too troublesome.

The **IIOP-RMI/CSIv2** also requires the use of multiple heavyweight client libraries. In the case of Payara Server the client library (either referenced by the `gf-client.jar` library or the `payara-embedded-all` dependency) is almost as big as the entire server as it's essentially a special form of the ACC (Application Client Container). For this reason a much-needed modernization of the transport and security protocols was needed, and for the environments described only one protocol really works, and that is the HTTP(S) protocol.

Payara Server features an additional complimentary EJB remoting technology based on the HTTP(S) protocol while favoring the use of a thin client library that make remote applications much lighter while circumventing known challenges for the Internet and other scenarios.

HTTP(S) for EJB Remoting in Payara Server is a completely different feature from the classic IIOP-RMI/CSIv2-based feature, and does not intend to replace the transport layer protocol used on it, rather it is implemented as an additional independent feature.

TX Propagation and Security Propagation is **not supported** by EJB Remoting in Payara Server.

In the current version of this feature, not all remote EJB features are implemented yet.

Configuring HTTP(S) for Remote EJBs

HTTP(S) for EJB remoting in Payara Server makes use of a special web endpoint on which is located by default on the path `/ejb-invoker`.

This endpoint is disabled out of the box, and it can be enabled using the `set-ejb-invoker-configuration` asadmin command.

Configuring the Thin Client Dependency

Client applications that wish to use HTTP(S) as the transport protocol when calling remote EJBs will have to use a **special thin-client** dependency. To do this, you can add the following Maven dependency to your client project:

```
<dependency>
    <groupId>fish.payara.extras</groupId>
    <artifactId>ejb-http-client</artifactId>
    <version>{page-version}</version>
</dependency>
```

This artifact requires a patched version of the Jersey client which is pulled intransitive. This

patched version is available within our Payara Nexus Repository. The Maven repository definition is present in the pom.xml file of the `ejb-http-client` artifact. However, when your dependencies are managed by a private artifact repository, for example, you might need to update it to refer to the Payara Nexus repository.

Also, we recommend having a look at the BOM feature so that versions can be defined more consistently.

Finally, the code that executes the call to the remote EJB must be modified in some manner. To obtain a type-safe proxy for any remote EJB bean, the traditional approach via JNDI is still used. An example is given below:

1. First, consider the following remote EJB interface:

```
@Remote
public interface BeanRemote {
    String method();
}
```

2. Second, consider a (secured) EJB that implements that interface and resides in a EJB application called "test" deployed on a Payara server instance that is listening in `http://localhost:8080`:

```
@Stateless
public class Bean implements BeanRemote, Serializable {
    private static final long serialVersionUID = 1L;
    @Override
    @RolesAllowed("g1")
    public String method() {
        return "method";
    }
}
```

3. Given the above, the following client code can be used to obtain a proxy to the `BeanRemote` bean and invoke a remote method defined on it:

```
import static javax.naming.Context.INITIAL_CONTEXT_FACTORY;
import static javax.naming.Context.PROVIDER_URL;
import java.util.Properties;
import javax.naming.Context;
import javax.naming.InitialContext;

public class RemoteEJBLiteClient{
    public static void main(String... args) throws NamingException{
        Properties environment = new Properties();
        environment.put(INITIAL_CONTEXT_FACTORY,
"fish.payara.ejb.http.client.RemoteEJBContextFactory");
        environment.put(PROVIDER_URL, "http://localhost:8080/ejb-invoker");
        InitialContext ejbRemoteContext = new InitialContext(environment);
```

```
        BeanRemote beanRemote = (BeanRemote)
ejbRemoteContext.lookup("java:global/test/Bean");
        beanRemote.method(); // returns "method"
    }
}
```

Calling a Secured Remote EJB

When calling a secured EJB using the `ejb-invoker` endpoint, there are some considerations in place for the client code:

1. If the remote EJB is secured with transport confidentiality (and integrity) enabled like this:

   ```
   <ejb>
       <ejb-name>Bean</ejb-name>
       <ior-security-config>
           <transport-config>
               <integrity>REQUIRED</integrity>
               <confidentiality>REQUIRED</confidentiality>
               <establish-trust-in-target>SUPPORTED</establish-trust-in-target>
               <establish-trust-in-client>SUPPORTED</establish-trust-in-client>
           </transport-config>
       </ior-security-config>
   </ejb>
   ```

   Then, the corresponding HTTP endpoint to use would be `https://localhost:8181/ejb-invoker` instead.

2. If the remote EJB also has authentication enabled (via username and password credentials) like this:

   ```
   <ejb>
       <ejb-name>Bean</ejb-name>
       <as-context>
           <auth-method>USERNAME_PASSWORD</auth-method>
           <realm>default</realm>
           <required>true</required>
       </as-context>
   </ejb>
   ```

   Then the credentials required to correctly authenticate the user for the call have to be specified in the JNDI context with the following properties:

   - `javax.naming.Context.SECURITY_PRINCIPAL` for the username
   - `javax.naming.Context.SECURITY_CREDENTIALS` for the password

Here's an example of the complete client code used to call a secured remote EJB:

```
import static javax.naming.Context.INITIAL_CONTEXT_FACTORY;
import static javax.naming.Context.PROVIDER_URL;
import static javax.naming.Context.SECURITY_CREDENTIALS;
import static javax.naming.Context.SECURITY_PRINCIPAL;
import java.util.Properties;
import javax.naming.Context;
import javax.naming.InitialContext;
public class RemoteEJBLiteClient{

    public static void main(String... args) throws NamingException{
        Properties environment = new Properties();

environment.put(INITIAL_CONTEXT_FACTORY,"fish.payara.ejb.http.client.RemoteEJBContextF
actory");
        environment.put(PROVIDER_URL, "https://localhost:8181/ejb-invoker");
        environment.put(SECURITY_PRINCIPAL, "u1");
        environment.put(SECURITY_CREDENTIALS, "p1");
        InitialContext ejbRemoteContext = new InitialContext(environment);
        BeanRemote beanRemote = (BeanRemote)
ejbRemoteContext.lookup("java:global/test/Bean");
        beanRemote.method(); // returns "method"
    }
}
```

When accessing secured EJBs you **should** use only HTTPS (that means, enabling confidential transport requirements to the remote EJB), as the submitted credentials will be transferred in clear text (not encrypted, only base64 encoded), which is a security risk you should avoid in any production environment.

JNDI Customization Options

Under the covers the remote EJB proxy uses a JAX-RS (Jersey) REST client builder in order to establish communication with the remote server. If you want to customize and modify the parameters for this communication (timeouts, keystores, etc.) the following JNDI context properties can be used to this end:

Table 190. `JNDI Options for Custom HTTP(S) Communication`

Property	Behaviour	Type
`fish.payara.connectTimeout`	The connection timeout. A value of **0** represents that the wait is indefinite. Negative values are not allowed. Unit is microseconds.	`Number` (from which it's `Long` value is taken) or a `String` that can be converted to a `Long` value.

Property	Behaviour	Type
`fish.payara.readTimeout`	The timeout to read a response. If the remote Payara doesn't respond within the defined time a ProcessingException is thrown with a `TimeoutException` as its cause. A value of **0** represents that the wait is indefinite. Negative values are not allowed. Unit is microseconds.	`Number` (from which it's `Long` value is taken) or a `String` that can be converted to a `Long` value.
`fish.payara.keyStore`	The key store to be used by the proxy. The key store contains the private key as well as certificates with its associated public keys.	Instance of `java.security.KeyStore` or a `String` representing its fully qualified classname.
`fish.payara.trustStore`	The trust store to be used by the proxy. The trust store must contain the certificates that are needed to communicate with the remote Payara Server.	Instance of `java.security.KeyStore` or a `String` representing its fully qualified classname.
`fish.payara.sslContext`	The SSL context that will be used by the proxy for creating secured connections to the Payara remote server. This context **must** be fully initialized, including the trust and key managers. Should not be used in conjunction with the `fish.payara.keyStore` and/or `fish.payara.trustStore` properties.	Instance of `javax.net.ssl.SSLContext` or a `String` representing its fully qualified classname.
`fish.payara.hostnameVerifier`	The hostname verifier to be used by the proxy to verify the endpoint's hostname against the identification information of it.	Instance of a `javax.net.ssl.HostnameVerifier` or a `String` representing its fully qualified classname.
`fish.payara.provider.principal`	The principal to be used by the proxy to access the secured endpoint.	Instance of a `String`.
`fish.payara.provider.credentials`	The credentials to be used by the proxy to access the secured endpoint.	Instance of a `String`.
`fish.payara.provider.authType`	To specify the authentication type of the secured endpoint. By default `BASIC` is defined.	Instance of a `String`.
`fish.payara.requestFilter`	To register the custom filter for the client request invoked by proxy.	Instance of a `jakarta.ws.rs.client.ClientRequestFilter` or a `Class` implementing `jakarta.ws.rs.client.ClientRequestFilter`.

Property	Behaviour	Type
`fish.payara.responseFilter`	To register the custom filter for the client response received by proxy.	Instance of a `jakarta.ws.rs.client.ClientResponseFilter ` or a `Class` implementing `jakarta.ws.rs.client.ClientResponseFilter`.
`fish.payara.executorService`	The executor service that will be used for executing asynchronous tasks. *(for future use)*	Instance of `java.util.concurrent.ExecutorService` or a `String` representing its fully qualified classname.
`fish.payara.scheduledExecutorService`	The executor service that will be used for executing scheduled asynchronous tasks. *(For future use)*	Instance of `java.util.concurrent.ScheduledExecutorService` or string representing fully qualified classname.
`fish.payara.withConfig`	The configuration for the internal JAX-RS/Jersey REST client.	Instance of `jakarta.ws.rs.core.Configuration` or a `String` representing its fully qualified classname.
`fish.payara.clientAdapter`	Implementation of client side adapter to use for intercepting JNDI lookups (see below)	Instance of `fish.payara.ejb.http.client.adapter.ClientAdapter`

The constants are also exposed as static attributes of the `fish.payara.ejb.http.client.RemoteEJBContextFactory` class.

System Properties Fallbacks

The JNDI customization options listed above as well the environment variables defined in `javax.naming.Context` (except `APPLET`) can be set by setting a system property of the same name that will act as a fallback.

That means it will not override an environment variable that is already present but would be used in the case that it is not defined when `InitialContextFactory.getInitialContext` is invoked.

Client-side adapter

EJB Lite connector is, in its current form, suited for invoking stateless remote EJBs. However, if you're using the connector with existing clients, those may depend on stateful interactions, like invoking stateful EJBs or accessing application server data sources and connection factories.

Client side adapters serve the purpose of emulating stateful behavior at the client and delegate the requests to stateful backend, when all information from the client is collected.

The API of client side adapters is prescribed by interface `fish.payara.ejb.http.client.adapter.ClientAdapter`:

```
public interface ClientAdapter {
```

```
    /*
     * @param jndiName jndi name requested for lookup
     * @param remoteContext naming context for remote EJB invocation
     * @return Optional.of(proxy) if adapter provides a proxy for given name,
Optional.empty() otherwise
     * @throws NamingException if downstream lookup fails, or other validation doesn't
pass
     */
    Optional<Object> makeLocalProxy(String jndiName, Context remoteContext)
        throws NamingException;
}
```

To make use of the adapter, put an instance of `ClientAdapter` into JNDI context property `fish.payara.clientAdapter`. Every JNDI lookup will be first passed to the adapter instance in such case. If adapter returns a non-empty `Optional` value, tit will be passed back to the client.

Composing multiple adapters

Client side emulation might require stubbing diverse JNDI names and return types, and handling all of that in a single ClientAdapter implementation would result in not very maintainable code. Therefore, the client library offers two classes that help with composition of multiple Client adapters into the parent instance to be passed to `RemoteEJBContextFactory`:

- `CompositeClientAdapter` concatenates multiple client adapter instances, calling adapters in a defined order and returning first non-empty proxy provided by the adapters.
- `ClientAdapterCustomizer` is a decorator, that helps separate JNDI name matching from instantiation of client adapter.

Most used method of customizer is `matchPrefix`, which will only call downstream adapter when requested JNDI name matches prefix.

This prefix is stripped before invoking the downstream adapter.

Composite Client Adapter example

```
public class Application{
    public static void main(String[] args){
        Properties props = new Properties();
        props.put(Context.INITIAL_CONTEXT_FACTORY,
RemoteEJBContextFactory.FACTORY_CLASS);
        props.put(Context.PROVIDER_URL, "http://not.relevant/");
        props.put(RemoteEJBContextFactory.CLIENT_ADAPTER,
                CompositeClientAdapter.newBuilder()
                    .register(customize(new
ConnectionFactoryAdapter()).matchPrefix("jms/"),
                            customize(QueueAdapter.class).matchPrefix("queue/"))
                    .build()
                );
        Context context = new InitialContext(props);
```

```
    }
}
```

See API documentation of the client library for detailed description of `ClientAdapterCustomizer` methods and contracts of `CompositeClientAdapter`.

Known Limitations

Serialization Limitations

The HTTP adapter utilizes JSON-B for serialization. This places limits on types of objects that can be transmitted as method arguments or return types. The serialization can be customized by means of JSON-B annotations.

1. By default, only public properties and fields are transferred
2. Complex object graphs should form a tree and not contain cyclic references
3. Polymorphism is not supported by default

Programming Model Limitations

The HTTP adapter uses stateless HTTP requests. In its current form, it is unfit for invoking stateful objects like `@Stateful` Enterprise Java Beans, or using server resources like `DataSource` or `ConnectionFactory`.

Developing Java Clients

This chapter describes how to develop, assemble, and deploy remote Java clients.

The Web Profile of Payara Server supports the Jakarta Enterprise Beans 4.0 Lite specification, which allows enterprise beans within web applications, among other features. The full Payara Server supports the entire EJB 4.0 specification. For details, see Jakarta Enterprise Beans.
Accordingly, the Application Client Container is supported only in the Full Profile, not in the Web Profile.
JMS resources are supported only in the Full Profile, not in the Web Profile. See Using the Java Message Service.

Introducing the Application Client Container

The Application Client Container (ACC) includes a set of Java classes, libraries, and other files that are required for and distributed with Java client programs that execute in their own Java Virtual Machine (JVM). The ACC manages the execution of Jakarta EE application client components (application clients), which are used to access a variety of Jakarta EE services (such as JMS

resources, EJB components, web services, security, and so on.) from a JVM **outside** Payara Server.

The ACC communicates with Payara Server using RMI-IIOP protocol and manages the details of RMI-IIOP communication using the client ORB that is bundled within it.

Compared to other Jakarta EE containers, the ACC is lightweight.

For information about debugging application clients, see Application Client Debugging.

Interoperability between application clients and Payara Servers running under different Payara Platform major versions is not supported. The same can be said if both server and client are running under different major Java versions.

ACC Security

The ACC determines when authentication is needed. This typically occurs when the client refers to an EJB component that requires authorization or when annotations in the client's `main` class trigger resource injection which, in turn, requires contact with the server's naming service.

To authenticate the end user, the ACC prompts for any required information, such as a username and password. The ACC itself provides a very simple dialog box to prompt for and read these values.

The ACC integrates with Payara Server's authentication system. It also supports SSL (Secure Socket Layer)/IIOP if configured and when necessary; see Using RMI/IIOP Over SSL.

You can provide an alternate implementation to gather authentication information, tailored to the needs of the application client. To do so, include the class to perform these duties in the application client and identify the fully-qualified name of this class in the `callback-handler` element of the `application-client.xml` descriptor for the client. The ACC uses this class instead of its default class for asking for and reading the authentication information.

The class must implement the `javax.security.auth.callback.CallbackHandler` interface. See the Jakarta EE Platform specification, section 10.2, **Application Clients: Security**, for more details.

Application clients can use a programmatic login mechanism by using the `ProgrammaticLogin` Class.

ACC Naming

The client container enables the application clients to use the Java Naming and Directory Interface (JNDI) to look up Jakarta EE services (such as JMS resources, EJB components, web services, security, and so on.) and to reference configurable parameters set at the time of deployment.

Application Client Annotation

Annotation is supported for the main class and the optional callback handler class in application clients. For more information, see "Deployment Descriptors and Annotations" in the Payara Server Application Deployment section.

Java Web Start

Java Web Start is no longer part of the Java SDK since Java 11 and is no longer a recommended solution to distribute application client binaries from the server. Using Java Web Start is not a supported solution, so consider using it at your own risk.

Java Web Start allows your application client to be easily launched and automatically downloaded and updated. It is enabled for all application clients by default. For more information, see Using Java Web Start.

Application Client JAR File

When copying the downloaded application client to another location, make sure to include the JAR files containing the dependent classes as well. You can also use the `asadmin get-client-stubs` command to retrieve the `appclient` and all associated application JAR files and place them in another location.

Developing Clients Using the ACC

This section describes the procedure to develop, assemble, and deploy client applications using the ACC.

To Access an EJB Component From an Application Client

1. In your client code, reference the EJB component by using an `@EJB` annotation or by looking up the JNDI name as defined in the `ejb-jar.xml` file.
   For more information about naming and lookups, see Accessing the Naming Context.
   If load balancing is enabled as in Step 7 and the EJB components being accessed are in a different cluster, the endpoint list must be included in the lookup, as follows:

   ```
   corbaname:host1:port1,host2:port2,.../NameService#ejb/jndi-name
   ```

2. Define the `@EJB` annotations or the `ejb-ref` elements in the `application-client.xml` file. Define the corresponding `ejb-ref` elements in the `payara-application-client.xml` file.
   For more information on the `payara-application-client.xml` file, see "The payara-application-client.xml file" in the Payara Server Application Deployment section. For a general explanation of how to map JNDI names using reference elements, see Mapping References.
3. Deploy the application client and EJB component together in an application.
   To get the client JAR file, use the `--retrieve` option of the `asadmin deploy` command.
   To retrieve the stubs and ties generated during deployment, use the `asadmin get-client-stubs` command.
4. Ensure that the client JAR file includes the following files:
   - A Java class to access the bean.
   - The `application-client.xml` - (optional) Jakarta EE application client deployment descriptor.
   - `payara-application-client.xml` - (optional) Payara Server specific client deployment

descriptor. For information on the `payara-application-client.xml` file, see "The payara-application-client.xml file" in the Payara Server Application Deployment section.

- The `MANIFEST.MF` file. This file contains a reference to the `main` class, which states the complete package prefix and class name of the Java client.

5. Prepare the client machine.
   If you are using the `appclient` script, package the Payara Server system files required to launch application clients on remote systems using the `package-appclient` script, then retrieve the application client itself using the `asadmin get-client-stubs` command.

   For more information, see Using the `package-appclient` Script .

6. To access EJB components that are residing in a remote system, make the following changes to the `sun-acc.xml` file or the `appclient` script.

   - Define the `target-server` element's `address` and `port` attributes to reference the remote server machine and its ORB port. See "target-server" in the Payara Server Application Deployment section.
   - Use the `-targetserver` option of the `appclient` script to reference the remote server machine and its ORB port.For more information, see Running an Application Client Using the `appclient` Script.

     To determine the ORB port on the remote server, use the `asadmin get` command. For example:

     ```
     asadmin --host <remote-host> get server-config.iiop-service.iiop-listener.iiop-listener1.port
     ```

7. To set up load balancing and failover of remote EJB references, define at least two `target-server` elements in the `sun-acc.xml` file or the `appclient` script. If the Payara Server instance on which the application client is deployed participates in a cluster or deployment group, the ACC finds all currently active IIOP endpoints in the cluster automatically. However, a client should have at least two endpoints specified for bootstrapping purposes, in case one of the endpoints has failed.

   The `target-server` elements in the `sun-acc.xml` file specify one or more IIOP endpoints used for load balancing. The `address` attribute is an IPv4 address or host name, and the `port` attribute specifies the port number.

   See "client-container" in the Payara Server Application Deployment section.

   The `--targetserver` option of the `appclient` script specifies one or more IIOP endpoints used for load balancing. For more information, see Running an Application Client Using the `appclient` Script.

Next Steps

- For instructions on running the application client, see Using Java Web Start or Running an Application Client Using the `appclient` Script.

- For more information about RMI-IIOP load balancing and failover, see "RMI-IIOP Load Balancing and Failover" in the Payara Server High Availability section.

To Access a JMS Resource From an Application Client

1. Create a JMS client.

   For detailed instructions on developing a JMS client, see "Jakarta Messaging Examples" in The Jakarta EE Tutorial.

2. Next, configure a JMS resource in Payara Server.

   For information on configuring JMS resources, see "Administering JMS Connection Factories and Destinations" in the Payara Server General Administration section.

3. Define the `@Resource` or `@Resources` annotations or the `resource-ref` elements in the `application-client.xml` file. Define the corresponding `resource-ref` elements in the `payara-application-client.xml` file.
   For more information on the `payara-application-client.xml` file, see "The payara-application-client.xml file" in the Payara Server Application Deployment section. For a general explanation of how to map JNDI names using reference elements, see Mapping References.
4. Ensure that the client JAR file includes the following files:
   - A Java class to access the resource.
   - `application-client.xml` - (optional) Jakarta EE application client deployment descriptor.
   - `payara-application-client.xml` - (optional) Payara Server specific client deployment descriptor. For information on the `payara-application-client.xml` file, see "The payara-application-client.xml file" in the Payara Server Application Deployment section.
   - The `MANIFEST.MF` file. This file contains a reference to the `main` class, which states the complete package prefix and class name of the Java client.
5. Prepare the client machine.

   This step is not needed if the client and server machines are the same.

   If you are using the `appclient` script, package the Payara Server system files required to launch application clients on remote systems using the `package-appclient` script, then retrieve the application client itself using the `asadmin get-client-stubs` command.

   For more information, see Using the `package-appclient` Script

6. Run the application client.

   See Using Java Web Start or Running an Application Client Using the `appclient` Script.

Using Java Web Start

Java Web Start is no longer part of the JDK since Java 11 and is no longer a recommended solution to distribute application client binaries.
To use Java Web Start, you'll have to manually install an implementation on the

local machine where the Application client is intended to run.
Using Java Web Start is not a supported solution, so consider using it at your own risk.

Java Web Start allows your application client to be easily launched and automatically downloaded and updated.

Enabling and Disabling Java Web Start

Java Web Start is enabled for all application clients by default.

The application developer or deployer can specify that Java Web Start is always disabled for an application client by setting the value of the `eligible` element to `false` in the `payara-application-client.xml` file.

The server administrator can disable Java Web Start for a previously deployed eligible application client using the `asadmin set` command.

To disable Java Web Start for all eligible application clients in an application, use the following command:

```
asadmin set applications.application.app-name.property.java-web-start-enabled="false"
```

To disable Java Web Start for a stand-alone eligible application client, use the following command:

```
asadmin set applications.application.module-name.property.java-web-start-
enabled="false"
```

Setting `java-web-start-enabled="true"` re-enables Java Web Start for an eligible application client.

Downloading and Launching an Application Client

If Java Web Start is enabled for your deployed application client, you can launch it for testing. Simply click on the *Launch* button next to the application client or application's listing on the App Client Modules page in the Administration Console.

On other machines, you can download and launch the application client using Java Web Start in the following ways:

- Using a web browser, directly enter the URL for the application client. See The Application Client URL.
- Click on a link to the application client from a web page.
- Use the Java Web Start command `javaws`, specifying the URL of the application client as a command line argument.
- If the application has previously been downloaded using Java Web Start, you have additional alternatives:

- Use the desktop icon that Java Web Start created for the application client. When Java Web Start downloads an application client for the first time it asks you if such an icon should be created.
- Use the Java Web Start control panel to launch the application client.

Whenever you launch an application client, Java Web Start contacts the server to see if a newer client version is available. This means you can redeploy an application client without having to worry about whether client machines have the latest version.

The Application Client URL

The default URL for an application or module generally is as follows:

```
http(s)://host:port/context-root
```

The default URL for a stand-alone application client module is as follows:

```
http://host:port/appclient-module-id
```

The default URL for an application client module embedded within an application is as follows.

The relative path to the application client JAR file is included.

```
http://host:port/application-id/appclient-path
```

If the context-root, `appclient-module-id`, or `application-id` is not specified during deployment, the name of the JAR or EAR file without the extension is used.

If the application client module or application is not in JAR or EAR file format, an `appclient-module-id` or `application-id` is generated.

Regardless of how the context-root or id is determined, it is written to the server log when you deploy the application. For details about naming, see "Naming Standards" in the Payara Server Application Deployment section.

To set a different URL for an application client, use the `context-root` sub-element of the `java-web-start-access` element in the `payara-application-client.xml` file. This overrides the `appclient-module-id` or `application-id`.

You can also pass arguments to the ACC or to the application client's `main` method as query parameters in the URL. If multiple application client arguments are specified, they are passed in the order specified.

A question mark separates the context root from the arguments. Ampersands (`&`) separate the arguments and their values. Each argument and each value must begin with the `arg=` prefix.

Here is an example URL with a `-color` argument for a stand-alone application client. The `-color`

argument is passed to the application client's `main` method:

```
http://localhost:8080/testClient?arg=-color&arg=red
```

If you are using the `javaws` URL command to launch Java Web Start with a URL that contains arguments, enclose the URL in double quotes (") to avoid breaking the URL at the ampersand (&) symbol.

Ideally, you should build your production application clients with user-friendly interfaces that collect information which might otherwise be gathered as command-line arguments. This minimizes the degree to which users must customize the URLs that launch application clients using Java Web Start.

Command-line argument support is useful in a development environment and for existing application clients that depend on it.

Signing JAR Files Used in Java Web Start

Java Web Start enforces a security sandbox. By default, it grants any application, including application clients, only minimal privileges. Because Java Web Start applications can be so easily downloaded, Java Web Start provides protection from potentially harmful programs that might be accessible over the network.

If an application requires a higher privilege level than the sandbox permits, the code that needs privileges must be in a JAR file that was signed.

When Java Web Start downloads such a signed JAR file, it displays information about the certificate that was used to sign the JAR if that certificate is not trusted. It then asks you whether you want to trust that signed code. If you agree, the code receives elevated permissions and runs. If you reject the signed code, Java Web Start does not start the downloaded application.

Your first Java Web Start launch of an application client is likely to involve this prompting because by default Payara Server uses a self-signed certificate that is not linked to a trusted authority.

Payara Server serves two types of signed JAR files in response to Java Web Start requests. One type is a JAR file installed as part of the Payara Server, which starts an application client during a Java Web start launch: as-install`/lib/gf-client.jar`.

The other type is a generated application client JAR file. As part of deployment, the Payara Server generates a new application client JAR file that contains classes, resources, and descriptors needed to run the application client on end-user systems. When you deploy an application with the `asadmin deploy` command's `--retrieve` option, use the `asadmin get-client-stubs` command, or select the **Generate RMIStubs** option from the EJB Modules deployment page in the Administration Console, this is one of the JAR files retrieved to your system. Because application clients need access beyond the minimal sandbox permissions to work in the Java Web Start environment, the generated application client JAR file must be signed before it can be downloaded to and executed on an end-user system.

A JAR file can be signed automatically or manually.

Automatically Signing JAR Files

Payara Server automatically creates a signed version of the required JAR file if none exists. When a Java Web Start request for the `gf-client.jar` file arrives, the Payara Server looks for the `domain-dir/java-web-start/gf-client.jar` file. When a request for an application's generated application client JAR file arrives, the Payara Server looks in the `domain-dir/java-web-start/app-name` directory for a file with the same name as the generated JAR file created during deployment.

In either case, if the requested signed JAR file is absent or older than its unsigned counterpart, Payara Server creates a signed version of the JAR file automatically and deposits it in the relevant directory. Whether Payara Server just signed the JAR file or not, it serves the file from the `domain-dir/java-web-start` directory tree in response to the Java Web Start request.

To sign these JAR files, by default Payara Server uses its self-signed certificate. When you create a new domain by using the `asadmin create-domain` command, the Payara Server creates a self-signed certificate and adds it to the domain's key store (the same applies to the default domains included in the server's installation bundle).

A self-signed certificate is generally untrustworthy because no certification authority vouches for its authenticity.

The automatic signing feature uses the same certificate to create all required signed JAR files.

To minimize impacts to application users, all Java Web Start applications should be signed with a trusted certificate instead of the Payara Server self-signed certificate.

If you use the Payara Server Java Web Start feature or deploy applications that provide their own Java Web Start applications, perform the following steps:

1. Obtain a trusted certificate from a certification authority if your organization does not already have one.
2. Stop the Payara Server domain and corresponding instances, clusters or deployment groups.
3. Replace the self-signed certificate with the trusted certificate by importing the trusted certificate into the keystore using the `s1as` alias.

   By default, the keystore is located at `domain-dir/config/keystore.p12`.

   For more information about importing a trusted certificate into the domain keystore, see "Administering JSSE Certificates" in the Payara Server Security Guide.

4. Delete any signed JARs already generated by Payara Server:
   a. At the command prompt, type:

   ```
   rm -rf ${domain-dir}/java_web_start
   ```

   b. For each application that contains an application client launched using Java Web Start, type:

```
rm -rf ${domain-dir}/generated/xml/app-name/signed
```

5. Restart the Payara Server domain and corresponding targets.

After you perform these steps, the first time a user launches an application client on their system, Java Web Start detects that the server's signed JARs are newer than those cached on the user's system and downloads them again. This happens on the first launch only, regardless of the client.

Even though the application client is now signed using a trusted certificate, users will again be asked whether to trust the downloaded application and can choose to skip that prompt for future launches.

Using the `jar-signing-alias` Deployment Property

The `asadmin deploy` command property `jar-signing-alias` specifies the alias for the security certificate with which the application client container JAR file is signed.

Java Web Start won't execute code requiring elevated permissions unless it resides in a JAR file signed with a certificate that the user's system trusts. For your convenience, Payara Server signs the JAR file automatically using the self-signed certificate from the domain, `s1as`. Java Web Start then asks the user whether to trust the code and displays the server's certificate information.

To sign this JAR file with a different certificate, first add the certificate to the domain keystore. You can use a certificate from a trusted authority, which avoids the Java Web Start prompt. To add a certificate to the domain keystore, see "Administering JSSE Certificates" in the Payara Server Security Guide.

Next, deploy your application using the `jar-signing-alias` property. For example:

```
asadmin deploy --property jar-signing-alias=MyAlias MyApp.ear
```

Error Handling

When an application client is launched using Java Web Start, any error that the application client logic does not catch and handle is written to `System.err` and displayed in a dialog box.

This display appears if an error occurs even before the application client logic receives control. It also appears if the application client code does not catch and handle errors itself.

Vendor Icon, Splash Screen, and Text

To specify a vendor-specific icon, splash screen, text string, or a combination of these for Java Web Start download and launch screens, use the `vendor`element in the `payara-application-client.xml` file. The complete format of this element's data is as follows:

```
<vendor>icon-image-URI::splash-screen-image-URI::vendor-text</vendor>
```

The following example vendor element contains an icon, a splash screen, and a text string:

```
<vendor>images/icon.jpg::otherDir/splash.jpg::MyCorp, Inc.</vendor>
```

The following example vendor element contains an icon and a text string:

```
<vendor>images/icon.jpg::MyCorp, Inc.</vendor>
```

The following example vendor element contains a splash screen and a text string; note the initial double colon:

```
<vendor>::otherDir/splash.jpg::MyCorp, Inc.</vendor>
```

The following example vendor element contains only a text string:

```
<vendor>MyCorp, Inc.</vendor>
```

The default value is the text string `Application Client`.

You can also specify a vendor-specific icon, splash screen, text string, or a combination by using a custom JNLP file; see Creating a Custom JNLP File.

Creating a Custom JNLP File

You can partially customize the Java Network Launching Protocol (JNLP) file that Payara Server uses for Java Web Start.

For more information about JNLP, see the JNLP Specification and API Documentation.

Specifying the JNLP File in the Deployment Descriptor

To specify a custom JNLP file for Java Web Start, use the `jnlp-doc` element in the `payara-application-client.xml` file. If `none` is specified, a default JNLP file is generated.

The value of the `jnlp-doc` element is a relative path with the following format:

```
[path-to-JAR-in-EAR!]path-to-JNLP-in-JAR
```

The default `path-to-JAR-in-EAR` is the current application client JAR file. For example, if the JNLP file is in the application client JAR file at `custom/myInfo.jnlp`, the element value would look like this:

```
<java-web-start-access>
   <jnlp-doc>custom/myInfo.jnlp</jnlp-doc>
</java-web-start-access>
```

If the application client is inside an EAR file, you can place the custom JNLP file inside another JAR file in the EAR.

For example, if the JNLP file is in a JAR file at `other/myLib.jar`, the element value would look like this, with an exclamation point (`!`) separating the path to the JAR from the path in the JAR:

```
<java-web-start-access>
   <jnlp-doc>other/myLib.jar!custom/myInfo.jnlp</jnlp-doc>
</java-web-start-access>
```

For more information about the `payara-application-client.xml` file, see the Payara Server Application Deployment section.

Referring to JAR Files from the JNLP File

As with any JNLP document, the custom JNLP file can refer to JAR files the application client requires.

Do not specify every JAR on which the client depends. Payara Server automatically handles JAR files that the Jakarta EE specification requires to be available to the application client. This includes JAR files listed in the application client JAR file's manifest `Class-Path` and JAR files in the EAR file's library directory (if any) and their transitive closures. The custom JNLP file should specify only those JAR files the client needs that Payara Server would not otherwise include.

Package these JAR files in the EAR file, as with any JAR file required by an application client. Use relative URIs in the `<jar href="⋯">` and `<nativelib href="⋯">` elements to point to these JAR files. The codebase that Payara Server assigns for the final client JNLP file corresponds to the top level of the EAR file.

Therefore, relative `href` references correspond directly to the relative path to the JAR files within the EAR file.

Neither the Jakarta EE specification nor Payara Server supports packaging JAR files inside the application client JAR file itself. Nothing prevents this, but Payara Server does no special processing of such JAR files. They do not appear in the runtime class path, and they cannot be referenced from the custom JNLP file as well.

Referring to Other JNLP Files

The JNLP file can also refer to other custom JNLP files using `<extension href="⋯"/>` elements. To be consistent with relative `href` references to JAR files, the relative `href` references to JNLP files are resolved within the EAR file. You can place these JNLP files directly in the EAR file or inside JAR files that the EAR file contains.

Use one of these formats for these `href` references:

```
[path-to-JAR-in-EAR!]path-to-JNLP-in-JAR
```

```
path-to-JNLP-in-EAR
```

Note that these formats are not equivalent to the format of the `jnlp-doc` element in the `payara-application-client.xml` file.

These formats follow the standard entry-within-a-JAR URI syntax and semantics. Support for this syntax comes from the automated Java Web Start support in Payara Server. This is not a feature of Java Web Start or the JNLP standard.

Combining Custom and Automatically Generated Content

Payara Server recognizes these types of content in the JNLP file:

Owned
: Payara Server owns the content and ignores any custom content

Merged
: Automatically generated content and custom content are merged

Defaulted
: Custom content is used if present, otherwise default content is provided

You can compose a complete JNLP file and package it with the application client. Payara Server then combines it with its automatically generated JNLP file.

You can also provide content that only adds to or replaces what Payara Server generates. The custom content must conform to the general structure of the JNLP format so that Payara Server can properly place it in the final JNLP file.

For example, to specify a single native library to be included only for Windows systems, the new element to add might be as follows:

```
<nativelib href="windows/myLib.jar"/>
```

However, you must indicate where in the overall document this element belongs. The actual custom JNLP file should look like this:

```
<jnlp>
   <resources os="Windows">
      <nativelib href="windows/myLib.jar"/>
   </resources>
</jnlp>
```

Payara Server provides default `<information>` and `<resources>` elements, without specifying attributes such as `os`, `arch`, `platform`, or `locale`. Payara Server merges its own content within those elements with custom content under those elements. Further, you can provide your own

`<information>` and `<resources>` elements (and fragments within them) that specify at least one of these attributes.

In general, you can perform the following customizations:

- Override the Payara Server defaults for the child elements of `<information>` elements that have no attribute settings for `os`, `arch`, `platform`, and `locale`.

  Among these child elements are `<title>`, `<vendor>`, `<description>`, `<icon>`, and so on.

- Add `<information>` elements with `os`, `arch`, `platform`, or `locale` settings. You can also add child elements.
- Add child elements of `<resources>` elements that have no attribute settings for `os`, `arch`, or `locale`.

  Among these child elements are `<jar>`, `<property>`, `<nativelib>`, and so on.

  You can also customize attributes of the `<java>` child element.

- Add `<resources>` elements that specify at least one of `os`, `arch`, or `locale`. You can also add child elements.

This flexibility allows you to add JAR files to the application (including platform-specific native libraries) and set properties to control the behavior of your application clients.

The following tables provide more detail about what parts of the JNLP file you can add to and modify.

Table 191. Owned JNLP File Content

JNLP File Fragment	Description
`<jnlp codebase="xxx">...</jnlp>`	Payara Server controls this content for application clients packaged in EAR files. The developer controls this content for application clients packaged in WAR files.
`<jnlp href="xxx">...</jnlp>`	Payara Server controls this content for application clients packaged in EAR files. The developer controls this content for application clients packaged in WAR files.

`<jnlp>`
`  <security>...</security>`
`</jnlp>`
	Payara Server must control the permissions requested for each JNLP file. All permissions are needed for the main file, which launches the ACC. The permissions requested for other JNLP documents depend on whether the JAR files referenced in those documents are signed.

JNLP File Fragment	Description

`<jnlp>`
`  <application-desc>`
`  <argument> ... </argument>`
`  </application-desc>`
`</jnlp>`
	Payara Server sets the `main-class` and the arguments to be passed to the client.

Table 192. Defaulted JNLP File Content

JNLP File Fragment	Description
`<jnlp spec="xxx">...</jnlp>`	Specifies the JNLP specification version.

`<jnlp>`
`  <information>...</information>`
`</jnlp>`
	Specifies the application title, vendor, home page, various description text values, icon images, and whether offline execution is allowed.

`<jnlp>`
`  <resources>`
`  <java version="xxx" java-vm-args="yyy"></java>`
`  </resources>`
`</jnlp>`
	Specifies the Java SE version or selected VM parameter settings.

Table 193. Merged JNLP File Content

JNLP File Fragment	Description

`<jnlp>`
`  <information os="" platform="" arch="" locale=""></information>`
`</jnlp>`
	You can specify one or more of the `os`, `arch`, `platform`, and `locale` attributes for the `<information>` element. You can also specify child elements; Payara Server provides no default children.

`<jnlp>`
`  <resources os="" platform="" arch="" locale=""></resources>`
`</jnlp>`
	You can specify one or more of the `os`, `arch`, `platform`, and `locale` attributes for the `<resources>` element. You can also specify child elements; Payara Server provides no default children.

`<jnlp>`
`  <resources>`
`  <jar>...</jar>`
`  </resources>`
`</jnlp>`
	Adds JAR files to be included in the application to the JAR files provided by Payara Server.

JNLP File Fragment	Description
`<jnlp>   <resources>   <nativelib>...</nativelib>   </resources> </jnlp>`	Adds native libraries to be included in the application. Each entry in a JAR listed in a `<nativelib>` element must be a native library for the correct platform. The full syntax of the `<nativelib>` element lets the developer specify the platform for that native library.
`<jnlp>   <resources>   <property></property>   </resources> </jnlp>`	Adds system properties to be included in the application to the system properties defined by Payara Server.
`<jnlp>   <resources>   <extension>...</extension>   </resources> </jnlp>`	Specifies another custom JNLP file.
`<jnlp>   <component-desc></component-desc> </jnlp>`	Includes another custom JNLP file that specifies a component extension.
`<jnlp>   <installer-desc></installer-desc> </jnlp>`	Includes another custom JNLP file that specifies an installer extension.

Using the Embeddable ACC

You can embed the ACC into your application client. If you place the `as-install/lib/gf-client.jar` file in your runtime classpath, your application creates the ACC after your application code has started, then requests that the ACC start the application client portion. The basic model for coding with the embeddable ACC is as follows:

1. Create a builder object.
2. Operate on the builder to configure the ACC.
3. Obtain a new ACC instance from the builder.
4. Present a client archive or class to the ACC instance.
5. Start the client running within the newly created ACC instance.

Your code should follow this general pattern:

```
// one TargetServer for each ORB endpoint for bootstrapping
```

```
TargetServer[] servers = ...;

// Get a builder to set up the ACC
AppClientContainer.Builder builder = AppClientContainer.newBuilder(servers);

// Fine-tune the ACC's configuration. Note ability to "chain" invocations.
builder.callbackHandler("com.acme.MyHandler").authRealm("myRealm"); // Modify config

// Get a container for a client.
URI clientURI = ...; // URI to the client JAR
AppClientContainer acc = builder.newContainer(clientURI);

or

Class mainClass = ...;
AppClientContainer acc = builder.newContainer(mainClass);

// In either case, start the client running.
String[] appArgs = ...;
acc.startClient(appArgs); // Start the client

...

acc.close(); // close the ACC
```

The ACC loads the application client's `main` class, performs any required injection, and transfers control to the `static main` method. The ACC's `run` method returns to the calling application as soon as the client's `main` method returns to the ACC.

If the application client's `main` method starts any asynchronous activity, that work continues after the ACC returns. The ACC has no knowledge of whether the client's `main` method triggers asynchronous work.

Therefore, if the client causes work on threads other than the calling thread, and if the embedding application needs to know when the client's asynchronous work completes, the embedding application and the client must agree on how this happens.

The ACC's shutdown handling is invoked from the ACC's `close` method. The calling application can invoke `acc.close()` to close down any services started by the ACC.

If the application client code started any asynchronous activity that might still depend on ACC services, invoking `close` before that asynchronous activity completes could cause unpredictable and undesirable results.

The shutdown handling is also run automatically at VM shutdown if the code has not invoked `close` before then.

The ACC does not prevent the calling application from creating or running more than one ACC instance during a single execution of the application either serially or concurrently. However, other services used by the ACC (transaction manager,

> security, ORB, and so on) might or might not support such serial or concurrent reuse.

Running an Application Client Using the `appclient` Script

To run an application client, you can launch the ACC using the `appclient` script, whether Java Web Start is enabled. This script is located in the `as-install/glassfish/bin` directory.

Using the `package-appclient` Script

You can package the Payara Server system files required to launch application clients on remote systems into a single JAR file using the `package-appclient` script. This script is located in the `as-install/glassfish/bin` directory.

The `client.policy` File

The `client.policy` file is the policy file used by the application client. Each application client has a `client.policy` file.

The default policy file limits the permissions of Jakarta EE deployed application clients to the minimal set of permissions required for these applications to operate correctly. If an application client requires more than this default set of permissions, edit the `client.policy` file to add the custom permissions that your application client needs.

For more information about the permissions you can set in the `client.policy` file, see Permissions in the JDK.

Using RMI/IIOP Over SSL

You can configure RMI/IIOP over SSL in two ways: using a username and password, or using a client certificate.

To use a username and password, configure the `ior-security-config` element in the `payara-ejb-jar.xml` file. The following configuration establishes SSL between an application client and an EJB component using a username and password.

The user has to log in to the ACC using either the `sun-acc.xml` mechanism or the Programmatic Login Using the `ProgrammaticLogin` Class mechanism.

```
<ior-security-config>
  <transport-config>
    <integrity>required</integrity>
    <confidentiality>required</confidentiality>
    <establish-trust-in-target>supported</establish-trust-in-target>
    <establish-trust-in-client>none</establish-trust-in-client>
  </transport-config>
  <as-context>
    <auth-method>username_password</auth-method>
    <realm>default</realm>
    <required>true</required>
  </as-context>
```

```
 <sas-context>
    <caller-propagation>none</caller-propagation>
 </sas-context>
</ior-security-config>
```

To use a client certificate, configure the `ior-security-config` element in the `payara-ejb-jar.xml` file.

The following configuration establishes secure transport between an application client and an EJB component using a client certificate.

```
<ior-security-config>
  <transport-config>
    <integrity>required</integrity>
    <confidentiality>required</confidentiality>
    <establish-trust-in-target>supported</establish-trust-in-target>
    <establish-trust-in-client>required</establish-trust-in-client>
  </transport-config>
  <as-context>
    <auth-method>none</auth-method>
    <realm>default</realm>
    <required>false</required>
  </as-context>
  <sas-context>
    <caller-propagation>none</caller-propagation>
  </sas-context>
</ior-security-config>
```

To use a client certificate, you must also specify the system properties for the keystore and truststore to be used in establishing SSL.

To use SSL with the Application Client Container (ACC), you need to set these system properties in one of the following ways:

- Use the new syntax of the `appclient` script and specify the system properties as JVM options. See Running an Application Client Using the `appclient` Script.
- Set the environment variable `VMARGS` in the shell. For example, in the `ksh` or `bash` shell, the command to set this environment variable would be as follows:

  ```
  export VMARGS="-Djavax.net.ssl.keyStore=${keystore.db.file}
  -Djavax.net.ssl.trustStore=${truststore.db.file}
  -Djavax.net.ssl.keyStorePassword=${ssl.password}
  -Djavax.net.ssl.trustStorePassword=${ssl.password}"
  ```

Connecting to a Remote EJB Module Through a Firewall

To deploy and run an application client that connects to an EJB module on a Payara Server instance that is behind a firewall, you must set ORB Virtual Address Agent Implementation (**ORBVAA**)

options. Use the `asadmin create-jvm-options` command as follows:

```
asadmin create-jvm-options -Dcom.sun.corba.ee.ORBVAAHost=public-IP-adress
asadmin create-jvm-options -Dcom.sun.corba.ee.ORBVAAPort=public-port
asadmin create-jvm-options
-Dcom.sun.corba.ee.ORBUserConfigurators.com.sun.corba.ee.impl.plugin.hwlb.VirtualAddre
ssAgentImpl=x
```

Set the `ORBVAAHost` and `ORBVAAPort` options to the host and port of the public address. The `ORBUserConfigurators` option tells the ORB to create an instance of the `VirtualAddressAgentImpl` class and invoke the `configure` method on the resulting object, which must implement the com.sun.corba.ee.spi.orb.ORBConfigurator interface.

The `ORBUserConfigurators` value doesn't matter.Together, these options create an ORB that in turn creates `Object` references (the underlying implementation of remote EJB references) containing the public address, while the ORB listens on the private address specified for the IIOP port in the Payara Server configuration.

Specifying a Splash Screen

Java SE offers splash screen support, either through a Java command-line option or a manifest entry in the application's JAR file.

To take advantage of this Java SE feature in your application client, you can do one of the following:

- Create the appclient JAR file so that its manifest contains a `SplashScreen-Image` entry that specifies the path to the image in the client.The `java` command displays the splash screen before starting the ACC or your client, just as with any Java application.
- Use the new `appclient ⋯ -jar` launch format, using the `-splash` command-line option at runtime or the `SplashScreen-Image` manifest entry at development time.

  See Running an Application Client Using the `appclient` Script.

- In the environment that runs the `appclient` script, set the `VMOPTS` environment variable to include the `-splash` option before invoking the `appclient` script to launch the client.
- Build an application client that uses the embeddable ACC feature and specify the splash screen image using one of the following:
  - The `-splash` option of the `java` command
  - `SplashScreen-Image` in the manifest for your program (not the manifest for the application client)

    See Using the Embeddable ACC.

During application (EAR file) deployment, the Payara Server generates facade JAR files, one for the application and one for each application client in the application. During application client module deployment Payara Server generates a single facade JAR for the application client.

The `appclient` script supports splash screens inside the application client JAR only if you launch an application client facade or appclient client JAR. If you launch the facade for an application or the un-deployed application itself, the `appclient` script cannot take advantage of the splash screen feature.

Setting Login Retries

You can set a JVM option using the `appclient` script that determines the number of login retries allowed. This option is `-Dorg.glassfish.appclient.acc.maxLoginRetries=n` where `n` is a positive integer. The default number of retries is `3`.

This retry loop happens when the ACC attempts to perform injection if you annotated the client's `main` class (for example, using `@Resource`).

If instead of annotations your client uses the `InitialContext` explicitly to look up remote resources, the retry loop does not apply.

In this case, you could write logic to catch an exception around the lookup and retry explicitly.

Using Libraries with Application Clients

The Libraries field in the Administration Console's deployment page and the `--libraries` option of the `asadmin deploy` command do not apply to application clients.

Neither do the `as-install/lib`, `domain-dir/lib`, and `domain-dir/lib/classes` directories comprising the Common Class Loader.

These apply only to applications and modules deployed to the server. For more information, see Class Loaders.

To use libraries with an application client, package the application client in an application (EAR file). Then, either place the libraries in the `/lib` directory of the EAR file or specify their location in the application client JAR file's manifest `Class-Path`.

Developing Clients Without the ACC

This section describes the procedure to create, assemble, and deploy a Java-based client that is not packaged using the Application Client Container (ACC).

To access an EJB component from a stand-alone client

1. In your client code, instantiate the `InitialContext`:

   ```
   InitialContext ctx = new InitialContext();
   ```

   It is not necessary to explicitly instantiate a naming context that points to the `CosNaming` service.

2. In the client code, look up the home object by specifying the JNDI name of the home object. Here is an EJB 2.x example:

```
Object ref = ctx.lookup("jndi-name");
BeanAHome = (BeanAHome)PortableRemoteObject.narrow(ref,BeanAHome.class);
```

Here is an EJB 3.x+ example:

```
BeanRemoteBusiness bean =(BeanRemoteBusiness)
ctx.lookup("com.acme.BeanRemoteBusiness");
```

If load balancing is enabled as in Step 6 and the EJB components being accessed are in a different cluster or deployment group, the endpoint list must be included in the lookup, as follows:

```
corbaname:host1:port1,host2:port2,.../NameService#ejb/jndi-name
```

3. Deploy the EJB component to be accessed.

   For more information on deployment, see "About Deployment Tools" in the Payara Server Application Deployment section.

4. Copy the `as-install/lib/gf-client.jar` file to the client machine and include it in the classpath on the client side.

   The `gf-client.jar` file references the Payara Server JAR files in its `MANIFEST.MF` file. If there is no Payara Server installation on the client machine, you must also copy the `as-install/modules` directory to the client machine and maintain its directory structure relative to the `as-install/lib/gf-client.jar` file. Or you can use the `package-appclient` script; see Using the `package-appclient` Script.

5. To access EJB components that are residing in a remote system, set the following system properties for the Java Virtual Machine startup options:

   ```
   -Dorg.omg.CORBA.ORBInitialHost=${ORBhost}
   -Dorg.omg.CORBA.ORBInitialPort=${ORBport}
   ```

   Here `ORBhost` is the Payara Server hostname and `ORBport` is the ORB port number (default is `3700` for the default server instance, named `server`).

   You can use the `asadmin get` command to get the IIOP port numbers. For example:

   ```
   asadmin get "configs.config.server-config.iiop-service.iiop-listener.orb-listener-
   1.*"
   ```

6. To set up load balancing and remote EJB reference failover, define the `endpoints` property as follows:

```
-Dcom.sun.appserv.iiop.endpoints=host1:port1,host2:port2,...
```

The `endpoints` property specifies a comma-separated list of one or more IIOP endpoints used for load balancing. An IIOP endpoint is in the form `host:port`, where the host is an IPv4 address or host name, and the port specifies the port number.

If the `endpoints` list is changed dynamically in the code, the new list is used only if a new `InitialContext` is created.

7. Make sure the `etc/hosts` file on the client machine maps the Payara Server hostname and external IP address correctly.
8. Run the stand-alone client.

   As long as the client environment is set appropriately and the JVM is compatible, you merely need to run the application's `main` class.

To access an EJB component from a server-side module

A server-side module can be a servlet, another EJB component, or another type of module.

1. In your module code, instantiate the `InitialContext`:

   ```
   InitialContext ctx = new InitialContext();
   ```

   It is not necessary to explicitly instantiate a naming context that points to the `CosNaming` service. To set up load balancing and remote EJB reference failover, define the `endpoints` property as follows:

   ```
   Hashtable env = new Hashtable();
   env.put("com.sun.appserv.iiop.endpoints","host1:port1,host2:port2,...");
   InitialContext ctx = new InitialConext(env);
   ```

   The `endpoints` property specifies a comma-separated list of one or more IIOP endpoints used for load balancing. An IIOP endpoint is in the form `host:port`, where the host is an IPv4 address or host name, and the port specifies the port number.

   You can use the `asadmin get` command to get the IIOP port numbers. If the `endpoints` list is changed dynamically in the code, the new list is used only if a new `InitialContext` is created. For example:

   ```
   asadmin get "configs.config.server-config.iiop-service.iiop-listener.orb-listener-
   1.*"
   ```

2. In the module code, look up the home object by specifying the JNDI name of the home object. Here is an EJB 2.x example:

```
Object ref = ctx.lookup("jndi-name");
BeanAHome = (BeanAHome)PortableRemoteObject.narrow(ref,BeanAHome.class);
```

Here is an EJB 3.x+ example:

```
BeanRemoteBusiness bean =(BeanRemoteBusiness)
ctx.lookup("com.acme.BeanRemoteBusiness");
```

If load balancing is enabled as in Step 1 and the EJB components being accessed are in a different cluster or deployment group, the endpoint list must be included in the lookup, as follows:

```
corbaname:host1:port1,host2:port2,.../NameService#ejb/jndi-name
```

For more information about naming and lookups, see Accessing the Naming Context.

3. Deploy the EJB component to be accessed. For more information on deployment, see "About Deployment Tools" in the Application Deployment section.
4. To access EJB components that are residing in a remote system, set the following system properties for the Java Virtual Machine startup options:

   ```
   -Dorg.omg.CORBA.ORBInitialHost=${ORBhost}
   -Dorg.omg.CORBA.ORBInitialPort=${ORBport}
   ```

   Here `ORBhost` is the Application Server hostname and `ORBport` is the ORB port number (default is `3700` for the default server instance, named `server`).

5. Deploy the module.

   For more information on deployment, see "About Deployment Tools" in Payara Server Application Deployment section.

To access a JMS resource from a stand-alone client

1. Create a JMS client.

   For detailed instructions on developing a JMS client, see "Jakarta Messaging Examples" in The Jakarta EE Tutorial.

2. Configure a JMS resource on Payara Server.

   For information on configuring JMS resources, see "Administering JMS Connection Factories and Destinations" in the Payara Server General Administration section.

3. Copy the following JAR files to the client machine and include them in the classpath on the client side:

- `gf-client.jar` - available at `as-install/lib`
- `imqjmsra.jar` - available at `as-install/lib/install/applications/jmsra`

The `gf-client.jar` file references the Payara Server JAR files in its `MANIFEST.MF` file. If there is no Payara Server installation on the client machine, you must also copy the `as-install/modules` directory to the client machine and maintain its directory structure relative to the as-install`/lib/gf-client.jar` file. Or you can use the `package-appclient` script; see Using the `package-appclient` Script.

4. To access EJB components that are residing in a remote system, set the following system properties for the Java Virtual Machine startup options:

```
-Dorg.omg.CORBA.ORBInitialHost=${ORBhost}
-Dorg.omg.CORBA.ORBInitialPort=${ORBport}
```

Here `ORBhost` is the Application Server hostname and `ORBport` is the ORB port number (default is `3700` for the default server instance, named `server`). You can use the `asadmin get` command to get the IIOP port numbers. For example:

```
asadmin get "configs.config.server-config.iiop-service.iiop-listener.orb-listener-
1.*"
```

5. Run the stand-alone client.

As long as the client environment is set appropriately and the JVM is compatible, you merely need to run the application's `main` class.

Developing Connectors

This section strictly applies to Payara Server Full Profile.

This chapter describes Payara Server support for the Jakarta Connectors specification.

Jakarta Connectors provides a Java solution to the problem of connectivity between multiple application servers and existing enterprise information systems (EIS). By using Jakarta Connectors, EIS vendors no longer need to customize their product for each application server. Application server vendors who conform to Jakarta Connectors do not need to write custom code to add connectivity to a new EIS.

This chapter uses the terms **connector** and **resource adapter** interchangeably. Both terms refer to a resource adapter module that is developed in conformance with the Jakarta Connectors Specification.

If you installed the Web Profile, connector modules that use only outbound communication features and work-management that does not involve inbound communication features are supported. Other connector features are supported

> only in Full Profile.

For more information about connectors, see "Resource Adapters and Contracts" in the Jakarta EE Tutorial.

Connector Support in Payara Server

Payara Server supports the development and deployment of resource adapters that are compatible with the Jakarta Connector specification in the following versions:

- The Connector 1.0 specification defines the outbound connectivity system contracts between the resource adapter and Payara Server.
- The Connector 1.5 specification introduces major additions in defining system level contracts between the Payara Server and the resource adapter with respect to inbound connectivity, life cycle management, and thread management.
- The Connector 1.6 specification introduces further additions in defining system level contracts between the Payara Server and the resource adapter with respect to the following:

  Generic work context contract

  A generic contract that enables a resource adapter to control the execution context of a `Work` instance that it has submitted to Payara Server for execution. The `Generic` work contract provides the mechanism for a resource adapter to augment the runtime context of a `Work` instance with additional contextual information flown-in from the EIS. This contract enables a resource adapter to control, in a more flexible manner, the contexts in which the `Work` instances submitted by it are executed by the application server's `WorkManager`.

  Security work context

  A standard contract that enables a resource adapter to establish security information while submitting a `Work` instance for execution to a `WorkManager` and while delivering messages-to-message endpoints residing in the Payara Server. This contract provides a mechanism to support the execution of a `Work` instance in the context of an established identity. It also supports the propagation of user information or `Principal` information from an EIS to a `MessageEndpoint` during message inflow.

  Transaction context

  The transaction context contract between the resource adapter and the application server leverages the Generic Work Context mechanism by describing a standard `WorkContext`, the `TransactionContext`. It represents the standard interface a resource adapter can use to propagate transaction context information from the EIS to the application server.

- The Connector 2.0 specification moves the old Java Connectors Architecture specification (JCA) to Jakarta EE.
- The Connector 2.1 specification, as part of Jakarta EE 10 has introduced Java SE 11 as the minimum requirement to run Jakarta EE applications.

Connector Architecture for JMS and JDBC

In the Administration Console, connector, JMS, and JDBC resources are handled differently, but they

use the same underlying Connector architecture.

In Payara Server, all communication to an EIS, whether to a message provider or an RDBMS, happens through the Connector architecture. To provide JMS infrastructure to clients, Payara Server uses the **Open Message Queue** (OpenMQ) software. To provide JDBC infrastructure to clients, Payara Server uses its own JDBC system resource adapters. Payara Server automatically makes these system resource adapters available to any client that requires them.

For more information about JMS in the Payara Server, see Using the Java Message Service.

For more information about JDBC in the Payara Server, see Using the JDBC API for Database Access.

Connector Configuration

Payara Server does not need to use `sun-ra.xml` deployment descriptor, which previous versions used (as with GlassFish), to store server-specific deployment information inside a Resource Adapter Archive (RAR) file. (However, the `sun-ra.xml` file is still supported for backward compatibility.) Instead, the information is stored in the server configuration.

As a result, you can create multiple connector connection pools for a connection definition in a functional resource adapter instance, and you can create multiple user-accessible connector resources (that is, registering a resource with a JNDI name) for a connector connection pool.

Dynamic changes can be made to connector connection pools and the connector resource properties without restarting Payara Server.

Advanced Connector Configuration Options

Thread Associations

Connectors can submit work instances to Payara Server for execution. By default, Payara Server services work requests for all connectors from its default thread pool. However, you can associate a specific user-created thread pool to service work requests from a connector. A thread pool can service work requests from multiple resource adapters.

To create a thread pool:

- In the Administration Console, select *Thread Pools* under the relevant configuration.
- Use the `asadmin create-threadpool` command. For details, see the create-threadpool.

To associate a connector with a thread pool:

- In the Administration Console, open the Applications component and select Resource Adapter Configs. Specify the name of the thread pool in the Thread Pool ID field.
- Use the `--threadpoolid` option of the `asadmin create-resource-adapter-config` command. For details, see the create-resource-adapter-config.

If you create a resource adapter configuration for a connector module that is already deployed, the connector module deployment is restarted with the new

configuration properties.

Security Maps

Create a security map for a connector connection pool to map an application principal or a user group to a backend EIS principal. The security map is usually used in situations where one or more EIS back end principals are used to execute operations (on the EIS) initiated by various principals or user groups in the application.

To create or update security maps for a connector connection pool:

- In the Administration Console, open the *Resources* component, select *Connectors*, select *Connector Connection Pools*, then select the corresponding connector connection pool, and select the _ Security Maps_ tab.
- Use the `asadmin create-connector-security-map` command. For details, see the"create-connector-security-map.

If a security map already exists for a connector connection pool, the new security map is appended to the previous one. The connector security map configuration supports the use of the wildcard asterisk (*) to indicate all users or all user groups.

When an application principal initiates a request to an EIS, Payara Server first checks for an exact match to a mapped back end EIS principal using the security map defined for the connector connection pool. If there is no exact match, Payara Server uses the wild card character specification, if any, to determine the mapped back end EIS principal.

Work Security Maps

A work security map for a resource adapter maps an EIS principal or group to an application principal or group. A work security map is useful in situations where one or more application principals execute operations initiated by principals or user groups in the EIS. A resource adapter can have multiple work security maps. A work security map can map either principals or groups, but not both.

To create a work security map, use the `asadmin create-connector-work-security-map` command. For details, see the create-connector-work-security-map.

The work security map configuration supports the wildcard asterisk (*) character to indicate all users or all user groups. When an EIS principal sends a request to Payara Server, it will first check for an exact match to a mapped application principal using the work security map defined for the resource adapter.

If there is no exact match, Payara Server uses the wild card character specification, if any, to determine the application principal.

Overriding Configuration Properties

You can override the properties (`config-property` elements) specified in the `ra.xml` file of a resource adapter:

- In the Administration Console, open the *Resources* component and select *Resource Adapter Configs*. Create a new resource adapter configuration or select an existing one to edit. Then enter property names and values in the *Additional Properties* table.
- Use the `asadmin create-resource-adapter-config` command to create a configuration for a resource adapter. Use this command's `--property` option to specify a name-value pair for a resource adapter property. For details, see the create-resource-adapter-config.

You can specify configuration properties either before or after resource adapter deployment. If you specify properties after deploying the resource adapter, the existing resource adapter is restarted with the new properties.

You can also use token replacement for overriding resource adapter configuration properties in individual server instances when the resource adapter is deployed to a cluster. For example, for a property called `inboundPort`, you can assign the value `${inboundPort}`. You can then assign a different value to this system property for each server instance. Changes to system properties take effect upon server restart.

Testing a Connector Connection Pool

You can test a connector connection pool for usability in one of these ways:

- In the Administration Console, open the *Resources* component, open the *Connectors* component, select *Connection Pools*, and select the connection pool you want to test. Then select the *Ping* button in the top right corner of the page.
- Use the `asadmin ping-connection-pool` command. For details, see the ping-connection-pool.

Both these commands fail and display an error message unless they successfully connect to the connection pool.

You can also specify that a connection pool is automatically tested when created or reconfigured by setting the *Ping* attribute to `true` (the default is `false`) in one of the following ways:

- Enter a *Ping* value in the *Connector Connection Pools* page in the Administration Console.
- Specify the `--ping` option in the `asadmin create-connector-connection-pool` command. For more information, see the create-connector-connection-pool.

Flushing a Connector Connection Pool

Flushing a connector connection pool recreates all the connections in the pool and brings the pool to the steady pool size without the need for reconfiguring the pool. Connection pool reconfiguration can result in application redeployment, which is a time-consuming operation. Flushing destroys existing connections, and any existing transactions are lost and must be retired.

You can flush a connector connection pool in one of these ways:

- In the Administration Console, open the *Resources* component, open the *Connectors* component, select *Connection Pools*, and select the connection pool you want to flush. Then select the *Flush* button in the top right corner of the page.
- Use the `asadmin flush-connection-pool` command. For details, see the flush-connection-pool.

Handling Invalid Connections

If a resource adapter generates a `ConnectionErrorOccured` event, Payara Server considers the connection invalid and removes the connection from the connection pool. Typically, a resource adapter generates a `ConnectionErrorOccured` event when it finds a `ManagedConnection` object unusable. Reasons can be network failure with the EIS, EIS failure, fatal problems with the resource adapter, and so on.

If the `fail-all-connections` setting in the connection pool configuration is set to `true`, and a single connection fails, all connections are closed and recreated. If this setting is `false`, individual connections are recreated only when they are used. The default is `false`.

The `is-connection-validation-required` setting specifies whether connections have to be validated before being given to the application. If a resource's validation fails, it is destroyed, and a new resource is created and returned. The default value is `false`.

The `prefer-validate-over-recreate` property specifies that validating idle connections is preferable to closing them. This property has no effect on non-idle connections. If set to `true`, idle connections are validated during pool resizing, and only those found to be invalid are destroyed and recreated. If `false`, all idle connections are destroyed and recreated during pool resizing. The default value is `false`.

You can set the `fail-all-connections`, `is-connection-validation-required`, and `prefer-validate-over-recreate` configuration settings during creation of a connector connection pool. Or, you can use the `asadmin set` command to dynamically reconfigure a setting. For example:

```
asadmin set server.resources.connector-connection-pool.CCP1.fail-all-
connections="true"
asadmin set server.resources.connector-connection-pool.CCP1.is-connection-validation-
required="true"
asadmin set server.resources.connector-connection-pool.CCP1.property.prefer-validate-
over-recreate="true"
```

The interface ValidatingManagedConnectionFactory exposes the method `getInvalidConnections` to allow retrieval of the invalid connections. Payara Server checks if the resource adapter implements this interface, and if it does, invalid connections are removed when the connection pool is resized.

Setting the Shutdown Timeout

According to the Jakarta Connectors specification, while an application server shuts down, all resource adapters SHOULD be stopped. A resource adapter might hang during shutdown, since shutdown is typically a resource intensive operation. To avoid such a situation, you can set a timeout that aborts resource adapter shutdown if exceeded.

The default timeout is `30 seconds` per resource adapter module. To configure this timeout:

- In the Administration Console, select *Connector Service* under the relevant configuration and edit the *Shutdown Timeout* field.
- Use the following `asadmin set` command:

```
asadmin set server.connector-service.shutdown-timeout-in-seconds="num-secs"
```

Payara Server deactivates all message-driven bean deployments before stopping a resource adapter.

Specifying the Class Loading Policy

Use the `class-loading-policy` setting to determine which resource adapters are accessible to applications. Allowed values are:

`derived`
: Applications access resource adapters based on references in their deployment descriptors. These references can be `resource-ref`, `resource-env-ref`, `resource-adapter-mid`, or equivalent annotations.

`global`
: All stand-alone resource adapters are available to all applications.

To configure this setting, use the `asadmin set` command. For example:

```
asadmin set server.connector-service.class-loading-policy="global"
```

Using Last Agent Optimization of Transactions

Transactions that involve multiple resources or multiple participant processes are distributed or global transactions. A global transaction can involve one non-XA resource if last agent optimization is enabled. Otherwise, ALL resources must be XA-aware.

For more information about transactions in Payara Server, see Using the Transaction Service.

The Jakarta Connectors specification requires that if a resource adapter supports `XATransaction`, the `ManagedConnection` created from that resource adapter must support BOTH distributed and local transactions. Therefore, even if a resource adapter supports `XATransaction`, you can configure its connector connection pools as non-XA or without transaction support for better performance.

A non-XA resource adapter becomes the last agent in the transactions in which it participates.

The value of the connection pool configuration property `transaction-support` defaults to the value of the `transaction-support` property in the `ra.xml` file.

The connection pool configuration property can override the `ra.xml` file property if the transaction level in the connection pool configuration property is lower. If the value in the connection pool configuration property is higher, it is ignored.

Disabling Pooling for a Connection

To disable connection pooling, set the *Pooling* attribute to `false`. The default is `true`. You can enable or disable connection pooling in one of the following ways:

- Enter a *Pooling* value in the *Connector Connection Pools* page in the Administration Console.
- Specify the `--pooling` option in the `asadmin create-connector-connection-pool` command. For more information, see the create-connector-connection-pool.

Using Application-Scoped Connectors

You can define an application-scoped connector or other resource for an enterprise application, web module, EJB module, connector module, or application client module by supplying a `payara-resources.xml` or `glassfish-resources.xml` deployment descriptor file. For details, see "Application-Scoped Resources" in the Payara Server Application Deployment section.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

Inbound Communication Support

The Jakarta Connectors specification defines the transaction and message inflow system contracts for achieving inbound connectivity from an EIS. The message inflow contract also serves as a standard message provider's pluggability contract, thereby allowing various message providers to seamlessly plug in their products with any application server that supports the message inflow contract.

In the inbound communication model, the EIS initiates all communication to an application. An application can be composed of enterprise beans (session, entity, or message-driven beans), which reside in an EJB container.

Incoming messages are received through a message endpoint, which is a message-driven bean. This message-driven bean asynchronously consumes messages from a message provider. An application can also synchronously send and receive messages directly using messaging style APIs.

A resource adapter supporting inbound communication provides an instance of an `ActivationSpec` JavaBean class for each supported message listener type. Each class contains a set of configurable properties that specify endpoint activation configuration information during message-driven bean deployment. The required `config-property` element in the `ra.xml` file provides a list of configuration property names required for each activation specification.

An endpoint activation fails if the required property values are not specified. Values for the properties that are overridden in the message-driven bean's deployment descriptor are applied to the `ActivationSpec` JavaBean when the message-driven bean is deployed.

Administered objects can also be specified for a resource adapter, and these JavaBeans are specific to a messaging style or message provider. For example, some messaging styles may need applications to use special administered objects (such as `Queue` and `Topic` objects in JMS).

Applications use these objects to send and synchronously receive messages using connection objects using messaging style APIs. For more information about administered objects, see Using the Java Message Service.

Outbound Communication Support

The Jakarta Connectors specification defines the system contracts for achieving outbound connectivity from an EIS. A resource adapter supporting outbound communication provides an instance of a `ManagedConnectionFactory` JavaBean class. A `ManagedConnectionFactory` JavaBean represents outbound connectivity information to an EIS instance from an application.

Version 1.6 of the specification introduced a mechanism through which the transaction level of a `ManagedConnectionFactory` can be detected at runtime. During the configuration of a `ManagedConnectionFactory` in the Connector Connection Pools page in the Administration Console, the Administration Console can instantiate the `ManagedConnectionFactory` and show the level of transaction support.

The three levels are `no-tx`, `local-tx`, `xa-tx`. If a `ManagedConnectionFactory` returns `local-tx` as the level it can support, it is assumed that `xa-tx` is not supported, and the Administration Console shows only `no-tx` and `local-tx` as the available support levels.

Configuring a Message Driven Bean to Use a Resource Adapter

The Connectors specification's message inflow contract provides a generic mechanism to plug in a wide-range of message providers, including JMS, into a Java-EE-compatible application server. Message providers use a resource adapter and dispatch messages to message endpoints, which are implemented as message-driven beans.

The message-driven bean developer provides activation configuration information in the message-driven bean's `ejb-jar.xml` file. Configuration information includes messaging-style-specific configuration details, and possibly message-provider-specific details as well. The message-driven bean deployer uses this configuration information to set up the activation specification JavaBean. The activation configuration properties specified in `ejb-jar.xml` override configuration properties in the activation specification definition in the `ra.xml` file.

According to the Jakarta Enterprise Beans specification, the messaging-style-specific descriptor elements contained within the activation configuration element are not specified because they are specific to a messaging provider. In the following sample message-driven bean `ejb-jar.xml`, a message-driven bean has the following activation configuration property names: `destinationType`, `SubscriptionDurability`, and `MessageSelector`.

```
<!--  A sample MDB that listens to a JMS Topic -->
<!-- message-driven bean deployment descriptor -->
 <activation-config>
   <activation-config-property>
     <activation-config-property-name>
       destinationType
     </activation-config-property-name>
     <activation-config-property-value>
```

```
      jakarta.jms.Topic
    </activation-config-property-value>
  </activation-config-property>
  <activation-config-property>
    <activation-config-property-name>
      SubscriptionDurability
    </activation-config-property-name>
    <activation-config-property-value>
      Durable
    </activation-config-property-value>
  </activation-config-property>
  <activation-config-property>
    <activation-config-property-name>
      MessageSelector
    </activation-config-property-name>
    <activation-config-property-value>
      JMSType = 'car' AND color = 'blue'
    </activation-config-property-value>
  </activation-config-property>
 ...
 </activation-config>
```

When the message-driven bean is deployed, the value for the `resource-adapter-mid` element in the `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml` file is set to the resource adapter module name that delivers messages to the message endpoint (to the message-driven bean). In the following example, the `jmsra` JMS resource adapter, which is the bundled resource adapter for the Message Queue message provider, is specified as the resource adapter module identifier for the `SampleMDB` bean.

```
<payara-ejb-jar>
<enterprise-beans>
    <unique-id>1</unique-id>
    <ejb>
       <ejb-name>SampleMDB</ejb-name>
       <jndi-name>SampleQueue</jndi-name>
    <!-- JNDI name of the destination from which messages would be
         delivered from MDB needs to listen to -->
    ...
    <mdb-resource-adapter>
       <resource-adapter-mid>jmsra</resource-adapter-mid>
       <!-- Resource Adapter Module Id that would deliver messages to
            this message endpoint -->
       </mdb-resource-adapter>
    ...
 </ejb>
 ...
</enterprise-beans>
...
</payara-ejb-jar>
```

When the message-driven bean is deployed, Payara Server uses the `resourceadapter-mid` setting to associate the resource adapter with a message endpoint through the message inflow contract. This message inflow contract with the server gives the resource adapter a handle to the `MessageEndpointFactory` and the `ActivationSpec` JavaBean, and the adapter uses this handle to deliver messages to the message endpoint instances (which are created by the `MessageEndpointFactory`).

When a message-driven bean first created for use on Payara Server is deployed, the connector runtime transparently transforms the previous deployment style to the current connector-based deployment style. If the deployer specifies neither a `resource-adapter-mid` element nor the Message Queue resource adapter's activation configuration properties, the Connector runtime maps the message-driven bean to the `jmsra` system resource adapter and converts the JMS-specific configuration to the Message Queue resource adapter's activation configuration properties.

Developing OSGi-enabled Applications

This chapter describes the features and interfaces that Payara Server provides to develop OSGi-enabled Enterprise applications.

Overview of OSGi Application and Payara Server

Payara Server is a certified Jakarta EE implementation, so it provides the latest Jakarta EE APIs and frameworks. It is built using OSGi technology, and includes as its OSGi module management subsystem the Apache Felix OSGi framework, which is a fully-compliant implementation of the OSGi Service Platform R7 specification. Payara Server supports deployment of OSGi-based applications using this framework.

OSGi applications can make use of core as well as enterprise OSGi features. Payara Server makes available many of its Jakarta EE platform services, such as the transaction service, HTTP service, JDBC Service and JMS, as OSGi services. It also enables use of Jakarta EE programming model in OSGi applications, so enterprise Jakarta application developers can continue to leverage their existing skills in OSGi-based applications. See Benefits of Using OSGi in Enterprise Jakarta Applications for more information.

OSGi applications are deployed as one or more OSGi bundles, and the Payara Server deployment and administration infrastructure enables you to deploy and manage your OSGi bundles. This chapter classifies OSGi bundles into two categories based on the features they use:

Plain OSGi Application Bundles

Bundles that do not contain any Jakarta EE components. See Developing Plain OSGi Bundles.

Hybrid Application Bundles

Bundles that are an OSGi bundle as wells as a Jakarta EE module. At runtime, such modules have both an OSGi bundle context and a Jakarta EE context. Payara Server supports the following hybrid application bundles:

- Web Application Bundles (or WABs) , see Developing Web Application Bundles.

- EJB Application Bundles, see Developing EJB Application Bundles.

Benefits of Using OSGi in Enterprise Jakarta Applications

Enterprise applications typically need transactional, secured access to data stores, messaging systems and other such enterprise information systems, and have to cater to a wide variety of clients such as web browsers and desktop applications, and so on. Jakarta EE makes development of such applications easier with a rich set of APIs and frameworks. It also provides a scalable, reliable and easy to administer runtime to host such applications.

The OSGi platform complements these features with modularity. It enables applications to be separated into smaller, reusable modules with a well-defined and robust dependency specification.

A module explicitly specifies its capabilities and requirements. This explicit dependency specification encourages developers to visualize dependencies among their modules and help them make their modules highly cohesive and less coupled. The OSGi module system is dynamic: It allows modules to be added and removed at runtime.

OSGi has very good support for versioning too: It supports **package versioning** as well as **module versioning**. In fact, it allows multiple versions of the same package to coexist in the same runtime, thus allowing greater flexibility to deployers. The service layer of the OSGi platform encourages a more service-oriented approach to build complex systems.

The service-oriented approach and dynamic module system used together allow a system to be more agile during development as well as in production. It makes them better suited to run in a Platform-as-a-Service (PaaS) environment.

With Payara Server, you do not have to chose one of the two platforms. A hybrid approach like OSGi enabling your Jakarta EE applications allows new capabilities to applications hitherto unavailable to applications built using just one of the two platforms.

Developing OSGi Application Bundles for Payara Server

Payara Server enables interaction between OSGi components and Jakarta EE components.

OSGi services managed by the OSGi framework can invoke Jakarta EE components managed by the Jakarta EE container and vice versa. For example, developers can declaratively export EJBs as OSGi services without having to write any OSGi code. This allows any plain OSGi component, which is running without the Jakarta EE context, to discover the EJB and invoke it.

Similarly, Jakarta EE components can locate OSGi services provided by plain OSGi bundles and use them as well. Payara Server extends the Jakarta EE Context and Dependency Injection (CDI) framework to make it easier for Jakarta EE components to consume dynamic OSGi services in a type-safe manner.

Developing Plain OSGi Bundles

Jakarta EE components (like an EJB or Servlet) can look up Jakarta EE platform services using JNDI names in the associated Jakarta EE naming context. Such code can rely on the Jakarta EE container to inject the required services as well. Unfortunately, neither of them works when the code runs outside a Jakarta EE context.

An example of such code is the `BundleActivator` of an OSGi bundle. For such code to access Jakarta EE platform services, Payara Server makes key services and resources of the underlying Jakarta EE platform available as OSGi services.

Thus, an OSGi bundle deployed in Payara Server can access these services using OSGi Service look-up APIs or by using a white board pattern. The following Jakarta EE services are available as OSGi services:

- HTTP Service
- Transaction Service
- JDBC Data Source Service
- JMS Resource Service

HTTP Service

The Payara Server web container is made available as a service for OSGi users who do not use OSGi Web Application Bundles (WABs).

This service is made available using the standard OSGi/HTTP service specification, which is a lightweight API that predates the concept of a web application as we know it today.

This simple API allows users to register servlets and static resources dynamically and draw a boundary around them in the form of a `HttpContext`.

This simple API can be used to build feature-rich web application, such as the Felix Web Console for example.

The Payara Server web container has one or more **virtual servers**. A virtual server has one or more web application deployed in it. Each web application has a distinct context path.

Each virtual server has a set of HTTP listeners. Each HTTP listener listens on a particular port. When multiple virtual servers are present, one of them is treated as the default virtual server. Every virtual server comes configured with a default web application. The default web application is used to serve static content from the `docroot` directory of a Payara Server domain. This default web application uses `/` as the context path. A web application contains static and dynamic resources. Each virtual server is mapped to an `org.osgi.services.http.HttpService` instance. When there are multiple virtual servers present, there will be multiple occurrences of `HttpService` registered in the service registry.

In order to distinguish one service from another, each service is registered with a service property named `VirtualServer`, whose value is the name of the virtual server.

The service corresponding to default virtual server has the highest ranking, so when looking up a service of type `HttpService` without any additional criteria returns the `HttpService` corresponding to the default virtual server. In a typical installation, the default virtual server is configured to listen on port `8080` for the HTTP protocol and port `8181` for the HTTPS protocol.

The context path `/` is reserved for the default web application. Every resource and servlet registered using the `registerResource()` and `registerServlet()` methods of `HttpService` are made

available under a special context path named `/osgi` in the virtual server. The `/osgi` context path can be changed to some other value by setting an appropriate value in the OSGi configuration property or in a system property called `org.glassfish.osgihttp.ContextPath`.

For example, a `HelloWorldServlet` component will be available at `http://localhost:8080/osgi/helloworld` when the following code is executed:

```
HttpService httpService = getHttpService(); // Obtain HttpService
httpService.registerServlet(httpService.registerServlet("/helloworld", new
HelloWorldServlet(), null, ctx);
```

Transaction Service

The Jakarta Transaction API (JTA) defines three interfaces to interact with the transaction management system: `UserTransaction`, `TransactionManager`, and `TransactionSynchronizationRegistry`. They all belong to the `jakarta.transaction` package. `TransactionManager`and `TransactionSynchronizationRegistry` are intended for system level code, such as a persistence provider. Whereas, `UserTransaction` is the entity that you should use to control user-managed transactions.

All the objects of the underlying JTA layer are made available in the OSGi service registry using the following service interfaces:

- `jakarta.transaction.UserTransaction`
- `jakarta.transaction.TransactionManager`
- `jakarta.transaction.TransactionSynchronisationRegistry`

There is no additional service property associated with them. Although `UserTransaction` appears to be a singleton, in reality any call to it gets rerouted to the actual transaction associated with the calling thread. Code that runs in the context of a Jakarta EE component typically gets a handle on `UserTransaction` by doing a JNDI lookup in the component naming context or by using injection, as shown here:

```
var utx = (UserTransaction)(new InitialContext().lookup("java:comp/UserTransaction"));
```

or

```
@Resource
UserTransaction utx;
```

When certain code (such as an OSGi Bundle Activator), which does not have a Jakarta EE component context, wants to get hold of `UserTransaction`, or any of the other JTA artifacts, then they can look it up in the service registry. Here is an example of such code:

```
BundleContext context; // An OSGi context must be present
```

```
var txRef = context.getServiceReference(UserTransaction.class.getName());
var utx = (UserTransaction)context.getService(txRef);
```

JDBC Data Source Service

Any JDBC data source created in Payara Server is automatically made available as an OSGi Service; therefore, OSGi bundles can track availability of JDBC data sources using the `ServiceTracking` facility of the OSGi platform.

The life of the OSGi service matches that of the underlying data source created in Payara Server.

Payara Server registers each JDBC data source as an OSGi service with `objectClass = "javax.sql.DataSource"` and a service property called `jndi-name`, which is set to the JNDI name of the data source.

Here is a code sample that looks up a data source service:

```
@Inject
@OSGiService(filter = "(jndi-name=jdbc/MyDS)")
private DataSource ds;
```

JMS Resource Service

Like JDBC data sources, JMS administered objects, such as destinations and connection factories, are also automatically made available as OSGi services.

Their service mappings are as follows.

JMS Object	Service Interface	Service Properties	Comments
JMS Queue destination	`jakarta.jms.Queue`	`jndi-name`	`jndi-name` is set to the JNDI name of the queue
JMS Topic destination	`jakarta.jms.Topic`	`jndi-name`	`jndi-name` is set to the JNDI name of the topic
JMS connection factory	• `jakarta.jms.QueueConnectionFactory` • `jakarta.jms.TopicConnectionFactory` • `jakarta.jms.ConnectionFactory`	`jndi-name`	`jndi-name` is set to the JNDI name of the topic. The actual service interface depends on which type of connection factory was created.

Developing Web Application Bundles

When a web application is packaged and deployed as an OSGi bundle, it is called a **Web Application Bundle (WAB)**. WAB support is based on the OSGi Web Application specification, which is part of the OSGi Service Platform, Enterprise Specification, Release 7. A WAB is packaged as an OSGi bundle, so all the OSGi packaging rules apply to WAB packaging.

When a WAB is not packaged like a WAR, the OSGi Web Container of Payara Server maps the WAB to the hierarchical structure of web application using the following rules:

- The root of the WAB corresponds to the `docroot` of the web application.
- Every JAR in the `Bundle-ClassPath` attribute of the WAB is treated like a JAR located in `WEB-INF/lib/.`
- Every directory except "." in the `Bundle-ClassPath` attribute of the WAB is treated like the `WEB-INF/classes/.` directory.
- A `Bundle-ClassPath` entry of type "." is treated as if the entire WAB is a JAR located in `WEB-INF/lib/.`
- `Bundle-ClassPath` includes the `Bundle-ClassPath` entries of any attached fragment bundles.

We strongly recommend that you package the WAB exactly like a WAR, with only additional OSGi metadata to prevent triggering any conflicts with the rules mentioned above.

WAB Metadata

In addition to the standard OSGi metadata, the main attributes of the `META-INF/MANIFEST.MF` of the WAB must have an additional attribute called `Web-ContextPath`.

The `Web-ContextPath` attribute specifies the value of the context path of the web application. Since the root of a WAB is mapped to the `docroot` of the web application, it should not be used in the `Bundle-ClassPath` attribute.

Moreover, `WEB-INF/classes/` should be specified ahead of `WEB-INF/lib/` in the `Bundle-ClassPath` in order to be compliant with the search order used for traditional WAR files.

Assuming the WAB is structured as follows:

```
foo.war/
   index.html
   foo.jsp
   WEB-INF/classes/
      foo/BarServlet.class
   WEB-INF/lib/lib1.jar
   WEB-INF/lib/lib2.jar
```

Then the OSGi metadata for the WAB as specified in `META-INF/MANIFEST.MF` of the WAB would appear as follows:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-SymbolicName: com.acme.foo
Bundle-Version: 1.0
Bundle-Name: Foo Web Application Bundle Version 1.0
Import-Package: jakarta.servlet; jakarta.servlet.http, version=[3.0, 4.0, 5.0)
Bundle-ClassPath: WEB-INF/classes, WEB-INF/lib/lib1.jar, WEB-INF/lib/lib2.jar
Web-ContextPath: /foo
```

How WABs Consume OSGi Services

Since a WAB has a valid `Bundle-Context`, it can consume OSGi services. Although you are free to use any OSGi API to locate OSGi services, Payara Server makes it easy for WAB users to use OSGi services by virtue of extending the Context and Dependency Injection (CDI) framework. Here's an example of the injection of an OSGi Service into a Servlet:

```
@WebServlet
public class MyServlet extends HttpServlet {

    @Inject
    @OSGiService(dynamic=true)
    FooService fooService;
}
```

OSGi CDI Extension for WAB

Payara Server includes a CDI extension that enables web applications, such as servlets, that are part of WABs to express a type-safe dependency on an OSGi service using CDI APIs.

An OSGi service can be provided by any OSGi bundle without any knowledge of Jakarta EE/CDI, and they are allowed to be injected transparently in a type-safe manner into a web application.

A custom CDI Qualifier, `@org.glassfish.osgicdi.OSGiService`, is used by the component to represent dependency on an OSGi service. The qualifier has additional metadata to customize the service discovery and injection behavior.

The following `@OsgiService` attributes are currently available:

- `serviceCriteria` — An LDAP filter query used for service selection in the OSGi service registry.
- `waitTimeout` — Waits the specified duration for a service that matches the criteria specified to appear in the OSGi service registry.
- `dynamic` — Dynamically obtain a service reference (`true`/`false`).

Since OSGi services are dynamic, they may not match the life cycle of the application component that has injected a reference to the service. Through the `dynamic` attribute, you can indicate that a service reference can be obtained dynamically or not.

> For stateless or idempotent services, a dynamic reference to a service implementation would be useful. The container then injects a proxy to the service and dynamically switches to an available implementation when the current service reference is invalid.

Example

In this example, Bundle B0 defines a service contract called `com.acme.Foo` and exports the `com.acme` package for use by other bundles.

Bundle B1 in turn provides a service implementation, `FooImpl`, of the `com.acme.Foo` interface. It then registers the service FooImpl service with the OSGi service registry with `com.acme.Foo` as the service interface.

Bundle B2 is a hybrid application bundle that imports the `com.acme` package. It has a component called `BarServlet` that expresses a dependency to `com.acme.Foo` by adding a field/setter method and qualifies that injection point with a `@OsgiService` annotation.

For instance, `BarServlet` looks like this:

```
@Servlet
public class BarServlet extends HttpServlet{

    @Inject
    @OSGiService(dynamic=true)
    private com.acme.Foo f;
}
```

EJB Application Bundles

Another type of hybrid application bundle is the EJB Application Bundle. When an EJB Jar is packaged with additional OSGi metadata and deployed as an OSGi bundle it is called an EJB Application Bundle.

Payara Server supports only packaging the OSGi bundle as a simple JAR file with the required OSGi metadata, just as you would package an `ejb-jar` file.

Required EJB Metadata

An EJB Application Bundle must have a manifest metadata attribute called `Export-EJB` in order to be considered as an EJB Bundle. Here's an example of an EJB Application Bundle with this metadata attribute:

```
myEjb.jar/
   com/acme/Foo
   com/acme/impl/FooEJB
   META-INF/MANIFEST.MF
```

And here's how its Manifest entries look like:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-SymbolicName: com.acme.foo EJB bundle
Bundle-Version: 1.0.0.BETA
Bundle-Name: com.acme.foo EJB bundle version 1.0.0.BETA
Export-EJB: ALL
Export-Package: com.acme; version=1.0
Import-Package: jakarta.ejb; version=[3.0, 4.0), com.acme; version=[1.0, 1.1)
```

How EJB Bundles Consume OSGi Services

Since an EJB has a valid Bundle-Context, it can consume OSGi services. Although you are free to use any OSGi API to locate OSGi services, Payara Server makes it easy to use OSGi services by virtue of extending the Context and Dependency Injection (CDI) framework.

Here's an example of injection of an OSGi Service into a stateless bean:

```
@Stateless
public class MyEJB {

    @Inject
    @OSGiService(dynamic=true)
    Foo foo;
}
```

Using the OSGi CDI Extension With EJB Bundles

Payara Server includes a CDI extension that enables EJB application bundles to express a type-safe dependency on an OSGi Service using CDI APIs.

An OSGi service can be provided by any OSGi bundle without any knowledge of Jakarta EE/CDI, and they are allowed to be injected transparently in a type-safe manner into an EJB bundle.

A custom CDI Qualifier, `@org.glassfish.osgicdi.OSGiService`, is used by the component to represent dependency on an OSGi service. The qualifier has additional metadata to customize the service discovery and injection behavior.

The following `@OsgiService` attributes are currently available:

- `serviceCriteria` — An LDAP filter query used for service selection.
- `waitTimeout` — Waits for specified duration for a service to appear in the OSGi service registry.
- `dynamic` — Dynamically obtain a service reference (`true`/`false`).

Deploying OSGi Bundles in Payara Server

For instruction on deploying OSGi bundle, see "OSGi Bundle Deployment Guidelines" in the Payara

Server Application Deployment section.

Using the JDBC API for Database Access

This chapter describes how to use the Java Database Connectivity (JDBC) API for database access with Payara Server.

This chapter also provides high level JDBC implementation instructions for servlets and EJB components deployed in Payara Server.

Payara Server does not support connection pooling or transactions for an application's database access if it does not use standard Jakarta EE `DataSource` objects.

Statements

Using an Initialization Statement

You can specify a SQL statement that executes each time a **physical** connection to the database is created (not reused) from a JDBC connection pool. This is useful for setting request or session specific properties and is suited for homogeneous requests in a single application.

Set the **Init SQL** attribute of the JDBC connection pool to the SQL string to be executed in one of the following ways:

- Enter an *Init SQL value* in the *Edit Connection Pool Advanced Attributes* page in the Administration Console.
- Specify the `--initsql` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `init-sql` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.DerbyPool.init-sql="sql-string"
```

Setting a Statement Timeout

An abnormally long-running SQL query executed by an application may leave it in a hanging state unless a timeout is explicitly set on the statement. Setting a statement timeout guarantees that all queries automatically time out if not completed within the specified period.

When statements are created, the `queryTimeout` is set according to the statement timeout setting. This works only when the underlying JDBC driver supports `queryTimeout` for `Statement`, `PreparedStatement`, `CallableStatement`, and `ResultSet`.

You can specify a statement timeout in the following ways:

- Enter a *Statement Timeout* value in the *Edit Connection Pool Advance Attributes* page in the Administration Console.
- Specify the `--statementtimeout` option in the `asadmin create-jdbc-connection-pool` command.

Statement Leak Detection and Leaked Statement Reclamation

If SQL statements are not closed by an application after use, it is possible for the application to run out of cursors. Enabling statement leak detection causes statements to be considered as leaked if they are not closed within a specified period. Additionally, leaked statements can be reclaimed automatically.

To enable statement leak detection, set *Statement Leak Timeout In Seconds* for the JDBC connection pool to a positive, nonzero value in one of the following ways:

- Specify the `--statementleaktimeout` option in the `create-jdbc-connection-pool` subcommand. For more information, see `create-jdbc-connection-pool`.
- Specify the `statement-leak-timeout-in-seconds` option in the `set` subcommand. For example:

```
asadmin set resources.jdbc-connection-pool.pool-name.statement-leak-timeout-in-
seconds=300
```

When selecting a value for *Statement Leak Timeout In Seconds*, make sure that:

- It is less than the *Connection Leak Timeout*; otherwise, the connection could be closed before the statement leak is recognized.
- It is greater than the *Statement Timeout*; otherwise, a long-running query could be mistaken as a statement leak.

After enabling statement leak detection, enable leaked statement reclamation by setting the *Reclaim Leaked Statements* setting for the JDBC connection pool to a `true` value in one of the following ways:

- Specify the `--statementleakreclaim=true` option in the `create-jdbc-connection-pool` subcommand. For more information, see `create-jdbc-connection-pool`.
- Specify the `statement-leak-reclaim` option in the `set` subcommand. For example:

```
asadmin set resources.jdbc-connection-pool.pool-name.statement-leak-reclaim=true
```

Statement Caching

Statement caching stores statements, prepared statements, and callable statements that are executed repeatedly by applications in a cache, thereby improving performance. Instead of the statement being prepared each time, the cache is searched for an existing match. The overhead of parsing and creating new statements each time is eliminated.

Statement caching is usually a feature of the JDBC driver. Payara Server provides caching for drivers that do not support caching, so consider using this feature after studying whether your JDBC driver supports statement caching.

To enable this feature, set the *Statement Cache Size* for the JDBC connection pool in one of the following ways:

- Enter a *Statement Cache Size* value in the *Edit Connection Pool Advanced Attributes* page in the Administration Console.
- Specify the `--statementcachesize` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `statement-cache-size` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.DerbyPool.statement-cache-
size=10
```

By default, this attribute is set to zero and the statement caching is turned off.

To enable statement caching, you can set any positive nonzero value. The built-in cache eviction strategy is **LRU-based** (Least Recently Used).

When a connection pool is flushed, the connections in the statement cache are recreated.

SQL Trace Listeners

Payara Server provides support for custom SQL Trace Listeners. A **SQL Trace Listener** is registered against a data source and is called after each method call made on the JDBC connection pool.

SQL Trace Listeners allows developers to track all calls to the database and can be used to develop custom auditing, error handling or monitoring components. SQL Trace Listeners can be enabled globally on a data source if the class that implements it is on the server's *classpath*, or can be enabled on application specific data sources by including them in the application's WAR or EAR.

SQL Trace listener Interface

The SQL Trace Listener interface is shown below:

```
public interface SQLTraceListener {
    /**
     * Notify listeners with SQL trace information.
     * @param record SQLTraceRecord that has information related
     * to the SQL operation
     */
    public void sqlTrace(SQLTraceRecord record);

}
```

To write a custom trace listener you need to implement the interface and override the `sqlTrace` method. The `SQLTraceRecord` object contains information about the executed call to the JDBC connection pool. The following is the list of properties that can be queried using their respective **getter** methods:

```
/**
 * Thread ID from which SQL statement originated.
 */
```

```
private long threadID;

/**
 * Thread Name from which SQL statement originated.
 */
private String threadName;

/**
 * Pool Name in which the SQL statement is executed.
 */
private String poolName;

/**
 * Type of SQL query. Could be PreparedStatement, CallableStatement or
 * other object types.
 */
private String className;

/**
 * Method that executed the query.
 */
private String methodName;

/**
 * Time of execution of query.
 */
private long timeStamp;

/**
 * Parameters of the method that executed the SQL query. Includes information
 * like SQL query, arguments and so on.
 */
private Object[] params;
```

SQL Trace Listener Example

The following code fragment illustrates an example SQL trace listener that just logs the executed call to the server's log file:

```
public class SQLTraceLogger implements SQLTraceListener {

    private static Logger _logger = initLogger();

    private static Logger initLogger() {
        _logger = LogDomains.getLogger(SQLTraceLogger.class,
LogDomains.SQL_TRACE_LOGGER);
        return _logger;
    }

    public SQLTraceLogger() {
```

```
    }

    public void sqlTrace(SQLTraceRecord record) {
        _logger.log(Level.FINE, record.toString());
    }
}
```

SQL Trace Listener Logger

Payara Server provides an SQL tracing logger to log the SQL operations in the form of `SQLTraceRecord` objects in the `server.log` file. The module name under which the SQL operation is logged is `javax.enterprise.resource.sqltrace`.

SQL traces are logged as `FINE` messages along with the module name to enable easy filtering of the SQL logs. A sample SQL trace record looks like this:

```
[#|2009-11-27T15:46:52.202+0530|FINE|Payara Server main-
7|jakarta.enterprise.resource.sqltrace.com.sun.gjc.util
|_ThreadID=29;_ThreadName=Thread-
1;ClassName=com.sun.gjc.util.SQLTraceLogger;MethodName=sqlTrace;
|ThreadID=77 | ThreadName=p: thread-pool-1; w: 6 | TimeStamp=1259317012202
| ClassName=com.sun.gjc.spi.jdbc40.PreparedStatementWrapper40 |
MethodName=executeUpdate
| arg[0]=insert into table1(colName) values(100) | arg[1]=columnNames | |#]
```

This trace shows that an `executeUpdate(String sql, String columnNames)` operation is being done.

When SQL statement tracing is enabled and JDBC connection pool monitoring is enabled, Payara Server maintains a tracing cache of recent queries and their frequency of use. The following JDBC connection pool properties can be configured to control this cache and the monitoring statistics available from it:

`time-to-keep-queries-in-minutes`

Specifies how long in minutes to keep a query in the tracing cache, tracking its frequency of use. The default value is `5` minutes.

`number-of-top-queries-to-report`

Specifies how many of the most used queries, in frequency order, are listed the monitoring statistic. The default value is `10` queries.

Set these parameters in one of the following ways:

- Add them as custom properties in the *Edit JDBC Connection Pool Properties* page in the Administration Console.
- Specify them using the `--property` option in the `create-jdbc-connection-pool` subcommand. For more information, see `create-jdbc-connection-pool`.
- Set them using the `set` subcommand. For example:

```
asadmin set resources.jdbc-connection-pool.pool-name.property.time-to-keep-queries-
in-minutes=10
```

Configuring SQL Trace Listeners

To configure the listeners used by a connection pool set the *SQL Trace Listeners* attribute to a comma-separated list of trace listener implementation classes in one of the following ways:

- Enter an *SQL Trace Listeners* value in the *Edit Connection Pool Advanced Attributes* page in the Administration Console.
- Specify the `--sqltracelisteners` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `sql-trace-listeners` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.DerbyPool.sql-trace-
listeners=listeners
```

To make custom implementations of this interface available to Payara Server, place the implementation classes in `as-install/lib`.

More information on how to configure SQL Trace listeners can be read in the JDBC Connection Pool configuration of Payara Server's administration section.

Connections

Transparent Pool Reconfiguration

When the properties or attributes of a JDBC connection pool are changed, the connection pool is destroyed and re-created. Normally, applications using the connection pool must be redeployed as a consequence. This restriction can be avoided by enabling transparent JDBC connection pool reconfiguration. When this feature is enabled, applications do not need to be redeployed. Instead, requests for a new connections are blocked until the reconfiguration operation completes.

Connection requests from any "in-flight" transactions are served using the old pool configuration to complete the transaction. Then, connections are created using the pool's new configuration, and any blocked connection requests are served with connections from the re-created pool.

To enable transparent JDBC connection pool reconfiguration, set the `dynamic-reconfiguration-wait-timeout-in-seconds` property of the JDBC connection pool to a positive, nonzero value in one of the following ways:

- Add it as a property in the *Edit JDBC Connection Pool Properties* page in the Administration Console.
- Specify it using the `--property` option in the `create-jdbc-connection-pool` subcommand. For more information, see `create-jdbc-connection-pool`.
- Set it using the `set` subcommand. For example:

```
asadmin set resources.jdbc-connection-pool.pool-name.property.dynamic-
reconfiguration-wait-timeout-in-seconds=15
```

This property specifies the time in seconds to wait for in-use connections to close and in-flight transactions to complete. Any connections in use or transaction in flight past this time must be retried.

Disabling Pooling

To disable connection pooling, set the *Pooling* attribute to false. The default is `true`. You can enable or disable connection pooling in one of the following ways:

- Enter a Pooling value in the *Edit Connection Pool Advanced Attributes* page in the Administration Console.
- Specify the `--pooling` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `pooling` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.H2Pool.pooling=false
```

The `pooling` option and the system property `com.sun.enterprise.connectors.SwitchoffACCConnectionPooling`, which turns off connection pooling in the Application Client Container, do not affect each other.

An exception is thrown if `associate-with-thread` is set to `true` and pooling is disabled. An exception is thrown if you attempt to flush a connection pool when pooling is disabled. A warning is logged if the following attributes are used, because they are useful only in a pooled environment:

- `connection-validation`
- `validate-atmost-once-period`
- `match-connections`
- `max-connection-usage`
- `idle-timeout`

Associating Connections with Threads

To associate connections with a thread, set the *Associate With Thread* attribute to `true`. The default is `false`. A `true` setting allows connections to be saved as `ThreadLocal` in the calling thread.

Connections get reclaimed only when the calling thread dies or when the calling thread is not in use and the pool has run out of connections.

If the setting is `false`, the thread must obtain a connection from the pool each time the thread requires a connection.

The *Associate With Thread* attribute associates connections with a thread such that when the same

thread is in need of connections, it can reuse the connections already associated with that thread. In this case, the overhead of getting connections from the pool is avoided.

However, when this value is set to `true`, you should verify that the value of the *Max Pool Size* attribute is comparable to the *Max Thread Pool Size* attribute of the thread pool. If the *Max Thread Pool Size* value is much higher than the *Max Pool Size* value, a lot of time is spent associating connections with a new thread after dissociating them from an older one. Use this attribute in cases where the thread pool should reuse connections to avoid this overhead.

You can set the Associate With Thread attribute in the following ways:

- Enter an *Associate With Thread* value in the *Edit Connection Pool Advanced* Attributes page in the Administration Console.
- Specify the `--associatewiththread` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `associate-with-thread` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.DerbyPool.associate-with-
thread=true
```

Custom Connection Validation

You can specify a custom implementation for *Connection Validation* that is faster or optimized for a specific database.

Set the *Validation Method* attribute to the value `custom-validation`.

Payara Server provides a public interface, `org.glassfish.api.jdbc.ConnectionValidation`, which you can implement to plug in your custom implementation.

The *Validation Classname* attribute, specifies the fully qualified name of the class that implements the `ConnectionValidation` interface.

The *Validation Classname* attribute is required if *Connection Validation* is enabled and *Validation Method* is set to *Custom Validation*.

To enable this feature, set *Connection Validation*, *Validation Method*, and *Validation Classname* for the JDBC connection pool in one of the following ways:

- Enter *Connection Validation*, *Validation Method*, and *Validation Classname* values in the *Edit Connection Pool Advanced Attributes* page in the Administration Console.

  You can select from among validation class names for common databases in the *Validation Classname* field.

- Specify the `--isconnectionvalidatereq`, `--validationmethod`, and `--validationclassname` options in the `asadmin create-jdbc-connection-pool` command.
- Specify the `is-connection-validation-required`, `connection-validation-method`, and `validation-classname` options in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.MyPool.is-connection-validation-
required=true
asadmin set domain1.resources.jdbc-connection-pool.MyPool.connection-validation-
method=custom-validation
asadmin set domain1.resources.jdbc-connection-pool.MyPool.validation-
classname=impl-class
```

By default, optimized validation mechanisms are provided for DB2, H2, Apache Derby, MSSQL, MySQL, Oracle, PostgreSQL and Sybase databases.

Additionally, for JDBC 4.0 compliant database drivers, a validation mechanism is provided that uses the `Connection.isValid(0)` implementation.

Sharing Connections

When multiple connections acquired by an application use the same JDBC resource, the connection pool provides connection sharing within the same transaction scope.

For example, suppose **Bean A** starts a transaction and obtains a connection, then calls a method in **Bean B**. If **Bean B** acquires a connection to the same JDBC resource with the same sign-on information, and if **Bean A** completes the transaction, the connection can be shared.

Connections obtained through a resource are shared only if the resource reference declared by the Jakarta EE component allows it to be shareable. This is specified in a component's deployment descriptor by setting the `res-sharing-scope` element to `Shareable` for the particular resource reference.
To turn off connection sharing, set `res-sharing-scope` to `Unshareable`.

For general information about connections and JDBC URLs, see "Administering Database Connectivity" in the Payara Server General Administration section.

Marking Bad Connections

The default `DataSource` implementation in Payara Server provides a `markConnectionAsBad` method. A marked bad connection is removed from its connection pool when it is closed and is not returned to the pool. The method signature is as follows:

```
public class Datasource{

    public void markConnectionAsBad(java.sql.Connection connection){
    }
}
```

For example:

```
public class ApplicationComponent{
```

```
    public void operation(){
        var ds = (com.sun.appserv.jdbc.DataSource)context.lookup("jdbc/myDataSource");
        try(var con = ds.getConnection(); //Connection will be destroyed during close.
            var stmt = con.createStatement()){
           stmt.executeUpdate("Update");
        }
        catch (BadConnectionException e){
           ds.markConnectionAsBad(con);
        }
    }
}
```

Handling Invalid Connections

If a `ConnectionErrorOccured` event occurs, Payara Server considers the connection invalid and removes the connection from the connection pool. Typically, a JDBC driver generates a `ConnectionErrorOccured` event when it finds a `ManagedConnection` object unusable. Reasons can be database failure, network failure with the database, fatal problems with the connection pool, and so on.

If the `fail-all-connections` setting in the connection pool configuration is set to `true`, and a single connection fails, all connections are closed and recreated. If this setting is `false`, individual connections are recreated only when they are used. The default is `false`.

The `is-connection-validation-required` setting specifies whether connections have to be validated before being given to the application. If a resource's validation fails, it is destroyed, and a new resource is created and returned. The default is `false`.

The `prefer-validate-over-recreate` property specifies that validating idle connections is preferable to closing them. This property has no effect on non-idle connections. If set to `true`, idle connections are validated during pool resizing, and only those found to be invalid are destroyed and recreated.

If `false`, all idle connections are destroyed and recreated during pool resizing. The default is `false`.

You can set the `fail-all-connections`, `is-connection-validation-required`, and `prefer-validate-over-recreate` configuration settings during creation of a JDBC connection pool. Or, you can use the `asadmin set` command to dynamically reconfigure these settings. For example:

```
asadmin set server.resources.jdbc-connection-pool.MyPool.fail-all-connections="true"
asadmin set server.resources.jdbc-connection-pool.MyPool.is-connection-validation-
required="true"
asadmin set server.resources.jdbc-connection-pool.MyPool.property.prefer-validate-
over-recreate="true"
```

The interface `ValidatingManagedConnectionFactory` exposes the method `getInvalidConnections` to allow retrieval of the invalid connections.
Payara Server checks if the JDBC driver implements this interface, and if it does, invalid connections are automatically removed when the connection pool is

> resized.

Connection Wrapping

Wrapping Connections

If the *Wrap JDBC Objects* option is `true` (the default), wrapped JDBC objects are returned for `Statement`, `PreparedStatement`, `CallableStatement`, `ResultSet`, and `DatabaseMetaData`.

This option ensures that `Statement.getConnection()` is the same as `DataSource.getConnection()`. Therefore, this option should be `true` when both `Statement.getConnection()` and `DataSource.getConnection()` are done.

You can specify the *Wrap JDBC Objects* option in the following ways:

- Check or uncheck the *Wrap JDBC Objects* box on the *Edit Connection Pool Advanced Attributes* page in the Administration Console.
- Specify the `--wrapjdbcobjects` option in the `asadmin create-jdbc-connection-pool` command.

Obtaining a Physical Connection From a Wrapped Connection

The default `DataSource` implementation in Payara Server provides a `getConnection` method that retrieves the JDBC driver's `SQLConnection` from Payara Server's `Connection` wrapper.

The method signature is as follows:

```
import java.sql.Connection;

public class Connection{
    public Connection getConnection(Connection con) throws java.sql.SQLException;
}
```

For example:

```
import java.sql.Connection;

public class MyComponent{

    public void operation(){
        var ctx = new InitialContext();
        var ds = (com.sun.appserv.jdbc.DataSource)ctx.lookup("jdbc/MyBase");

        try(var con = ds.getConnection(); //return wrapped connection to pool on
close.
            var drivercon = ds.getConnection(con)){
            // Do db operations.
        }
    }
```

```
}
```

Using the `Connection.unwrap()` Method

Using the `Connection.unwrap()` method on a vendor-provided interface returns an object or a wrapper object implementing the vendor-provided interface, which the application can make use of to do vendor-specific database operations. Use the `Connection.isWrapperFor()` method on a vendor-provided interface to check whether the connection can provide an implementation of the vendor-provided interface.

Check your corresponding JDBC driver vendor's documentation for information on these interfaces.

Allowing Non-Component Callers

You can allow non-Jakarta-EE components, such as third party persistence managers, to use a managed JDBC connection pool.

The returned connection is automatically enlisted with the transaction context obtained from the transaction manager. Standard Jakarta EE components can also use such pools.

Connections obtained by non-component callers are not automatically closed at the end of a transaction by the container. They must be explicitly closed by the caller.

You can enable non-component callers in the following ways:

- Check the *Allow Non Component* Callers box on the *Edit Connection Pool Advanced Attributes* page in the Administration Console. The default is `false`.
- Specify the `--allownoncomponentcallers` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `allow-non-component-callers` option in the `asadmin set` command. For example:

  ```
  asadmin set domain1.resources.jdbc-connection-pool.DerbyPool.allow-non-component-
  callers=true
  ```

- Create a JDBC resource with a `__pm` suffix.

Accessing a `DataSource` using the `Synchronization.beforeCompletion()` method requires setting *Allow Non Component Callers* to `true`. For more information about the Transaction Synchronization Registry, see The Transaction Manager, the Transaction Synchronization Registry, and `UserTransaction`.

Using Application-Scoped Resources

You can define an application-scoped database or other resources for an enterprise application, web module, EJB module, connector module, or application client module by supplying a `payara-`

`resources.xml` deployment descriptor file.

For more details, see "Application-Scoped Resources" in the Payara Server Application Deployment section.

JDBC Development Guidelines

In Jakarta EE applications and above, a JDBC data source can be deployed by adding the `@DataSourceDefinition` annotation to a managed component (like and `@Stateless` EJB bean for example). The **Log JDBC Calls** setting can be configured using this annotation as well:

```
@DataSourceDefinition(
    name = "java:app/MyApp/MyDS",
    className = "org.h2.jdbcx.JdbcDataSource",
    url = "jdbc:h2:mem:test",
    properties = {"fish.payara.log-jdbc-calls=true"})
public class JDBCComponent{

}
```

The Data source definition can also be added to a deployment descriptor of an application, for example in the `web.xml` standard deployment descriptor:

```
<data-source>
   <name>java:global/ExampleDataSource</name>
   <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
   <server-name>localhost</server-name>
   <port-number>3306</port-number>
   <database-name>mysql</database-name>
   <user>test</user>
   <password>test</password>
   <!-- Example of how to use a Payara Server specific custom connection pool setting
-->
   <property>
       <name>fish.payara.log-jdbc-calls</name>
       <value>true</value>
   </property>
</data-source>
```

Or in the definition of a `jdbc-connection-pool` in a `payara-resources.xml` file:

```
<jdbc-connection-pool name="examplePool"
        res-type="javax.sql.DataSource"
        datasource-classname="org.h2.jdbcx.JdbcDataSource" log-jdbc-calls="true">
    <property name="user" value="test"/>
    <property name="password" value="test"/>
    <property name="url" value="java:global/ExampleDataSource"/>
```

```
</jdbc-connection-pool>
```

This can also be done in the creation of a JDBC Connection Pool with the `--logjdbccalls` option.

```
asadmin create jdbc-connection-pool --datasourceclassname org.h2.jdbcx.JdbcDataSource
--restype javax.sql.XADataSource --logjdbccalls=true examplePool
```

Likewise, you can configure the Slow Query Log Threshold time by setting the property `fish.payara.slow-query-threshold-in-seconds`, SQL Trace Listener classes by setting the property `fish.payara.sql-trace-listeners` in the `@DataSourceDefinition` annotation.

The below example shows the Slow Query Log Threshold and SQL Trace Listener set in the web.xml file.

```
<data-source>
   <name>java:global/ExampleDataSource</name>
   <class-name>com.mysql.jdbc.jdbc2.optional.MysqlXADataSource</class-name>
   <server-name>localhost</server-name>
   <port-number>3306</port-number>
   <database-name>mysql</database-name>
   <user>test</user>
   <password>test</password>
   <!-- Example of how to use a Payara specific custom connection pool setting -->
   <property>
       <name>fish.payara.log-jdbc-calls</name>
       <value>true</value>
   </property>
   <property>
       <name>fish.payara.slow-query-threshold-in-seconds</name>
       <value>5</value>
   </property>
   <property>
       <name>fish.payara.sql-trace-listeners</name>

<value>fish.payara.examples.payaramicro.datasource.example.CustomSQLTracer</value>
   </property>
</data-source>
```

Slow Query Trace Example

Below is an example `WARNING` trace for a slow query recollected from the server's log:

```
[#|2016-02-01T22:39:29.289+0000|WARNING|Payara
4.1|jakarta.enterprise.resource.sqltrace.com.sun.gjc.util|_ThreadID=61;_ThreadName=htt
p-listener-1(2);_TimeMillis=1454366369289;_LevelValue=900;|
  SQL Query Exceeded Threshold Time: 5000(ms): Time Taken: 10000(ms)
Query was SELECT ID, AGE, BIO, BIRTHDATE, BIRTHDAY, DATEFORMAT, DATEOFBIRTH,
```

```
DATEOFHIRE, EMAIL, HIREDATE, HIREDAY, MEMBERAGE, NAME, TODAYSDATE FROM MEMBERENTITY
WHERE (NAME = ?);

Using the Transaction Service

The Jakarta EE platform provides several abstractions that simplify development of dependable transaction processing for applications. This chapter discusses Jakarta EE transactions and transaction support in the Payara Platform.

For more information about the Jakarta Transactions API (JTA) and Java Transaction Service (JTS), see "Administering Transactions" in Payara Server General Administration section and in the Jakarta Transactions specification.

You might also want to read "Transactions" in The Jakarta EE Tutorial.

Handling Transactions with Databases

Using JDBC Transaction Isolation Levels

Not all database vendors support all transaction isolation levels available in the JDBC API. Payara Server allows specifying any isolation level your database supports. The following table defines transaction isolation levels.

Table 194. Transaction Isolation Levels

Transaction Isolation Level	`getTransactionIsolation` Return Value	Description
`read-uncommitted`	1	Dirty reads, non-repeatable reads, and phantom reads can occur.
`read-committed`	2	Dirty reads are prevented; non-repeatable reads and phantom reads can occur.
`repeatable-read`	4	Dirty reads and non-repeatable reads are prevented; phantom reads can occur.
`serializable`	8	Dirty reads, non-repeatable reads and phantom reads are prevented.

By default, the transaction isolation level is undefined (empty), and the JDBC driver's default isolation level is used. You can specify the transaction isolation level in the following ways:

- Select the value from the *Transaction Isolation* drop-down list on the *New JDBC Connection Pool* or *Edit Connection Pool* page in the Administration Console.
- Specify the `--isolationlevel` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `transaction-isolation-level` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.H2Pool.transaction-isolation-
level=serializable
```

You cannot execute the `setTransactionIsolation` method during a transaction.

You can set the default transaction isolation level for a JDBC connection pool. For details, see "To Create a JDBC Connection Pool" in the Payara Server General Administration section.

To verify that a level is supported by your database management system, test your database programmatically using the `supportsTransactionIsolationLevel` method in `java.sql.DatabaseMetaData`, as shown in the following example:

```
var ctx = new InitialContext();
var ds = (DataSource) ctx.lookup("jdbc/MyDatasource");
var con = ds.getConnection();
var dbmd = con.getMetaData();

if (dbmd.supportsTransactionIsolationLevel(TRANSACTION_SERIALIZABLE){
    Connection.setTransactionIsolation(TRANSACTION_SERIALIZABLE);
}
```

For more information about these isolation levels and what they mean, see the JDBC API specification.

Setting or resetting the transaction isolation level for every `getConnection` call can

> degrade performance. So by default, the isolation level is not guaranteed.

Applications that change the transaction isolation level on a pooled connection programmatically risk polluting the JDBC connection pool, which can lead to errors. If an application changes the isolation level, enabling the `is-isolation-level-guaranteed` setting in the pool can minimize such errors.

You can guarantee the transaction isolation level in the following ways:

- Check the *Isolation Level Guaranteed* box on the *New JDBC Connection Pool* or *Edit Connection Pool* page in the Administration Console.
- Specify the `--isisolationguaranteed` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `is-isolation-level-guaranteed` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.H2Pool.is-isolation-level-
guaranteed=true
```

Using Non-Transactional Connections

You can specify a non-transactional database connection in any of these ways:

- Check the *Non-Transactional Connections* box on the N*ew JDBC Connection Pool* or *Edit Connection Pool* page in the Administration Console.
- Specify the `--nontransactionalconnections` option in the `asadmin create-jdbc-connection-pool` command.
- Specify the `non-transactional-connections` option in the `asadmin set` command. For example:

```
asadmin set domain1.resources.jdbc-connection-pool.H2Pool.non-transactional-
connections=true
```

- Use the Payara Platform's `DataSource` implementation, which provides a `getNonTxConnection` method. This method retrieves a JDBC connection that is not in the scope of any transaction. There are two variants:

```
public java.sql.Connection getNonTxConnection() throws java.sql.SQLException

public java.sql.Connection getNonTxConnection(String user, String password) throws
java.sql.SQLException
```

- Create a resource with the JNDI name ending in the `__nontx` suffix. This forces all connections looked up using this resource to be non-transactional.

Typically, a connection is enlisted in the context of the transaction in which a `getConnection` call is invoked. However, a non-transactional connection is not enlisted in a transaction context even if a

transaction is in progress.

The main advantage of using non-transactional connections is that the overhead incurred in enlisting and de-listing connections in transaction contexts is avoided.

Use these connections carefully.

For example, if a non-transactional connection is used to query the database while a transaction is in progress that modifies the database, the query retrieves the unmodified data in the database.

This is because the in-progress transaction hasn't committed. For another example, if a non-transactional connection modifies the database and a transaction that is running simultaneously rolls back, the changes made by the non-transactional connection are not rolled back.

Here is a typical use case for a non-transactional connection: a component that is updating a database in a transaction context spanning over several iterations of a loop can refresh cached data by using a non-transactional connection to read data before the transaction commits.

Handling Transactions with Enterprise Beans

This section describes the transaction support built into the Jakarta Enterprise Beans programming model.

As a developer, you can write an application that updates data in multiple databases distributed across multiple sites. The application might use EJB servers from different vendors.

Flat Transactions

The Jakarta Enterprise Beans specification support for flat (as opposed to nested) transactions. In a flat transaction, each transaction is decoupled and remains independent of other transactions in the system. Another transaction cannot start in the same thread until the current transaction ends.

Flat transactions are the most prevalent model and are supported by most commercial database systems. Although nested transactions offer a finer granularity of control over transactions, they are supported by far fewer commercial database systems.

Global and Local Transactions

Both local and global transactions are demarcated using the `jakarta.transaction.UserTransaction` interface, which the client must use. Local transactions bypass the XA commit protocol and are faster.

For more information, see The Transaction Manager, the Transaction Synchronization Registry, and `UserTransaction`.

Commit Options

The EJB specification's transaction guidelines are designed to give the container the flexibility to select the disposition of the instance state at the time a transaction is committed. This allows the container to best manage caching an entity object's state and associating an entity object identity with the EJB instances.

There are three commit-time options:

Option A

The container caches a ready instance between transactions. The container ensures that the instance has exclusive access to the state of the object in persistent storage.

In this case, the container does not have to synchronize the instance's state from the persistent storage at the beginning of the next transaction.

Commit option A is not supported in Payara Platform's EJB implementation.

Option B

The container caches a ready instance between transactions, but the container does not ensure that the instance has exclusive access to the state of the object in persistent storage.

This is the default commit option set in the Payara Platform.

In this case, the container must synchronize the instance's state by invoking the `ejbLoad` lifecycle method from persistent storage at the beginning of the next transaction.

Option C

The container does not cache a ready instance between transactions, but instead returns the instance to the pool of available instances after a transaction has completed.

The life cycle for every business method invocation under commit option C looks like this.

```
ejbActivate   ejbLoad   business method   ejbStore   ejbPassivate
```

If there is more than one transactional client concurrently accessing the same entity, the first client gets the ready instance and subsequent concurrent clients get new instances from the pool.

The `payara-ejb-jar.xml` deployment descriptor has an element, `commit-option`, that specifies the commit option to be used. Based on the specified commit option, the appropriate handler is instantiated.

Bean-Level Container-Managed Transaction Timeouts

The transaction timeout for the domain is specified using the *Transaction Timeout* setting of the server's Transaction Service.

A transaction started by the container must commit (or rollback) within this time, regardless of whether the transaction is suspended (and resumed), or the transaction is marked for rollback. The default value, `0`, specifies that the server waits indefinitely for a transaction to complete.

To override this timeout for an individual bean, use the optional `cmt-timeout-in-seconds` element in `payara-ejb-jar.xml`. The default value, `0`, specifies that the Transaction Service timeout is used.

The value of `cmt-timeout-in-seconds` is used for all methods in the bean that start a new container-managed transaction.

This timeout value is not used if the bean joins a client transaction.

Handling Transactions with Jakarta Messaging

Transactions and Non-Persistent Messages

During transaction recovery, non-persistent messages might be lost. If the broker fails between the transaction manager `prepare` and `commit` operations, any non-persistent message in the transaction is lost and cannot be delivered.

A message that is not saved to a persistent store is not available for transaction recovery.

Using the ConfigurableTransactionSupport Interface

The Jakarta Connectors specification allows a resource adapter to use the `transaction-support` attribute to specify the level of transaction support that the resource adapter handles.

However, the resource adapter vendor does not have a mechanism to figure out the current transactional context in which a `ManagedConnectionFactory` is used.

If a `ManagedConnectionFactory` implements an optional interface called `com.sun.appserv.connectors.spi.ConfigurableTransactionSupport`, Payara Server notifies the `ManagedConnectionFactory` of the `transaction-support` configured for the connector connection pool when the `ManagedConnectionFactory` instance is created for the pool.

Connections obtained from the pool can then be used with a transaction level at or lower than the configured value. For example, a connection obtained from a pool that is set to `XA_TRANSACTION` could be used as a `LOCAL` resource in a last-agent-optimized transaction or in a non-transactional context.

The Transaction Manager, the Transaction Synchronization Registry, and `UserTransaction`

To access a `UserTransaction` instance, you can either look it up using the `java:comp/UserTransaction` JNDI name or inject it using the `@Resource` annotation.

Accessing a `DataSource` using the `Synchronization.beforeCompletion()` method requires setting the *Allow Non-Component Callers* option of its corresponding JDBC Connection Pool to `true`.

The default setting is `false`. For more information about non-component callers, see Allowing Non-Component Callers.

If possible, you should use the `jakarta.transaction.TransactionSynchronizationRegistry` interface instead of `jakarta.transaction.TransactionManager` , for portability. You can look up the implementation of this interface by using the JNDI name `java:comp/TransactionSynchronizationRegistry`.

For details, see the `TransactionSynchronizationRegistryInterface` API documentation and the Jakarta Transactions specification.

If accessing the `jakarta.transaction.TransactionManager` implementation is absolutely necessary, you can look up the Payara Platform's implementation of this interface using the JNDI name `java:appserver/TransactionManager`.

This lookup should not be used by application code under any circumstances.

Using the Java Naming and Directory Interface

A naming service maintains a set of bindings, which relate names to objects. The Payara Platform's naming service is based on the Java Naming and Directory Interface (JNDI) API. The JNDI API allows application components and clients to look up distributed resources, services, and EJB components.

For general information about the JNDI API, see `http://www.oracle.com/technetwork/java/jndi/index.html`.

Payara Server's Web Profile supports the EJB 4.0 Lite specification, which allows enterprise beans within web applications, among other features. The Full Profile supports the entire EJB 4.0 specification. For details, see Jakarta Enterprise Beans.

Accessing the Naming Context

Payara Server provides a naming environment, or context, which is compliant with standard Jakarta EE requirements. A `Context` object provides the methods for binding names to objects, unbinding names from objects, renaming objects, and listing the bindings.

The `InitialContext` is the handle to the Jakarta EE naming service that application components and clients use for lookups.

The JNDI API also provides subcontext functionality. Much like a directory in a file system, a subcontext is a context within a context. This hierarchical structure permits better organization of information. For naming services that support subcontexts, the `Context` class also provides methods for creating and destroying subcontexts.

Each resource within a server instance must have a unique name. However, two resources in different server instances or different domains can have the same name.

Portable Global JNDI Names

If an EJB component is a kind of session bean, and it is deployed to any implementation supporting the Jakarta Enterprise Beans 4.0 specification, it automatically has one or more portable JNDI names defined based on the syntax in the specification.

This is true of existing EJB 3.0 and 2.x applications that are deployed to an implementation supporting EJB 3.1 or newer versions.

No code changes are required to the bean class itself in order to have the portable global JNDI name

automatically assigned when deployed to an EJB container.

For more information, see the Jakarta EE Platform Specification, section 5.2.2, "Application Component Environment Namespaces", and the EJB 4.0 Specification, section 4.4. Access in the Global JNDI Namespace.

If the `disable-nonportable-jndi-names` property is set to `false` (the default), a Payara Server JNDI name is assigned in addition to a portable global JNDI name.

Payara Server Vendor-Specific Global JNDI Names

Payara Server vendor-specific global JNDI names are assigned according to the following precedence rules:

1. A global JNDI name assigned in the `payara-ejb-jar.xml`, `payara-web.xml`, or `payara-application-client.xml` deployment descriptor file has the highest precedence. See Mapping References.
2. A global JNDI name assigned in a `mapped-name` element in the `ejb-jar.xml`, `web.xml`, or `application-client.xml` deployment descriptor file has the second-highest precedence. The following elements have `mapped-name` sub-elements: `resource-ref`, `resource-env-ref`, `ejb-ref`, `message-destination`, `message-destination-ref`, `session`, `message-driven`, and `entity`.
3. A global JNDI name assigned in a `mappedName` attribute of an annotation has the third-highest precedence. The following annotations have `mappedName` attributes: `@jakarta.annotation.Resource`, `@jakarta.ejb.EJB`, `@jakarta.ejb.Stateless`, `@jakarta.ejb.Singleton`, `@jakarta.ejb.Stateful`, and `@javax.ejb.MessageDriven`.
4. In most cases, a default global JNDI name is assigned (and recorded in the server log) if no name is assigned in deployment descriptors or annotations.
    - For a session or entity bean, a Payara Server specific JNDI name is assigned as follows:
        - For an EJB 2.x dependency or a session or entity bean with a remote interface, the default is the fully qualified name of the home interface.
        - For an EJB 3.0+ dependency or a session bean with a remote interface, the default is the fully qualified name of the remote business interface.
        - If both EJB 2.x and EJB 3.0 remote interfaces are specified, or if more than one 3.0 remote interface is specified, there is no Payara Server specific default.

          For an entity bean, a global JNDI name must be assigned.
    - For all other component dependencies that must be mapped to global JNDI names, the default is the name of the dependency relative to `java:comp/env`.

      For example, in the `@Resource(name="jdbc/Foo") DataSource ds;` annotation, the global JNDI name is `jdbc/Foo`.

Disabling Payara Server JNDI Names

The EJB specification supported by Payara Server defines portable EJB JNDI names for session beans. Because of this, there is less need to continue to use older vendor-specific JNDI names.

By default, Payara Server specific JNDI names are generated automatically for backward compatibility. However, this can lead to some ease-of-use issues.

For example, deploying two different applications containing a remote EJB component that exposes the same remote interface causes a conflict between the default JNDI names.

The default handling of JNDI specific names in Payara Server can be managed by using the `asadmin` command:

```
asadmin> set server.ejb-container.property.disable-nonportable-jndi-names="true"
```

The `disable-nonportable-jndi-names` property is a boolean flag that can take the following values:

`false`
: Enables the automatic use of Payara Server specific JNDI names in addition to portable global JNDI names. This is the default setting.

`true`
: Disables the automatic use of specific JNDI names. In all cases, only portable global JNDI names are used.

This setting applies to all session beans deployed in the server.

Accessing EJB Components Using the `CosNaming` Naming Context

The preferred way of accessing the naming service, even in code that runs outside a Jakarta EE container, is to use the no-argument `InitialContext` constructor.

However, if EJB client code explicitly instantiates an `InitialContext` that points to the `CosNaming` naming service, it is necessary to set the `java.naming.factory.initial` property to `org.glassfish.jndi.cosnaming.CNCtxFactory` in the client JVM software when accessing EJB components.

You can set this property using the `asadmin create-jvm-options` command, as follows:

```
asadmin> create-jvm-options
-Djava.naming.factory.initial=org.glassfish.jndi.cosnaming.CNCtxFactory
```

Or you can set this property in the code, as follows:

```
try {
    var properties = new Properties();
    properties.put("java.naming.factory.initial",
"org.glassfish.jndi.cosnaming.CNCtxFactory");
}
```

The `java.naming.factory.initial` property applies to only one instance. The property is neither

cluster or deployment group-aware.

Accessing EJB Components in a Remote Payara Server

The recommended approach for looking up an EJB component in a remote Payara Server from a client that is a servlet or EJB component is to use the Interoperable Naming Service syntax.

Host and port information is prepended to any global JNDI names and is automatically resolved during the lookup. The syntax for an interoperable global name is as follows:

```
corbaname:iiop:${host}:${port}#{ejbName}
```

This makes the programming model for accessing EJB components in another Payara Server exactly the same as accessing them in the same server. The deployer can change the way the EJB components are physically distributed without having to change the code.

For Jakarta EE components, the code still performs a `java:comp/env` lookup on an EJB reference. The only difference is that the deployer maps the `ejb-ref` element to an interoperable name in a Payara Server deployment descriptor file instead of to a simple global JNDI name.

For example, suppose a servlet looks up an EJB reference using `java:comp/env/ejb/Foo`, and the target EJB component has a global JNDI name of `a/b/Foo`.

The `ejb-ref` element in `glassfish-web.xml` or `payara-web.xml` looks like this:

```
<ejb-ref>
   <ejb-ref-name>ejb/Foo</ejb-ref-name>
   <jndi-name>corbaname:iiop:host:port#a/b/Foo</jndi-name>
</ejb-ref>
```

The code looks like this:

```
Context ic = new InitialContext();
Object o = ic.lookup("java:comp/env/ejb/Foo");
```

For a client that doesn't run within a Jakarta EE container, the code just uses the interoperable global name instead of the simple global JNDI name. For example:

```
Context ic = new InitialContext();
Object o = ic.lookup("corbaname:iiop:host:port#a/b/Foo");
```

Objects stored in the interoperable naming context and component-specific (`java:comp/env`) naming contexts are transient. On each server startup or application reloading, all relevant objects are re-bound to the namespace.

glassfish-web.xml is deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

Configuring Resources

Payara Server exposes special resources in the naming context environment.

External JNDI Resources

An external JNDI resource defines custom JNDI contexts and implements the `javax.naming.spi.InitialContextFactory` interface. There is no specific JNDI parent context for external JNDI resources, except for the standard `java:comp/env/`.

Create an external JNDI resource in one of these ways:

- To create an external JNDI resource using the Administration Console, open the *Resources* component, open the *JNDI* component, and select *External Resources*.
- To create an external JNDI resource, use the `asadmin create-jndi-resource` command.

Custom Resources

A custom resource specifies a custom server-wide resource object factory that implements the `javax.naming.spi.ObjectFactory` interface. There is no specific JNDI parent context for external JNDI resources, except for the standard `java:comp/env/`.

Create a custom resource in one of these ways:

- To create a custom resource using the Administration Console, open the *Resources* component, open the *JNDI* component, and select *Custom Resources*.
- To create a custom resource, use the `asadmin create-custom-resource` command.

Built-in Factories for Custom Resources

Payara Server provides built-in factories for the following types of custom resources:

- JavaBeans
- Properties
- Java Primitives and String objects
- URLs

It is possible to create custom resources by using a `payara-resources.xml` or `glassfish-resources.xml` deployment descriptor. To this effect, several template files for these built-in factories and a `README` file are available at `as-install/lib/install/templates/resources/custom/`.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

JavaBeanFactory

To create a custom resource that provides instances of a JavaBean class, follow these steps:

1. Set the custom resource's factory class to `org.glassfish.resources.custom.factory.JavaBeanFactory`.
2. Create a property in the custom resource for each setter method in the JavaBean class.

   For example, if the JavaBean class has a method named `setAccount`, specify a property named `account` and give it a value.

3. Make sure the JavaBean class is accessible to the Payara Server.

   For example, you can place the JavaBean class in the `as-install/lib` directory.

PropertiesFactory

To create a custom resource that provides configuration properties to applications, set the custom resource's factory class to `org.glassfish.resources.custom.factory.PropertiesFactory`, then specify one or both of the following:

- Create a property in the custom resource named `org.glassfish.resources.custom.factory.PropertiesFactory.fileName` and specify as its value the path to a properties file or an XML file.

  The path can be absolute or relative to the installation directory. The file must be accessible to the operating system user running the Payara Server's process.

  If an XML file is specified, it must match the document type definition (DTD) specified in the API definition of java.util.Properties.

- Create the desired properties directly as properties of the custom resource.

  If both the `fileName` property and other properties are specified, the resulting property set is the union of the contents of both.

  If the same property is defined in the file and directly in the custom resource, the value of the latter takes precedence.

PrimitivesAndStringFactory

To create a custom resource that provides Java primitives to applications, follow these steps:

1. Set the custom resource's factory class to `org.glassfish.resources.custom.factory.PrimitivesAndStringFactory`.
2. Set the custom resource's resource type to one of the following or its fully qualified wrapper class name equivalent:
   - `int`
   - `long`
   - `double`

- `float`
- `char`
- `short`
- `byte`
- `boolean`
- `String`

3. Create a property in the custom resource named `value` and give it the value needed by the application.

   For example, If the application requires a `double` of value `22.1`, create a property with the name `value` and the value `22.1`.

URLFactory

To create a custom resource that provides URL instances to applications, follow these steps:

1. Set the custom resource's factory class to `org.glassfish.resources.custom.factory.URLObjectFactory`.
2. Choose which of the following constructors to use:
   - `URL(protocol, host, port, file)`
   - `URL(protocol, host, file)`
   - `URL(spec)`
3. Define properties according to the chosen constructor.

   For example, for the first constructor, define properties named `protocol`, `host`, `port`, and `file`. Example values might be `http`, `localhost`, `8085`, and `index.html`, respectively.

   For the third constructor, define a property named `spec` and assign it the value of the entire URL.

Using Application-Scoped Resources

You can define an application-scoped JNDI resource for an enterprise application, web module, EJB module, connector module, or application client module by supplying a `glassfish-resources.xml` or `payara-resources.xml` deployment descriptor file.

glassfish-resources.xml is deprecated and support will be removed in a future release. It is recommended to use payara-resources.xml instead.

For details, see "Application-Scoped Resources" in the Application Deployment section.

Using a Custom `jndi.properties` File

To use a custom `jndi.properties` file, JAR it and place it in the `domain-dir/lib` directory. This adds the custom `jndi.properties` file to the Common class loader. For more information about class loading, see Class Loaders.

For each property found in more than one `jndi.properties` file, the Jakarta EE naming service either uses the first value found or concatenates all values, whichever makes sense at runtime.

Mapping References

The following XML elements in the Payara Server deployment descriptors map resource references in application client, EJB, and web application components to JNDI names configured in Payara Server:

`resource-env-ref`

Maps the `@Resource` or `@Resources` annotation (or the `resource-env-ref` element in the corresponding Jakarta EE XML file) to the absolute JNDI name configured in Payara Server.

`resource-ref`

Maps the `@Resource` or `@Resources` annotation (or the `resource-ref` element in the corresponding Jakarta EE XML file) to the absolute JNDI name configured in Payara Server.

`ejb-ref`

Maps the `@EJB` annotation (or the `ejb-ref` element in the corresponding Jakarta EE XML file) to the absolute JNDI name configured in Payara Server.

JNDI names for EJB components must be unique. For example, appending the application name and the module name to the EJB name is one way to guarantee unique names.

In this case, `mycompany.pkging.pkgingEJB.MyEJB` would be the JNDI name for an EJB in the module `pkgingEJB.jar`, which is packaged in the `pkging.ear` application.

These elements are part of the `glassfish-web.xml`/`payara-web.xml`, `glassfish-application-client.xml`/`payara-application-client.xml`, `glassfish-ejb-jar.xml`/`payara-ejb-jar.xml`, and `glassfish-application.xml`/`payara-application.xml` deployment descriptor files.

glassfish-* deployment descriptors are deprecated and support will be removed in a future release. It is recommended to use the payara-* equivalents instead.

For more information about how these elements behave in each of the deployment descriptor files, see "Elements of the Payara Server Deployment Descriptors" in the Payara Server Application Deployment section.

The following is an example of a JDBC resource lookup to showcase how to reference resource factories. The same principle is applicable to all resources (such as JMS destinations, JavaMail sessions, and so on).

The `@Resource` annotation in the application code looks like this:

```
@Resource(name="jdbc/helloDbDs")
javax.sql.DataSource ds;
```

This references a resource with the JNDI name of `java:jdbc/helloDbDs`. If this is the JNDI name of the JDBC resource configured in Payara Server, the annotation alone is enough to reference the resource.

However, you can use a Payara Server specific deployment descriptor to override the annotation. For example, the `resource-ref` element in the `payara-web.xml` file maps the `res-ref-name` (the name specified in the annotation) to the JNDI name of another JDBC resource configured in Payara Server.

```
<resource-ref>
   <res-ref-name>jdbc/helloDbDs</res-ref-name>
   <jndi-name>jdbc/helloDbDataSource</jndi-name>
</resource-ref>
```

Using Jakarta Messaging

This chapter describes how to use the Jakarta Messaging (JMS) API. Payara Server has a fully integrated JMS provider: the **Open Message Queue** software.

JMS resources are supported only in the Full Profile, not in the Web Profile.

For information about the JMS, see "Messaging" in The Jakarta EE Tutorial.

For detailed information about JMS concepts and JMS support in Payara Server, see "Administering Jakarta Messaging (JMS)" in the Payara Server General Administration section.

Using Application-Scoped JMS Resources

You can define an application-scoped JMS or other resource for an enterprise application, web module, EJB module, connector module, or application client module by supplying a `payara-resources.xml` deployment descriptor file. For details, see "Application-Scoped Resources" in the Payara Server Application Deployment section.

Load-Balanced Message Inflow

You can configure `ActivationSpec` properties of the `jmsra` resource adapter in the `payara-ejb-jar.xml` file for a message-driven bean using `activation-config-property` elements. Whenever a message-driven bean (`EndPointFactory`) is deployed, the connector runtime engine finds these properties and configures them accordingly in the resource adapter.

See "activation-config-property" in the Payara Server Application Deployment section.

Payara Server transparently enables messages to be delivered in random fashion to message-driven beans having the same `ClientID`.

The `ClientID` is required for durable subscribers.
For non-durable subscribers in which the `ClientID` is not configured, all instances of a specific message-driven bean that subscribe to same topic are considered

equal.

When a message-driven bean is deployed to multiple instances of Payara Server, only one of the message-driven beans receives the message. If multiple distinct message-driven beans subscribe to same topic, one instance of each message-driven bean receives a copy of the message.

To support multiple consumers using the same queue, set the `maxNumActiveConsumers` property of the physical destination to a large value. If this property is set, the **Open Message Queue** software allows multiple message-driven beans to consume messages from the same queue.

The message is delivered randomly to the message-driven beans. If `maxNumActiveConsumers` is set to `-1`, there is no limit to the number of consumers.

To ensure that local delivery is preferred, set `addresslist-behavior` to `priority`. This setting specifies that the first broker in the `AddressList` is selected first.

This first broker is the local co-located message queue instance. If this broker is unavailable, connection attempts are made to brokers in the order in which they are listed in the `AddressList`. This setting is the default for Payara Server instances that belong to a cluster or deployment group.

Authentication With `ConnectionFactory`

If your web, EJB, or client module has `res-auth` set to `Container`, but you use the `ConnectionFactory.createConnection("user","password")` method to get a connection, Payara Server searches the container for authentication information before using the supplied user and password.

Delivering SOAP Messages Using the JMS API

Web service clients use the Simple Object Access Protocol (SOAP) to communicate with web services. SOAP uses a combination of XML-based data structuring and Hyper Text Transfer Protocol (HTTP) to define a standardized way of invoking methods in objects distributed in diverse operating environments across the Internet.

You can take advantage of the JMS provider's reliable messaging when delivering SOAP messages. You can convert a SOAP message into a JMS message, send the JMS message, then convert the JMS message back into a SOAP message.

To Send SOAP Messages Using the JMS API

1. Import the `MessageTransformer` library.

   ```
   import com.sun.messaging.xml.MessageTransformer;
   ```

   This is the utility class whose methods you use to convert SOAP messages to JMS messages and vice-versa. You can then send a JMS message containing a SOAP payload as if it were a normal JMS message.

2. Initialize the `TopicConnectionFactory`, `TopicConnection`, `TopicSession`, and publisher components.

```
var tcf = new TopicConnectionFactory();
var tc = tcf.createTopicConnection();
var session = tc.createTopicSession(false,Session.AUTO_ACKNOWLEDGE);
var topic = session.createTopic(topicName);
var publisher = session.createPublisher(topic);
```

3. Construct a SOAP message using the **SOAP with Attachments API** for Java (SAAJ).

```
/*construct a default soap MessageFactory */
MessageFactory mf = MessageFactory.newInstance();
* Create a SOAP message object.*/
SOAPMessage soapMessage = mf.createMessage();
/** Get SOAP part.*/
SOAPPart soapPart = soapMessage.getSOAPPart();
/* Get SOAP envelope. */
SOAPEnvelope soapEnvelope = soapPart.getEnvelope();
/* Get SOAP body.*/
SOAPBody soapBody = soapEnvelope.getBody();
/* Create a name object. with name space */
/* http://www.sun.com/imq. */
Name name = soapEnvelope.createName("HelloWorld", "hw",
 "http://www.sun.com/imq");
* Add child element with the above name. */
SOAPElement element = soapBody.addChildElement(name)
/* Add another child element.*/
element.addTextNode( "Welcome to Payara Web Services." );
/* Create an atachment with activation API.*/
URL url = new URL ("http://java.sun.com/webservices/");
DataHandler dh = new DataHandler (url);
AttachmentPart ap = soapMessage.createAttachmentPart(dh);
/*set content type/ID. */
ap.setContentType("text/html");
ap.setContentId("cid-001");
/** add the attachment to the SOAP message.*/
soapMessage.addAttachmentPart(ap);
soapMessage.saveChanges();
```

4. Convert the SOAP message to a JMS message by calling the `MessageTransformer.SOAPMessageintoJMSMessage()` method.

```
Message m = MessageTransformer.SOAPMessageIntoJMSMessage(soapMessage, session);
```

5. Publish the JMS message.

```
publisher.publish(m);
```

6. Close the JMS connection.

```
tc.close();
```

To Receive SOAP Messages Using the JMS API

1. Import the `MessageTransformer` library.

```
import com.sun.messaging.xml.MessageTransformer;
```

This is the utility class whose methods you use to convert SOAP messages to JMS messages and vice-versa. The JMS message containing the SOAP payload is received as if it were a normal JMS message.

2. Initialize the `TopicConnectionFactory`, `TopicConnection`, `TopicSession`, `TopicSubscriber`, and Topic.

```
var messageFactory = MessageFactory.newInstance();
var tcf = new com.sun.messaging.TopicConnectionFactory();
var tc = tcf.createTopicConnection();
var session = tc.createTopicSession(false, Session.AUTO_ACKNOWLEDGE);
var topic = session.createTopic(topicName);
var subscriber = session.createSubscriber(topic);
var subscriber.setMessageListener(this);
tc.start();
```

3. Use the `OnMessage` method to receive the message. Use the `SOAPMessageFromJMSMessage` method to convert the JMS message to a SOAP message.

```
public void onMessage (Message message) {
    var soapMessage =
MessageTransformer.SOAPMessageFromJMSMessage(message,messageFactory);
}
```

4. Retrieve the content of the SOAP message.

Using Jakarta Mail

This chapter describes how to use the Jakarta Mail API, which provides a set of abstract classes defining objects that comprise a mail system.

Jakarta Mail resources are supported only in the Full Profile, not in the Web Profile.

Introducing Jakarta Mail

The Jakarta Mail API defines classes such as `Message`, `Store`, and `Transport`. The API can be extended and can be subclassed to provide new protocols and to add functionality when necessary. In addition, the API provides concrete subclasses of the abstract classes. These subclasses, including `MimeMessage` and `MimeBodyPart`, implement widely used Internet mail protocols and conform to the **RFC822** and **RFC2045** specifications. The Jakarta Mail API includes support for the **IMAP4**, **POP3**, and **SMTP** protocols.

The Jakarta Mail architectural components are as follows:

- The abstract layer declares classes, interfaces, and abstract methods intended to support mail handling functions that all mail systems support.
- The internet implementation layer implements part of the abstract layer using the **RFC822** and **MIME** internet standards.
- Jakarta Mail uses Jakarta Activation to encapsulate message data and to handle commands intended to interact with that data.

For more information, see "Administering the Jakarta Mail Service" in the Payara Server General Administration section and the Jakarta Mail specification.

Creating a Jakarta Mail Session

You can create a Jakarta Mail session in the following ways:

- In the Administration Console, open the *Resources* component and select *JavaMail Sessions*.
- Use the `asadmin create-mail-resource` command.

Jakarta Mail Session Properties

You can set properties for a Jakarta Mail `Session` object. Every property name must start with a `mail-` prefix. Payara Server changes the dash (`-`) character to a period (`.`) in the name of the property and saves the property to the `MailConfiguration` and Jakarta Mail `Session` objects. If the name of the property doesn't start with `mail-`, the property is ignored.

For example, if you want to define the property `mail.from` in a Jakarta Mail `Session` object, first define the property as follows:

- Name: `mail-from`
- Value: `john.doe@sun.com`

Looking Up a Jakarta Mail Session

The standard Java Naming and Directory Interface (JNDI) subcontext for Jakarta Mail sessions is `java:comp/env/mail`.

Registering Jakarta Mail sessions in the `mail` naming subcontext of a JNDI namespace, or in one of its child subcontexts, is a standard requirement.

The JNDI namespace is hierarchical, like a file system's directory structure, so it is easy to find and nest references. A Jakarta Mail session is bound to a logical JNDI name. The name identifies a subcontext, `mail`, of the root context, and a logical name. To change the Jakarta Mail session, you can change its entry in the JNDI namespace without having to modify the application.

The resource lookup in the application code looks like this:

```
var ic = new InitialContext();
var snName = "java:comp/env/mail/MyMailSession";
var session = (Session)ic.lookup(snName);
```

For more information about the JNDI API, see Using the Java Naming and Directory Interface.

Sending and Reading Messages Using Jakarta Mail

To Send a Message Using Jakarta Mail

1. Import the packages that you need.

   ```
   import java.util.*;
   import jakarta.activation.*;
   import jakarta.mail.*;
   import jakarta.mail.internet.*;
   import javax.naming.*;
   ```

2. Look up the Jakarta Mail session.

   ```
   var ic = new InitialContext();
   var snName = "java:comp/env/mail/MyMailSession";
   var session = (Session)ic.lookup(snName);
   ```

3. Override the Jakarta Mail session properties if necessary. For example:

   ```
   var props = session.getProperties();
   props.put("mail.from", "user2@mailserver.com");
   ```

4. Create a `MimeMessage`. The `msgRecipient`, `msgSubject`, and `msgTxt` variables in the following example contain input from the user:

   ```
   var msg = new MimeMessage(session);
   msg.setSubject(msgSubject);
   msg.setSentDate(new Date());
   msg.setFrom();
   msg.setRecipients(Message.RecipientType.TO, InternetAddress.parse(msgRecipient,
   false));
   ```

```
msg.setText(msgTxt);
```

5. Send the message.

```
Transport.send(msg);
```

To Read a Message Using Jakarta Mail

1. Import the packages that you need.

```
import java.util.*;
import jakarta.activation.*;
import jakarta.mail.*;
import jakarta.mail.internet.*;
import javax.naming.*;
```

2. Look up the Jakarta Mail session.

```
var ic = new InitialContext();
var snName = "java:comp/env/mail/MyMailSession";
var session = (jakarta.mail.Session)ic.lookup(snName);
```

3. Override the Jakarta Mail session properties if necessary. For example:

```
var props = session.getProperties();
props.put("mail.from", "user2@mailserver.com");
```

4. Get a `Store` object from the `Session`, then connect to the mail server using the `Store` object's `connect` method. You must supply a mail server name, a mail username, and a password:

```
var store = session.getStore();
store.connect("MailServer", "MailUser", "secret");
```

5. Retrieve the `INBOX` folder.

```
Folder folder = store.getFolder("INBOX");
```

6. It is efficient to read the `Message` objects (which represent messages on the server) into an array or a collection.

```
Message[] messages = folder.getMessages();
```

Using Application-Scoped Jakarta Mail Resources

You can define an application-scoped Jakarta Mail or other resource for an enterprise application, web module, EJB module, connector module, or application client module by supplying a `payara-resources.xml` deployment descriptor file.

For more details, see "Application-Scoped Resources" in the Payara Server Application Deployment section.

Using the Data Grid in your Applications

This section details how to use the underlying Data Grid Hazelcast instance in Payara Server within application code.

Accessing the Hazelcast instance via JNDI

By default, the JNDI name of the hazelcast instance is `payara/Hazelcast`, though this can be altered using the set-hazelcast-configuration command. You will need to import the following packages into your Java class:

```
import com.hazelcast.core.HazelcastInstance;
import javax.naming.Context;
import javax.naming.InitialContext;
```

To import the requisite Hazelcast classes, you will need to set add the Public API artefact as a dependency in the project's `pom.xml` file (in case of Maven projects), or have the Hazelcast JAR set as a project dependency (if using a non-Maven based project).

Here's the Maven dependency:

```
<dependency>
  <groupId>fish.payara.api</groupId>
  <artifactId>payara-api</artifactId>
  <version>${page-version}</version>
</dependency>
```

The Hazelcast JAR (for non-Maven projects), can either be downloaded from the Hazelcast website, or you can make use of the JAR that is packaged in Payara Server. The JAR packaged with Payara can be found at `<Payara Installation Directory>/glassfish/modules/hazelcast.jar`.

The following code sample will initialize a `HazelcastInstance` variable in the instance embedded in Payara:

```
public class Component{

    public void businessMethod(){
        var ctx = new InitialContext();
        HazelcastInstance instance = (HazelcastInstance)
```

```
ctx.lookup("payara/Hazelcast");
    }
}
```

It is recommended to wrap this block in a `try-catch` clause, since a `NamingException` exception can be generated due to the use of JNDI.

Using Hazelcast for Web and EJB Container Persistence

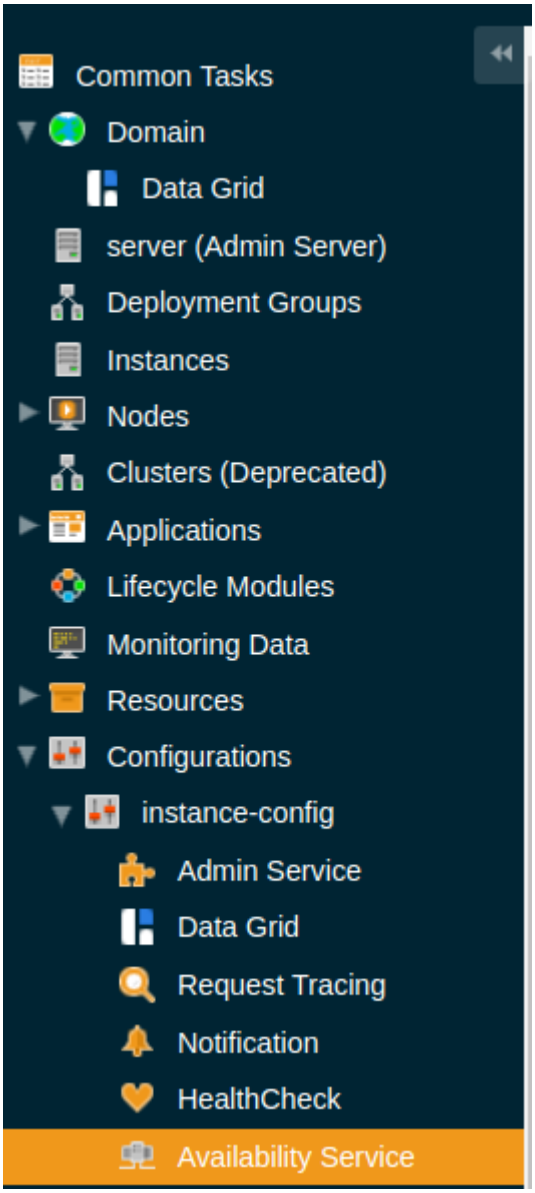
Hazelcast can be used as the persistence provider for both the Web and EJB containers.

Setting Hazelcast as the Persistence provider through the Admin Console

Payara Server's initial configuration has the `hazelcast` option as the default setting.

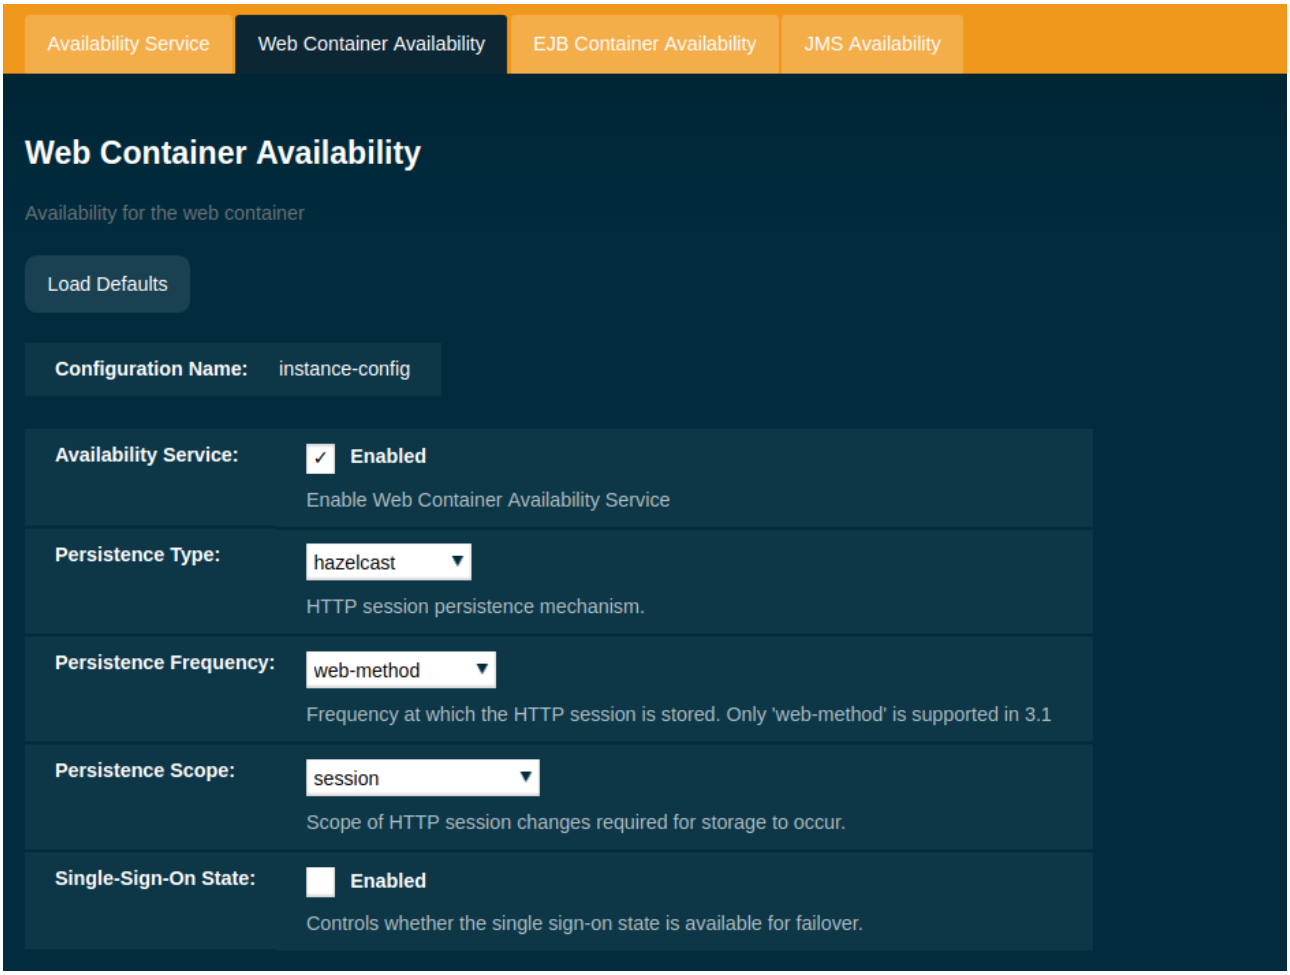
To set up Hazelcast for persistence:

1. Select the instance's configuration from the page tree:
2. Select *"Availability Service"* to view the *"Availability Service"* page:



Setting Web Persistence

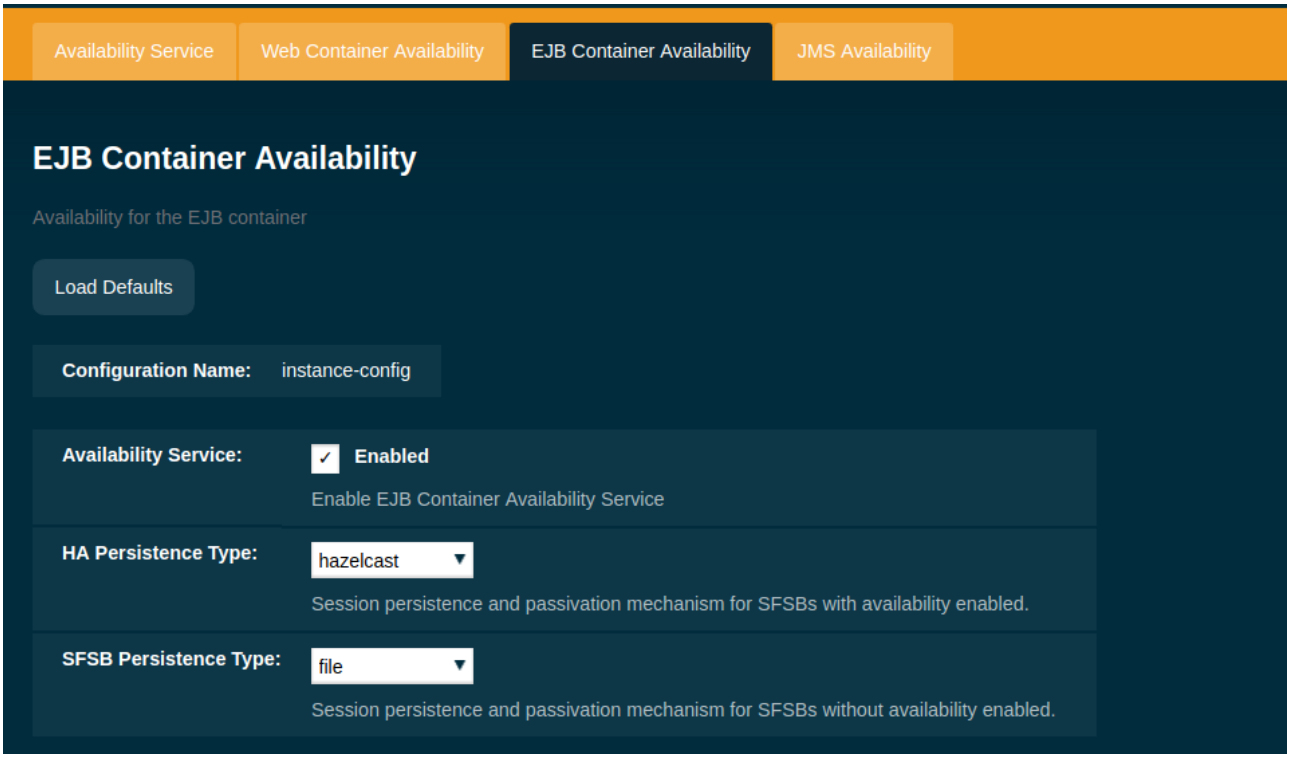
1. Open the "Web Container Availability" tab, and select "Hazelcast" from the *Persistence Type* drop-down menu:



2. Save the changes.

Setting EJB Persistence

1. Open the "EJB Container Availability" tab and select "Hazelcast" from the *Persistence Type* drop-down menu:



2. Save the changes.

Setting Hazelcast as the Persistence provider from the Command Line

To configure the persistence provider with the *asadmin* CLI, you have to use the *set* command.

For the Web Container

To set Hazelcast as the persistence provider of the Web Container, run the following command:

```
asadmin> set <cluster-config>.availability-service.web-container-
availability.persistence-type=hazelcast
```

For the EJB Container

To set Hazelcast as the persistence provider of the EJB Container, run the following command:

```
asadmin> set <cluster-config>.availability-service.ejb-container-availability.sfsb-ha-
persistence-type=hazelcast
```

Using the JCache API

This chapter covers how to use the JCache functionality in the Payara Platform.

JSR107 (JCache) is implemented in Payara Server by Hazelcast Community Edition.

JCache is not an official specification of the Jakarta Platform and any of its variant profiles.
Its inclusion in the Payara Platform is a product choice to leverage the capabilities of a caching API as the Jakarta Platform lacks an official API.

Accessing the Caching Provider and Cache Manager

To create a `Cache` instance you will need to access either a `CachingProvider` or a `CacheManager` instance at runtime. This can be done either declaratively via CDI injection or programmatically via JNDI lookup.

Using Injection

You can inject both `CachingProvider` and `CacheManager` instances in any CDI beans like this:

```
import javax.cache.CacheManager;
import javax.cache.spi.CachingProvider;
import jakarta.inject.Inject;

@ApplicationScoped
public class Component{
```

```
    @Inject
    CacheManager manager;
    @Inject
    CachingProvider provider;
}
```

Your WAR or JAR artifact must be an implicit or explicit bean archive.

Using JNDI

Both the `CachingProvider` and the `CachingManager` components can also be programmatically accessed through their JNDI names as well:

```
import javax.cache.spi.CachingProvider;
import javax.cache.CacheManager;

public class Component{

    public void businessMethod(){
        Context ctx = new InitialContext();
        CachingProvider provider = (CachingProvider)
ctx.lookup("payara/CachingProvider");
        CacheManager manager = (CacheManager) ctx.lookup("payara/CacheManager");
    }
}
```

Creating a Cache Instance

You can create a cache using either the `CacheManager.getCache` method, or by directly injecting the cache instance into a CDI bean.

Using Injection

Injecting a cache into a CDI bean is simple enough:

```
import jakarta.inject.Inject;
import javax.cache.Cache;

@ApplicationScoped
public class Component{

    @Inject
    Cache cache;
}
```

The name of this cache will be the canonical name of the class it is created in.

Caches created in this way will also have JMX statistics and management enabled.

Typed Cache Injection

A typed cache can also be injected in the same manner:

```
import jakarta.inject.Inject;
import javax.cache.Cache;

@ApplicationScoped
public class Component{

    @Inject
    Cache<Long, Property> cache;
}
```

Both key and value types must be `Serializable` so that the cache can be properly instantiated at runtime.

Injecting a Custom Cache

You can determine the name and other attributes of a cache created through injection using the `@NamedCache` annotation.

For example, to inject a cache with a custom name and with JMX management enabled:

```
import fish.payara.cdi.jsr107.impl.NamedCache;
import jakarta.inject.Inject;
import javax.cache.Cache;

@ApplicationScoped
public class Component{

    @NamedCache(cacheName = "custom", managementEnabled = true)
    @Inject
    Cache cache;
}
```

This annotation is part of the Payara Platform Public API

If you only want to set the name of the cache but don't want to depend on the `@NamedCache`, you can use the `@CacheDefaults` annotation on the bean class instead:

```
import jakarta.inject.Inject;
import javax.cache.Cache;
import javax.cache.annotation.CacheDefaults;
import jakarta.enterprise.context.ApplicationScoped;
```

```
@ApplicationScoped
@CacheDefaults(cacheName = "custom")
public class CacheBean {

    @Inject
    Cache cache;
}
```

Keep in mind that this solution only works if your bean has one injected cache only. If you are in a situation where you must inject more than one cache into the bean then consider using the `@NamedCache` annotation to avoid name collisions.

Using JCache Annotations

The Payara Platform supports cache definitions and operations on caches by using the standard set of annotations that are part of the JCache API:

`@CachePut`
: Puts the specified key and value in the cache.

`@CacheRemove`
: Removes an element from the cache that corresponds to the supplied key.

`@CacheDefaults`
: Allows the configuration of defaults for `CacheResult`, `CachePut`, `CacheRemove`, and `CacheRemoveAll` at the class level.

`@CacheKey`
: Marks a method parameter as the key of a cache.

`@CacheValue`
: Marks a method parameter as the value of a cache key.

- JCache API Javadoc

Using Request Tracing in Applications

Request Tracing in the Payara Platform is done either automatically, by using the MicroProfile OpenTracing `@Traced` annotation or by utilizing OpenTelemetry/OpenTracing APIs. This chapter covers manually decorating your applications to enable explicit Request Tracing.

Terminology

Traces & Spans

A Span is a named, timed operation that represents an individual unit of work, such as the

execution of a JAX-RS method. Since a Span is a unit of work, they typically contain references to other Spans to represent the work in its entirety.

A Trace is the term used to describe the collection of Spans that make up an entire request's lifecycle from the viewpoint of the Payara Platform: from the request hitting the server to it leaving. A Trace can be made up of simply one Span.

References

The references between Spans are of one of two types: "Child of" or "Follows from":

- *"Child of"* references are used to denote that a Span is the child of another Span, e.g. a sub-unit of work.
- *"Follows from"* references are used to denote that a Span was spawned by another Span, but is not a subunit of work of the parent Span (the parent Span does not depend on the child Span).

Tags and Logs

A Span Tag is simply a `key:value` pair that is added to a Span to provide details about the unit of work. For example, JAX-RS methods automatically set the `http.url` tag to provide information about the URL traced.

A Span Log is a Tag that is paired with a timestamp. As denoted by the name, this is typically used to add information to a Span about an event happening at a specific time during the duration of the Span (e.g. an error).

Using the `@Traced` Annotation

The `@Traced` annotation can be placed on CDI Bean methods to automatically trace each call of the method. You can also place the annotation on the class itself to trace all methods within the class, rather than adding the annotation to each method individually.

The `@Traced` annotation accepts two optional parameters:

`operationName`
: defines the operation name of the span. If left blank it will default to the canonical method signature.

`value`
: a boolean true or false to determine if the method should be traced. Defaults to true.

```
import org.eclipse.microprofile.opentracing.Traced;

@RequestScoped
public class TracedExample {

    @Traced
    public String method1() {
        return "anon1";
    }
```

```
    @Traced(operationName = "tracingTest")
    public String method2() {
        return "anon2";
    }

}
```

The `@Traced` the annotation operates as an Interceptor, so for the decorated methods of your CDI Beans to be traced they need to be a) not static or private, and b) accessed externally or via self-injection. This means that in the following example, `method1` of the above class would be traced, and `method2` would not:

```
@Path("/")
@RequestScoped
public class JaxrsEndpoints {

    @Inject
    TracedExample tracedExample;

    @GET
    public String method1Traced() {
        return tracedExample.method1();
    }

    @GET
    public String method2NotTraced() {
        return new TracedExample().method2();
    }

}
```

Annotations applied to methods take precedence over those applied to classes. This allows you to whitelist or blacklist methods for tracing.

The Maven dependency to add to your application to get access to the `@Traced` annotation is the following:

```
<dependency>
    <groupId>org.eclipse.microprofile.opentracing</groupId>
    <artifactId>microprofile-opentracing-api</artifactId>
    <version>{mpOpenTracingVersion}</version>
    <scope>provided</scope>
</dependency>
```

Using the OpenTracing `Tracer` class

The OpenTracing `Tracer` class allows you to manually start, finish, and add information to Spans.

To access the tracer in your applications, you can inject it like so:

```
import io.opentracing.Tracer;

public class TracedComponent{

    @Inject
    Tracer tracer;
}
```

You can only inject a Tracer when your application is running inside a Payara Platform runtime you cannot do so from a Java SE client. From a Java SE client you must use the OpenTracing.io `GlobalTracer` class, see here for more details.

Starting a Span, marking it as the active Span (the one from which any children will spawn), and ending it is done like so with a *try-with-resources* block:

```
import io.opentracing.Tracer;

public class TracedComponent{
    public void tracerExample() {
        try (Span span = tracer.buildSpan("example").startActive(true)) {
            // Code to trace
        }
    }
}
```

If you wish to add any Tags or Logs to your Spans, even those started by the `@Traced` annotation, you can do this like so:

```
import io.opentracing.Tracer;

@Path
@RequestScoped
public class TracedResource{

    @Inject
    Tracer tracer;

    @GET
    @Path
    @Traced
    public String example2() {
        tracer.activeSpan().setTag("exampleTag", "foo").log("exampleLog");
```

```
        return "anon";
    }
}
```

The `Tracer` class also gives you access to the `inject` and `extract` methods, which you can use for tracing across threads and processes. It is recommended however that you simply use a Managed Executor Service for your asynchronous tasks and the default JAX-RS client implementation or MicroProfile REST Client for JAX-RS calls as these will automatically do this for you.

Disabling Automatic Tracing of JAX-RS Methods and MicroProfile REST Client Calls

By default, calls to JAX-RS methods and any calls by a MicroProfile REST Client are traced.

Disabling Automatic Tracing of JAX-RS Methods

To disable tracing of JAX-RS methods, you can use the `@Traced` annotation on each method or class that you wish to skip tracing of.

```
import org.eclipse.microprofile.opentracing.Traced;

@Path("/")
@RequestScoped
public class JaxrsEndpoints {

    @Inject
    TracedExample tracedExample;

    // Automatically traced
    @GET
    public String method1Traced() {
        return tracedExample.method1();
    }

    // Tracing disabled
    @GET
    @Traced(false)
    public String method2NotTraced() {
        return new TracedExample().method2();
    }
}
```

You can also use tracing of JAX-RS methods by defining a skip pattern using a MicroProfile Config properties file or config source. These skip patterns accept Java regular expressions to match against the URI of your JAX-RS methods.

```
mp.opentracing.server.skip-pattern=/foo|/bar.*
```

Disabling Automatic Tracing of MicroProfile REST Client

To disable tracing of MicroProfile REST Client calls, annotate the client interface or method with `@Traced(false)`.

```
import org.eclipse.microprofile.opentracing.Traced;

@Traced(false)
@Path("/")
public interface ExampleClient {

    @GET
    @Path("test")
    @Produces(MediaType.TEXT_PLAIN)
    Response example();
}
```

Tracing APIs Compatibility

The following is an up-to-date compatibility matrix that list the compatible versions of OpenTelemetry and OpenTracing in the Payara Platform:

Payara Server & Micro Version	OpenTracing.io API Version	OpenTelemetry API Version
6.0.0 - main-7	0.33	1.29.0
5.36.0+	0.33	-
4.1.2.183 - 4.1.2.191 5.183 - 5.35.0	0.31	-
4.1.2.182 5.182	0.30	-

Features Not Currently Supported

The Payara Platform currently does not offer the following OpenTracing features:

- Conversion to or from OpenTracing `0.31` or newer APIs

Public API

Overview

This page contains information on using the Public API integrated within Payara Server and Payara Micro.

See the Payara API Javadoc for the complete public Payara API reference.

Use Cases

The Public API should be used in the following scenarios:

1. Java EE Developers and end users that develop web and enterprise applications that require Payara specific features outside the specifications (and **JCache**).
2. Contributors that want to develop extensions for Payara Server or Payara Micro.

Maven Coordinates

The Public API is released as a Maven artifact in **Payara Nexus**, in the `payara-artifacts` repository. To use it in a Maven project, set the following dependencies in your project's POM:

```
<dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>fish.payara.api</groupId>
            <artifactId>payara-bom</artifactId>
            <version>main-7</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
    </dependencies>
</dependencyManagement>

<dependencies>
    <dependency>
        <groupId>fish.payara.api</groupId>
        <artifactId>payara-api</artifactId>
        <scope>provided</scope>
    </dependency>
</dependencies>
```

For information on the Payara BOM, please see Maven Bom.

CDI Events

Payara Server is able to listen to and fire CDI events across the Hazelcast cluster. The CDI events can be fired and listened to by applications on Payara Server instances as well as Payara Micro instances provided that they are connected to the same cluster.

Requirements

Hazelcast must be enabled for all Payara Server instances and they must be able to connect to the same Hazelcast cluster. See the Data Grid section for more details.

Initializing the event bus

The event bus is initialized automatically after an application is started. No additional

configuration is necessary to fire and listen to remote events.

Firing remote CDI events

In order to fire a CDI event remotely, mark it with the `@Outbound` annotation:

```
@Inject
@fish.payara.micro.cdi.Outbound
Event<String> event;
```

The above will create an event with a String payload, which will be observable on remote instances in the cluster. An outbound event can be fired as any other CDI event:

```
event.fire("This is an event");
```

The payload passed as an argument to the `fire()` method has to implement the `Serializable` interface.

An outbound event will be fired asynchronously on a remote instance. If loopback is allowed, it will be fired also on the same instance, but in a different thread. Therefore the call doesn't block the current thread.

It's possible to use additional qualifiers to match event with observers. Any additional qualifier used with `@Outbound` will mean that the event will be matched with an `@Inbound` listener that accepts the qualifiers.

Observing remote CDI events

Outbound events are observed by every CDI bean with a listener method that is marked with the `@Inbound` qualifier:

```
public void receiveEvent(@Observes @Inbound String message) {
}
```

The observers may reside in any application running on one or more instances in a Hazelcast cluster, and they will listen to events fired in an application running on any instance within the same cluster. By default, events will be fired on all remote cluster instances (all instances except the one in which the event was fired).

An event will be matched with observers by the payload class, using the same rules as usual CDI events. Observers will receive events that are assignable to the observed class.

Additional options

Using CDI Qualifiers

It's possible to tag a remote event in a type-safe way using any CDI qualifier. Only observers that

match the qualifiers would receive such event.

A remote event with a qualifier `@MyQualifier` can be triggered like this:

```
@Inject
@fish.payara.micro.cdi.Outbound
@MyQualifier
Event<String> event;
...
event.fire("This is a qualified event");
```

This event can be observed only by an observer that contains the qualifier:

```
public void receiveEvent(@Observes @Inbound @MyQualifier String message) {
}
```

Event name

It is possible to tag a remote event with a name. In that case, only observers that listen to events of the same name will receive such events. To fire an event with a name:

```
@Inject
@Outbound(eventName = "MyEvent")
Event<String> event;
```

To receive the above named event:

```
public void receiveEvent(@Observes @Inbound("MyEvent") String message) {
}
```

Instance name

By default, all remote instances in the same cluster will receive an outbound event, which matches the observed class and event name. If you want to target specific instances in the cluster, it is possible to define one or more target instances for an outbound event:

```
@Inject
@Outbound(instanceName = "Instance-1")
Event<String> event;
```

Several instance names can be configured with an array:

```
@Inject
@Outbound(instanceName = {"Instance-1", "Instance-2"})
```

```
Event<String> event;
```

If you are using Payara Server, the name of the DAS instance is `server` by default. In the case of a separate standalone instance, use the instance's name in the configuration. If you are using Payara Micro, the instance's name is configured using the `--name` option, or is generated by if not configured (see the section link:/Technical Documentation/Payara Micro Documentation/Payara Micro Configuration and Management/Micro Management/Configuring An Instance.adoc[Payara Micro Instance Names,role=unresolved]).

Loopback

When an outbound event is fired, by default, it is treated as a remote message and will be delivered only to remote instances in the cluster. It will not be delivered to listeners on the same server instance.

If an event should be delivered to observers in the local instance as well, it can be done by setting the `loopBack` attribute to true:

```
@Inject
@Outbound(loopBack = true)
Event<String> event;
```

Dynamic configuration

If required, events can also be fired programmatically, not only using the static `@Outbound` annotation next to the injection point. Although there is no special API to support it, CDI already supports programmatic configuration of events.

The following is an example of how to configure and fire an outbound event programmatically without using any injection points:

```
CDI.current().getBeanManager().fireEvent("This is an event", new Outbound() {
    @Override
    public String eventName() {
        return System.getProperty("eventname");
    }

    @Override
    public boolean loopBack() {
        return Boolean.getBoolean(System.getProperty("loopback"));
    }

    @Override
    public String instanceName() {
        return System.getProperty("instanceName");
    }

    @Override
```

```
    public Class<? extends Annotation> annotationType() {
        return this.getClass();
    }
});
```

The above code creates a dynamic instance of the `@Outbound` annotation and fires the event `"This is an event"` using a bean manager retrieve via a static `CDI.current()` method.

Clustered Singleton

The Payara API provides a `@Clustered` annotation that makes `@ApplicationScoped` CDI beans or `@Singleton` EJB beans cluster-wide. This allows a single bean to be shared across an entire cluster.

How It Works

The singleton bean is deployed and will be available to all members of the cluster. Prior to any call to this bean, its latest version will be retrieved from a Hazelcast map, which will be possibly updated after the call is finished. In order to avoid race conditions or data corruption, a **Hazelcast distributed lock** for the bean will be optionally acquired so that only one method call can be executed in the cluster at a time.

Examples

Examples can be found here: https://github.com/payara/Payara-Examples/tree/master/javaee/clustered-singleton

`@Clustered` and EJB Timers

Persistent EJB Timers (which are the default) will work correctly with clustered singletons since they will only be executed in a single node of the cluster or deployment group.

If the purpose of a clustered singleton bean is to only define a persistent EJB timer which needs to be fired **once** per cluster or deployment group on a Payara Server domain, then it is better to use a stateless session bean instead. The default behaviour of Payara Server is to trigger expired persistence EJB timers once per deployment group or cluster, so the added redundancy provided by this feature is not necessary.

`@Clustered` and `@Startup` / `@Initialized @ApplicationScoped`

Care must be taken in this scenario. By default, the `@PostConstruct` lifecycle method is called for every instance in the cluster for these beans. This behavior needs to be disabled by using `@Clustered(callPostConstructOnAttach = false)` and possibly `callPreDestroyOnDetach = false` as well, so only the `@PostConstruct` method will be called only once per cluster. `@Observed @Initialized` methods are called for every instance in the cluster. The only valid method for cluster-wide initialization is to use the `@PostConstruct` lifecycle method configured as described above.

CDI Considerations and Notes

Since there are no default locks for CDI, `@Clustered` CDI `@ApplicationScoped` beans do not have distributed locks on by default. It is highly recommended to enable distributed locks for CDI Clustered beans: `@Clustered(lock = DistributedLockType.LOCK)` so there is no chance of race condition / data corruption for CDI Clustered beans.

Requirements and assumption

1. Hazelcast is required to be enabled (default)
2. `@Clustered` only works with `@ApplicationScoped` or `@Singleton` annotation, and in no other circumstance
3. All fields in the `@Clustered` `@Singleton` class need to be correctly Serializable
4. Works correctly only if accessed via @Injected proxy, not through direct access
5. Works with EJB timers correctly only if all timers are persistent (default)
6. All method calls to `@Clustered` beans operate on a local instance
7. Data corruption is possible if distributed lock is turned off and there is a race condition between method calls to the same bean on multiple cluster nodes simultaneously. In such a case, last method call wins the singleton state
8. Clustered singletons are stored in Hazelcast map under "Payara/(EJB/CDI)/singleton/<singletonComponentName>/[lock]"

It is also highly recommended to add a `serialVersionUID` variable to the `@Clustered` `@Singleton` class, in order to verify that a loaded class and the serialized object are compatible. A previously serialized entry in the Data Grid is compatible with an updated version of the same class.

```
private static final long serialVersionUID = 1234L;
```

Adding a `serialVersionUID` is expected to prevent serialization issues encountered by the Data Grid if your singleton's source code is updated regularly.

Usage

A singleton bean is made cluster-wide by annotating the class with the `@fish.payara.cluster.Clustered` qualifier as well as it's scope annotation.

Alternatively, you can use the `payara-ejb-jar.xml` to configure a Singleton EJB to be cluster-wide.

Example

An example for a CDI bean:

```
@Clustered
@jakarta.enterprise.context.ApplicationScoped
```

```
public class ClusterSingletonBean implements Serializable {

}
```

An example for a Singleton EJB:

```
@Clustered
@jakarta.ejb.Singleton
public class ClusterSingletonBean implements Serializable {

}
```

An example for a Singleton EJB using `payara-ejb.jar` (`clustered-key-name` is optional):

```
<payara-ejb-jar>
    <enterprise-beans>
        <ejb>
            <ejb-name>ClusteredSingleton</ejb-name>
            <clustered-bean>true</clustered-bean>
            <clustered-key-name>ClusteredSingleton</clustered-key-name>
        </ejb>
    </enterprise-beans>
</payara-ejb-jar>
```

Configuration

The `@Clustered` annotation has several configuration options. They are detailed below.

Table 195. Configuration Options

Option	XML element	Description	Default
keyName	clustered-key-name	The key in the distributed map to bind the clustered object to.	The name of the bean. If the bean is a CDI bean and has no assigned name, the bean class name will be used.
lock	clustered-lock-type	The type of distributed locking to be performed. For EJB beans, only `INHERIT` and `LOCK_NONE` are valid. For CDI beans, valid values are `LOCK` and `INHERIT`, which is equivalent to using `LOCK_NONE`.	`INHERIT`

Option	XML element	Description	Default
callPostConstructOnAttach	`clustered-attach-postconstruct`	Whether to call `@PostConstruct` each time the bean is created on a different node. Will result in multiple calls.	`true`
callPreDestroyOnDetach	`clustered-detach-predestroy`	Whether to call `@PreDestroy` when the singleton is destroyed on an instance while still being available on another. Will result in multiple calls.	`true`

Distributed Locking

Clustered singleton beans allow a locking type, to specify how the distributed object is locked when being accessed by multiple instances. The lock options are members of the class `fish.payara.cluster.DistributedLockType`, which are as follows:

- `LOCK` - Distributed locking will be performed.
- `LOCK_NONE` - No distributed locking will be performed.
- `INHERIT` - The locking behaviour will be inherited from the inherited class.

By default, `@Singleton` EJBs will use a distributed lock, and `@ApplicationScoped` CDI beans won't.

When a distributed object is locked, it will only be written by one thread across the entire cluster at any one time. Locks use system resources, but prevent synchronisation errors with the singleton data.

If a member holding a lock goes offline, the lock will become available again.

Transactions

Transactions in a clustered singleton work the same way that they would work in EJB or CDI depending on which scope annotation you're using. Transactions are not distributed through the whole cluster. When a transaction is created in a thread in one JVM, it must be handled and closed in the same thread; it cannot be passed onto a different server instance. Once the transaction is closed, the changes will be replicated to the rest of the cluster.

OAuth Support

The Payara API provides a `@OAuth2AuthorisationMechanism` annotation that creates an authorisation mechanism for OAuth2 support. This works in the same way as other authorisation mechanisms in the Java EE Security API.

Usage

The OAuth2 authentication mechanism is defined through the `@OAuth2AuthorisationMechanism` annotation. Specifying this in a valid place as defined by the Java EE Security API will create the mechanism. Often this may mean that any class is a valid position.

Example

Here's an example that configures a Google OAuth2 endpoint:

```
@OAuth2AuthenticationDefinition(
    authEndpoint="https://accounts.google.com/o/oauth2/v2/auth",
    tokenEndpoint="https://www.googleapis.com/oauth2/v4/token",
    clientId="{my-key}.apps.googleusercontent.com",
    clientSecret="{my-secret}",
    redirectURI="https://localhost:8181/{my-application}/callback",
    scope="email",
    extraParameters = {
        "testKey=testValue",
        "testKey2=testValue2"
    }
)
public class SecurityBean {

}
```

Once the user is authenticated they will not have any roles defined, regardless of the OAuth scope. Roles should be specified using `@DeclareRoles`. See this sample project for a more detailed example.

When defining a OAuth2 flow within an application deployed on Payara Server it is possible to retrieve the access token within any bean in the scope of the callback/redirectURI resource used to configure the authentication:

```
@WebServlet("/callback")
public class CallbackServlet extends HttpServlet {

    @Inject
    OAuth2AccessToken token;

    @Override
    protected void doGet(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException {
        PrintWriter out = response.getWriter();
        //Here's the access token
        out.println(token.getAccessToken());
    }
}
```

OAuth2 authorization support require the use of HTTP/2, so make sure to use the appropriate HTTP network listener when preparing your application.

Configuration

The `@OAuth2AuthenticationDefinition` annotation has several configuration options.

They are detailed below.

Table 196. Configuration Options

Option	Required	Description	Requirements
`authEndpoint`	true	The URL for the OAuth2 provider to provide authentication.	The endpoint must be HTTPS.
`tokenEndpoint`	true	The URL for the OAuth2 provider to give the authorisation token.	The endpoint must be HTTPS.
`clientId`	true	The client identifier issued when the application was registered.	N/A.
`clientSecret`	true	The client secret for the registered application.	N/A.
`scope`	false	The scopes requested from the OAuth provider.	N/A.
`redirectURI`	false	The URL to redirect the user to upon successful authentication.	Must be equal to one set in the OAuth2 Authentication provider.
`extraParameters`	false	An array of extra options to be sent to the OAuth provider.	Must be in the form `"key=value"`.

Expression Language Support

Additionally, the `@OAuth2AuthenticationDefinition` supports the use of expression language (EL) notation for dynamic configuration scenarios. This means that you can use any CDI bean properties to set the OAuth2 configuration like this:

```
@OAuth2AuthenticationDefinition(
    authEndpoint="#{oauth2ConfigBean.authEndpointURL}",
    tokenEndpoint="#{oauth2ConfigBean.tokenEndpointURL}",
    clientId="#{oauth2ConfigBean.clientId}",
    clientSecret="#{oauth2ConfigBean.clientSecret}",
```

```
    redirectURI="#{oauth2ConfigBean.redirectURI}"
)
public class SecurityBean {
}
```

Client Secret Aliasing

The client secret can be input directly, or for added security it can be aliased using any of the following features:

- Password Aliases
- Environment Variables / System Properties
- Config API

See Also

- OAuth v2 Official site

OpenID Connect Support

The Payara API provides a `@OpenIdAuthenticationDefinition` annotation that creates an authorization mechanism for OpenID Connect support. This works in the same way as other authorization mechanisms in the Java EE Security API.

Usage

The OpenID Connect authentication mechanism is defined through the `@OpenIdAuthenticationDefinition` annotation. Specifying this in a valid place as defined by the Java EE Security API will create the mechanism.

Example

Here's an example that configures a OpenID Connect client:

```
@OpenIdAuthenticationDefinition(
       providerURI = "https://sample-openid-server.com",
       clientId = "87068hgfg5675htfv6mrucov57bknst.apps.sample.com",
       clientSecret = "{my-secret}",
       redirectURI = "${baseURL}/callback",
       extraParameters = {
            "testKey=testValue",
            "testKey2=testValue2"
       }
)
public class SecurityBean {

}
```

See this sample project for a more detailed example.

When defining a OpenID Connect flow within an application deployed on Payara Server, it is possible to retrieve the access token, identity token, user claims and the other authentication information within any bean in the scope of the callback/redirectURI resource used to configure the authentication:

```
@WebServlet("/callback")
public class CallbackServlet extends HttpServlet {

    @Inject
    OpenIdContext context;

    @Override
    protected void doGet(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException {
        PrintWriter out = response.getWriter();
        //Here's the caller name
        out.println(context.getCallerName());
        //Here's the caller groups
        out.println(context.getCallerGroups());
        //Here's the unique subject identifier within the issuer
        out.println(context.getSubject());
        //Here's the access token
        out.println(context.getAccessToken());
        //Here's the identity token
        out.println(context.getIdentityToken());
        //Here's the user claims
        out.println(context.getClaimsJson());
    }
}
```

The original protected URL called is stored so that a redirect can be issued to this page after the callback from the OpenIdConnect provider is handled.

Only some basic redirect is supported namely a GET. Only the URL and query parameters are available, not the headers and the request body.

```
@WebServlet("/callback")
public class CallbackServlet extends HttpServlet {

    @Override
    protected void doGet(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException {
        // handling the OpenIdContext information. See previous example
        // Now return to original requested page

response.sendRedirect(request.getSession().getAttribute(OpenIdConstant.ORIGINAL_REQUES
T).toString());
```

```
    }
}
```

Configuration

OpenID Client can be configured with both `@OpenIdAuthenticationDefinition` annotation attributes and Microprofile Config properties. The annotation and MicroProfile properties has several configuration options.

If you are using MicroProfile Config properties and the value contains a placeholder that should not be resolved by MicroProfile Config itself but by the Server (like `payara.security.openid.redirectURI=${baseURL}/Callback`) make sure the value is properly escaped. It will otherwise result in `NoSuchElementException`. Here's an example how such a value should be escaped: `payara.security.openid.redirectURI=\\${baseURL}/Callback`

The annotation and MicroProfile properties has several configuration options. They are detailed below.

Table 197. Configuration Options for `@OpenIdAuthenticationDefinition`

Option	MP Config property	Required/Type	Description	Default value	Requirements
`providerURI`	`payara.security.openid.providerURI`	`false`	The provider URI to discover the metadata of the OpenID Connect provider. If not specified, metadata are read from `providerMetadata`.		The endpoint must be HTTPS.
`providerMetadata`		required if `providerURI` not specified, type: `@OpenIdProviderMetadata`	Alternative way to specify metadata if auto-configuration from `providerURI` can't be used.	`payara.security.openid.provider.*`	The endpoint must be HTTPS.
`clientId`	`payara.security.openid.clientId`	`true`	The client identifier issued when the application was registered.		N/A.

Option	MP Config property	Required/Type	Description	Default value	Requirements
`clientSecret`	`payara.security.openid.clientSecret`	`true`	The client secret for the registered application.		N/A.
`redirectURI`	`payara.security.openid.redirectURI`	`true`	The URL to redirect the user to upon successful authentication. Can include the variable `${baseURL}`, which is replaced by the URL of the application's context path (e.g. `https://myhost:8080/myapp`)	`${baseURL}/Callback`	Must be equal to one set in the OpenID Connect provider.
`scope`	`payara.security.openid.scope`	`false`	The scopes requested from the OpenID Connect provider.	{"openid", "email", "profile"}	N/A.
`responseType`	`payara.security.openid.responseType`	`false`	Response Type value defines the processing flow to be used.	code	N/A.
`responseMode`	`payara.security.openid.responseMode`	`false`	Informs the Authorization Server of the mechanism to be used for returning parameters from the Authorization Endpoint.		N/A.

Option	MP Config property	Required/Type	Description	Default value	Requirements
prompt	payara.security.openid.prompt	false	The prompt value specifies whether the authorization server prompts the user for re-authentication and consent.		N/A.
display	payara.security.openid.display	false	The display value specifying how the authorization server displays the authentication and consent user interface pages.	page	N/A.
useNonce	payara.security.openid.useNonce	false	Enables string value used to mitigate replay attacks.	true	N/A.
useSession	payara.security.openid.useSession	false	If enabled state & nonce value stored in session otherwise in cookies.	true	N/A.
jwksConnectTimeout	payara.security.openid.jwks.connect.timeout	false	Sets the connect timeout(in milliseconds) for remote JWKS retrieval.	500	Value must not be negative and if value is zero then infinite timeout.
jwksReadTimeout	payara.security.openid.jwks.read.timeout	false	Sets the read timeout(in milliseconds) for remote JWKS retrieval.	500	Value must not be negative and if value is zero then infinite timeout.

Option	MP Config property	Required/Type	Description	Default value	Requirements
tokenAutoRefresh	payara.security.openid.token.autoRefresh	false	Enables or disables the automatically performed refresh of Access and Refresh Token.	false	N/A.
tokenMinValidity	payara.security.openid.token.minValidity	false	Sets the minimum validity time(in milliseconds) the Access Token must be valid before it is considered expired.	10000	Value must not be negative.
claimsDefinition.callerNameClaim	payara.security.openid.callerNameClaim	false	Defines the name of callerName claim and maps the claim's value to caller name value in IdentityStore#validate.	preferred_username	N/A.
claimsDefinition.callerGroupsClaim	payara.security.openid.callerGroupsClaim	false	Defines the name of callerGroups claim and maps the claim's value to caller groups value in IdentityStore#validate.	groups	N/A.
proxyDefinition.hostName	payara.security.openid.proxyHostname	false	Defines the hostname of the proxied server.		N/A.
proxyDefinition.port	payara.security.openid.proxyPort	false	Defines the port of the proxied server.		N/A.

Option	MP Config property	Required/Type	Description	Default value	Requirements
`extraParameters`		`false`	An array of extra options to be sent to the OpenID Connect provider.		Must be in the form `key=value` and follow URL query pattern, i.e. `key1=value1&key2=value2&key2=value+with+spaces`. Key entries can be repeated
`logout`		@LogoutDefinition	Defines the functionality that is performed when the user logs out and defines the RP Session Management configuration.		

If both an annotation attribute and a MicroProfile Config property are defined for the same option then the MicroProfile Config property value always takes precedence over the `@OpenIdAuthenticationDefinition` annotation value.

Table 198. Configuration Options For `@OpenIdProviderMetadata`

Option	MP Config property	Description	Default value
`endSessionEndpoint`	`payara.security.openid.provider.endSessionEndpoint`	OIDC provider's logout endpoint URL. If set, overrides the URL obtained via the `end_session_endpoint` element of the OIDC provider's metadata.	
`disableScopeValidation`	`payara.security.openid.disableScopeValidation`	This property disables the scope validation for custom scope configurations	false

Expression Language Support

The `@OpenIdAuthenticationDefinition` supports the use of expression language (EL) notation for programmatic configuration scenarios. This means that you can use any CDI bean properties to set

the OpenID Connect configuration like this:

```
@OpenIdAuthenticationDefinition(
    providerURI="#{openidConfigBean.tokenEndpointURL}",
    clientId="#{openidConfigBean.clientId}",
    clientSecret="#{openidConfigBean.clientSecret}",
    redirectURI="#{openidConfigBean.redirectURI}"
)
public class SecurityBean {
}
```

By default, the EL expressions are evaluated only once after the application is loaded and the evaluated values are then remembered until the application is reloaded, for performance reasons. This means that although the configuration can be evaluated dynamically the first time it's needed, it's not possible to change the configuration later on.
If you need to dynamically modify the configuration during the lifetime of the application, follow the next section about multi-tenancy support.

Multi-tenancy Support (Session-scoped Configuration)

By default, the same configuration of the OpenID connector is applied for the whole application, for all authentication attempts. This is for performance reasons. The OpenID connector also supports re-evaluating the configuration for each user session, before each authentication attempt.

This is useful in a multi-tenant scenario to define a different configuration for each tenant. It's also useful if the user should be able to select which provider they want to use to authenticate.

To enable re-evaluation of the configuration for each user session, set the MicroProfile Configuration property `payara.security.openid.sessionScopedConfiguration` to `true`. To specify it directly in the application, you can place it in the microprofile-config.properties file in the `META-INF` directory on the classpath (in a WAR application it could be in `WEB-INF/classes/META-INF`).

With this enabled, it's possible to use EL expressions to dynamically adjust the configuration before each authentication attempt, e.g. based on any information in the incoming HTTP request. The information about the HTTP request can be retrieved from a `HttpServletRequest` object injected using `@Inject`.

It's not possible to use a different configuration for just a subset of secured resources. Once a user is authenticated, the authentication information is saved in the HTTP session. All secured resources will be accessed using the same user, having the same roles, until the user logs out.

Example of Multi-tenant Authentication

This example should showcase the following steps:

- Enable session-scoped OpenID Connect configuration

- Resolve the tenant name from an HTTP request query parameter
- Use the tenant name to read the configuration value from the respective link:/Technical Documentation/MicroProfile/Config/Overview.adoc[MicroProfile Config,role=unresolved] property
- Retrieve the value from an EL expression defined in the `@OpenIdAuthenticationDefinition` annotation

The tenant can also be resolved from a cookie, which is set the first time a user loads the application; from the domain name in the URL (if different tenants use a different domain name to access the same application); from a path prefix that follows the context root and prepends all application URLs (e.g. `contextroot/tenant1/index.xhtml`, `contextroot/tenant2/index.xhtml`).

1. Create a file `microprofile-config.properties` in your application (for a WAR application it would be in the `WEB-INF/classes/META-INF` directory), with the following contents:

   microprofile-config.properties

   ```
   payara.security.openid.tenant1.providerURI=<TENANT1_OPENID_PROVIDER_URI>
   payara.security.openid.tenant2.providerURI=<TENANT2_OPENID_PROVIDER_URI>
   payara.security.openid.sessionScopedConfiguration=true
   ```

   This will provide configuration for `tenant1` and `tenant2` tenants. For each additional tenant, add a new line for its `providerURI`.

2. Create an `OpenidConfigBean` class with the `tokenEndpointURL` method. This class will be a CDI bean that injects `HttpServletRequest` to get information about which tenant to use. It will also inject `Config` to retrieve the configuration about each tenant from the `microprofile-config.properties` file:

   OpenidConfigBeanEL.java

   ```
   @Named
   public class OpenidConfigBeanEL {

       @Inject
       HttpServletRequest request;

       @Inject
       Config config;

       private static final String BASE_OPENID_KEY = "payara.security.openid";

       public String getTokenEndpointURL() {
           String tenant = getTenant(request);  // a custom method to decide which
   tenant to use
           return config
                   .getOptionalValue(BASE_OPENID_KEY + "." + tenant + ".providerURI",
   String.class)
   ```

```
                // e.g. payara.security.openid.tenant1.providerURI for "tenant1"
tenant
                .orElseGet(() -> {
                    // read config for the "tenant1" tenant by default
                   return config.getValue(BASE_OPENID_KEY + ".tenant1.providerURI",
String.class);
                });
    }

    private String getTenant(HttpServletRequest request) {
        return request.getParameter("tenant"); // resolves the tenant name from a
query parameter
    }

}
```

3. Finally, configure the OpenID Connector using the `OpenIdAuthenticationDefinition` annotation that references the `getTokenEndpointURL()` in an EL expression:

SecurityBean.java

```
@OpenIdAuthenticationDefinition(
        providerURI = "#{openidConfigBean.tokenEndpointURL}",
        clientId = CLIENT_ID_VALUE,
        clientSecret = CLIENT_SECRET_VALUE,
        redirectURI = "${baseURL}/Callback"
)
public class SecurityBean {
}
```

Logout functionality

With the `logout` parameter of the `OpenIdAuthenticationDefinition` you can define the behavior when the user logs out of the application and defines how the RP session is managed.

Table 199. Configuration Options

Option	MP Config property	Required	Description	Default value
`notifyProvider`	`payara.security.openid.provider.notify.logout`	`false`	Notify the OIDC provider (OP) that the user has logged out of the application and might want to log out of the OP as well. If `true` then after having logged out the user from RP, redirects the End-User's User Agent to the OP's logout endpoint URL. This URL is normally obtained via the `end_session_endpoint` element of the OP's metadata or can be customized via `fish.payara.security.annotations.OpenIdProviderMetadata#endSessionEndpoint`	`false`
`redirectURI`	`payara.security.openid.logout.redirectURI`	`false`	The post logout redirect URI to which the RP is requesting that the End-User's User Agent be redirected after a logout has been performed. If the redirect URI is empty then redirect to OpenID connect provider *authorization_endpoint* for re-authentication.	

Option	MP Config property	Required	Description	Default value
accessTokenExpiry	payara.security.openid.logout.access.token.expiry	false	Whether the application session times out when the Access Token expires.	false
identityTokenExpiry	payara.security.openid.logout.identity.token.expiry	false	Whether the application session times out when the Identity Token expires.	false

A programmatic logout is performed by calling `OpenIdContext#logout()` which invalidates the RP's active OpenId Connect session.

If `fish.payara.security.annotations.LogoutDefinition#notifyProvider` is set to true then it redirects the End-User's User Agent to the `end_session_endpoint` to notify the OP that the user has logged out of the RP's application.

It will also ask the user whether they want to log out from the OP as well. After successful logout, the End-User's User Agent redirects back to the RP's `post_redirect_uri` configured via the `fish.payara.security.annotations.LogoutDefinition#redirectURI` property.

Proxy Definition

Using the `proxyDefinition` parameter of the `@OpenIdAuthenticationDefinition` annotation you can specify details regarding proxy mapping within the OpenID Connect client configuration. It contains attributes to specify the `hostName` and `port` of the proxied server. This addition facilitates the configuration of proxy mapping for requests traversing through reverse web proxies.

Moreover, the proxy configuration details (`hostName` and `port`) can be dynamically utilized to define the `redirectURI` within the `OpenIdAuthenticationDefinition`, replacing the `baseURL` placeholder if present. This allows for a more flexible setup, especially in scenarios involving reverse web proxies.

Scenarios without Proxy

- **Case 1**
  - `redirectURI` employs the `${baseURL}` placeholder, which defaults to `${baseURL}/Callback` when `redirectURI` is not explicitly defined.
  - Proxy definition is also absent.
  - → **Outcome:** The generated `redirectURI` should include the request's host and port. The registered Authorized Redirect URI in Google Cloud must contain a URL with the Payara Server instance's host and port.
- **Case 2**

- `redirectURI` is explicitly defined with the Payara Server instance's host and port.
- Proxy definition is not present.
- → **Outcome:** The registered Authorized Redirect URI in Google Cloud must contain a URL with the Payara Server instance's host and port.

Scenarios with Proxy

- **Case 3**
  - `redirectURI` employs the `${baseURL}` placeholder, defaulting to `${baseURL}/Callback` when `redirectURI` is not explicitly defined.
  - Proxy definition is included.
  - → **Outcome:** The generated `redirectURI` should include the proxy's host and port. The registered Authorized Redirect URI in Google Cloud must contain a URL with the proxy's host and port.
- **Case 4**
  - `redirectURI` is explicitly defined with the Payara Server instance's host and port.
  - Proxy definition is also present.
  - → **Outcome:** The registered Authorized Redirect URI in Google Cloud must contain a URL with the Payara Server instance's host and port.
- **Case 5**
  - `redirectURI` is explicitly defined with the Proxy's host and port.
  - Proxy definition is included.
  - → **Outcome:** The registered Authorized Redirect URI in Google Cloud must contain a URL with the proxy's host and port.

Provider Metadata

If the OpenId server doesn't provide autoconfiguration, or it is necessary to customize it, it is possible to set these values in the `providerMetadata` attribute of the `@OpenIdAuthenticationDefinition` annotation.

It's also possible to specify all values by using MicroProfile Config properties. None of the attributes are required in the annotation, but some options are required and must be specified either in the annotation or a MicroProfile property or must be provided by the OIDC provider.

The order of evaluation is: MicroProfile Config → `@OpenIdProviderMetadata` → automatic configuration on `providerURI` address.

When these values, which correspond to lists (e.g. `scopesSupported`, `responseTypesSupported`), are loaded from MicroProfile Config, they are separated by a comma, following MicroProfile Config Array conventions.

Table 200. Provider Metadata Options

Option	MP Config property	Required	Description
issuer	payara.security.openid.provider.issuer	true	The base address of OpenId Connect Provider (OIDC Provider).
authorizationEndpoint	payara.security.openid.provider.authorizationEndpoint	true	The URL for the OAuth2 provider to provide authentication.
tokenEndpoint	payara.security.openid.provider.tokenEndpoint	true	The URL for the OAuth2 provider to give the authorization token.
userinfoEndpoint	payara.security.openid.provider.userinfoEndpoint	true	An OAuth 2.0 Protected Resource that returns Claims about the authenticated End-User.
endSessionEndpoint	payara.security.openid.provider.endSessionEndpoint	false	OIDC Provider's endpoint to notify that the End-User has logged out of the site and might want to log out of the OIDC Provider as well.
jwksURI	payara.security.openid.provider.jwksURI	true	An OIDC Provider's JSON Web Key Set document.
scopesSupported	payara.security.openid.provider.scopesSupported	recommended	List of the OAuth 2.0 scope values that this server supports, e.g. `openid`.
responseTypesSupported	payara.security.openid.provider.responseTypeSupported	true	List of the OAuth 2.0 response_type values that this OIDC Provider supports, e.g. `code`, `id_token`, `token id_token`.
subjectTypesSupported	payara.security.openid.provider.subjectTypesSupported	true	List of the Subject Identifier types that this OIDC Provider supports. Valid types include `pairwise` and `public`.

Option	MP Config property	Required	Description
idTokenSigningAlgValuesSupported	payara.security.openid.provider.idTokenSigningAlgorithmsSupported	true	List of the JWS signing algorithms (algorithm values) supported by the OIDC Provider for the ID Token to encode the Claims in a JWT, e.g. RS256.
idTokenEncryptionAlgValuesSupported	payara.security.openid.provider.idTokenEncryptionAlgValuesSupported	false	List of the JWE encryption algorithms (alg values) supported by the OIDC Provider for the ID Token to encode the Claims in a JWT.
idTokenEncryptionEncValuesSupported	payara.security.openid.provider.idTokenEncryptionEncValuesSupported	false	List of the JWE encryption algorithms (enc values) supported by the OIDC Provider for the ID Token to encode the Claims in a JWT.
claimsSupported	payara.security.openid.provider.claimsSupported	recommended	List of the Claim Names of the Claims that the OIDC Provider MAY be able to supply values for. Note that for privacy or other reasons, this might not be an exhaustive list.

Client Secret Aliasing

The client secret can be input directly, or for added security it can be aliased using Microprofile Config

Environment Variables and System Properties can be used indirectly through MicroProfile Config.

Fetch Caller Data

As the OpenId Connect Client is built on top of Jakarta EE Security API, therefore `jakarta.security.enterprise.SecurityContext` interface can provide caller info which is available as a CDI bean and can be injected into any context-aware instance.

The Payara Public API also provides a `fish.payara.security.openid.api.OpenIdContext` interface

which is also available as a CDI bean and consist of the following methods:

- The `getCallerName()` method - Gets the caller name of the currently authenticated user.
- The `getCallerGroups()` method - Gets the groups associated with the caller.
- The `getSubject()` method - Subject Identifier. A locally unique and never reassigned identifier within the Issuer for the End-User, which is intended to be consumed by the Client.
- The `getTokenType()` method - Gets the token type value. The value MUST be `Bearer` or another token type value that the client has negotiated with the authorization server.
- The `getAccessToken()` method - Gets the authorization token that was received from the OpenId Connect provider.
- The `getIdentityToken()` method - Gets the identity token that was received from the OpenId Connect provider.
- The `getRefreshToken()` method - Returns the refresh token that is used by OIDC client to get a new access token.
- The `getExpiresIn()` method - Return the time that the access token is granted for, if it is set to expire.
- The `getClaimsJson()` method - Gets the User Claims JSON that was received from the `userinfo` endpoint.
- The `getClaims()` method - Gets the User Claims that were received from the `userinfo` endpoint.
- The `getProviderMetadata()` method - The OpenId Connect Provider's metadata document fetched via provider URI.

User Information from the ID Token

The `userClaimsFromIDToken` attribute that belongs to the `@OpenIdAuthenticationDefinition` will instruct the container to retrieve the user information details from the ID Token instead of calling the `userinfo` endpoint, as defined by the OpenID Connect standard workflow.

As such, this behaviour is non-standard and should be used on special cases.

To properly connect an application with Microsoft ADFS this property is required because by default Microsoft ADFS doesn't allow calls to the `userinfo` endpoint.

Table 201. Configuration Option

Option	MP Config Property Name	Required	Description	Default value
`userClaimsFromIDToken`	`payara.security.openid.userClaimsFromIDToken`	`false`	Instructs the container to retrieve user information from the ID Token	`false`

Example

```
@OpenIdAuthenticationDefinition(
       providerURI = "https://sample-openid-server.com",
       clientId = "87068hgfg5675htfv6mrucov57bknst.apps.sample.com",
       clientSecret = "{my-secret}",
       redirectURI = "${baseURL}/callback",
       userClaimsFromIDToken=true
)
public class SecurityBean {

}
```

Disable Scope Validation

By default, the OpenID Connect connector validates that a scope is reported as a supported scope by the provider. However, some providers support more scopes than they actually report as supported scopes.

To disable the validation and allow using such scopes, it's possible to use the `disableScopeValidation` property of `OpenIdProviderMetadata`. See the [Technical Documentation-Public API-OpenID Connect Support:::configuration] section for more details about this option.

Example

```
@OpenIdAuthenticationDefinition(
       providerURI = "https://sample-openid-server.com",
       clientId = "87068hgfg5675htfv6mrucov57bknst.apps.sample.com",
       clientSecret = "{my-secret}",
       redirectURI = "${baseURL}/callback",
       providerMetadata = @OpenIdProviderMetadata(disableScopeValidation = true))
public class SecurityBean {

}
```

Bearer Authentication and Authorization

In order to authenticate and authorize calls between services using the OpenID mechanism, it is possible to use authorization compatible with RFC 6750.

In this case, the access token presented to the resource service is an JWT token that is used to verify that the caller has access to OAuth2 protected resources.

Obtaining JWT Token

Obtaining the token is specific to the OAuth provider and the application. The usual approach is using Client Credentials Grant, where an application posts its clientId and secret to identity provider and receives access and refresh tokens in return.

Passing Token To The Resource Service

The obtained access token is passed with every request to the resource service by adding it into the `Authorization` HTTP header:

```
Authorization: Bearer access__token
```

Processing Bearer Authorization

When the `Bearer` authorization header is present in the request, the provided token is verified. It's validated that it comes from the expected issuer and hasn't expired.

Compared to the normal browser flow, no groups are automatically assigned to the identity. The reason for this is that machine-to-machine communication tends to be much more fine-grained and services might want to check more claims, such as `audience`.

The resource service is required to map the information in the JWT token to groups utilizing the `IdentityStore` interface. The OpenID connector provides the following classes to make this process possible:

`AccessTokenCallerPrincipal`

Caller principal subclass that contains access to all claims of passed JWT token

`BearerGroupIdentityStore`

A convenience base implementation of the necessary Jakarta EE security identity store.

```
@ApplicationScoped
@DeclareRoles({"user", "calendar-reader"})
public class Auth0BearerIdentityStore extends BearerGroupsIdentityStore {

    @Override
    protected Set<String> getCallerGroups(AccessTokenCallerPrincipal callerPrincipal)
{
        if (callerPrincipal.hasAudience("https://example.org/api/user")) {
            // if the token is for USER api, set this group
            return Set.of("user");
        }
        if (callerPrincipal.hasAudience("https://example.org/api/delegate")
                // delegate API is further constrained by scope
                &&
callerPrincipal.getAccessToken().getScope().contains("read:calendar")) {
            return Set.of("calendar-reader");
        }
        return Set.of();
    }
}
```

The Payara Platform also provides similar functionality by way of the MicroProfile JWT Authentication specification, which is limited only to securing JAX-RS resources. On the other hand, the OpenID Connect Bearer Authentication and Authorization feature is better aligned with the OpenID Connect support in Payara Platform and can also be used to secure other web resources like Jakarta Servlets, for example.

Integration with Specific Providers

Google Integration

The Payara Public API provides built-in support for Google OpenID Provider via the `@GoogleAuthenticationDefinition` annotation.

Request Refresh Token

To enable the refresh token feature, set the `tokenAutoRefresh` to true and add the `access_type` parameter value to `offline` so that application can refresh access tokens when the user is not present at the browser.

If application requests `offline` access then the application can receive access and refresh token. Once the application has a refresh token, it can obtain a new access token at any time or as older ones expire.

Otherwise, if an application requests `online` access, your application will only receive an access token

```
@GoogleAuthenticationDefinition(
    providerURI="#{openidConfigBean.tokenEndpointURL}",
    clientId="#{openidConfigBean.clientId}",
    clientSecret="#{openidConfigBean.clientSecret}",
    tokenAutoRefresh = true,
    extraParameters = {"access_type=offline", "approval_prompt=force"}
)
public class SecurityBean {
}
```

Azure AD Integration

The Payara Public API also provides built-in support for Azure AD OpenID Provider via the `@AzureAuthenticationDefinition` annotation.

Request Refresh Token

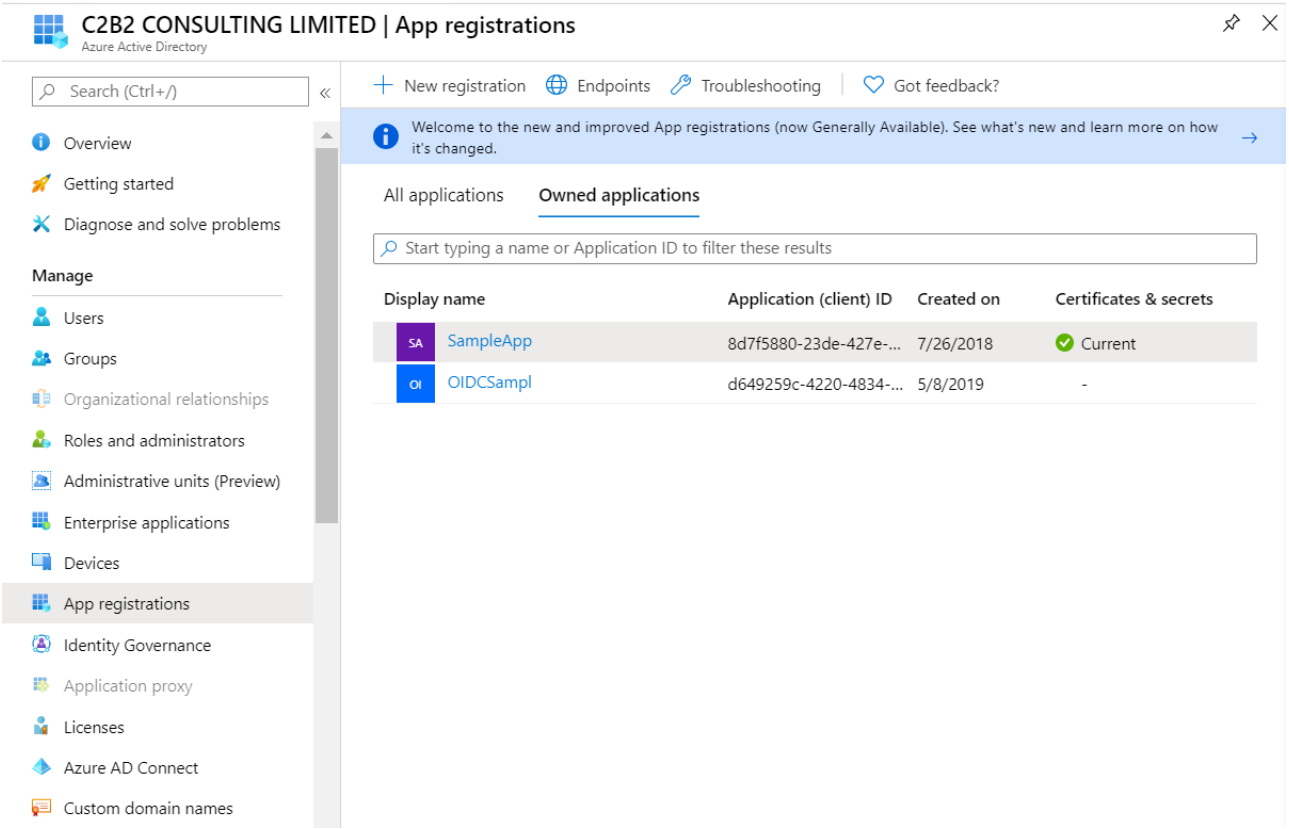
To receive the refresh token, set the `tokenAutoRefresh` to true and explicitly add the `offline_access` scope to the definition.

```
@AzureAuthenticationDefinition(
    providerURI="#{openidConfigBean.tokenEndpointURL}",
```

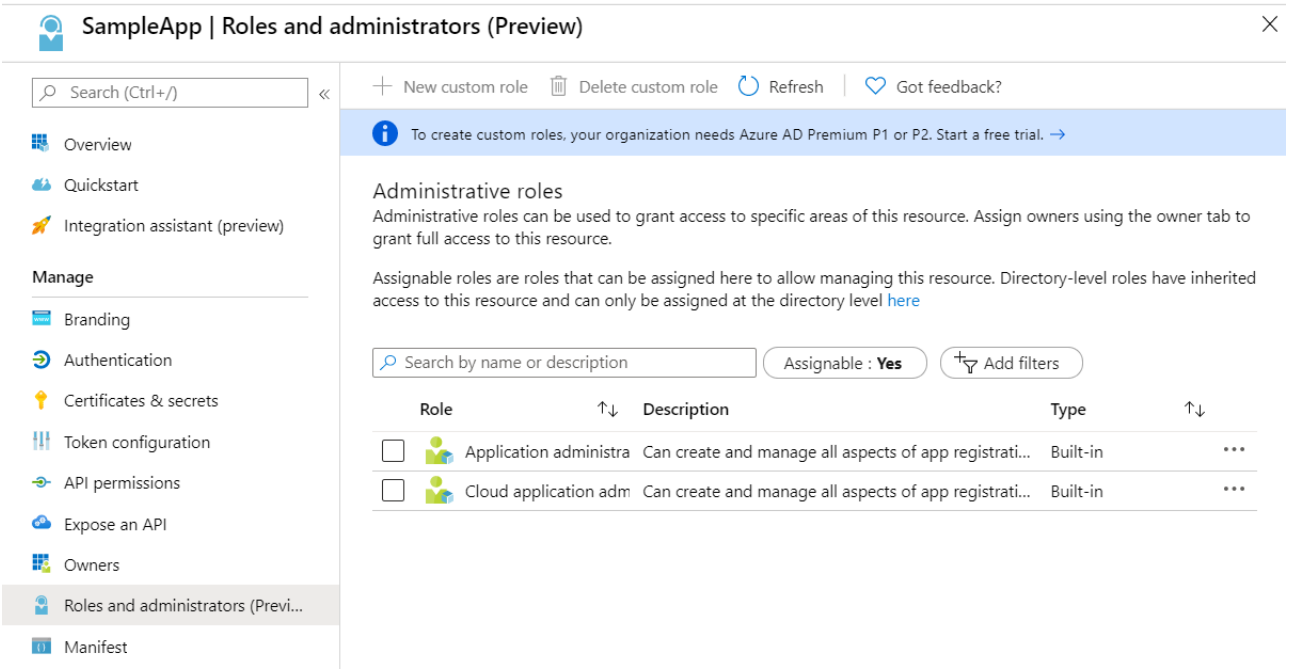
```
    clientId="#{openidConfigBean.clientId}",
    clientSecret="#{openidConfigBean.clientSecret}",
    tokenAutoRefresh = true,
    scope = {OPENID_SCOPE, EMAIL_SCOPE, PROFILE_SCOPE, OFFLINE_ACCESS_SCOPE}
)
public class SecurityBean {
}
```

Groups Mapping

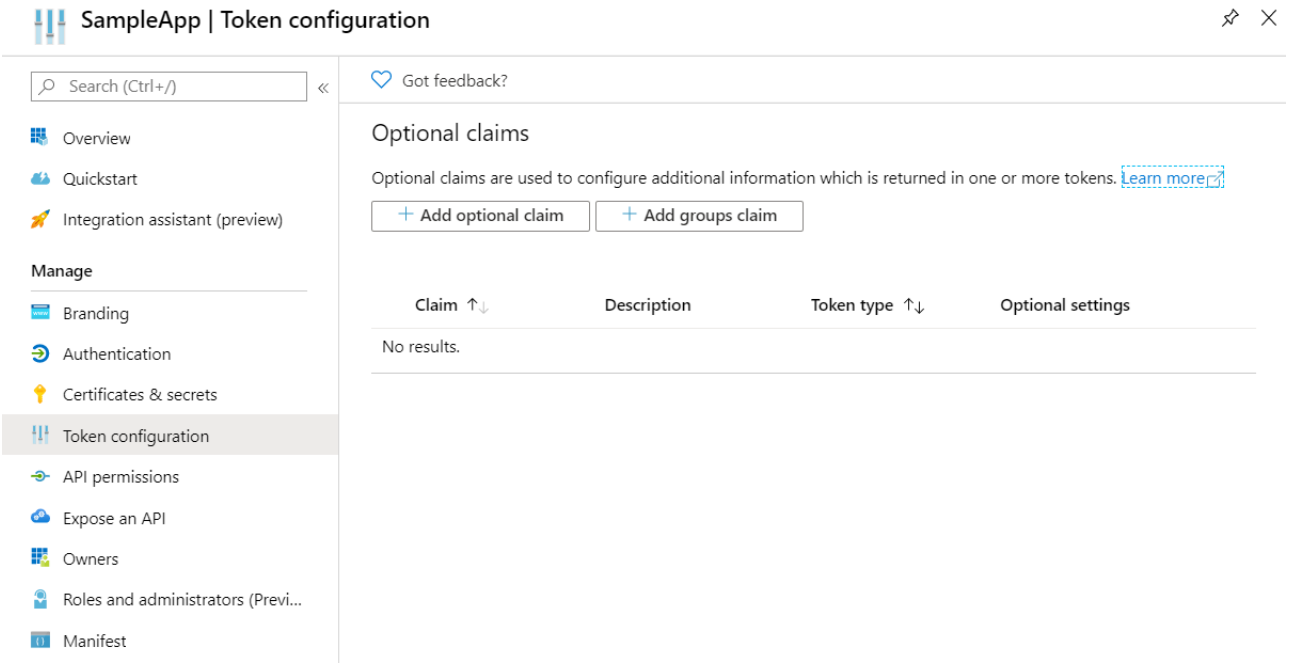
1. To add the groups to the registered application, Sign in to the Azure portal > Azure Active Directory → Manage → App registrations → select your application:



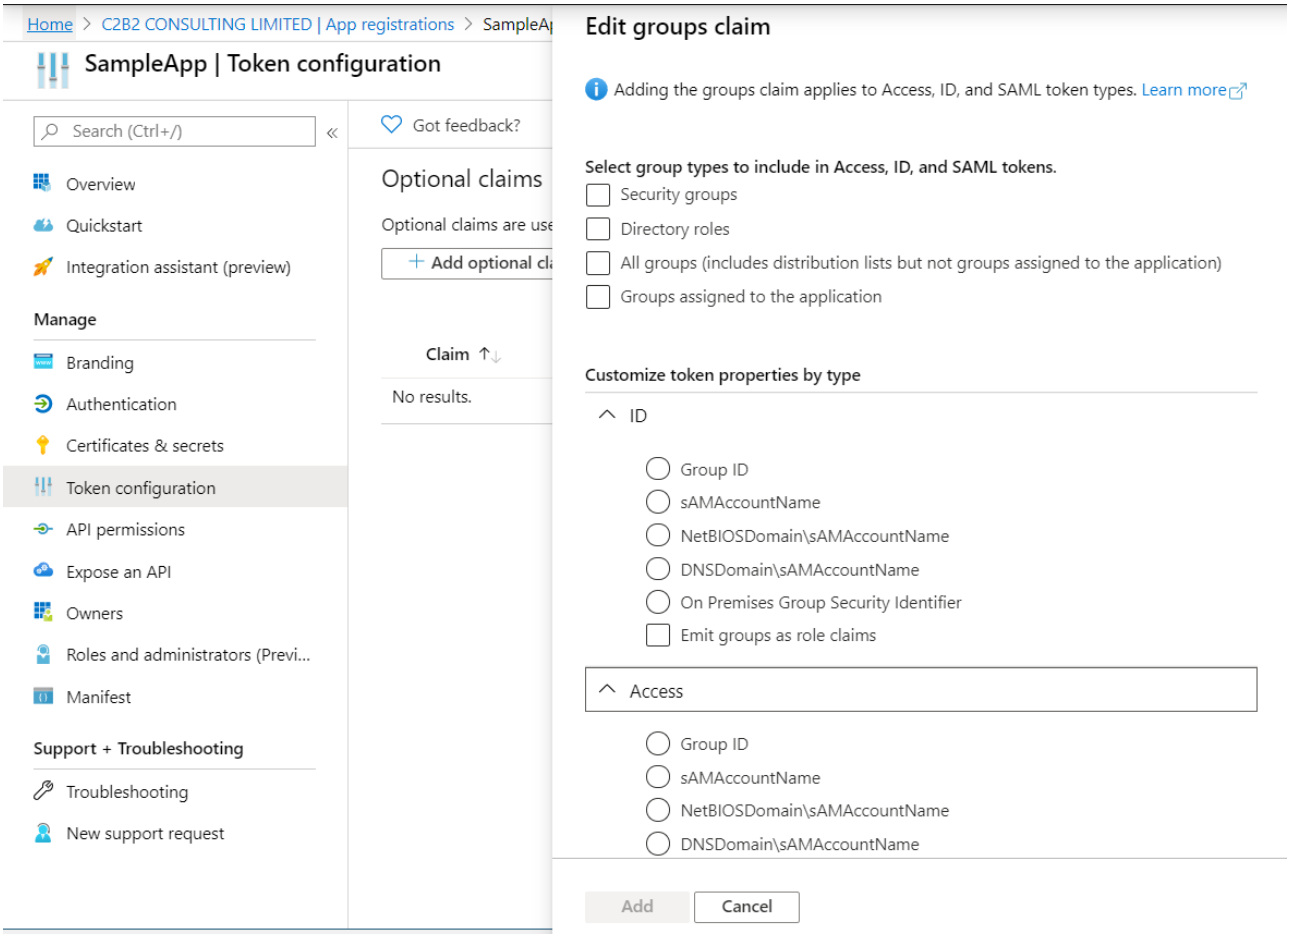
2. You may also add the custom roles via **Roles and administrators** under the **Manage** section:



3. Now to map group claims, select **Token configuration** under the **Manage** section:



4. Press **Add groups claim** button to select group types and customize the ID and/or Access Token properties:



5. Groups claim can also be defined via Azure **Manifest** under the **Manage** section which is a JSON configuration file.
6. To retrieve and map the caller name & groups from token claims, set the caller name & group claim definition to `preferred_username` & `groups`.

```
@AzureAuthenticationDefinition(
    providerURI="#{openidConfigBean.tokenEndpointURL}",
    clientId="#{openidConfigBean.clientId}",
    clientSecret="#{openidConfigBean.clientSecret}",
    claimsDefinition = @ClaimsDefinition(
            callerGroupsClaim = "groups",
            callerNameClaim = "preferred_username"
    )
)
public class SecurityBean {
}
```

Microsoft ADFS Integration

To enable integration for Microsoft ADFS it is needed to use the `userClaimsFromIDToken` annotation attribute.

See [Technical Documentation-Public API-OpenID Connect Support:::user-information-from-the-id-token] for more information.

Azure AD Scope Validation

To disable the scope validation for Azure AD integration it is needed to use the `disableScopeValidation` annotation attribute.

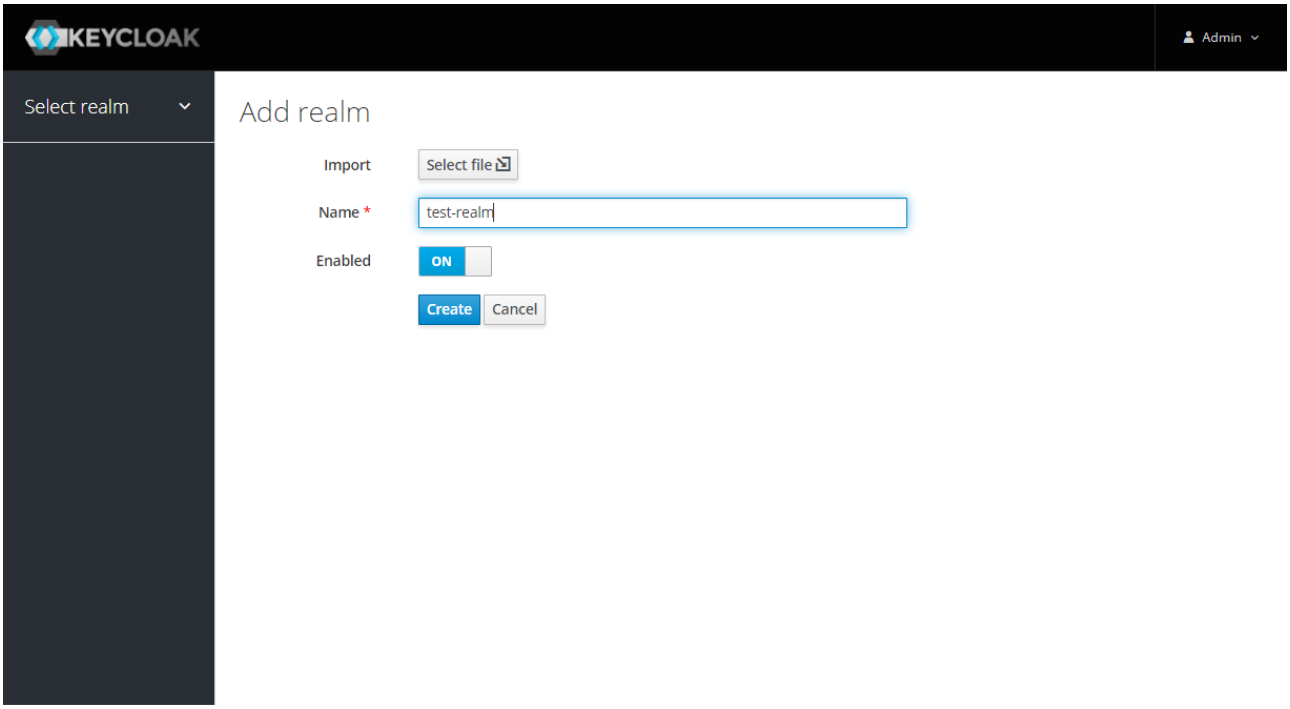
See [Technical Documentation-Public API-OpenID Connect Support:::disable-scope-validation] for more information.

Keycloak Integration

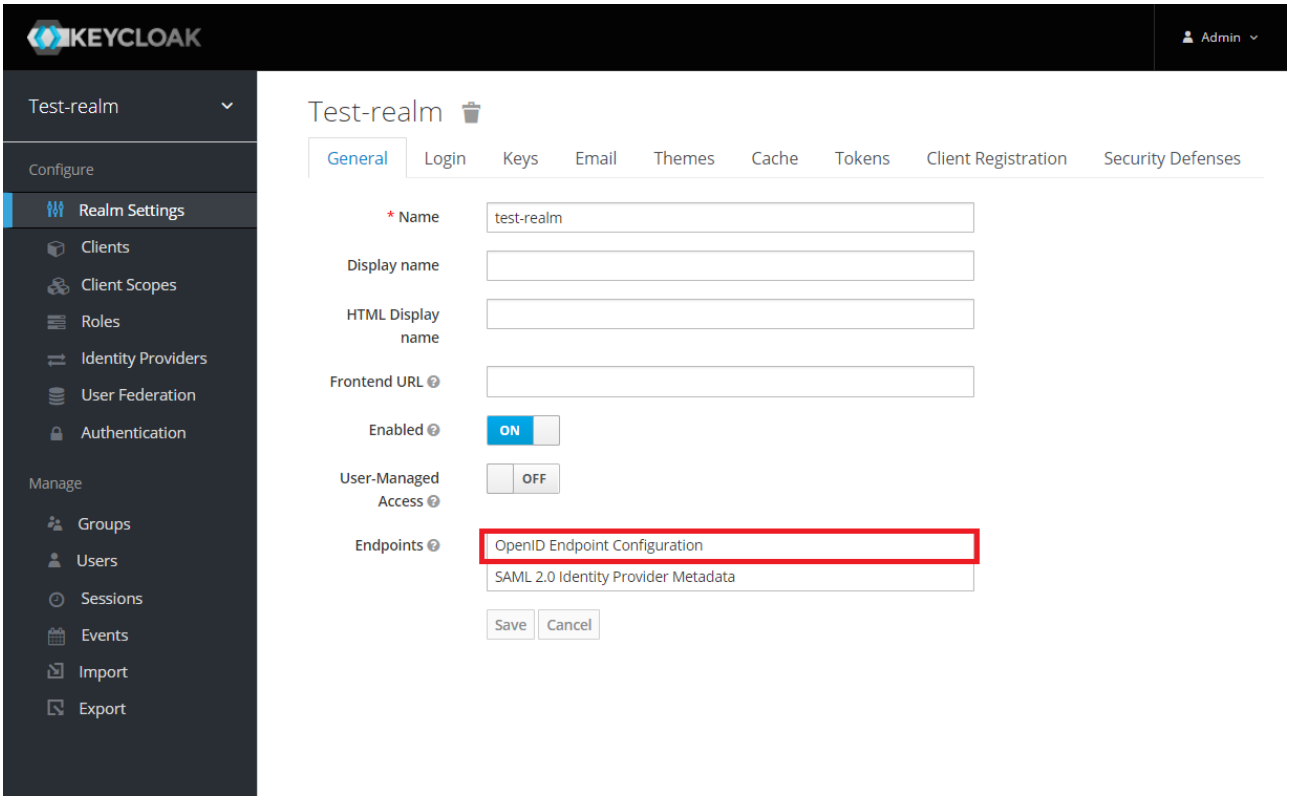
Keycloak is an Open Source Identity and Access Management Server, which is a OAuth2 and OpenID Connect(OIDC) protocol complaint. In this section,

the basic steps are described to set up a Keycloak OpenId provider:

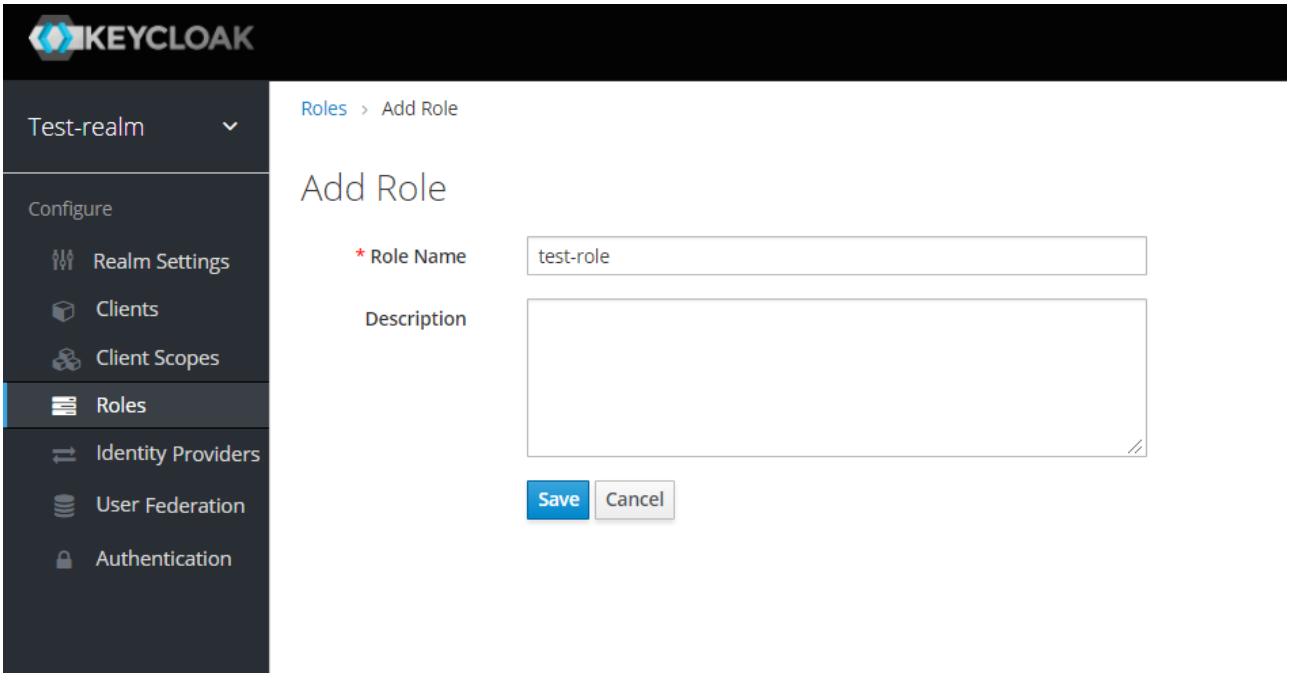
1. Refer to the Keycloak getting started documentation to run and setup Keycloak.
2. After Keycloak setup done, login to Keycloak admin console and add the new realm by pressing the **Add Realm** button:



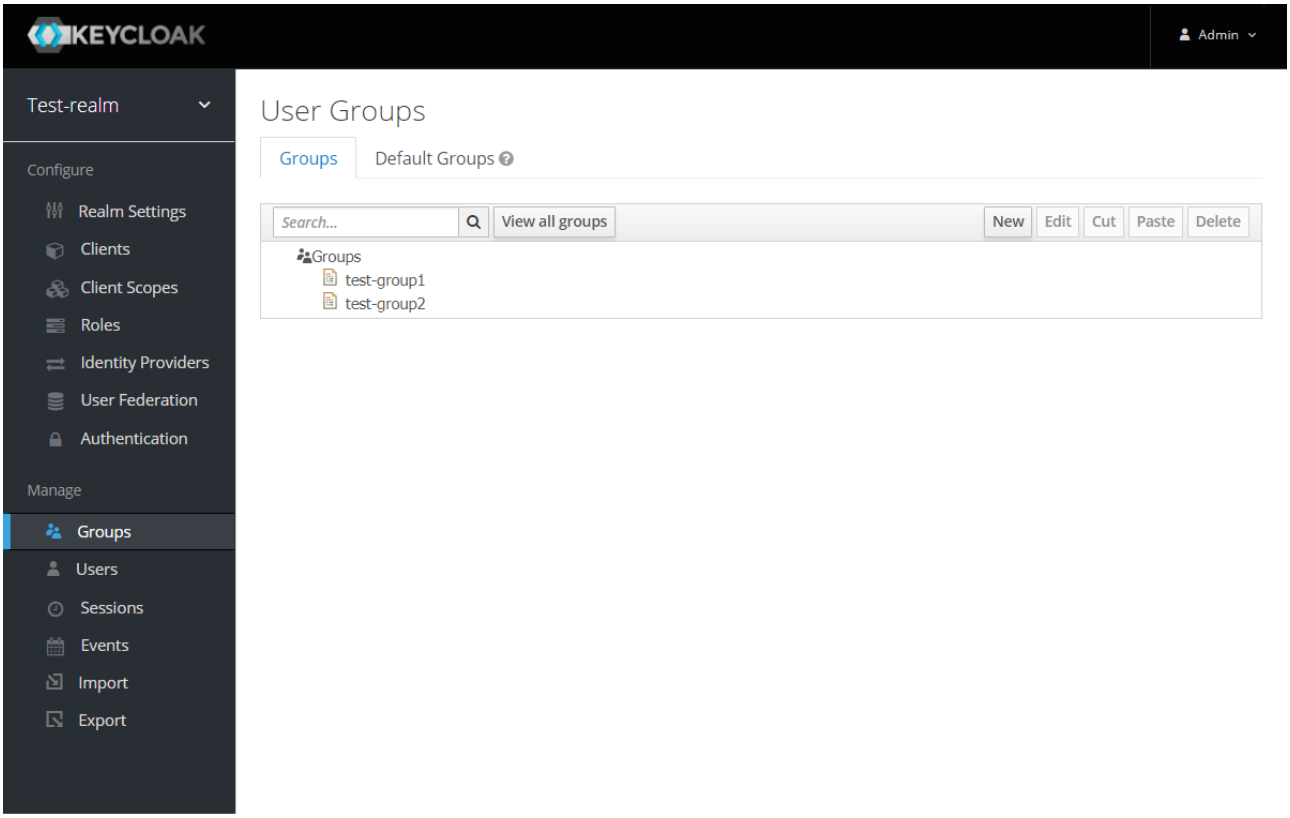
3. Copy the OpenId endpoint configuration URL from endpoint section:



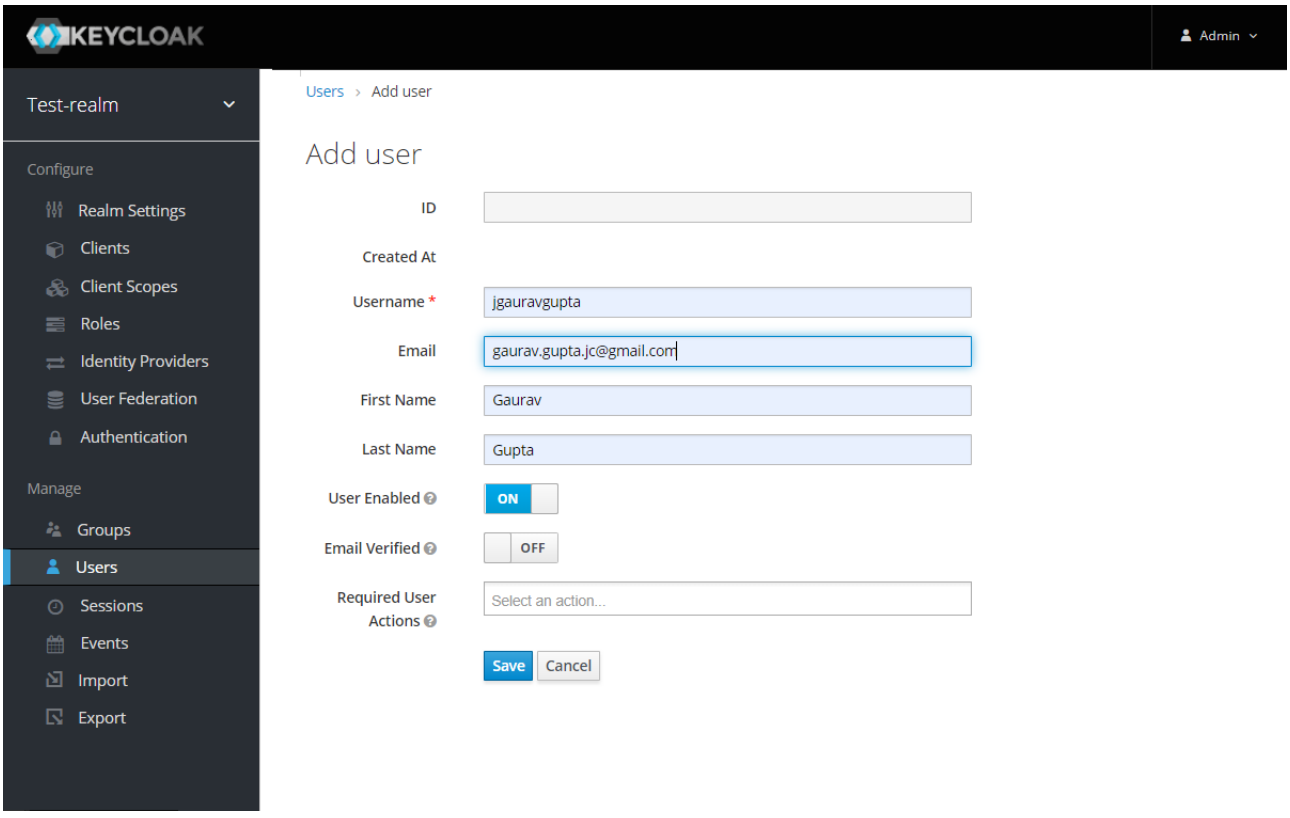
4. Now add the **Role** that will be used by the application to define which users will be authorized to access the application.



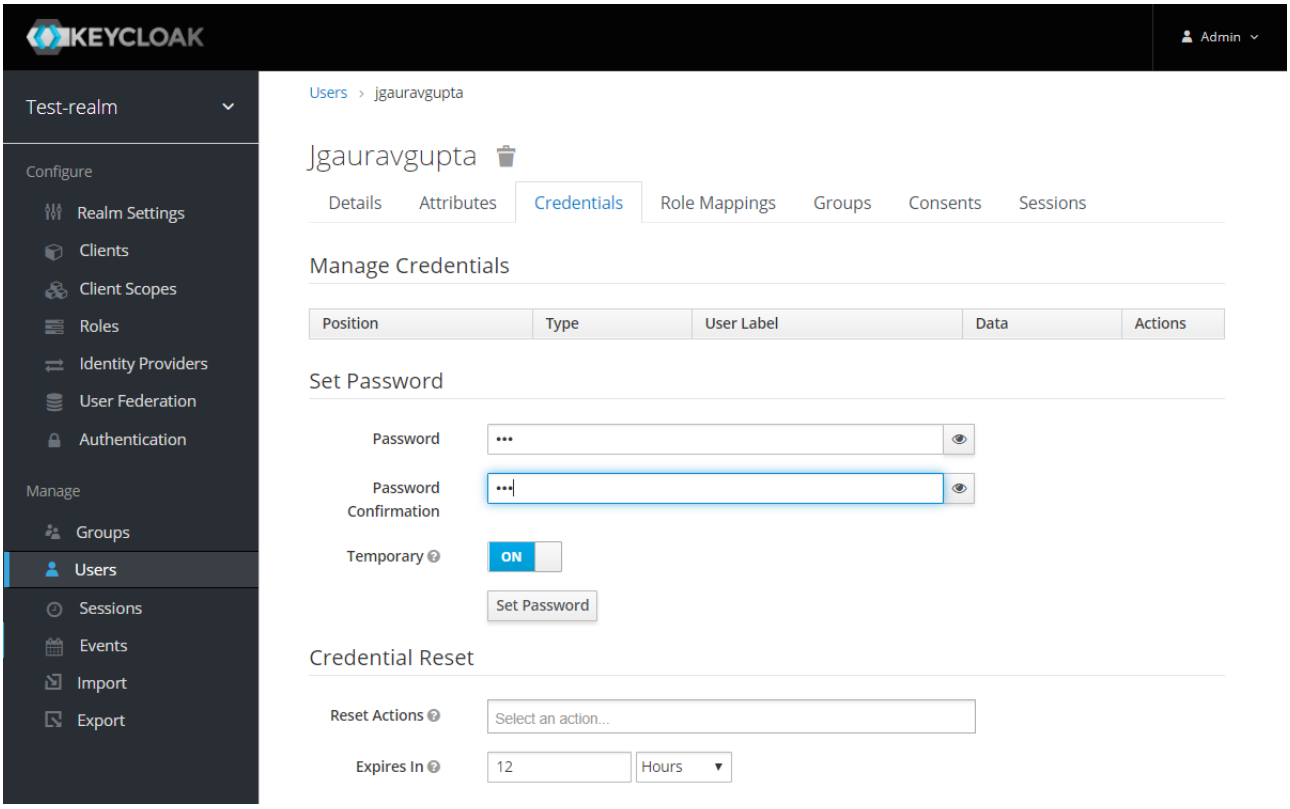
5. Create the **Groups**:



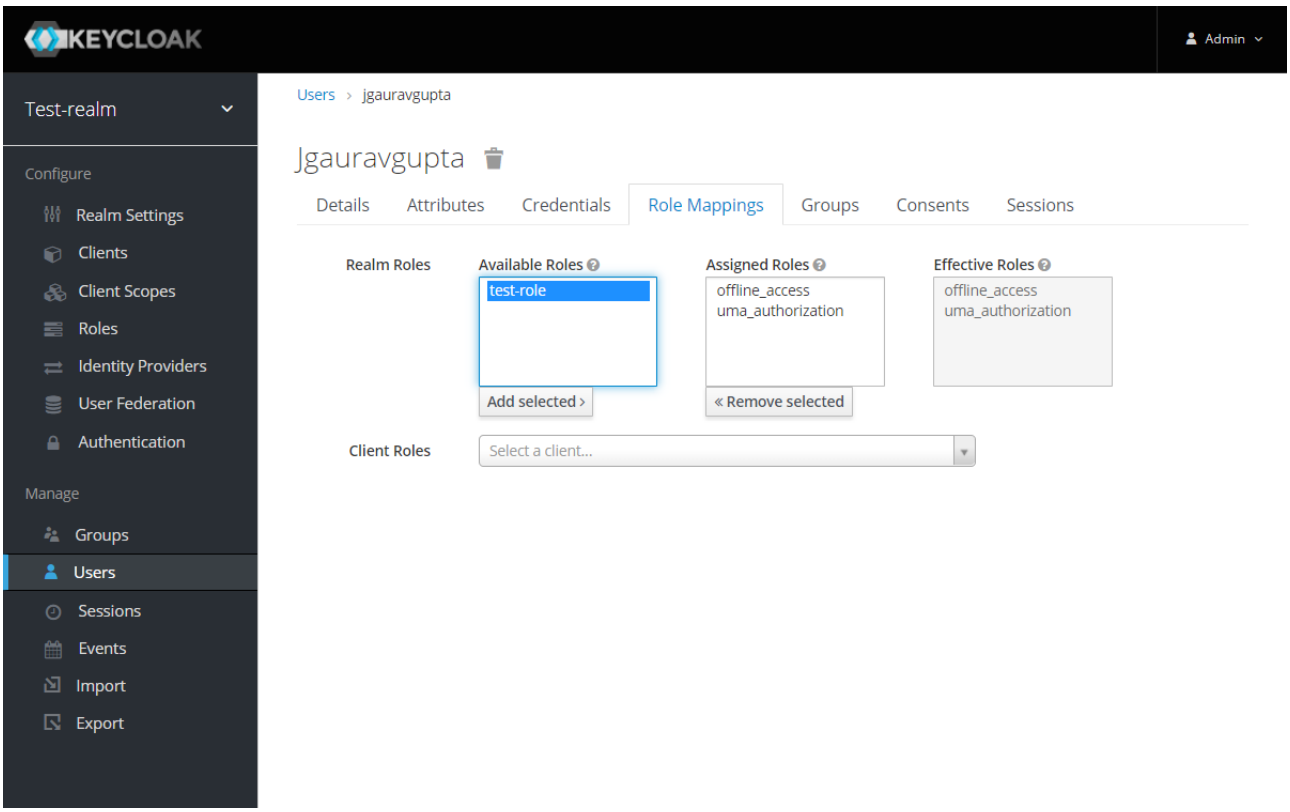
6. Add the **User**:



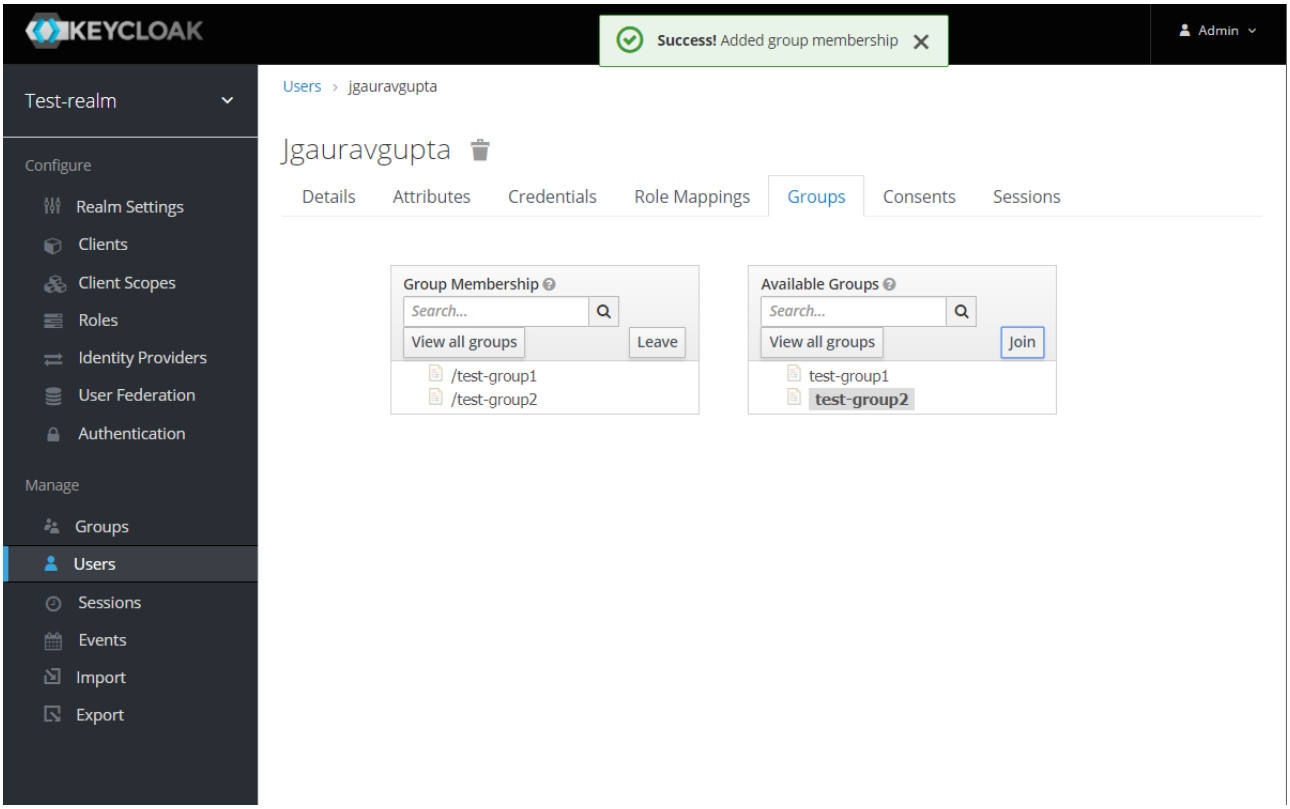
7. After the user is created, set a new **password** for the user:



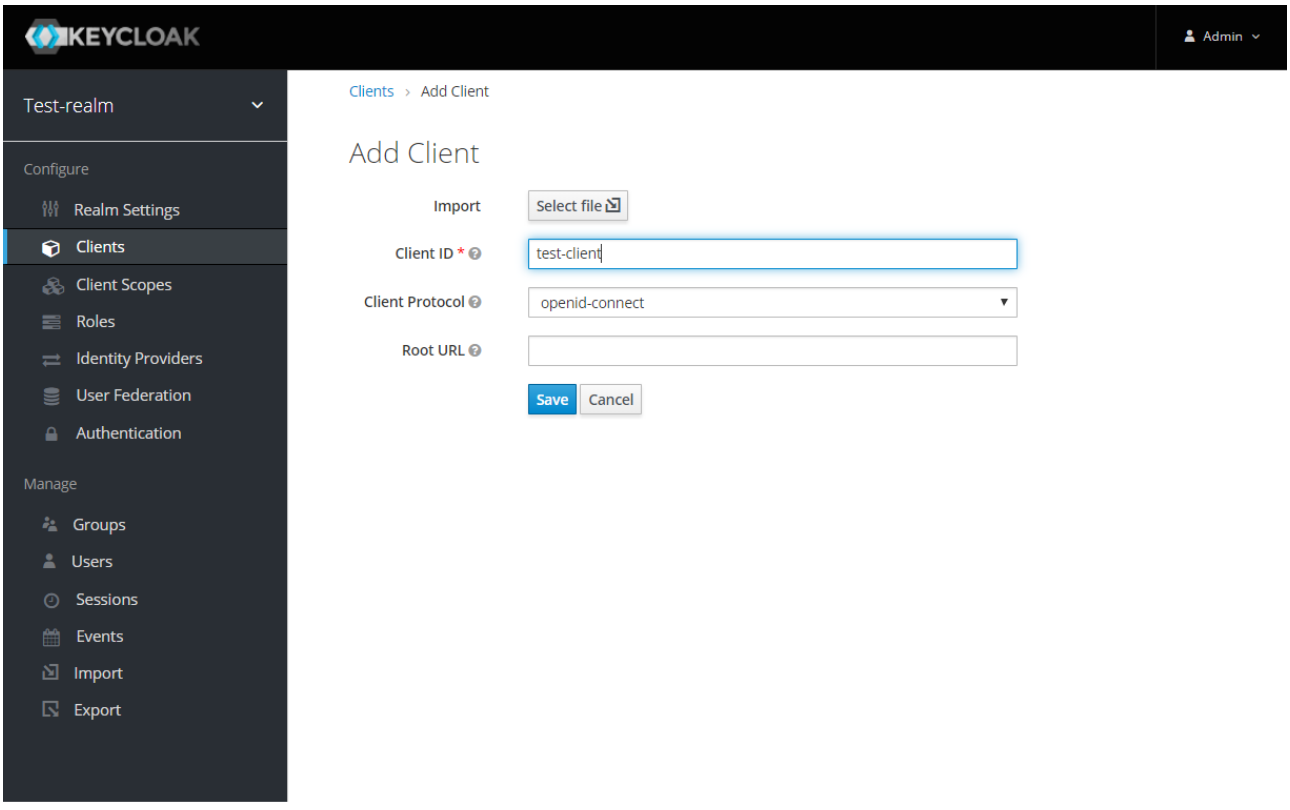
8. Now map the user to roles. Click on **Role Mappings** tab and assign the roles to the user from the available roles:



9. Assign the user to the groups. Click on **Groups** tab and join the groups from the available groups:

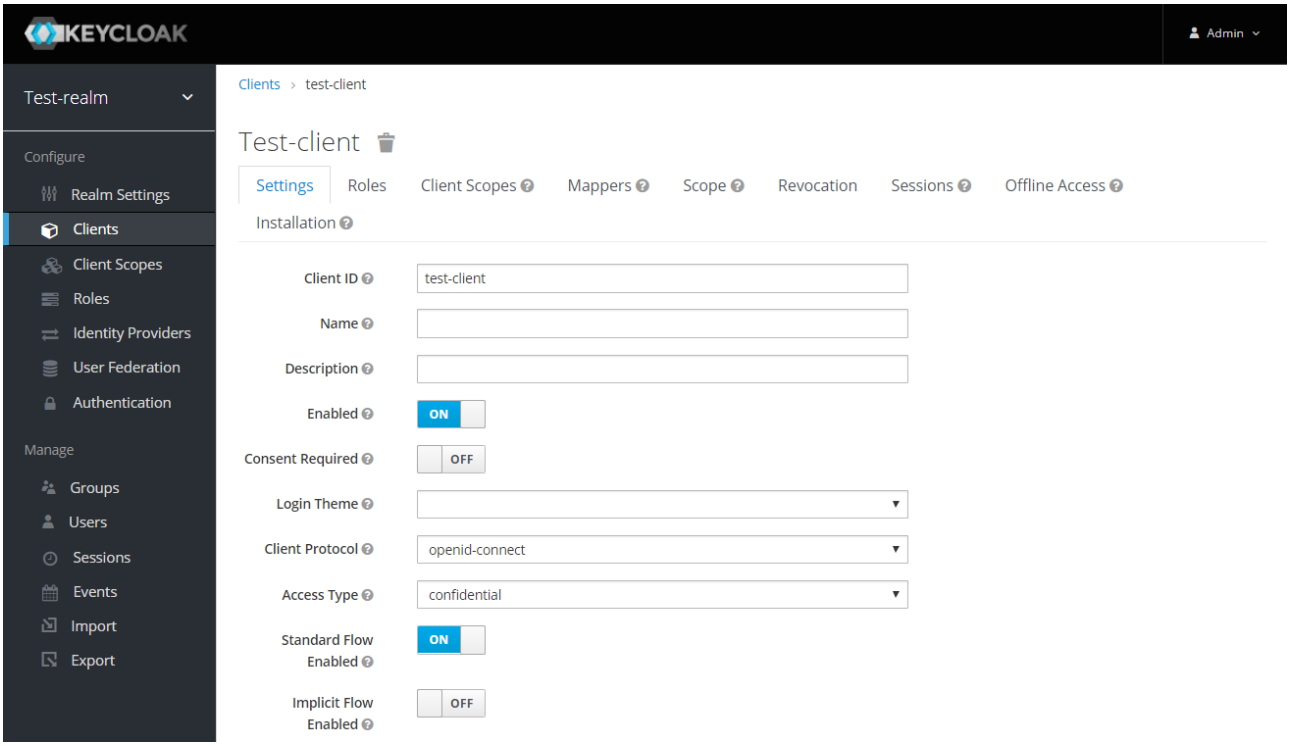


10. Create the OpenId Client by clicking the **Client** option from sidebar and press the **create** button:

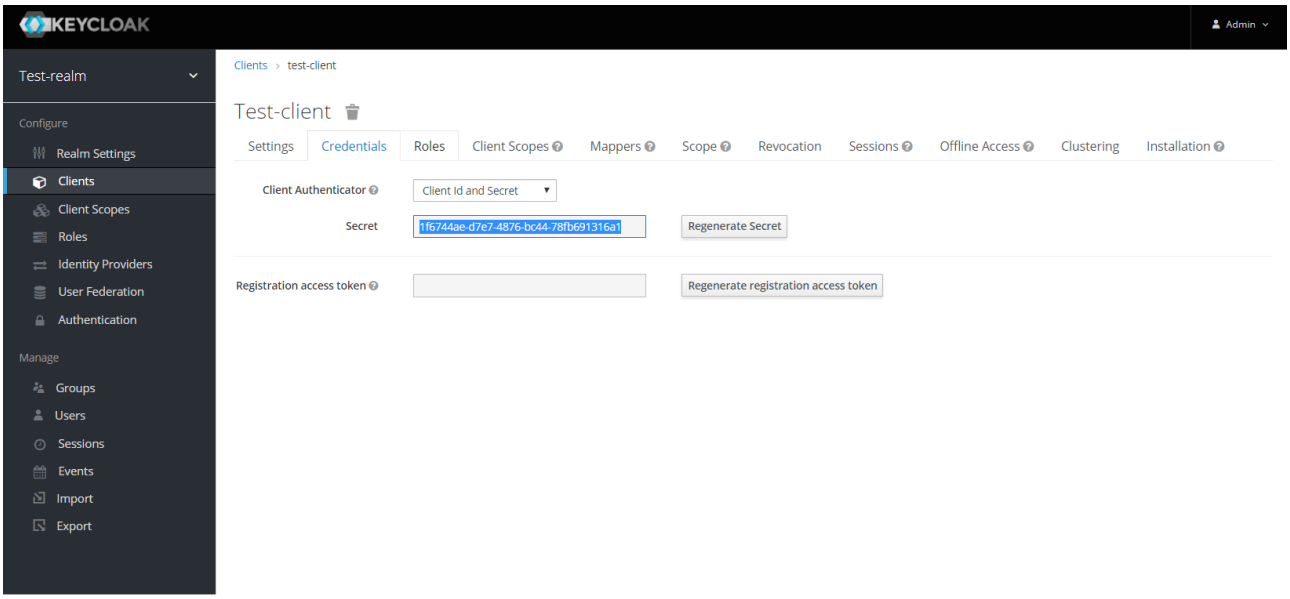


Enter the Client ID and select the Client Protocol **openid-connect** and press **Save**.

1. After the OpenId client is created change its **Access Type** to **confidential** and enter the valid **Redirect URIs**:



2. Next copy the client **secret** from **Credentials** tab.

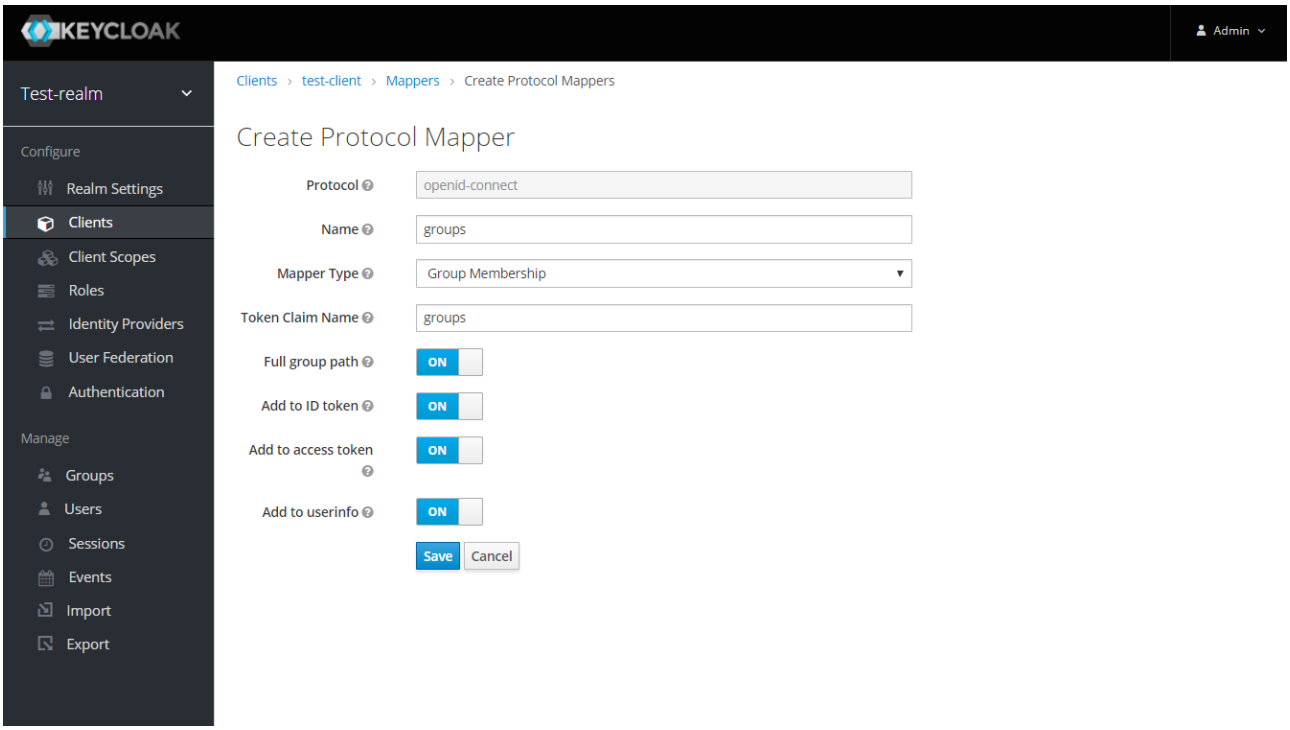


Here's an example that configures a OpenID Connect client for Keycloak provider. To test the KeyCloak OpenId provider, enter the copied client secret, client ID (client name) and the endpoint configuration URL:

```
@OpenIdAuthenticationDefinition(
    providerURI = "https://${keycloak-host}:${keycloak-port}/auth/realms/test-realm",
    clientId = "test-client",
    clientSecret = "1f6744ae-d7e7-4876-bc44-78fb691316a1"
)
public class SecurityBean {
}
```

Groups Mapping

1. To get the groups details in token claims, navigate to KeyCloak admin console → **OpenId Client** → **Mappers** tab → press **Create** button → Select **Group Membership** mapper type → enter the **Name** and **Token Claim Name** > press **Save**.



2. To retrieve and map the caller name & groups from token claims, set the caller name & group claim definition to `preferred_username` & `groups`.

```
@OpenIdAuthenticationDefinition(
    providerURI = "https://${keycloak-host}:${keycloak-port}/auth/realms/test-
realm",
    clientId = "test-client",
    clientSecret = "1f6744ae-d7e7-4876-bc44-78fb691316a1",
    claimsDefinition = @ClaimsDefinition(
            callerGroupsClaim = "groups",
            callerNameClaim = "preferred_username"
    )
)
public class SecurityBean {
}
```

Roles Permitted

The Payara Public API provides a `@RolesPermitted` annotation that creates an authorisation interceptor for usage with CDI beans. This largely works in the same way as the `@RolesAllowed` common annotation, which in Java EE/Jakarta EE is primarily used by the EJB specification.

Usage

The authorisation interceptor is defined through the `@RolesPermitted` annotation. Specifying this on an interceptable method of a non-passivation capable CDI bean will make that method eligible for interception by the corresponding interceptor. This interceptor will check that the caller of a method is any or all of the specified roles. If this holds, the call to the method proceeds. If not, an exception of type `CallerAccessException` is thrown.

The annotation can alternatively be placed at the class level of a CDI bean, in which case it will apply to all interceptable methods of that bean.

Examples of a non-passivation capable CDI bean are beans defined in the Request and Application scope.

Example

Here's an example of defining the roles authorized to call a single method:

```
@RequestScoped
public class TestRolesPermitted {

    @Inject
    Principal principal;

    @RolesPermitted("payaraAdmin")
    public String getUserName() {
        return principal.getName();
    }
}
```

See this sample project for a more detailed example.

Configuration

The `@RolesPermitted` annotation has several configuration options.

They are detailed below.

Table 202. Configuration Options

Option	Type	Required	Description
`value`	`String`	true	A static list of comma-separated roles which are allowed to access this method, or an EL expression used to resolve this list at runtime (*see below*).
`semantics`	`String`	no	Whether accessing caller must be in any one of the given roles (`OR`) or all given roles (`AND`). Defaults to `OR`.

Dynamic Roles

The `@RolesPermitted` annotation also allows to dynamically specify authorization roles that are allowed to call bean methods at runtime. With this feature, is possible to instruct the container to allow specific roles based on specific contextual information.

Dynamic roles are defined using an *Expression Language (EL) 3.0* `String` value which should resolve to a valid `String` array or `Collection` that corresponds to the roles permitted to call the corresponding method. This expression value has contextual access to any CDI-scoped bean at the time of the method call.

As a reminder, you can use the `self` bean name in order to refer to the method's bean and access any of its methods and properties at runtime.

In order to access the values of any relevant parameters via CDI beans in the method's signature, annotate them with the `jakarta.inject.Named` CDI annotation, and assign them the name which will be used in the expression value. If no names are provided for these parameters and the method only has one parameter, then it will be available as a bean with the `param` name.

Examples

Basic Example

The following example illustrates how to dynamically resolve a specific role based on the data received in the parameter. Assume that the application has declared multiple roles for each of one of the registered customers. Let's say that the application has 3 customers named `A`, `B` and `C`, in which case the following roles are defined:

- `Customer_A`
- `Customer_B`
- `Customer_C`

With each role granting authorization to each customer respectively. If we have a method for updating a customer's data based on a parameter received you can setup the corresponding authorization constraint like this:

```
@RolesPermitted("#{'Customer_'.concat(customer.name)}")
public void updateCustomer(@Named("customer") Customer customer){
    ...
}
```

As you can observe, the role name is evaluated at runtime by concatenating the `Customer_` prefix with the name of the customer, which is retrieved using the `customer` bean (which is injected in the context using the `@Named` annotation).

Advanced Expression Example

Based on the previous example, you can also let the corresponding expression be evaluated by calling a bean's method instead. Imagine that you could use a second variant, namely a product's name; in conjunction with the customer's name to evaluate authorization at runtime like this:

```
@RolesPermitted("#{self.findRole(customer, product)}")
public void updateCustomer(@Named("customer") Customer customer, @Named("product")
Product product){
    ...
}

public String findRole(Customer customer, Product product) {
    return customer.getType() + "_" + product.getModel();
}
```

By using the `self` bean name, we can call the bean's `findRole` method and pass it the two parameters defined in its signature.

Default Parameter Example

If no parameters are annotated with the `Named` annotation and the method has a single parameter then the `param` bean name can be used as a default reference like this:

```
@RolesPermitted("#{'CustomerCare_'.concat(param.name)}")
public void updateCustomer(Customer customer){
    ...
}
```

Security Extensions

This section documents available extensions for custom authentication mechanisms and identity store configurations that can be used in any Jakarta EE application.

Custom Authentication Mechanisms

The Payara Platform Public API offers the following custom authentication mechanisms for use cases that aren't covered in the Jakarta EE Security API.

Client Certificate Authentication Mechanism

The Jakarta EE Security API doesn't include any specific authentication mechanisms for support client certificate validation, so the `@CertificateAuthenticationMechanismDefinition` can be used to instruct any application to initiate client certificate validation when any HTTP request is to be authenticated.

This authentication mechanism will mostly be used in conjunction with the `@CertificateIdentityStoreDefinition` (see below for more information), since certificates are probably stored in a client certificate security realm.

Configuration

No specific configuration is needed for this annotation.

Example

The following code sample illustrates how to configure a client certificate authentication mechanism:

```
@ApplicationScoped
@ApplicationPath("/rest")
@DeclareRoles({ "a", "b" })
@CertificateAuthenticationMechanismDefinition
@CertificateIdentityStoreDefinition("certificate-realm")
public class MyRestApp extends Application {
}
```

Custom Identity Stores

By default, the Jakarta EE Security API only instructs containers to implement identity stores for the following types:

- LDAP directories through the `@LdapIdentityStoreDefinition` annotation.
- Relational databases through the `@DatabaseIdentityStoreDefinition` annotation.

The following annotations serve to provide additional identity store configurations, by allowing the mapping an existing Payara Platform security realm

Basic Realm Identity Store

The `@RealmIdentityStoreDefinition` annotation allows users to plug-in any existing security realm as a valid identity store definition.

No additional configuration settings or properties are available, so in case of needing further control over the store definition, see the more specific annotations defined below.

Configuration

The `@RealmIdentityStoreDefinition` annotation is configured with the options as shown below.

Option	Description	Default	Required
`value`	The name of an existing security realm.	<Default Realm>	`true`

Example

The following code sample illustrates how to configure the default `file` security realm as an identity store:

```
@ApplicationScoped
@ApplicationPath("/rest")
@DeclareRoles({ "a", "b"})
@BasicAuthenticationMechanismDefinition(realmName = "file")
@RealmIdentityStoreDefinition("file")
public class MyRestApp extends Application {
}
```

The `RealmIdentityStoreDefinition` is a **repeatable** annotation, hence multiple security realms can be used in sequence to define more than one identity store

```
@ApplicationScoped
@ApplicationPath("/rest")
@DeclareRoles({ "a", "b"})
@BasicAuthenticationMechanismDefinition
@RealmIdentityStoreDefinition("realm1")
@RealmIdentityStoreDefinition("realm2")
public class MyRestApp extends Application {
}
```

File Identity Store

The `@FileIdentityStoreDefinition` annotation allows users to plug in an existing file security realm (`com.sun.enterprise.security.auth.realm.file.FileRealm`) as a valid identity store definition.

If no realm is found with the defined name then a new realm will register on the server's configuration using the `create-auth-realm` asadmin command.

Configuration

The file realm identity store can be configured via both `@FileIdentityStoreDefinition` annotation attributes and MicroProfile Configuration properties. Here's a list of all available and equivalent settings:

Option	MP Config Property	Description	Default	Required
`value`		The name of the realm.	`file`	`true`
`file`	`payara.security.file`	The location of the file to store user credentials locally. If no file name is defined then the realm name is used as the file name.	<Realm Name>	`false`
`assignGroups`	`payara.security.file.assignGroups`	Users will get assigned membership to these groups automatically on successful authentication		`false`
`jaasContext`	`payara.security.file.jaasContext`	The JAAS Context of the file realm.	`fileRealm`	`false`

If both an annotation attribute and a MicroProfile Configuration property are defined for the same option then the configuration property always takes precedence.

Example

The following code sample illustrates how to configure a file realm identity store:

```
@ApplicationScoped
@ApplicationPath("/rest")
@DeclareRoles({ "a", "b"})
@BasicAuthenticationMechanismDefinition(realmName = "file-realm")
@FileIdentityStoreDefinition("file-realm")
public class MyRestApp extends Application {
```

```
}
```

Client Certificate Identity Store

The `@CertificateIdentityStoreDefinition` annotation allows users to plug-in an existing client `certificate` security realm (`com.sun.enterprise.security.auth.realm.certificate.CertificateRealm`) as a valid identity store definition.

If no realm is found with the defined name then a new realm will register on the server's configuration using the `create-auth-realm` asadmin command.

Configuration

The certificate realm identity store can be configured via both `@CertificateIdentityStoreDefinition` annotation attributes and MicroProfile Configuration properties. Here's a list of all available and equivalent settings:

Option	MP Config property	Description	Default	Required
`value`		The name of the certificate realm.	`certificate`	`true`
`assignGroups`	`payara.security.certificate.assignGroups`	Users will get assigned membership to these groups automatically on successful authentication.		`false`

If both an annotation attribute and a MicroProfile Configuration property are defined for the same option then the configuration property always takes precedence.

Example

The following code sample illustrates how to configure a certificate realm identity store:

```
@ApplicationScoped
@ApplicationPath("/rest")
@DeclareRoles({ "a", "b" })
@CertificateAuthenticationMechanismDefinition
@CertificateIdentityStoreDefinition("certificate-realm")
public class MyRestApp extends Application {
}
```

PAM Identity Store

The `@PamIdentityStoreDefinition` annotation allows users to plug-in an existing PAM (Privileged Access Management) security realm (`com.sun.enterprise.security.auth.realm.pam.PamRealm`) as a valid identity store definition.

If no realm is found with the defined name then a new realm will register on the server's configuration using the `create-auth-realm` asadmin command.

Configuration

The pam realm identity store can be configured via both `@PamIdentityStoreDefinition` annotation attributes and MicroProfile Configuration properties. Here's a list of all available and equivalent settings:

Option	MP Config property	Description	Default	Required
`value`		The name of PAM realm.		`true`
`assignGroups`	`payara.security.pam.assignGroups`	Users will get assigned membership to these groups automatically on successful authentication.		`false`
`jaasContext`	`payara.security.pam.jaasContext`	The JAAS Context of the PAM realm.	`pamRealm`	`false`

Example

The following code sample illustrates how to configure a PAM realm identity store:

```
@ApplicationScoped
@ApplicationPath("/rest")
@DeclareRoles({ "a", "b"})
@BasicAuthenticationMechanismDefinition(realmName = "pam-realm")
@PamIdentityStoreDefinition("pam-realm")
public class MyRestApp extends Application {
}
```

If both an annotation attribute and a MicroProfile Configuration property are defined for the same option then the configuration property always takes precedence.

Solaris Identity Store

The `@SolarisIdentityStoreDefinition` annotation allows users to plug in an existing Solaris security realm (`com.sun.enterprise.security.auth.realm.solaris.SolarisRealm`) as a valid identity store definition.

If no realm is found with the defined name then a new realm will register on the server's configuration using the `create-auth-realm` asadmin command.

Configuration

The Solaris realm identity store can be configured via both `@SolarisIdentityStoreDefinition` annotation attributes and MicroProfile Configuration properties. Here's a list of all available and equivalent settings:

Option	MP Config property	Description	Default	Required
`value`		The name of the Solaris realm.		`true`
`assignGroups`	`payara.security.solaris.assignGroups`	Users will get assigned membership to these groups automatically on successful authentication.		`false`
`jaasContext`	`payara.security.solaris.jaasContext`	The JAAS Context of the Solaris realm.	`solarisRealm`	`false`

If both an annotation attribute and a MicroProfile Configuration property are defined for the same option then the configuration property always takes precedence.

Example

The following code sample illustrates how to configure a Solaris realm identity store:

```
@ApplicationScoped
@ApplicationPath("/rest")
@DeclareRoles({ "a", "b"})
@BasicAuthenticationMechanismDefinition(realmName = "solaris-realm")
@SolarisIdentityStoreDefinition("solaris-realm")
public class MyRestApp extends Application {
}
```

MicroProfile

Overview

What is Eclipse MicroProfile?

The MicroProfile project was launched in June 2016 as a collaborative effort between Java application server vendors and the enterprise Java community to enable fast innovation.

MicroProfile is a specification which provides a set of APIs focused on microservices. The complete MicroProfile API is provided as a Bill Of Materials(BOM) which can be used by developers as a generic dependency provided by a vendor of their choice.

Payara has been part of the MicroProfile project from its inception and, therefore, supports all specifications of the MicroProfile Umbrella project.

Payara Support for MicroProfile

Version 6.1

Version 6.1 of MicroProfile is a minor release that updates Metrics, Config and Telemetry. Also, this version aligns with Jakarta EE 10 Core Profile and continues with the `jakarta.*` namespace alignment and allows to be certified with Java SE 11 or higher.

This is supported by Payara Platform Community starting from releases **7.2025.1** onwards

What does each specification contain?

Version	Specifications	Maven
6.1	• Jakarta EE Core Profile 10.0 • Config 3.1 • Metrics 5.1 • Health Check 4.0 • Fault Tolerance 4.0 • JWT Authentication 2.1 • OpenAPI 3.1 • Rest Client 3.0 • Telemetry Tracing 1.1	<dependency> <groupId>org.eclipse.microprofile</groupId> <artifactId>microprofile</artifactId> <version>6.1</version> <type>pom</type> <scope>provided</scope> </dependency>

Config

Overview

The Payara Platform main-7 provides MicroProfile Configuration 3.1

Background

The Config API was created to allow for the modification of application configuration from outside the application without needing the application to be repackaged.

The complete specification can be found on the Eclipse MicroProfile website.

Breaking changes introduced in MicroProfile Config 3.1 are listed in the official specification under Incompatible Changes

Config Sources

A `ConfigSource` is a definition of a source of configuration values that can be used by an application. In addition to the default ConfigSources outlined by the specification, the following are also supported ConfigSources:

Where multiple configuration properties exist, the property from a source with a higher ordinal number is preferred.

Source	Ordinal	Description
`directory`	90	Reads configuration properties from files in a specified directory. Each file name is the configuration property name and the contents of the file are the config property value. This config source can be used to read Kubernetes secrets files. + You can find out more about directory config sources here: Directory Config Sources
`toml`	95	Reads configuration properties from a specified TOML configuration file. + You can find out more about TOML config sources here: TOML Config Sources
`password`	105	Retrieves and stores config values in the password alias store. These will be available to all server instances in a domain.
`domain`	110	Retrieves and stores config values in the domain.xml as key values. These will then apply to all instances within a domain
`jndi`	115	Retrieves and stores config values within the JNDI tree. The property name being the dotted name path in the JNDI tree and the value being stored in the JNDI tree. These are modifiable by current admin console functionality.
`config`	120	Retrieves and stores config values at the level of the named configuration in the domain.xml; `server-config`, for example. MicroProfile Configuration property values will apply to all instances that use the Payara configuration specified.
`server`	130	Retrieves and stores config values at the level of the server in the domain.xml. Property values will only apply on the named server instance
`application`	140	Retrieves and stores config values at the level of the application. Property values will only be available for the specified application on all server instances it is deployed

Source	Ordinal	Description
`module`	150	Retrieves and stores config values at the level of an individual module within an application. Property values will only be available for the specified module on all server instances it is deployed
`cluster`	160	Retrieves and stores config values in the **Hazelcast** cluster as name value pairs. These will be available for all server instances that are members of the cluster.
`payara-expression`	170	Reads configuration properties from a `payara-expression-config.properties` file. This should be stored in the same location as your `microprofile-config.properties` file This file can be used to reference properties containing variables which will be translated to their actual values upon retrieval. + The property values should be in the format referenced here: Types of Variables
`cloud`	180	Reads configuration properties from various Cloud provider secret stores. + You can find out more about our supported cloud config sources here: Cloud Config Sources
`jdbc`	190	Reads configuration properties from a specified database table. + You can find out more about JDBC config sources here: JDBC Config Sources
`ldap`	200	Reads configuration properties from a specified LDAP directory. + You can find out more about LDAP config sources here: LDAP Config Sources

Converters

In addition to the standard converters specified by the API, Payara Platform's implementation includes out-of-the-box converters for URL and `InetAddress`.

These have `@Priority` of `1`, the same as the default converters.

Payara Platform Configuration Properties

In addition to the standard configuration properties, Payara Server and Micro provide a number of out-of-the-box config properties you can use in your application to find information about the runtime environment.

Property	Description
`payara.instance.type`	The type of the runtime from `DAS`, `INSTANCE`, `EMBEDDED`, `MICRO`
`payara.instance.name`	The name of the instance e.g. `server`
`payara.instance.root`	The directory which is the root of the instance installation
`payara.domain.name`	The name of the Payara domain
`payara.domain.installroot`	The directory which is the root of the Payara software installation

Property	Description
payara.config.dir	The directory in which the server's configuration files reside
payara.instance.starttime	The start time of the server in System.currentTimeMillis
payara.instance.config.name	The name of the configuration this server is using
payara.instance.admin.port	The administration port number of this instance
payara.instance.admin.host	The host IP address which the admin listener is listening on
payara.instance.http.port	The HTTP port for http-listener
payara.instance.http.address	The IP address the http listener is listening on
payara.instance.http.enabled	Whether the http listener is enabled
payara.instance.https.port	The HTTP port for https-listener
payara.instance.https.address	The IP address the https listener is listening on
payara.instance.https.enabled	Whether the https listener is enabled

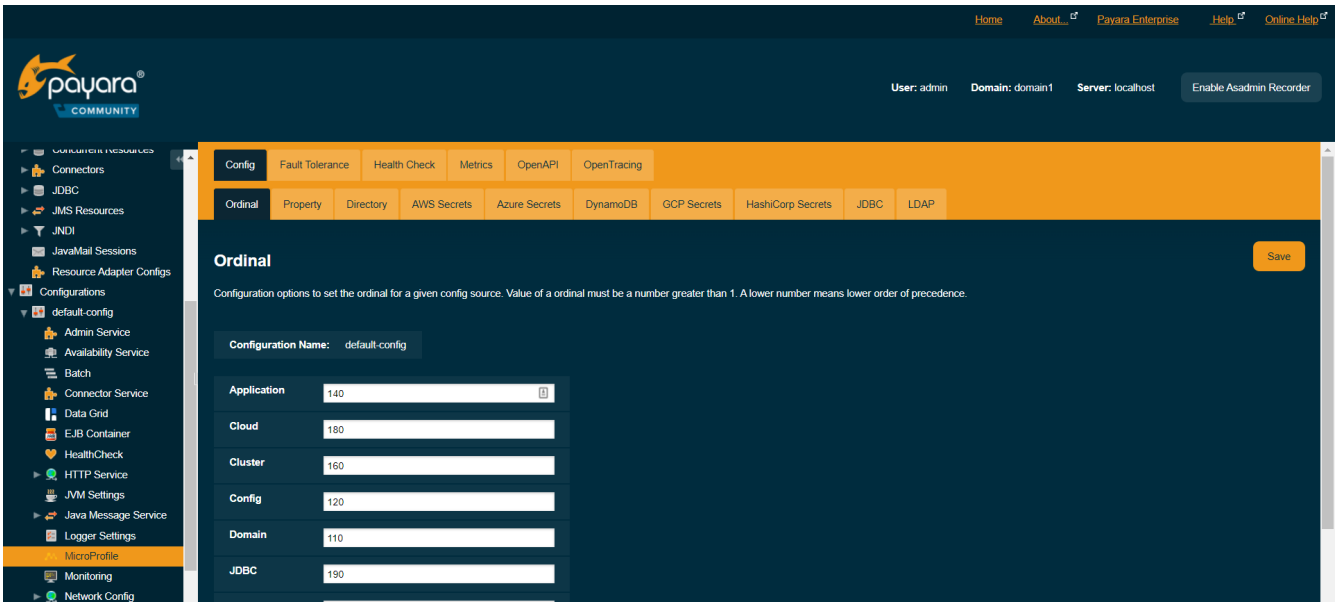
Payara Server offers additional facilities to configure specific settings of the MicroProfile Configuration API, described next.

Config Ordinal Configuration

Configuration variables ordinal values can be configured by using Admin Console or via the Asadmin CLI.

Using the Admin Console

To configure the ordinal value in the Admin Console, go to Configuration → [instance-configuration (like server-config)] → MicroProfile → Config → Ordinal:



Using Asadmin Commands

A `--source` value of `jndi` is not supported for these asadmin commands yet. The JNDI `ConfigSource` does exist and is usable from the Config API, though.

The following Asadmin commands can be used to manipulate configuration sources ordinal values:

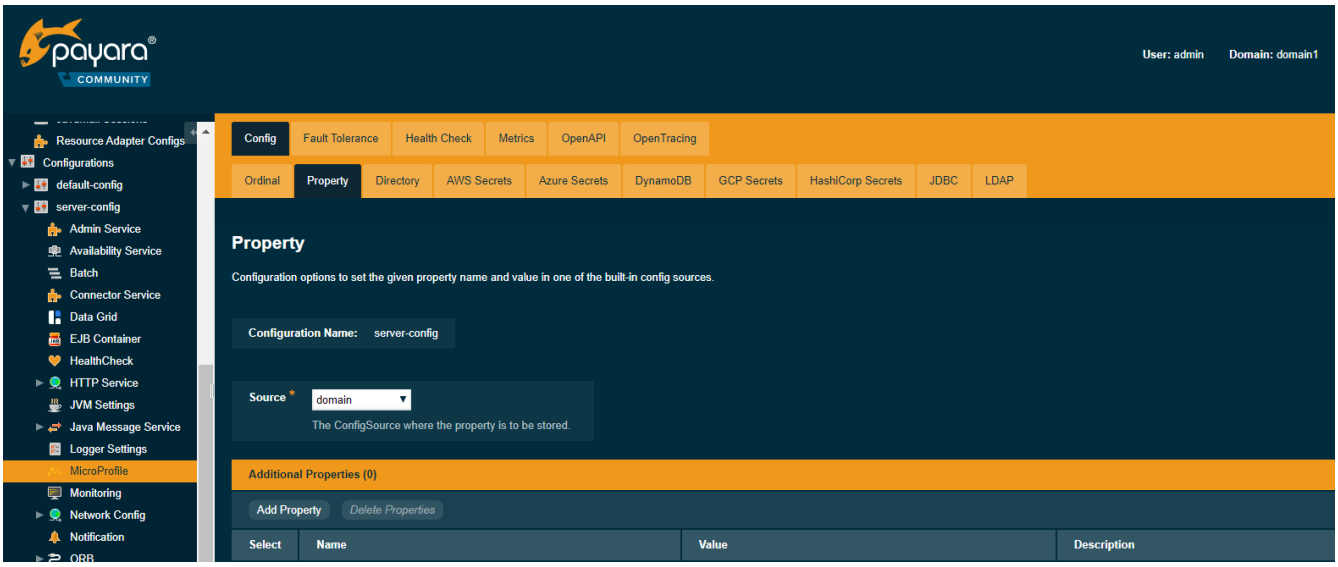
- `set-config-ordinal`
- `get-config-ordinal`

Configuration Property Manipulation

Configuration properties can be configured by using Admin Console or Asadmin commands.

Using the Admin Console

To configure the property in the Admin Console, go to Configuration → [instance-configuration (like server-config)] → MicroProfile → Config → Property:



Using Asadmin Commands

The following Asadmin commands can be used to directly configure MicroProfile configuration properties:

- `set-config-property`
- `get-config-property`
- `delete-config-property`

Cache Duration Configuration

The cache duration of the values of a configuration property can be configured by using Asadmin commands. By default, the cached value of properties have a TTL (time to live) of `60` seconds.

That means each individual property does not change for `60` seconds since it has been resolved before. Therefore, it can take up to `60` seconds for changes made visible by a source to become

effective.

If properties were not resolved recently, the change can become visible faster than the cache duration or even immediately because some time already passed since they had been last resolved and cached.

Use the `set-config-cache` to modify this setting.

Cloud

Overview

The **Cloud Configuration Sources** can be used to extract configuration properties from a secret store or a database of several different cloud providers.

The following sources are currently available:

- AWS Secrets Manager
- Azure Secrets
- DynamoDB Database
- GCP Secret Manager
- Hashicorp Secrets

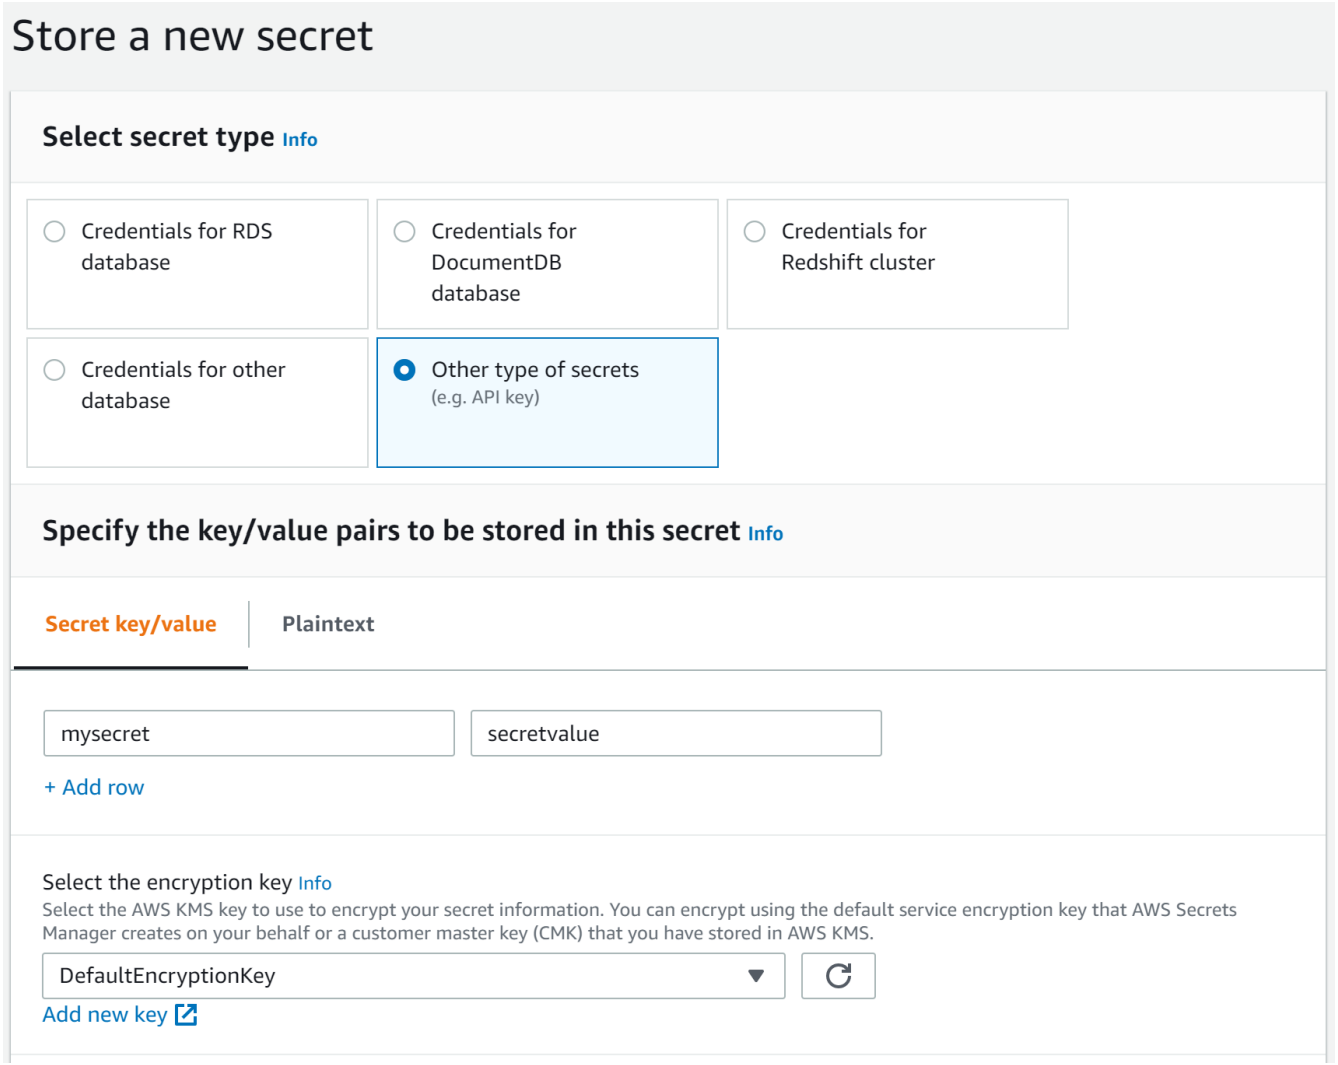
AWS

The AWS cloud config source takes configuration properties from AWS Secrets Manager.

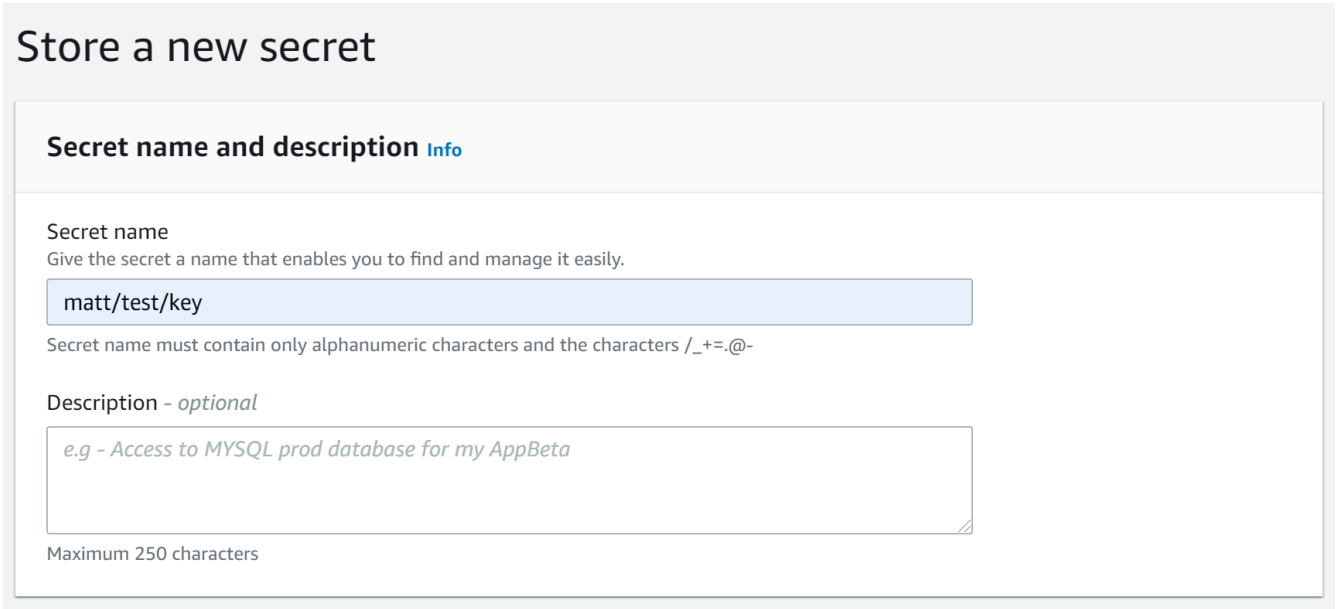
AWS Secret Creation

The AWS cloud config source takes configuration from a single named secret in a JSON format, with each object key being a config property name. To create a secret of this format, you must first go to the AWS secret manager home: https://console.aws.amazon.com/secretsmanager/home.

Once you've logged in, click the button to create a new secret. From here, you should specify the type as *Other type of secrets*. You'll be able to enter your config properties in a key/value format below, or leave blank for configuring through Payara Server.



On the next screen, you'll be able to enter your secret name. This will need giving to Payara Server in order to fetch the config properties from it.

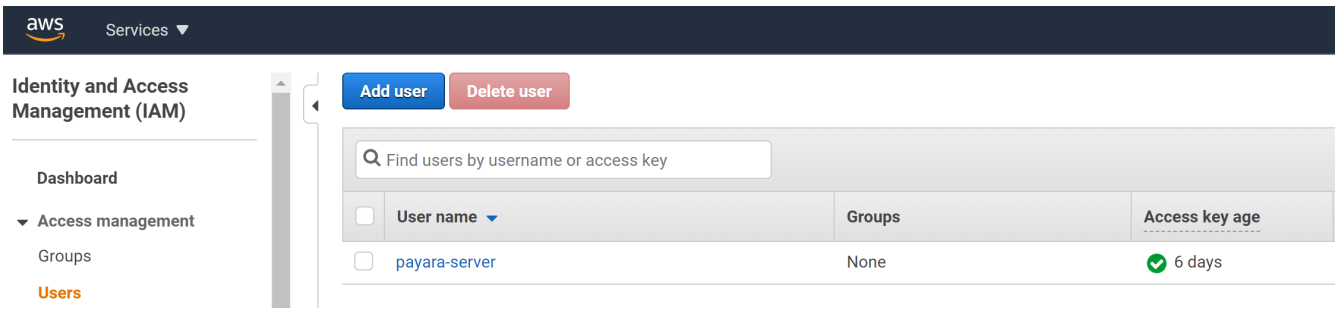


AWS IAM User

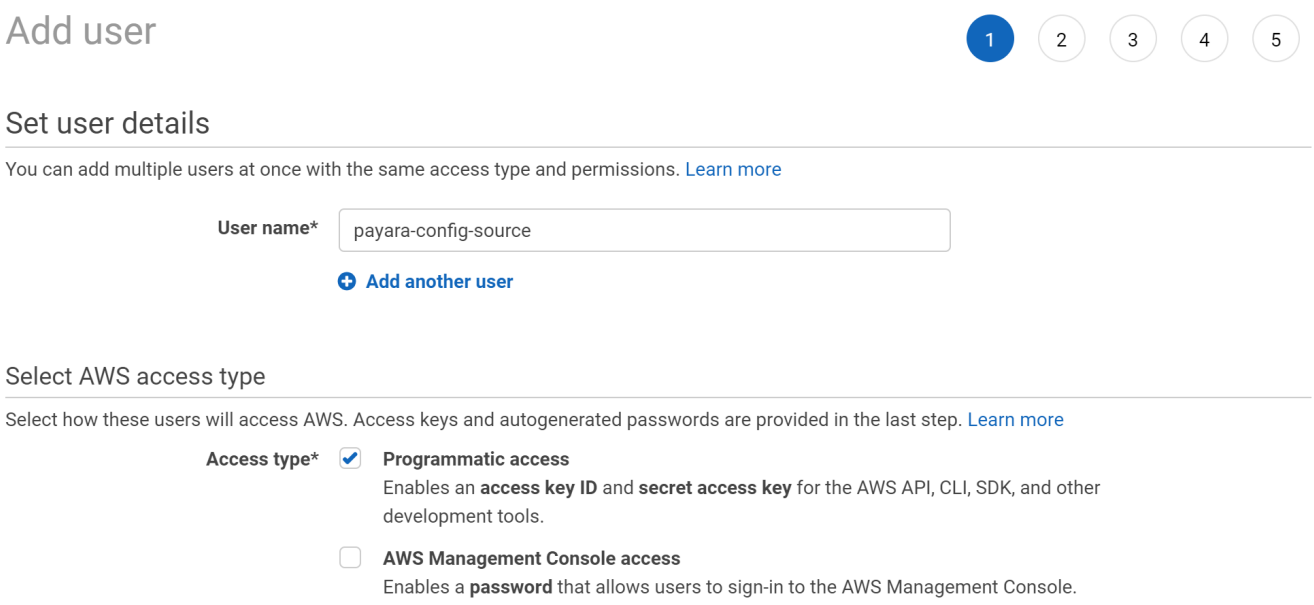
In order to connect to AWS Secrets Manager you need to know your project name as well as have an access key. Assuming you already have an AWS project and a secret created in AWS Secrets

Manager, you need to create an IAM user which Payara Server will use to access your AWS Secrets.

From the AWS console, visit the *IAM Users* dashboard by searching 'IAM' in the top search bar. From here, head to *Users* in the left menu. You'll see all your IAM users associated with this region.

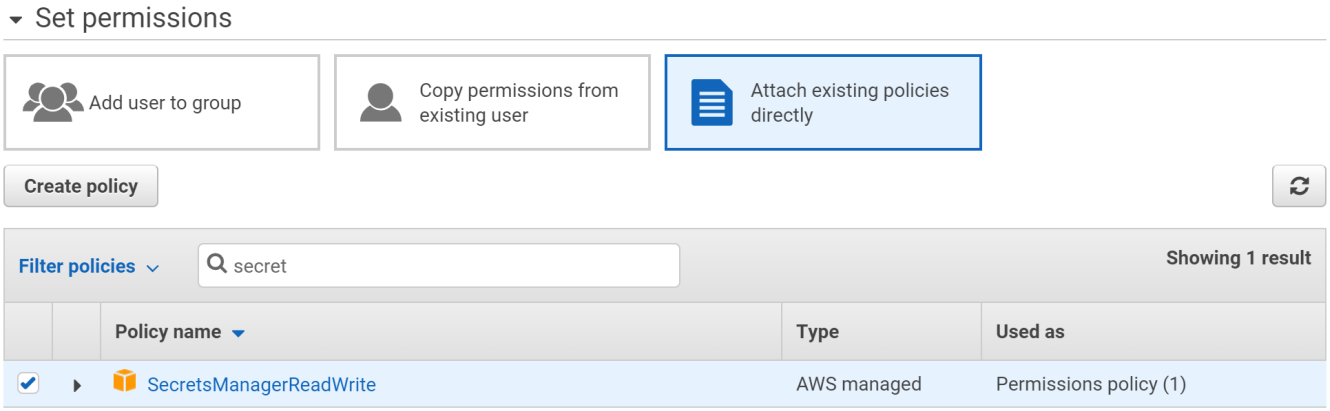


From here you can create a new IAM user. Skip this step if you already have an IAM user you want to use.



Set the IAM username. This isn't used by Payara, but will be helpful for your own reference. Make sure you enable *Programmatic access*, as this will be used by Payara Server to access your AWS Secrets.

Next, select your IAM user permissions.



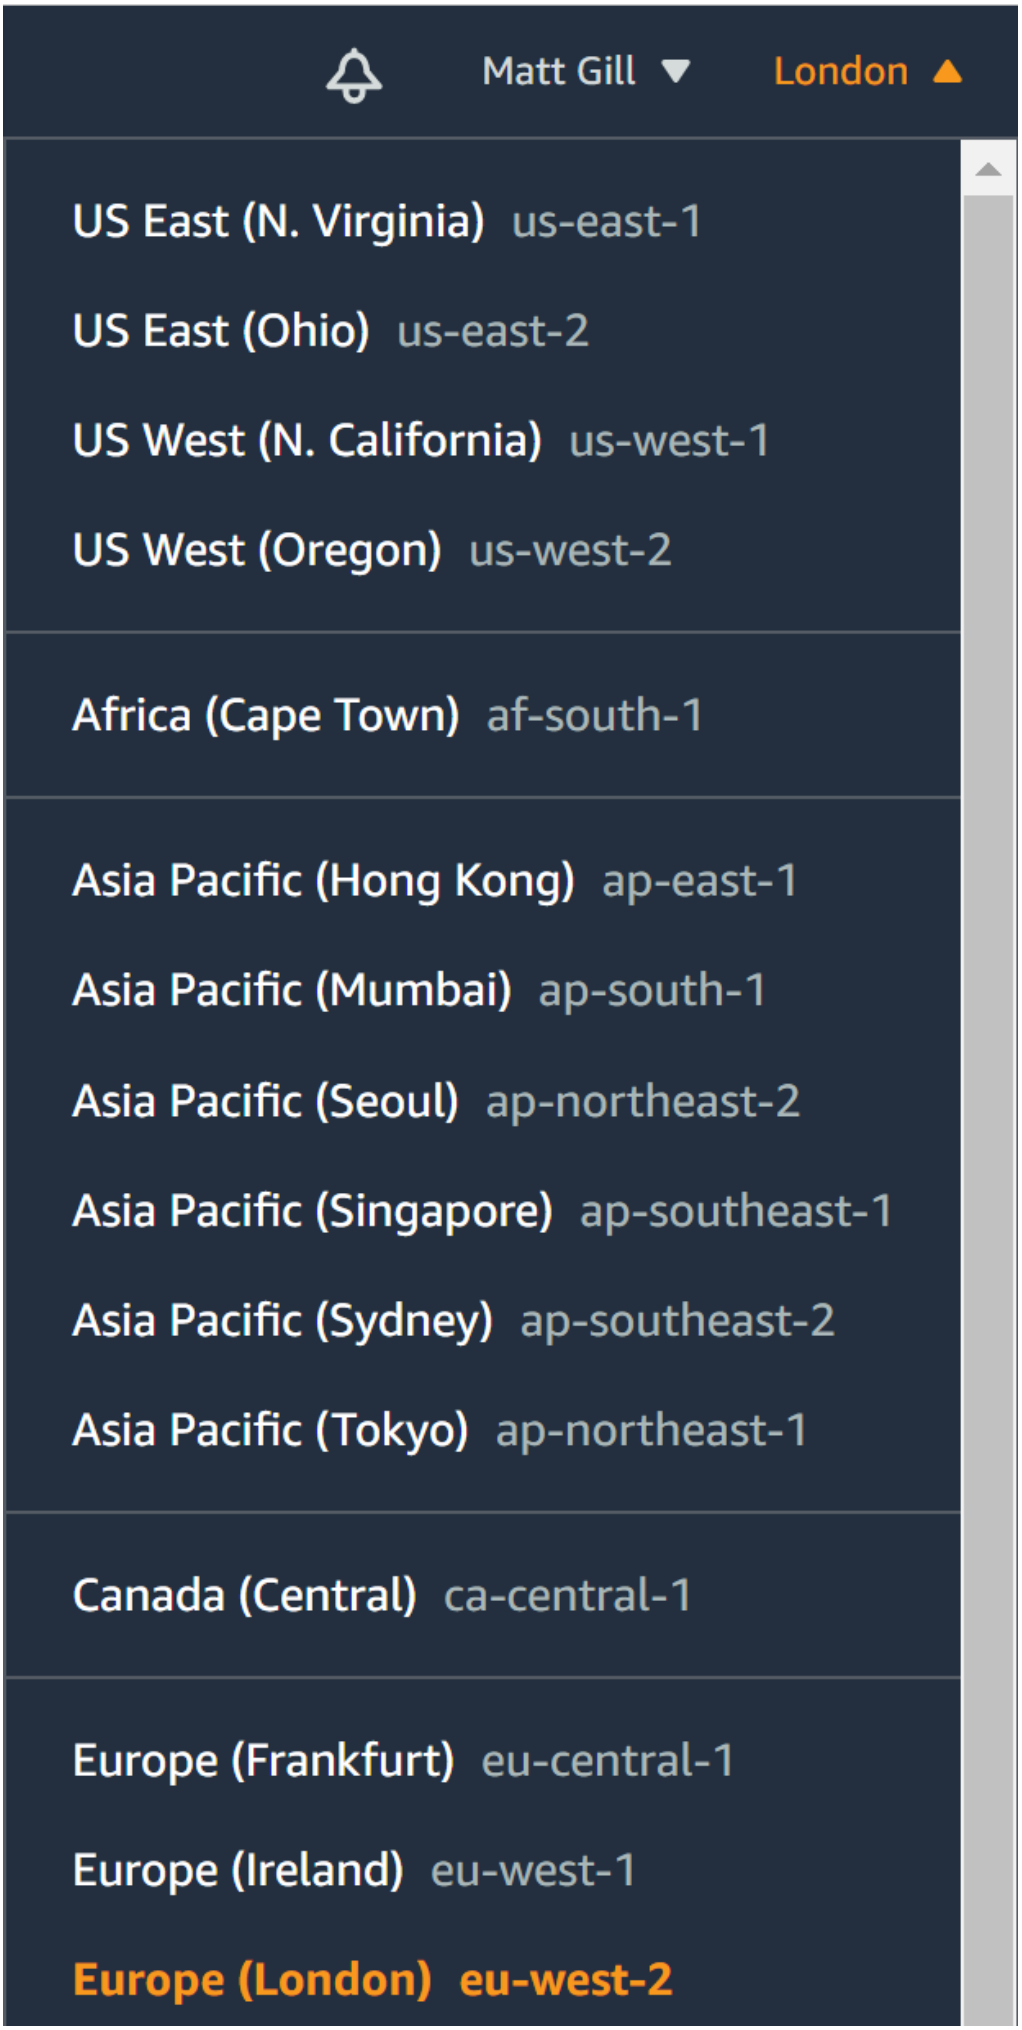
Whether you assign a group or select individual permissions, make sure the IAM user contains the *SecretsManagerReadWrite* permission, which will allow the user access to your secrets.

When you finish creating the IAM user, you'll be given an access key id and secret access key. These will need to be recorded, and passed to Payara Server as Password Aliases `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` respectively.

Configuration

You can configure AWS Secrets either via the admin console or the *asadmin* utility. You'll need the access key id, secret access key and secret name created from the AWS console in the previous sections, as well as the name of the AWS region. Make sure that the AWS Secrets Manager has been enabled in the specified region.

To find the region in the AWS console, check the top right dropdown:



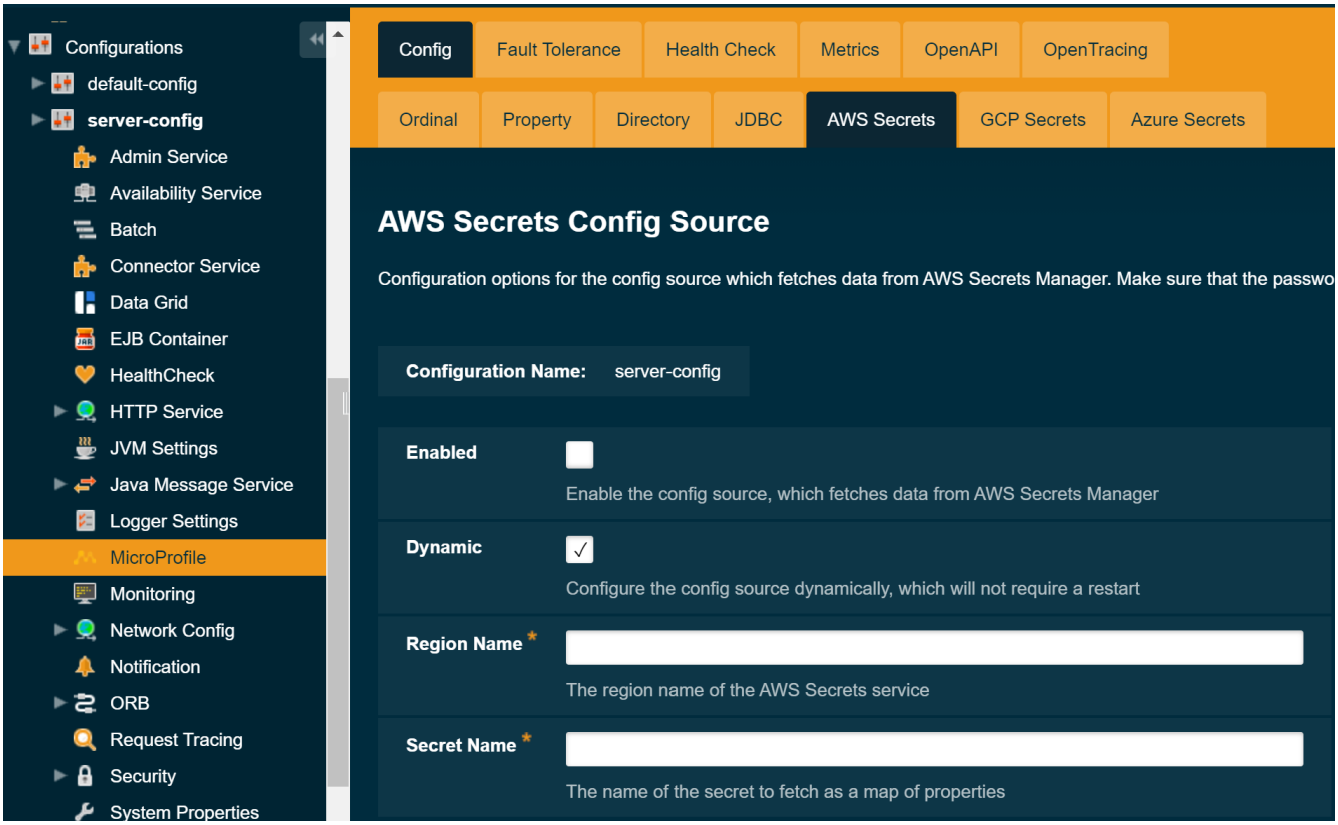
Matt Gill
London
US East (N. Virginia) us-east-1
US East (Ohio) us-east-2
US West (N. California) us-west-1
US West (Oregon) us-west-2
Africa (Cape Town) af-south-1
Asia Pacific (Hong Kong) ap-east-1
Asia Pacific (Mumbai) ap-south-1
Asia Pacific (Seoul) ap-northeast-2
Asia Pacific (Singapore) ap-southeast-1
Asia Pacific (Sydney) ap-southeast-2
Asia Pacific (Tokyo) ap-northeast-1
Canada (Central) ca-central-1
Europe (Frankfurt) eu-central-1
Europe (Ireland) eu-west-1
Europe (London) eu-west-2

The region name is the snake-case notation, not the full words. E.g. `eu-west-2`.

From the Admin Console

To configure the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` password aliases from the admin console, refer to the Password Aliases Admin Console configuration guide.

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `AWS Secrets`.



From here you can pass the name of the secret to access in AWS Secrets Manager, as well as the region name. You can also decide whether to apply these changes dynamically or on the next server restart. If the config source is enabled or disabled dynamically it will take effect across the server immediately.

From the Command Line

To configure the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` password aliases from the command line, refer to the Password Aliases Asadmin configuration guide.

To configure the AWS Secrets Cloud Config Source from the command line, use these commands:

- `set-aws-config-source-configuration`
- `get-aws-config-source-configuration`

Usage

Provided the required roles have been assigned to the IAM user in the AWS console, the secrets can be injected into any applicable MicroProfile Config injection point as with any other configuration

source.

The secrets can also be fetched, created and deleted from the `asadmin` utility.

To fetch a secret from AWS Secrets Manager:

```
asadmin get-config-property --source cloud --sourceName aws --propertyName mysecret

secretvalue
```

To create or change a secret from AWS Secrets Manager:

```
asadmin set-config-property --source cloud --sourceName aws --propertyName mysecret
--propertyValue secretvalue
```

To delete a secret from AWS Secrets Manager:

```
asadmin delete-config-property --source cloud --sourceName aws --propertyName mysecret
```

Azure

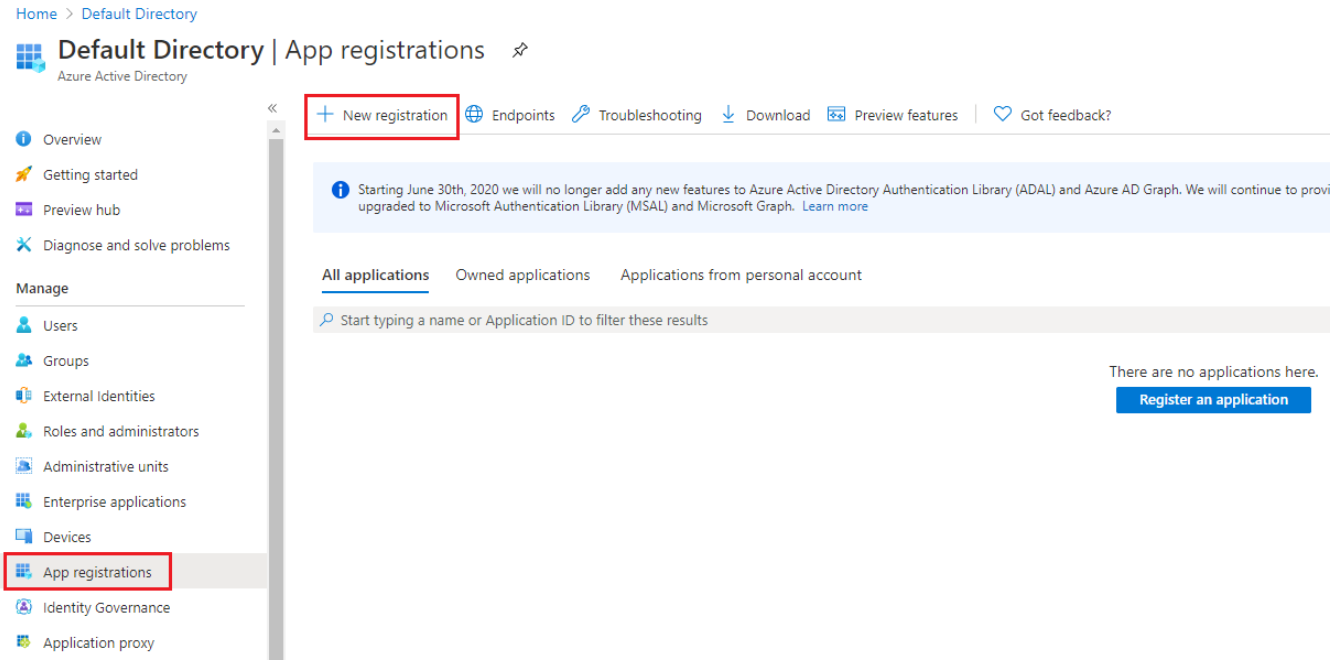
The Azure cloud config source takes configuration properties from Azure Key Vault Secrets.

Register Azure AD Application and Create Service Principle

If you haven't already, you will need to register an Azure Active Directory (Azure AD) application and create a service principal, so that the Microsoft identity platform can provide authentication and authorisation services. You can use the Azure portal to register your application and create a service principle.

1. Once you have signed in to your Azure portal, search and select Azure Active Directory
2. Select App registrations under the Manager section
3. Click New registration

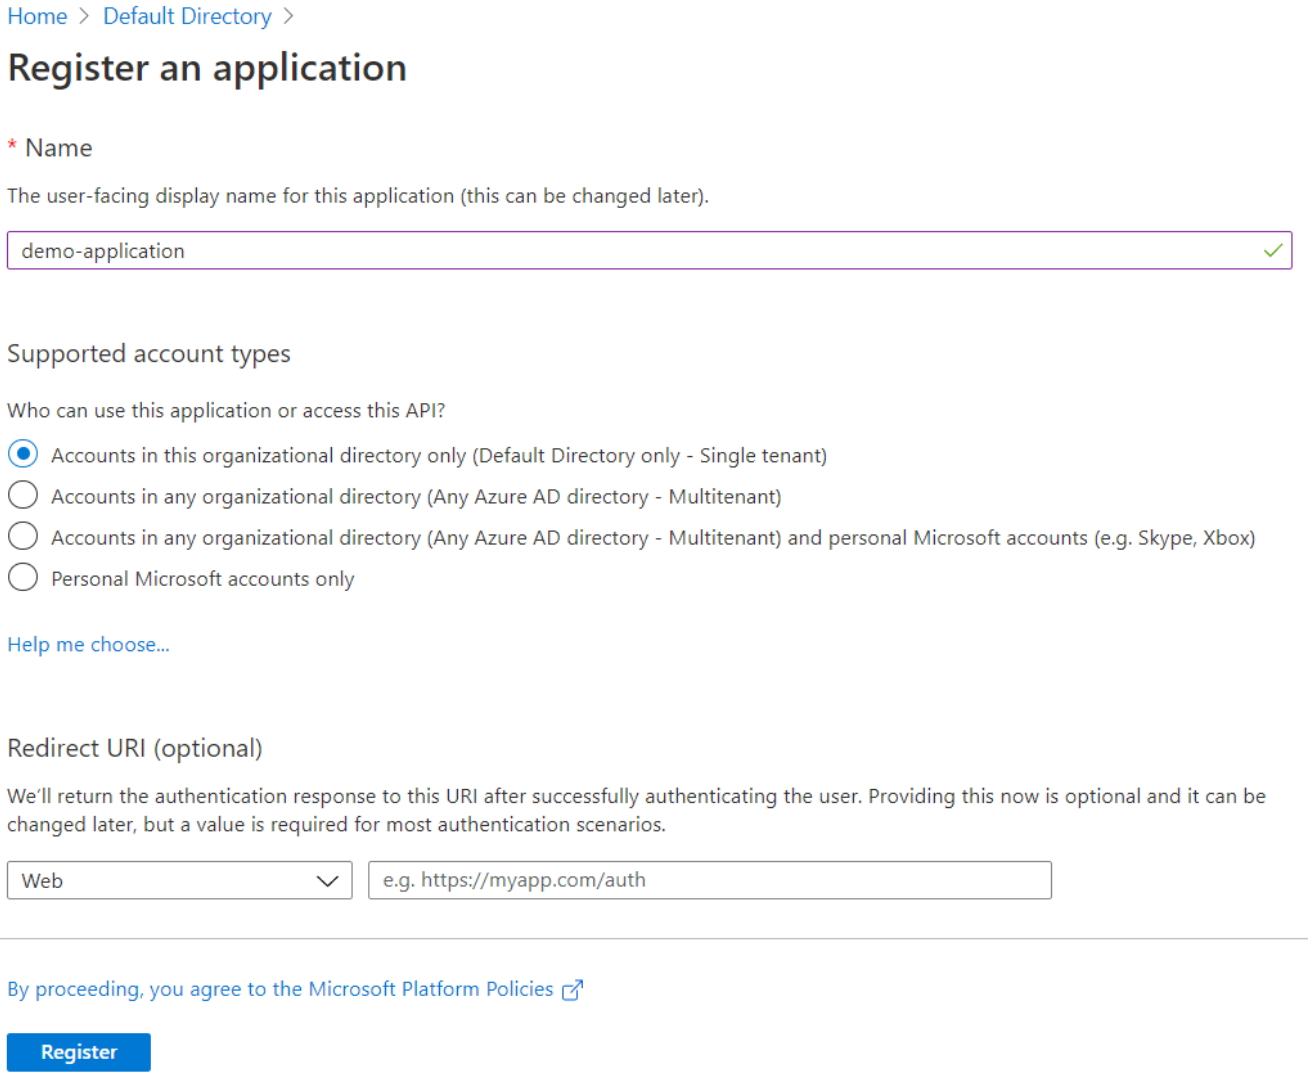
If you have access to multiple tenants and want to select a specific tenant to register with your application, use the Directory + subscription filter in the top menu.



Then on the *Register an application* page:

1. Specify a name for your application
2. Select the appropriate account types
3. Click Register to complete your application registration

Once the application registration is completed, the service principal is automatically created in your home tenant.

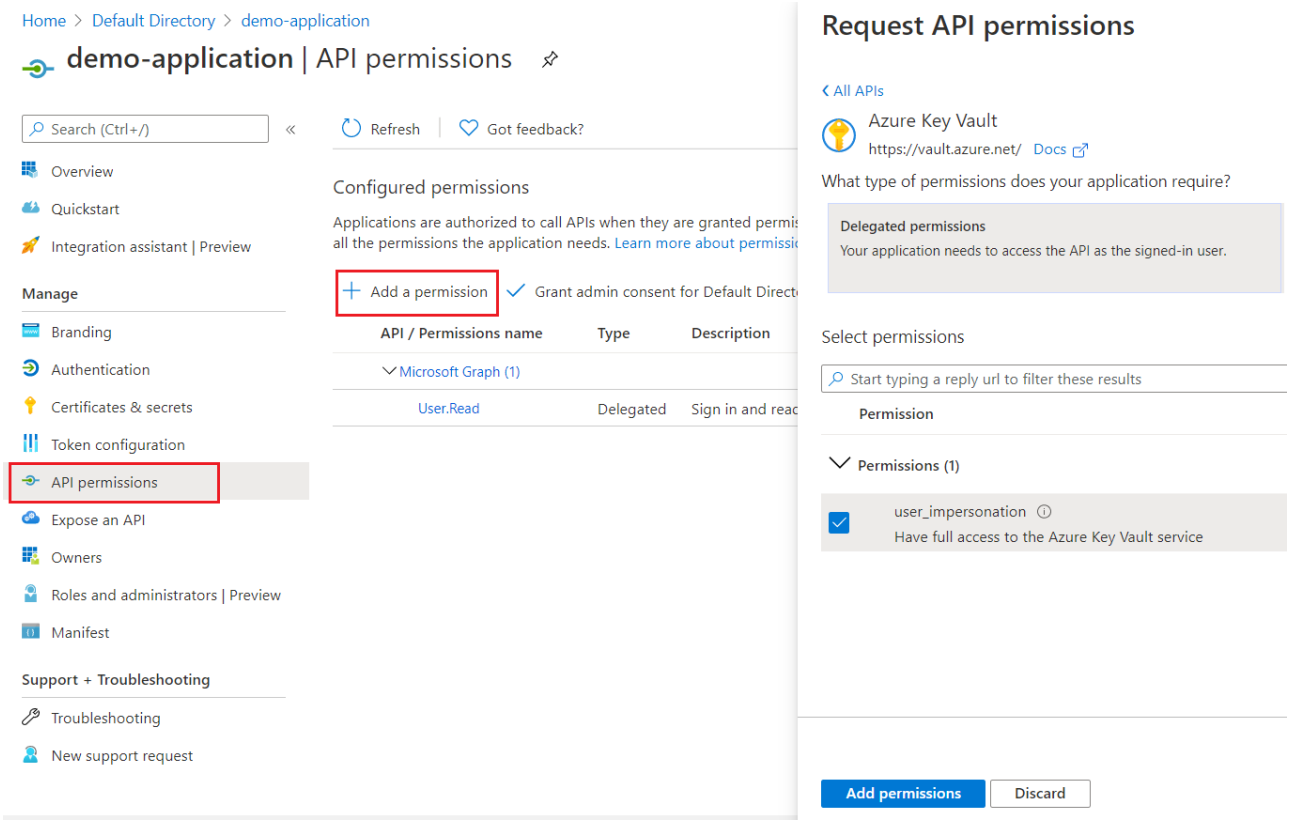


Application API Permissions

You will need to allow your application full access to the Azure Key Vault service to enable it to retrieve secrets from the vault. To do this, you will need to configure your application's API permissions.

You can learn more about permissions and consent here.

1. Select your application
2. Select API permissions under the Manage section
3. Click Add a permission
4. Select Azure Key Vault for the list of Microsoft APIs
5. Under the types of permissions, select Delegated permissions
6. Tick the *user_impersonation* checkbox
7. Click Add permissions



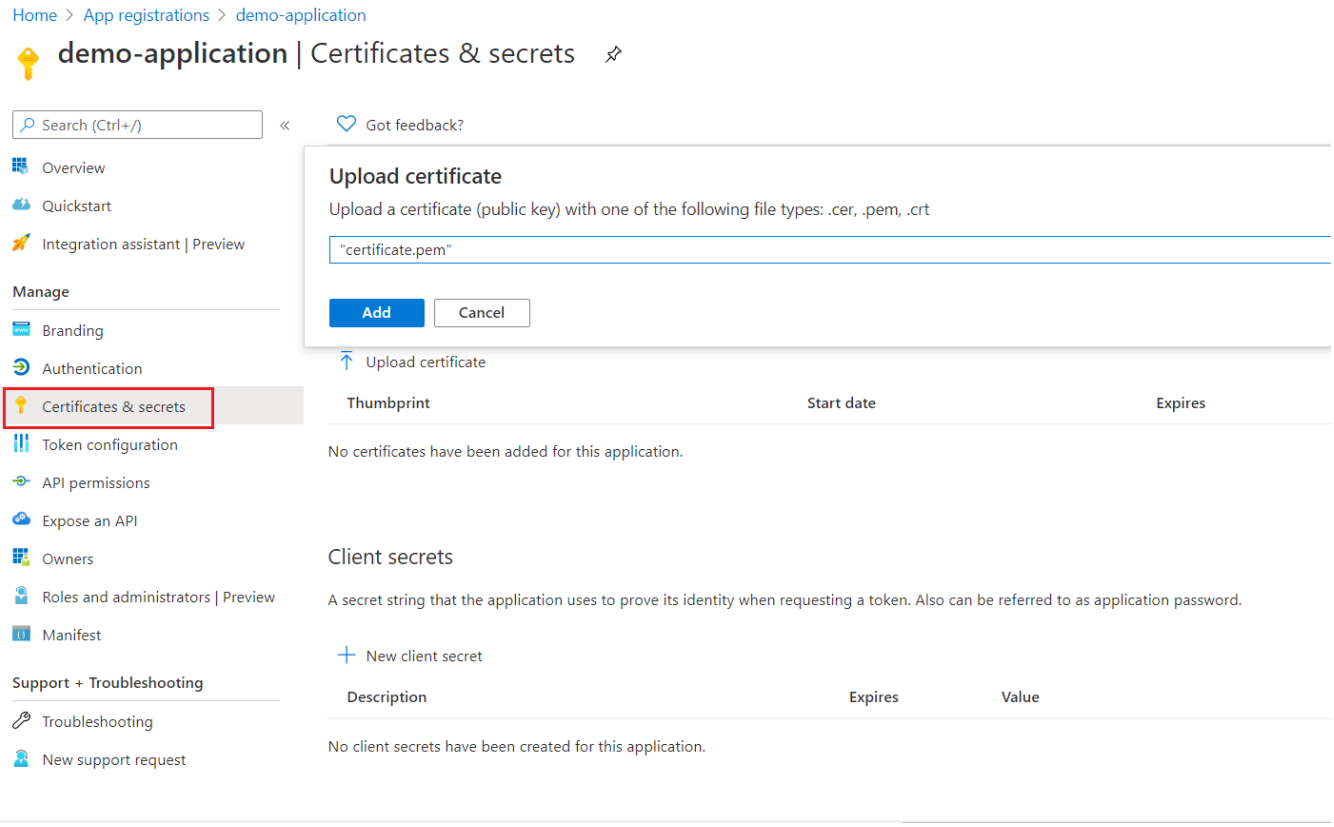
Adding Credentials

Credentials allow your application to authenticate as itself. Azure supports two options as credentials: client secret (a string) and certificate (public key). Currently, Payara Platform only supports certificate as they provide a higher level of assurance than client secrets.

You can upload your certificate for authentication using the following steps:

1. Select your application
2. Select Certificates & Secrets under the Manage section
3. Click Upload certificate
4. Choose a certificate
5. Click *Add*

Once the certificate is successfully uploaded, it should generate a *Thumbprint*, which will be required when we configure the *Azure Config* Source.

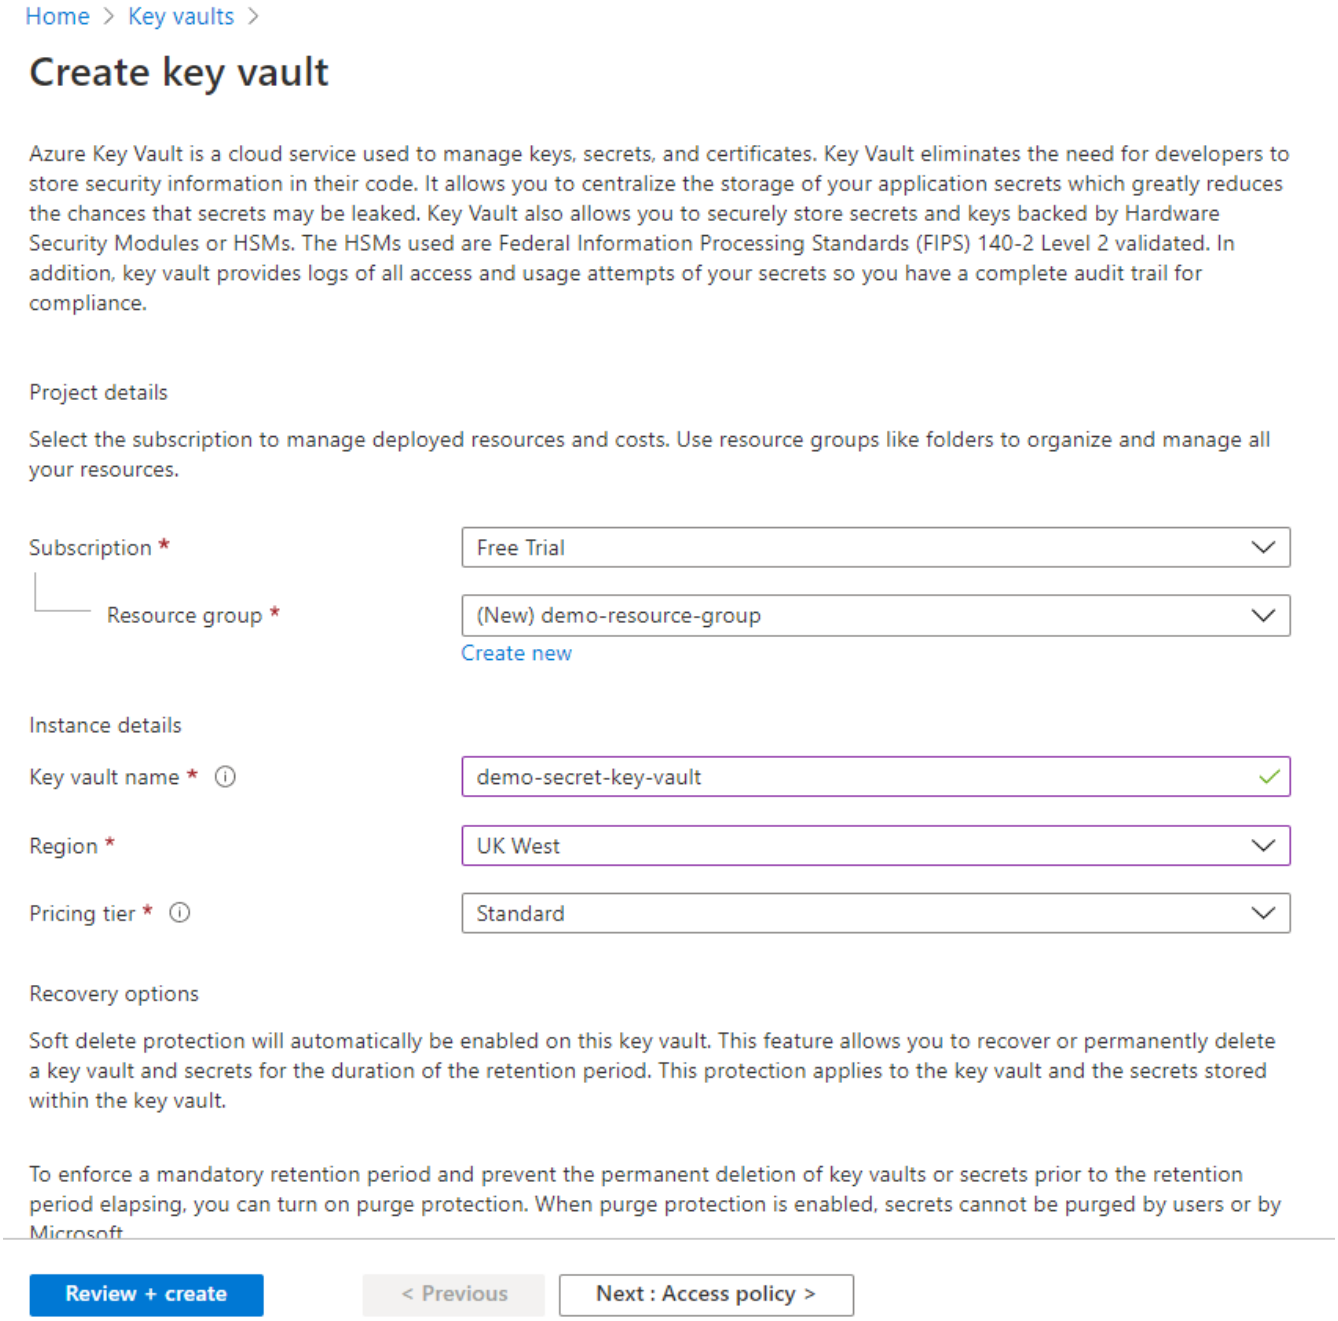


Create a Key Vault

To store your secrets securely, you will need to create a key vault.

1. Search for key vaults and select it
2. Click Add
3. Provide relevant information on the Create key vault page
4. Click *Review + create*

Although key vault allows storing of keys, secrets, and certificates, *Azure Config Source* currently only support secrets.



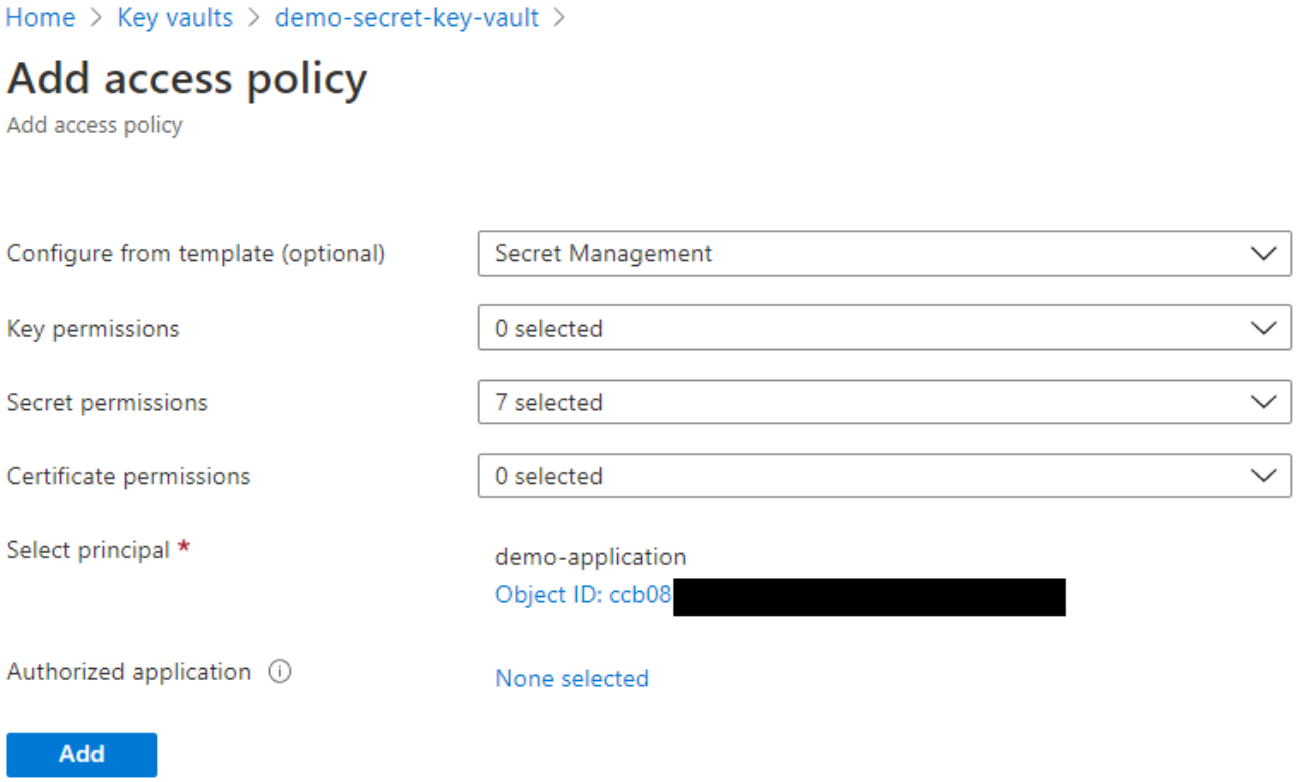
In the above diagram, the Basic section has been configured and the remaining sections have been left to their default settings. You can configure other sections, such as Access policy and Networking, to fit your requirements.

Configure access policies on Key Vault

To give your application access to the secrets in a key vault, you will need to add the application to the key vault's access policies.

1. Navigate to your key vault
2. Select Access policies under the Settings section
3. Click Add Access Policy
4. Under Configure from template, select Secret Management, as we don't require the other options

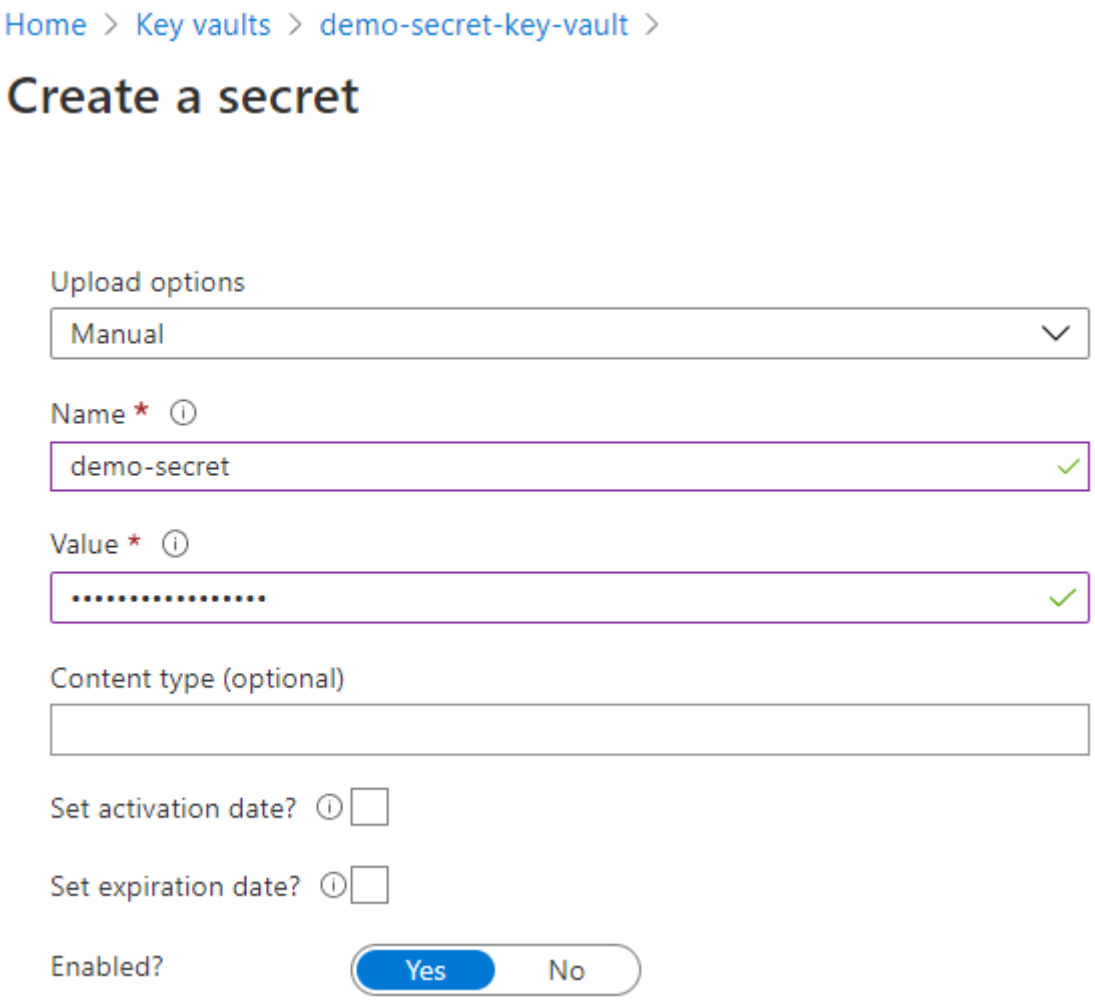
5. Select the service principal that you created previously
6. Click *Add*
7. Click *Save* to commit your changes



Add a Secret to Key Vault

To add a secret to the key vault:

1. Select the key vault you want to add your secret to
2. Click on Secrets under the Settings section
3. Click Generate/Import
4. Provide relevant information on the Create a secret page
5. Click Create



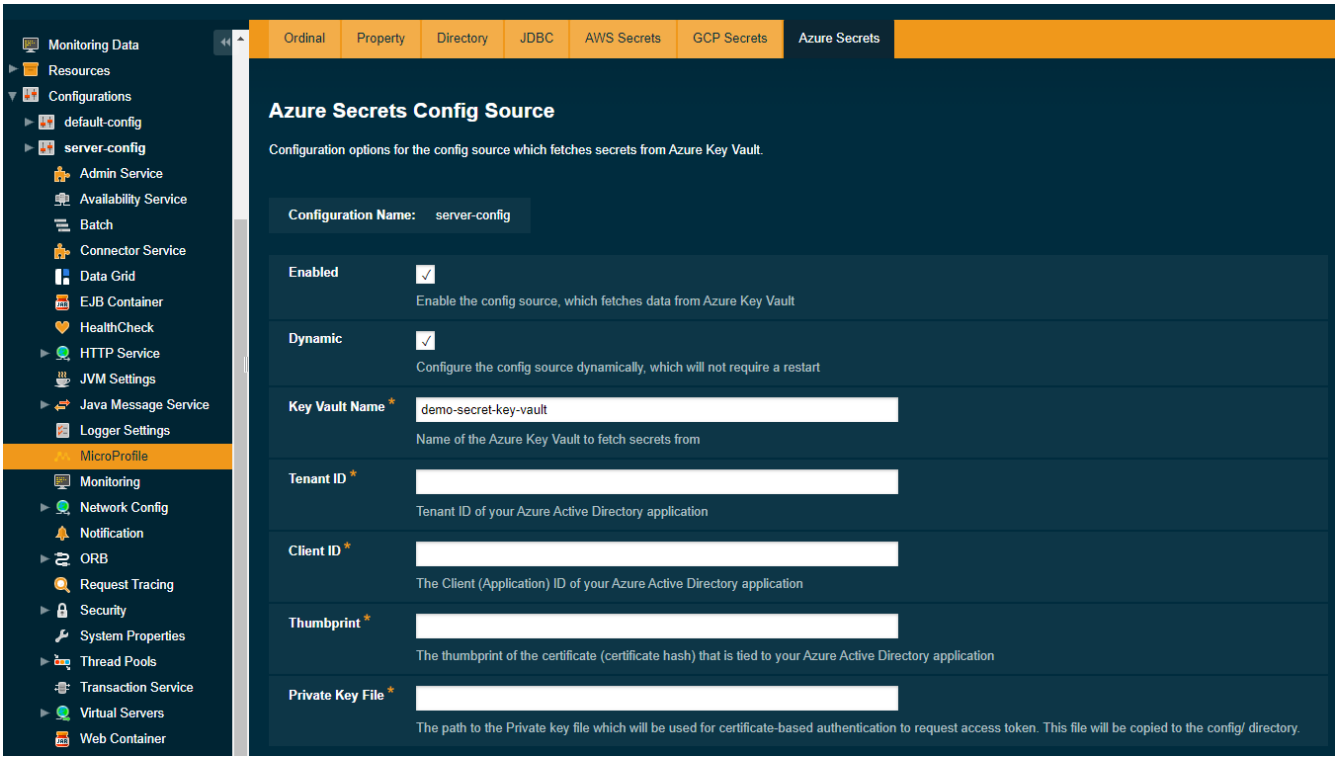
Configuration in Payara Server

You can configure Azure Secrets either via the admin console or the asadmin utility. You will need the name of your key vault, tenant ID and client ID of your application, your private key file and thumbprint generated by your application after you uploaded your certificate.

Your private key file will be copied into `domain-dir/config`.

From the Admin Console

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `Azure Secrets`.



From here, you can pass the name of the key vault, tenant ID and client ID of the application, absolute path to the private key file and thumbprint of the certificate.

You can also decide whether to apply these changes dynamically or on the next server restart. If the config source is enabled or disabled dynamically, it will take effect across the server immediately.

From the Command Line

To configure the Azure Config Source from the command line, use these commands:

- `set-azure-config-source-configuration`
- `get-azure-config-source-configuration`

Usage

Provided that all of the above sections are configured correctly, the secrets can be injected into any applicable MicroProfile Config injection point as with any other Config Source.

In Payara Server, these secrets can be fetched, created and deleted by using the `asadmin` utility.

To fetch a secret from a Key Vault:

```
asadmin get-config-property --source cloud --sourceName azure --propertyName demo-
secret
demo-secret-value
```

To create or change a secret in a Key Vault:

```
asadmin set-config-property --source cloud --sourceName azure --propertyName mysecret
```

```
--propertyValue secretvalue
```

To delete a secret from a Key Vault:

```
asadmin delete-config-property --source cloud --sourceName azure --propertyName
mysecret
```

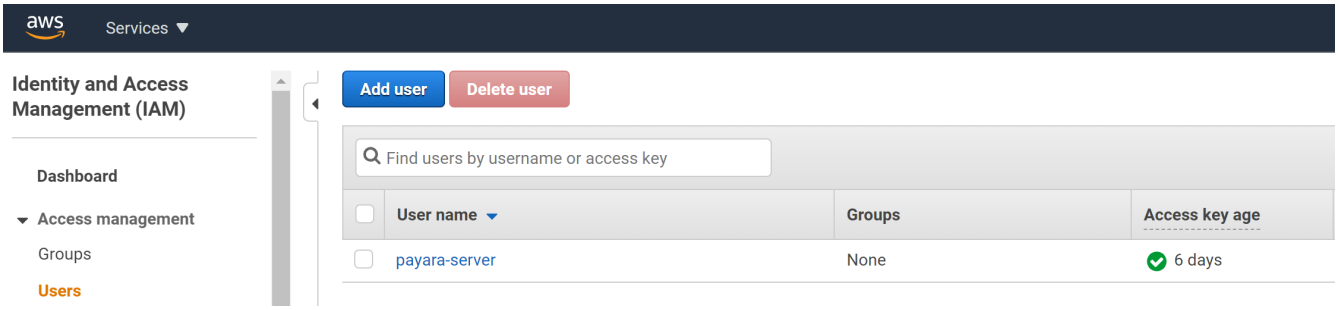
DynamoDB

The DynamoDB config source reads configuration properties from a DynamoDB database table. DynamoDB is a managed **NoSQL** database service provided by Amazon.

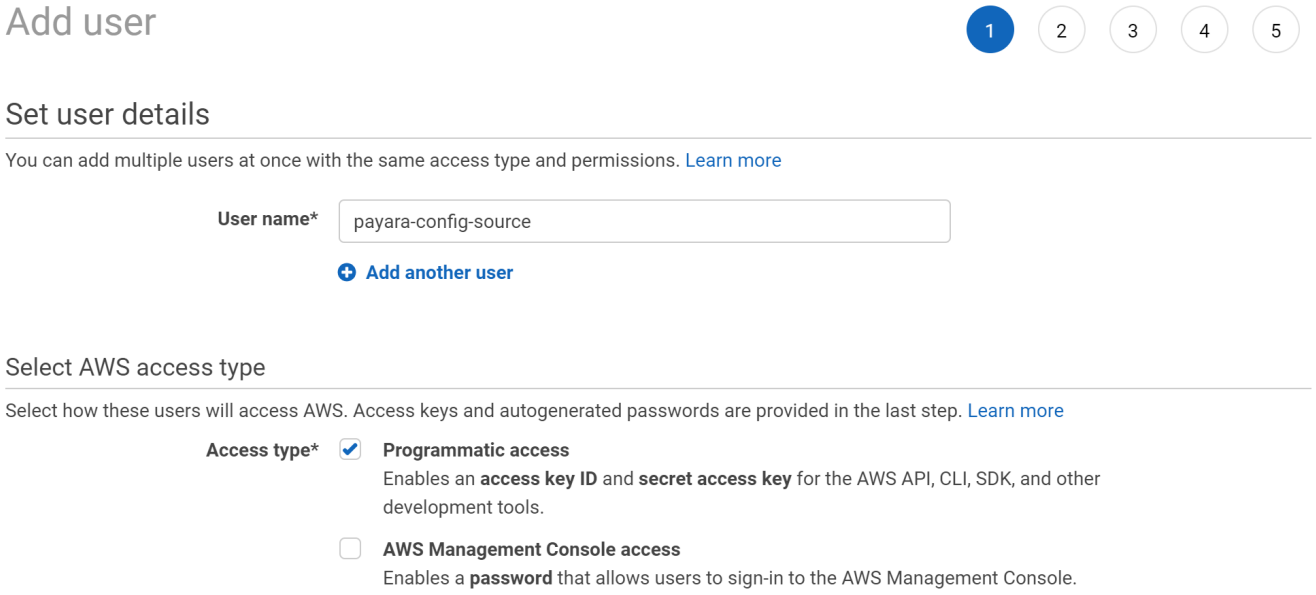
AWS IAM User

In order to access DynamoDB, you need an AWS access key. If you don't have an access key, you can create them from the AWS Management Console. To create access keys for an IAM user which Payara Server will use to access your DynamoDB.

From the AWS console, visit the *IAM Users* dashboard by searching 'IAM' in the top search bar. From here, head to *Users* in the left menu. You'll see all your IAM users associated with this region.

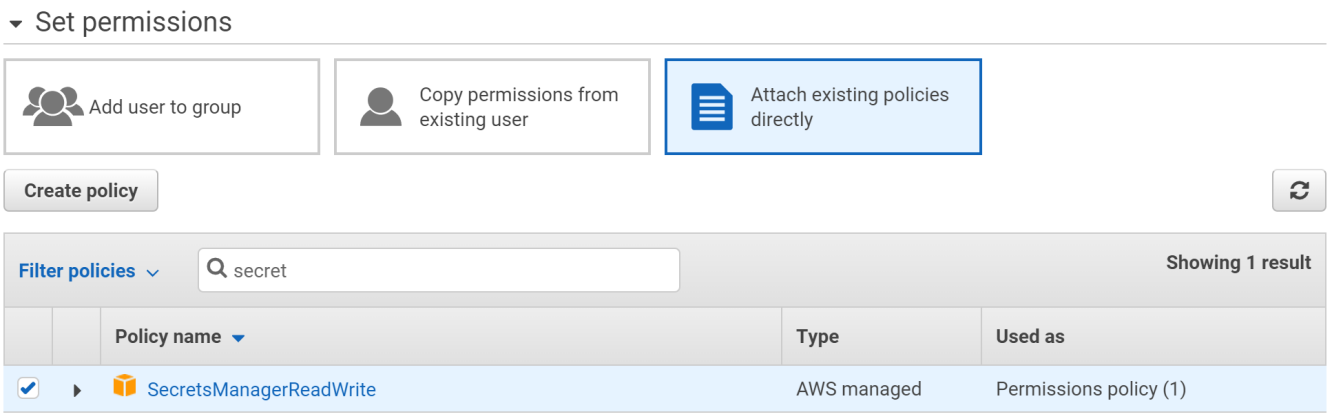


From here you can create a new IAM user. Skip this step if you already have an IAM user you want to use.



Set the IAM username. This isn't used by Payara Server but will be helpful for your own reference. Make sure you enable *Programmatic access*, as this will be used by Payara Server to access your AWS Secrets.

Next, select your IAM user permissions.



Whether you assign a group or select individual permissions, make sure the IAM user contains the *SecretsManagerReadWrite* permission, which will allow the user access to your secrets.

When you finish creating the IAM user, you'll be given an access key id and secret access key. These will need to be recorded and passed to Payara Server as Password Aliases `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` respectively.

Configuration in Payara Server

DynamoDB config source configuration is disabled by default but can be configured dynamically or statically like any other Payara service.

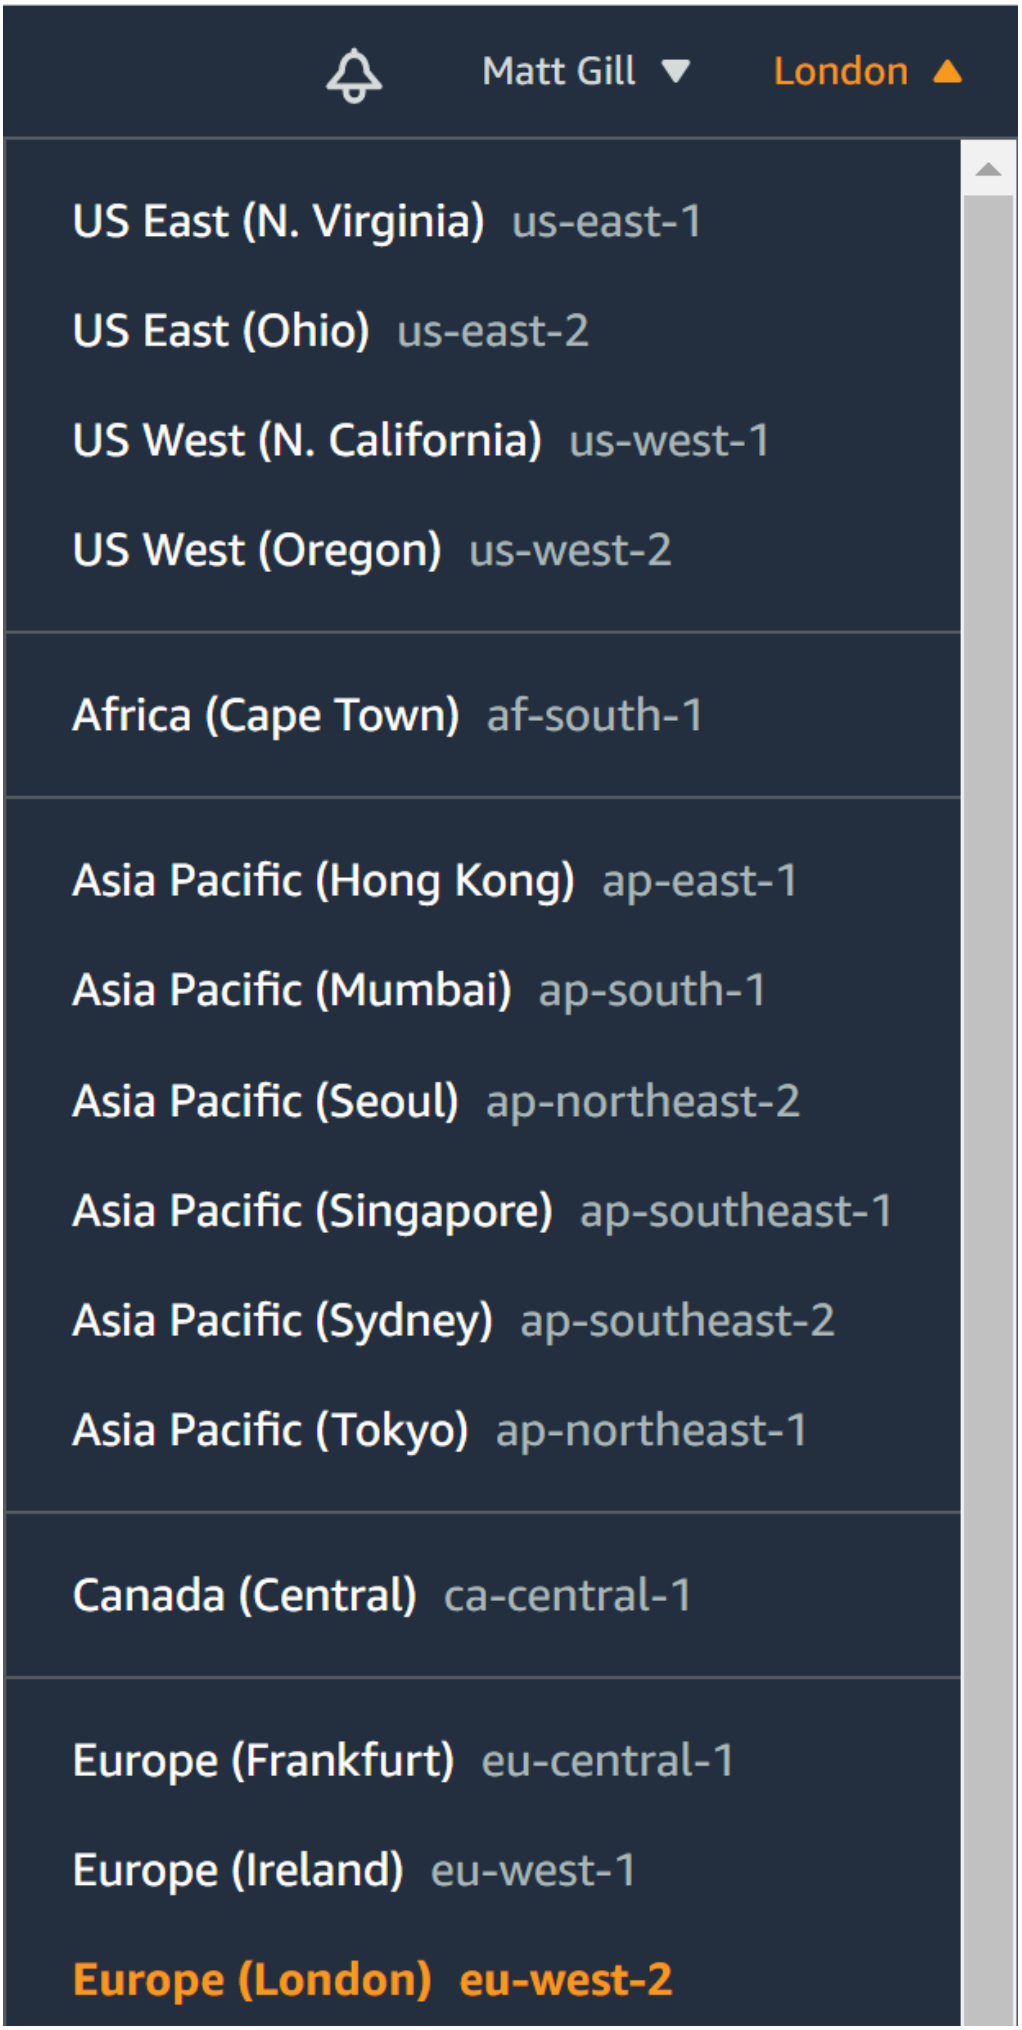
You can configure DynamoDB Config Source either via the admin console or the *asadmin* utility. You'll need the name of a database table, name of the key column containing the key and name of the column containing the value, as well as the name of the AWS region the DynamoDB table has

been created in.

The values from the key column will be used as the config property names and the values from the value column will be used as the config property value.

The type of the database columns for the `key` and `value` columns needs to be of type `String` or compatible.

To find the region in the AWS console, check the top right dropdown:



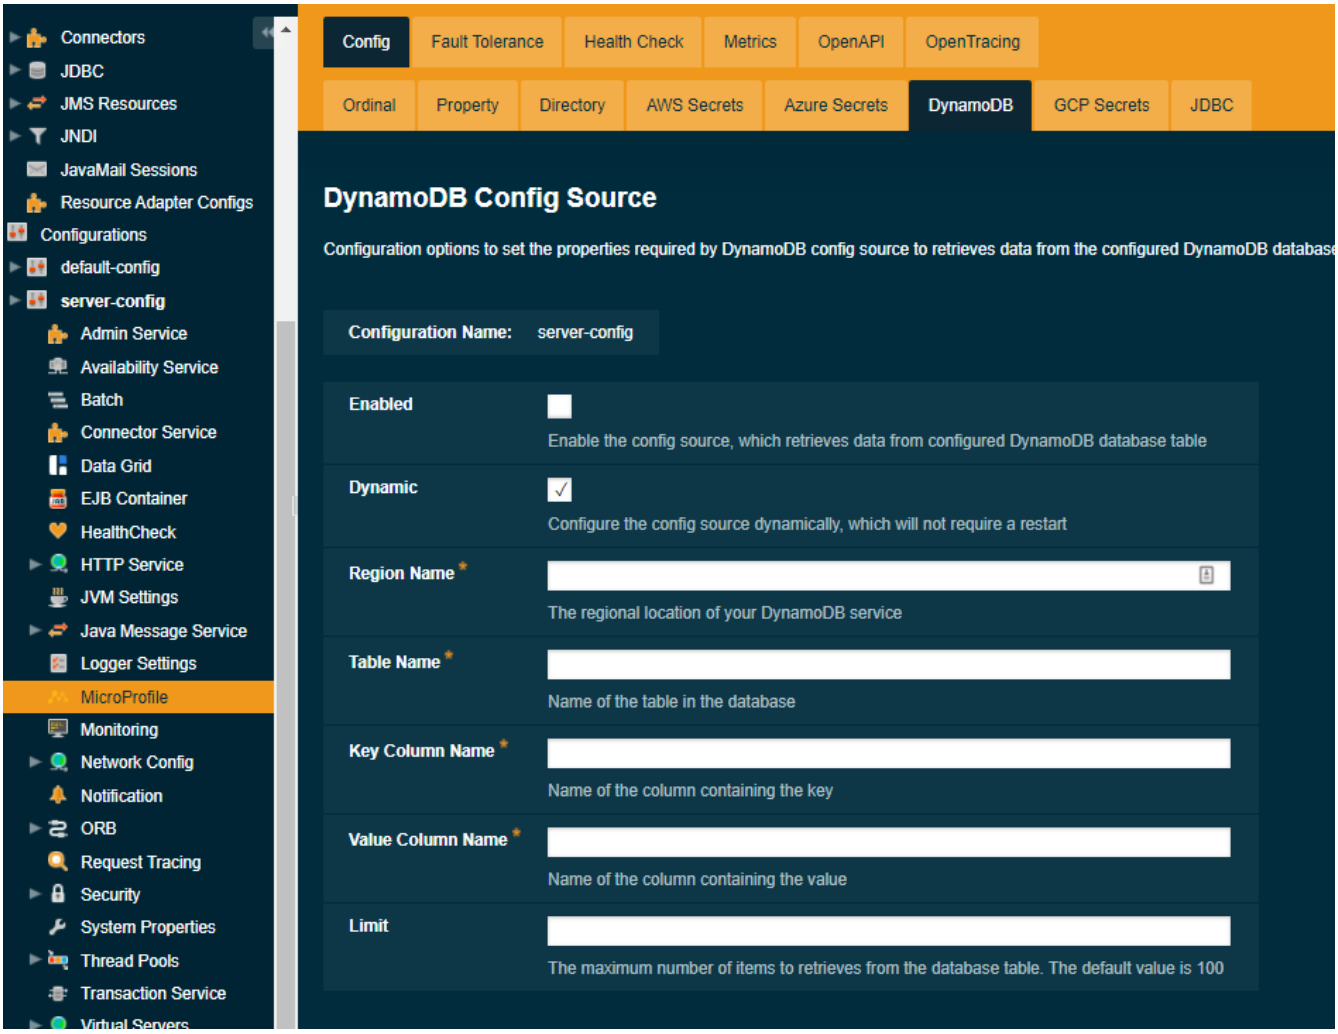
Matt Gill
London
US East (N. Virginia) us-east-1
US East (Ohio) us-east-2
US West (N. California) us-west-1
US West (Oregon) us-west-2
Africa (Cape Town) af-south-1
Asia Pacific (Hong Kong) ap-east-1
Asia Pacific (Mumbai) ap-south-1
Asia Pacific (Seoul) ap-northeast-2
Asia Pacific (Singapore) ap-southeast-1
Asia Pacific (Sydney) ap-southeast-2
Asia Pacific (Tokyo) ap-northeast-1
Canada (Central) ca-central-1
Europe (Frankfurt) eu-central-1
Europe (Ireland) eu-west-1
Europe (London) eu-west-2

The region name is the snake-case notation, not the full words. E.g. `eu-west-2`.

From the Admin Console

To configure the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` password aliases from the admin console, refer to the Password Aliases Admin Console configuration guide.

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `DynamoDB`.



From here you configure the name of the database table, the region name, name of the key column containing the key, name of the column containing the value and the maximum number of items to retrieves from the database table.

From the Command Line

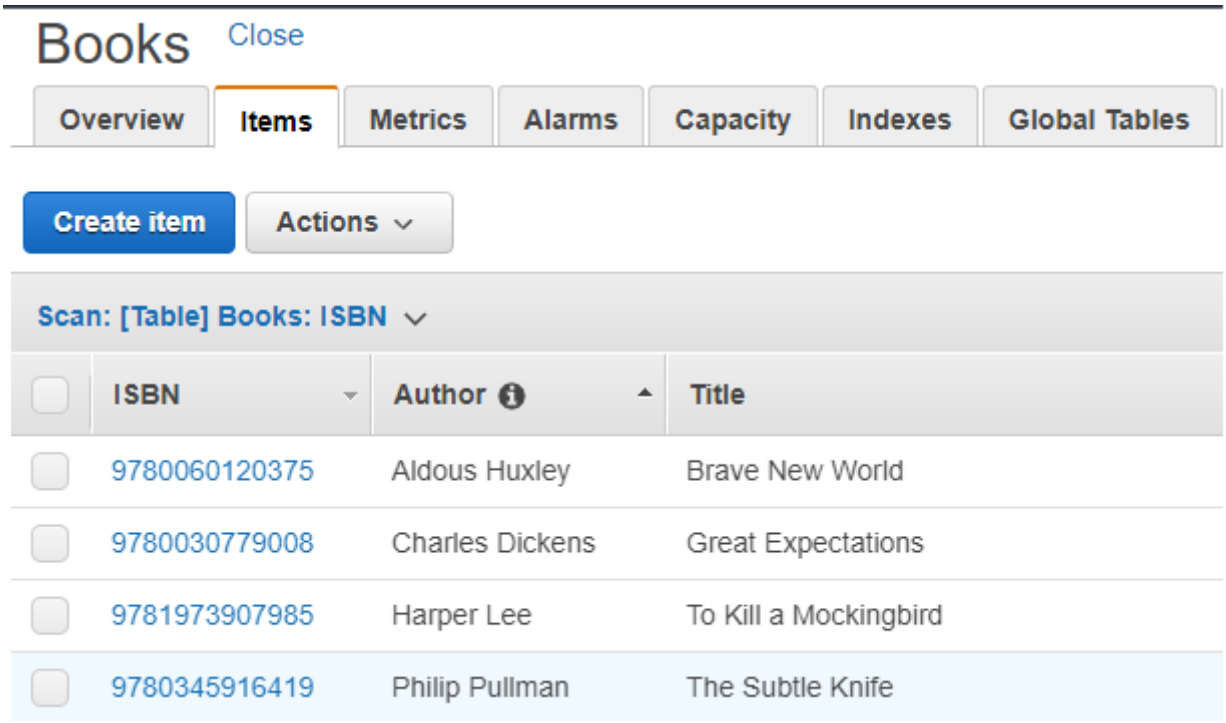
To configure the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` password aliases from the command line, refer to the Password Aliases Asadmin configuration guide.

To configure the DynamoDB config source from the command line, use these commands:

- `set-dynamodb-config-source-configuration`.
- `get-dynamodb-config-source-configuration`.

Usage

Once all required options are configured, you should be able to read configuration properties from a database table. For example, let's look at the following diagram. It shows a table named `Books` with columns ISBN, Author and Title.



If the key column name is set to ISBN and the value column name to Title. You can get the value of the Title column in relation to the ISBN column using the following command along with the ISBN value:

```
asadmin get-config-property --source cloud --sourcename dynamodb --propertyName
9780345916419
The Subtle Knife
Command get-config-property executed successfully.
```

Currently, DynamoDB config source only supports the `get-config-property` command and doesn't support the `set-config-property` and `delete-config-property` commands.

GCP

The GCP (Google Cloud Platform) Cloud config source takes configuration properties from the GCP Secret Manager.

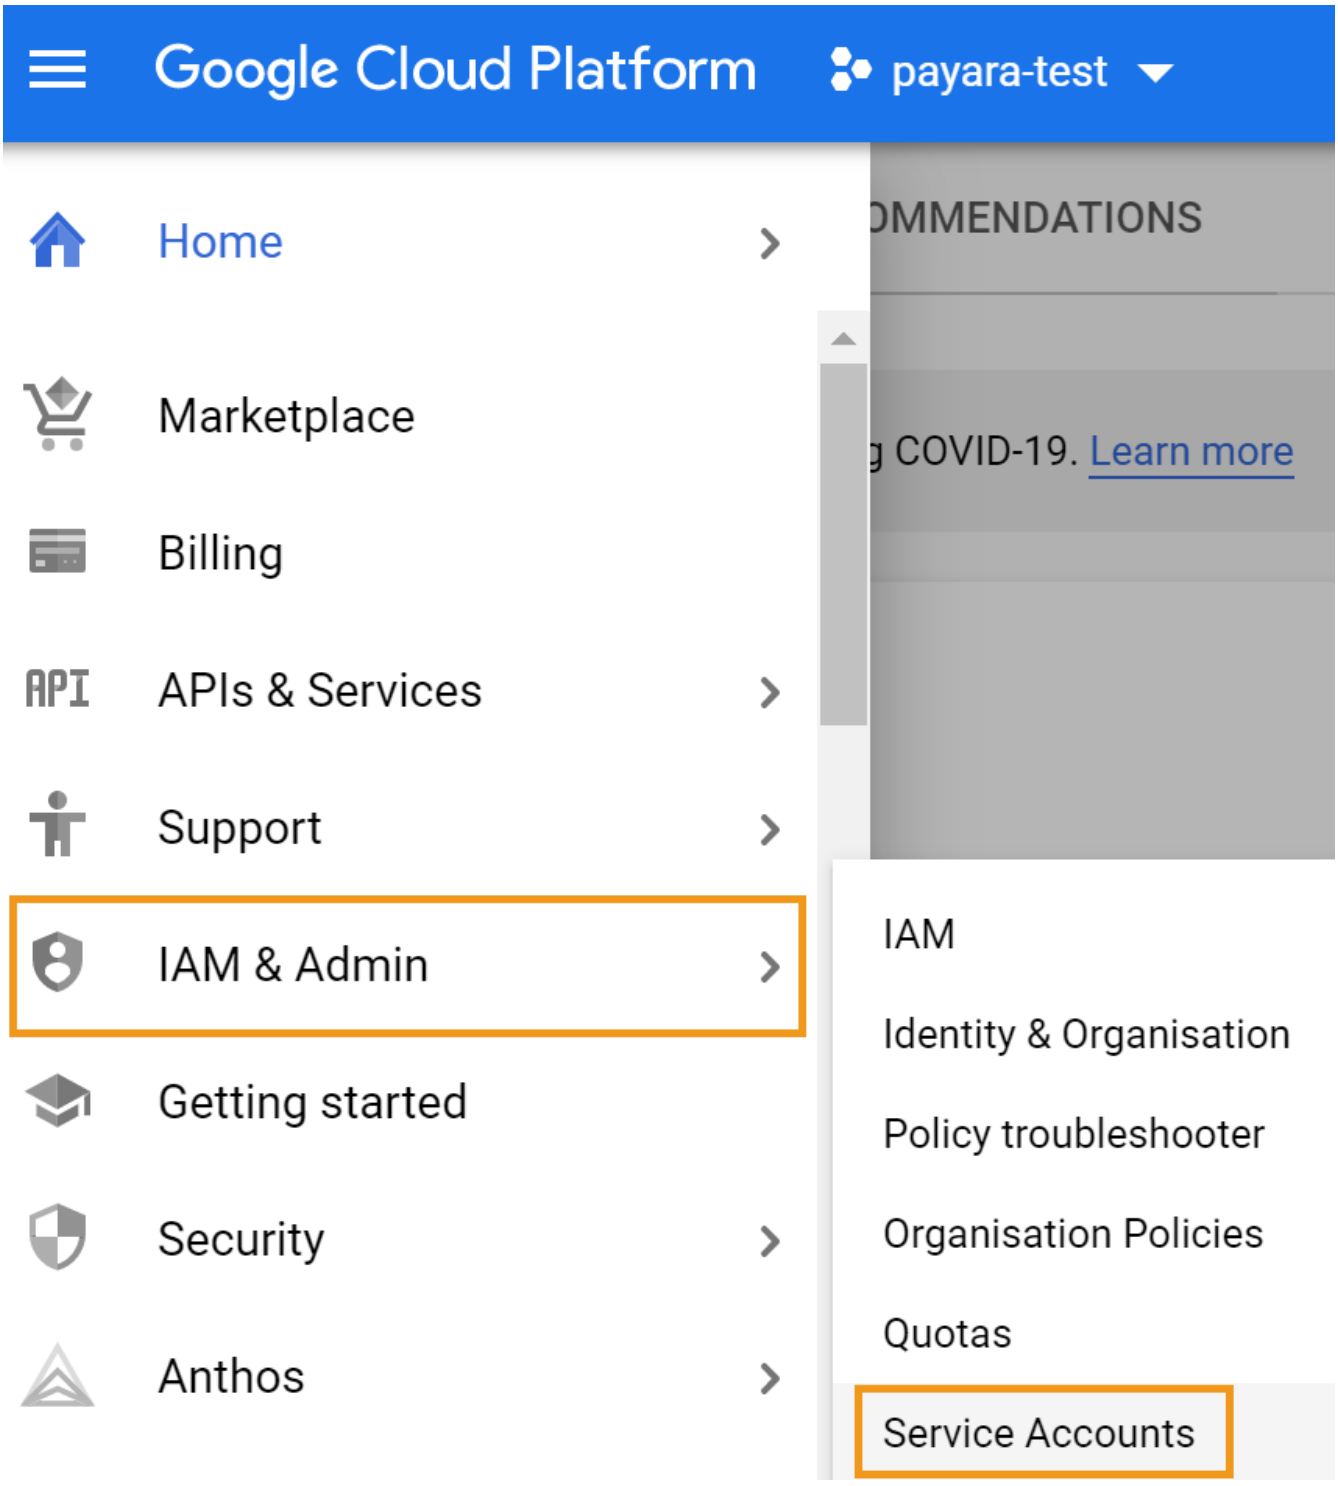
GCP Service Account

In order to connect to GCP Secret Manager you need to know your project name as well as have a service account access token. Assuming you already have a GCP project and a secret created in GCP Secrets Manager, you need to create a service account which Payara Server will use to access your GCP Secrets.

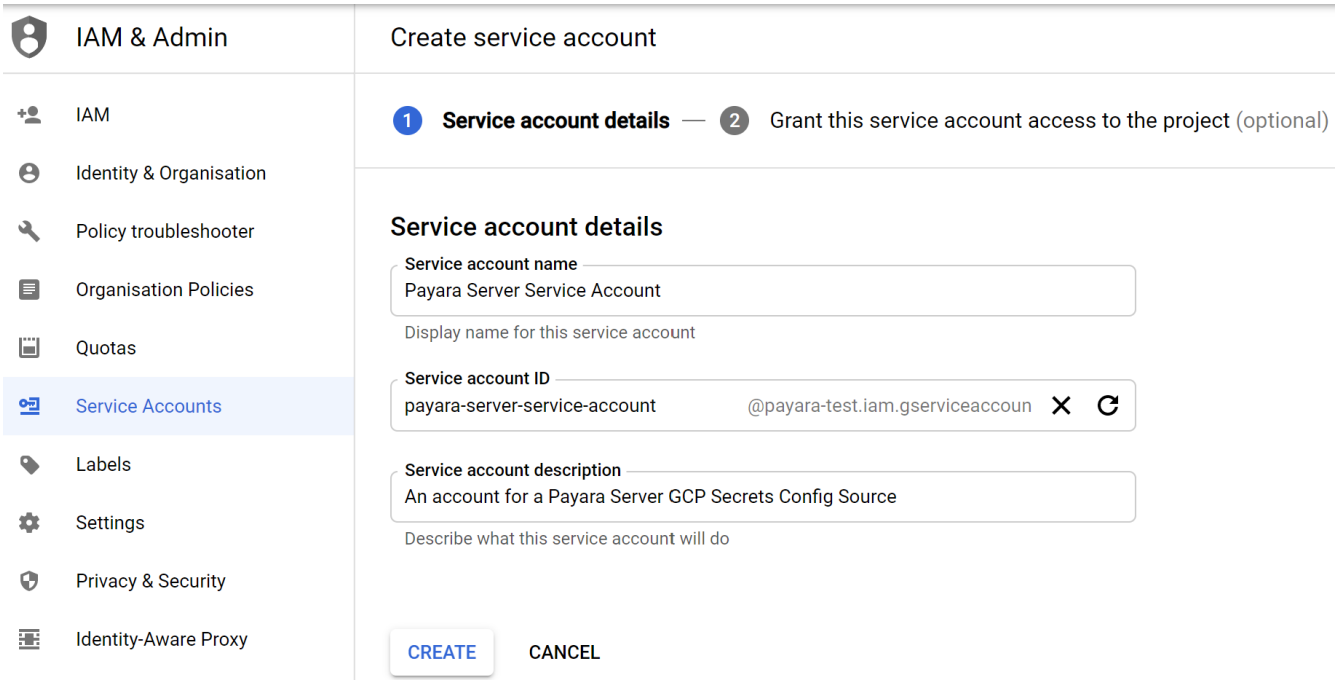
Visit the GCP cloud console: https://console.cloud.google.com/

Firstly, make sure you're on the right project. You can find your project name at the top of the GCP console.

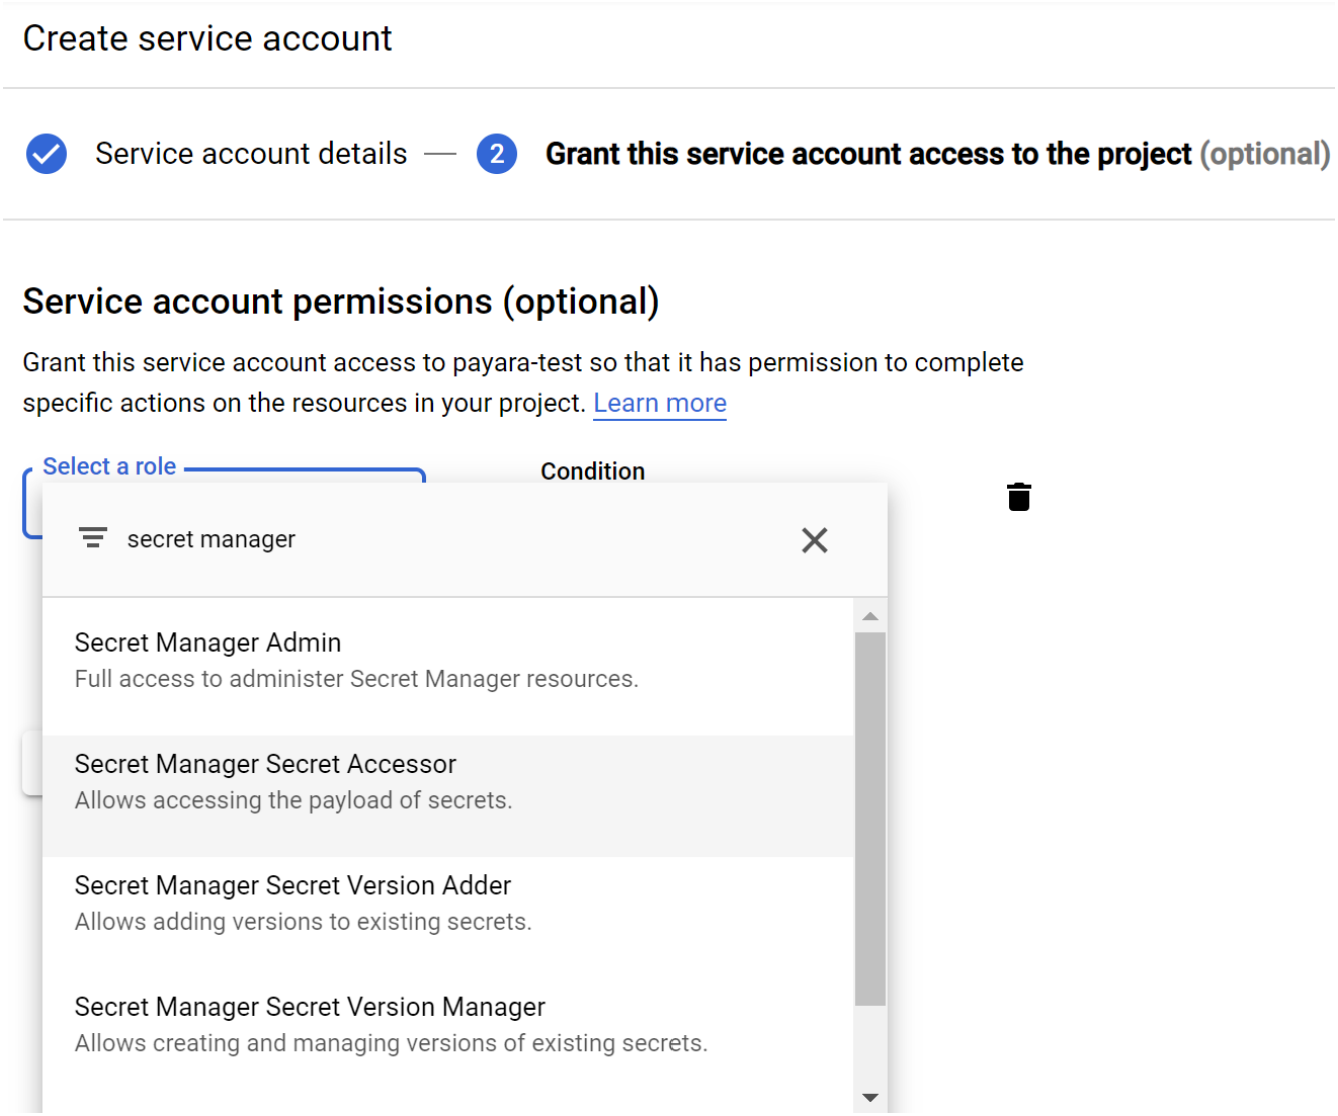
Next, visit the service account section of the project. You can find this from the top left menu → *IAM & Admin* → *Service Accounts*.



From here you can create a new service account. Skip this step if you already have a service account you want to use.



After this you'll need to add roles to your service account



You have a selection of roles:

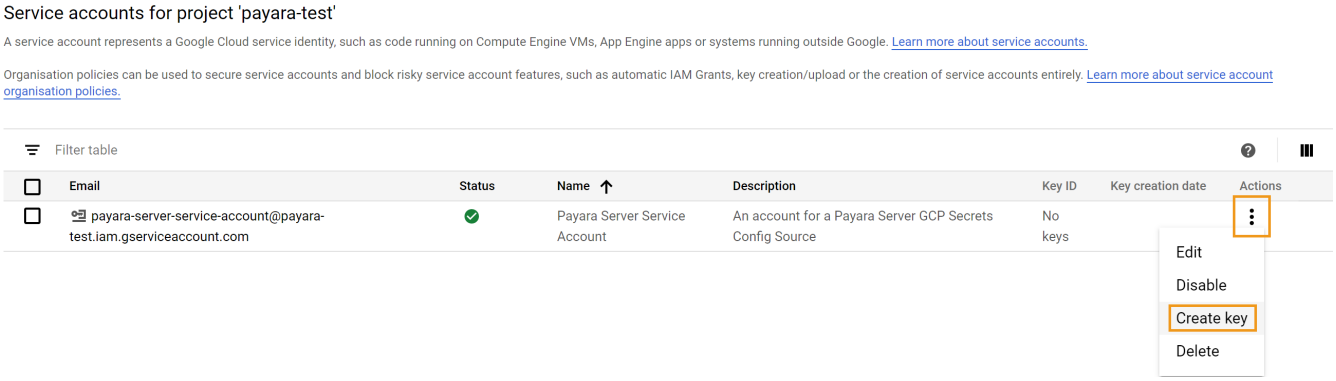
- ***Secret Manager Admin*** - full admin rights to manage secrets. Recommended when you want to delete or modify secrets through Payara Server
- ***Secret Manager Secret Accessor*** - ability to view secrets. Recommended when you only want to retrieve secrets through Payara Server
- ***Secret Manager Secret Version Adder*** - allows setting secret values
- ***Secret Manager Secret Version Manager*** - allows deleting secret values

Add whichever of these is appropriate for your use case.

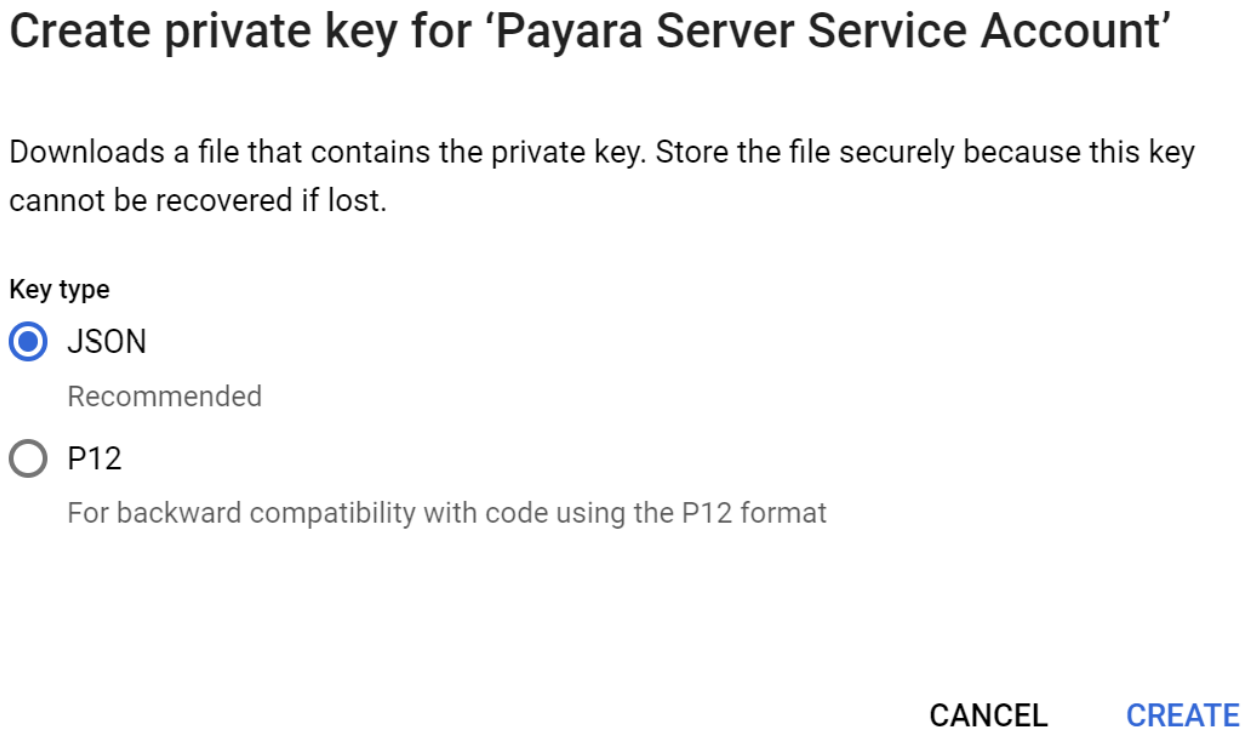
Skip step 3 if following the wizard, as no physical user will be required to use this service account.

Next, you'll need to download the access key for this service account.

Select the options icon for the service account you plan to use.



You'll be presented with an option to download the key in `JSON` or `P12` format. The GCP config source currently requires that the `JSON` format be used, so select this one.



This downloaded file can now be used by Payara Server to access GCP Secrets.

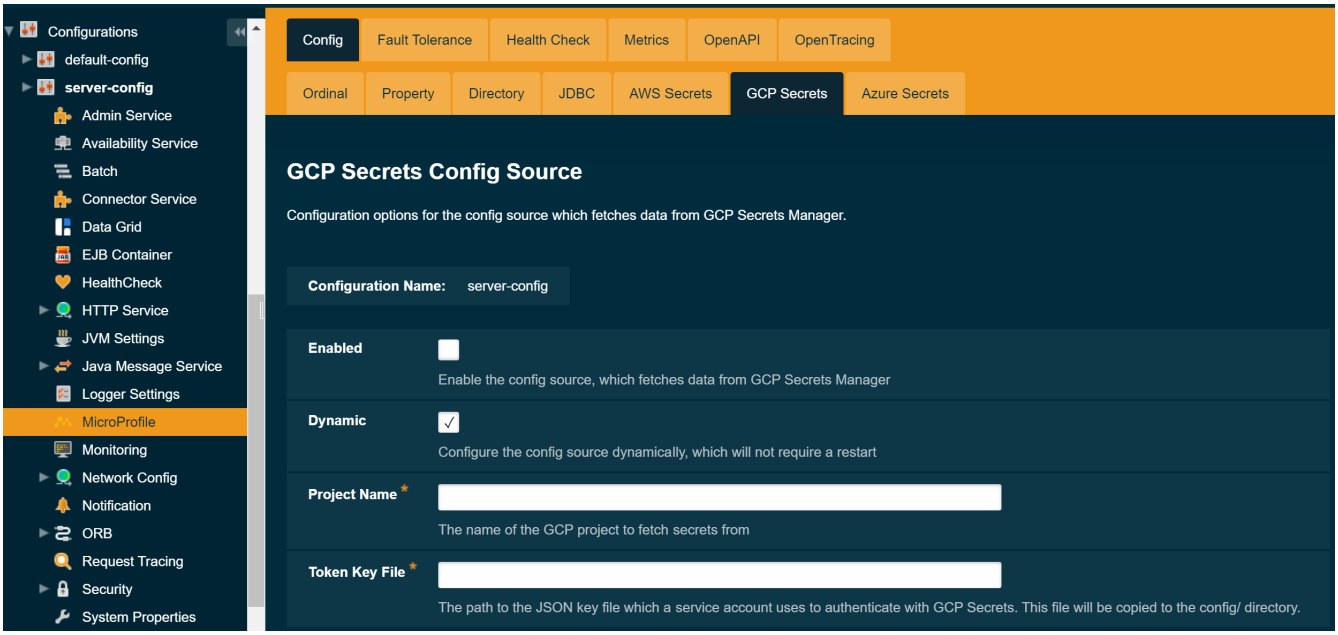
Configuration

You can configure GCP Secrets either via the admin console or the *asadmin* utility. You'll need the JSON key file created from the GCP console in the previous section, as well as the name of the project that you intend to use. Make sure that the GCP Secret Manager has been enabled for the specified project.

The JSON key file will be copied into the Payara Server `config/` directory, so it isn't required after passing it to the GCP Config Source configuration.

From the Admin Console

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `GCP Secrets`.



From here you can pass the absolute path to the json key file downloaded in the previous section, as well as the project name. You can also decide whether to apply these changes dynamically or on the next server restart.

If the config source is enabled or disabled dynamically it will take effect across the server immediately.

From the Command Line

To configure the GCP Secrets Cloud Config Source from the command line, use these commands:

- `set-gcp-config-source-configuration`
- `get-gcp-config-source-configuration`

Usage

Provided the required roles have been assigned to the Service Account in the GCP console, the

secrets can be injected into any applicable MicroProfile Config injection point as with any other Config Source. The secrets can also be fetched, created and deleted from the `asadmin` utility.

To fetch a secret from GCP Secret Manager:

```
asadmin get-config-property --source cloud --sourceName gcp --propertyName mysecret

secretvalue
```

To create or change a secret from GCP Secret Manager:

```
asadmin set-config-property --source cloud --sourceName gcp --propertyName mysecret
--propertyValue secretvalue
```

To delete a secret from GCP Secret Manager:

```
asadmin delete-config-property --source cloud --sourceName gcp --propertyName mysecret
```

Hashicorp

The HashiCorp Secrets Config Source takes configuration properties from HashiCorp Vault. You can learn more about HashiCorp on: https://www.vaultproject.io/

Prerequisite

This documentation assumes the following:

- You have successfully installed the HashiCorp Vault and have a running Vault server
- You are familiar with most, if not all, of the HashiCorp Vault technology and terminology. If not please read through their documentation before you attempt to use HashiCorp Secrets Config Source
- Your HashiCorp Vault is unsealed

Hashicorp config source only supports the Vault KV Secrets Engine.

Configuration in Payara Server

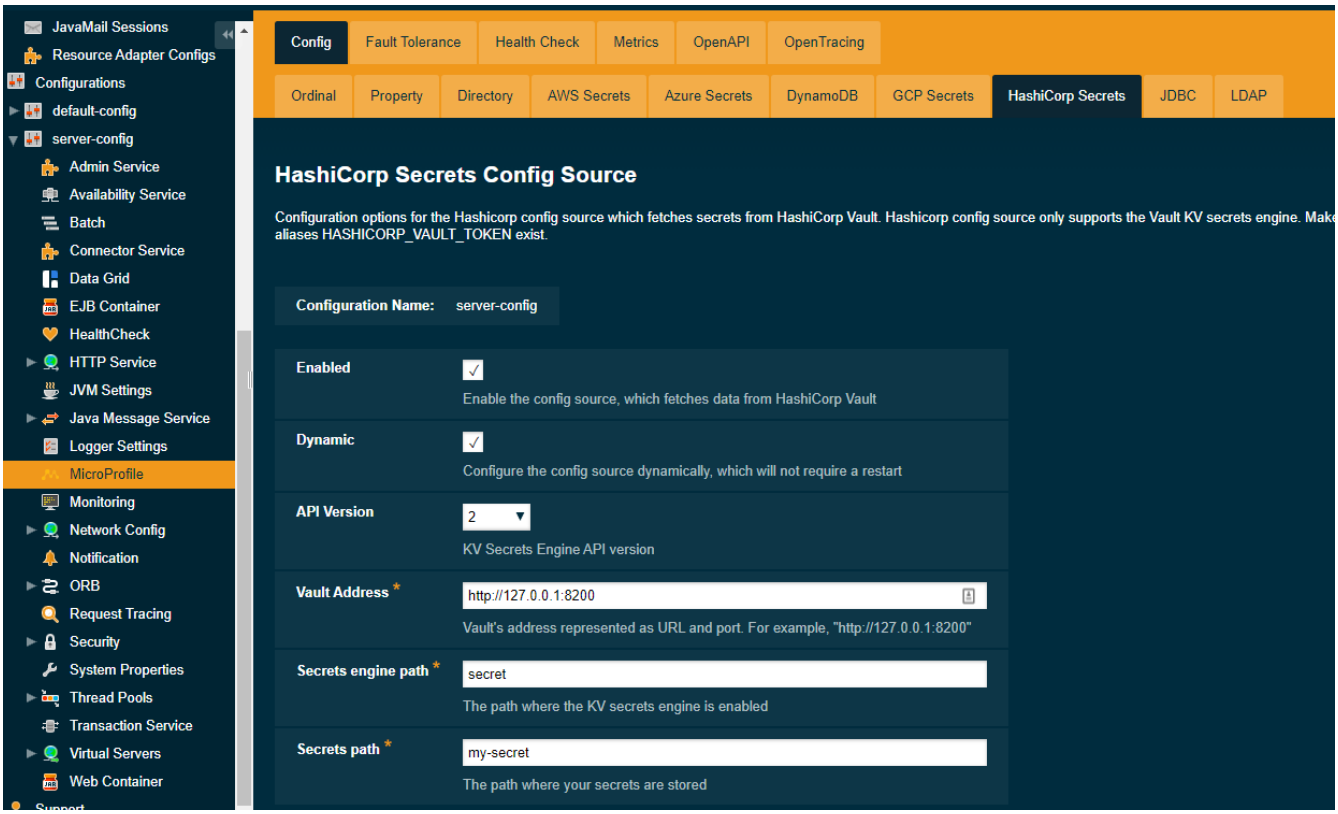
You can configure HashiCorp Secrets Config Source either via the admin console or the *asadmin* utility. You'll need a client token, the KV Secrets Engine API version, Vault's address represented as URL and port, the path where the KV Secrets Engine is enabled and the path where your secrets are stored.

By default, the KV Secrets Engine is enabled at the `/secret` path in Vault.

From the Admin Console

To configure the `HASHICORP_VAULT_TOKEN` password alias from the admin console, refer to the Password Aliases Admin Console configuration guide.

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `HashiCorp Secrets`.



From here you can select the KV Secrets Engine API version you want to use, configure the vault address, the path where the KV Secrets Engine is enabled and the path where your secrets are stored.

You can also decide whether to apply these changes dynamically or on the next server restart. If the config source is enabled or disabled dynamically it will take effect across the server immediately.

From the Command Line

To configure the `HASHICORP_VAULT_TOKEN` password alias from the admin console, refer to the Password Aliases Admin Console configuration guide.

To configure the HashiCorp Secrets Config Source from the command line, use these commands:

- `set-hashicorp-config-source-configuration`
- `get-hashicorp-config-source-configuration`

Usage

Provided that all of the above sections are configured correctly, the secrets can be injected into any applicable MicroProfile Config injection point as with any other Config Source. The secrets can also be fetched, created and deleted using the asadmin utility.

To fetch a secret form a HashiCorp Vault:

```
asadmin get-config-property --source cloud --sourcename hashicorp --propertyname
mysecret
```

To create or change a secret from a HashiCorp Vault:

```
asadmin set-config-property --source cloud --sourcename hashicorp --propertyname
mysecret --propertyValue secretvalue
```

To delete a secret from a HashiCorp Vault:

```
asadmin delete-config-property --source cloud --sourcename hashicorp --propertyname
mysecret
```

Directory

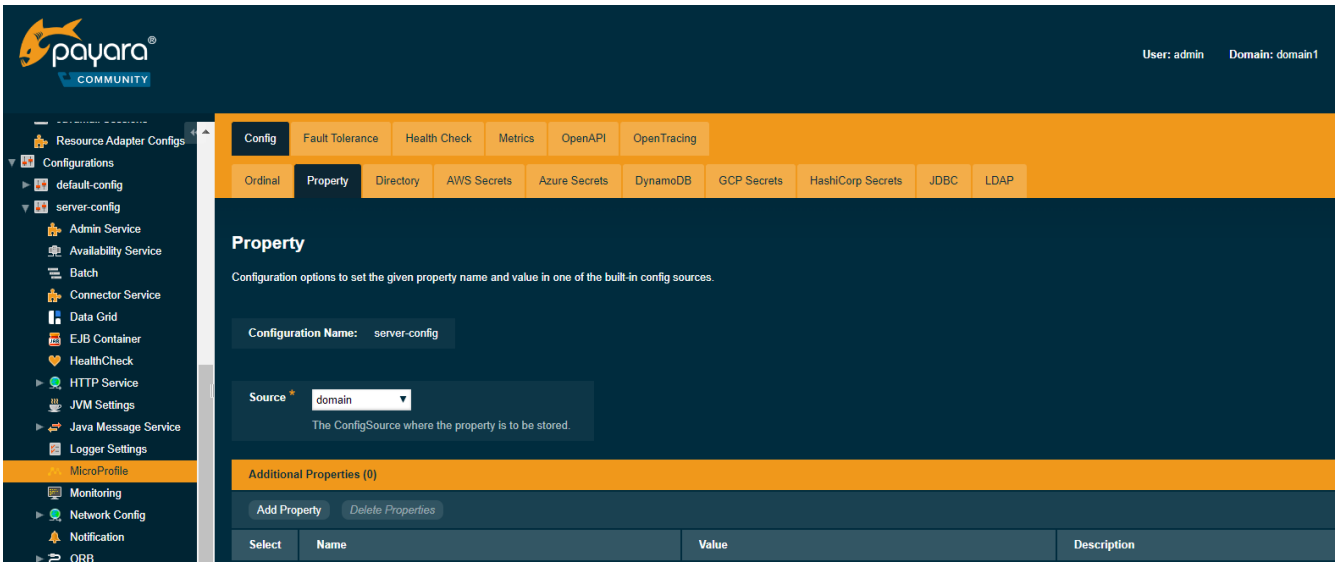
This page details how to configure and use the **Directory** configuration source in the Payara Platform.

Configuration

Config Directory can be configured by using Admin Console or Asadmin commands.

Using the Admin Console

To configure the Config Directory in the Admin Console, go to Configuration → [instance-configuration (like server-config)] → MicroProfile → Config → Directory:



Using Asadmin Commands

Use the following commands to configure and get the current settings of this configuration source:

- `set-config-dir`
- `get-config-dir`

Using Pre-boot and/or Postboot Scripts

When running a Payara Platform distribution in a container, there is no way to restart a running instance after configuring via an `asadmin` command without losing the changes to the domain configuration.

Thus, you should add the corresponding command to a boot script as described at Pre- and Postboot scripts.

See Payara Server Docker Image environment variables for details how to use this within non-micro containers.

Usage

Usually this config source is used to map secrets mounted by Kubernetes or Docker to a directory inside a running container.

Once you configured a directory to read a config (secrets) from, you need to make sure file names correspond to properties in your codebase.

Map property names to flat file hierarchy

1. Say you have two properties `property1` and `foo.bar.property2`.
2. Payara is configured with secret directory `/home/payara/secrets`
3. Secrets mounted as files to `/home/payara/secrets/property1` and `/home/payara/secrets/foo.bar.property2` will be read.

Remember that the files may only contain the secret or other configuration values. Plaintext files only, no file extensions allowed.

Map property names to a subdirectory structure

1. Say you have two properties `property1` and `foo.bar.property2`.
2. Payara is configured with secret directory `/home/payara/secrets`
3. Secrets mounted as files to `/home/payara/secrets/property1` and `/home/payara/secrets/foo/bar/property2` will be read.

Restrictions on the files content are the same as with the flat hierarchy.

Updates to files and subdirectories are picked up at runtime. Retrieving the config property again will use the updated values. This allows for clearing a value by removing the file, too.

Dots usage and depicting directories and file name

Dots in property names are used to reflect scopes, for example to distinguish different applications, modules, etc.

1. Any dots in the property name may correspond to changing from one directory to a subdirectory. Example: `foo.bar.test` could be a file `test` in `foo/bar/` path.
2. You may combine any number of dot-separated "components" into directories and file name. Example: `foo.bar.test.example` may be a file `test.example` in `foo/bar/` path or a file `example` in path `foo/bar.test/` and so on.
3. Do not use a file extension, as it would be taken as part of the property name.
4. The longest, most specific match "wins" for reading the value into the property. This allows to create scoped directory structures as you see fit. Example: `foo.bar/test.example` is less specific than `foo/bar/test.example` and so on.

You cannot use directories or files whose names start with a dot. They will be ignored, following the POSIX philosophy of hidden files and folders.

Symbolic links will be followed, so you can expose files from such hidden areas, allowing for all types of mangling with names etc. Don't link to directories, as the file monitors rely on real directories.

Kubernetes Example

You want to retrieve a (secret) value via property `foo.bar.property1`:

```
@ConfigProperty("foo.bar.property1")
```

You deployed a secret to your Kubernetes cluster:

```
apiVersion: v1
kind: Secret
metadata:
  name: foobar
type: Opaque
stringData:
  property1: "my-super-secret-value"
```

And your pod mounts it at `/home/payara/secrets/foo/bar` (only showing the relevant parts from the `Deployment` K8s YAML):

```
volumeMounts:
  - name: test-secrets
    mountPath: /home/payara/secrets/foo/bar
volumes:
  - name: test-secret
    secret:
      secretName: foobar
```

```
/ # ls -la /home/payara/secrets/foo/bar
```

```
total 3
drwxrwxrwt 3 root root  120 Nov 25 10:51 .
drwxr-xr-x 3 root root 4096 Nov 25 10:51 ..
drwxr-xr-x 2 root root   80 Nov 25 10:51 ..2020_11_25_10_51_55.283009570
lrwxrwxrwx 1 root root   31 Nov 25 10:51 ..data -> ..2020_11_25_10_51_55.283009570
lrwxrwxrwx 1 root root   15 Nov 25 10:51 property1 -> ..data/property1
```

The server instance will pick up the file and read its content as a value for property `foo.bar.property1`

JDBC

The JDBC config source reads configuration properties from a database table.

Configuration

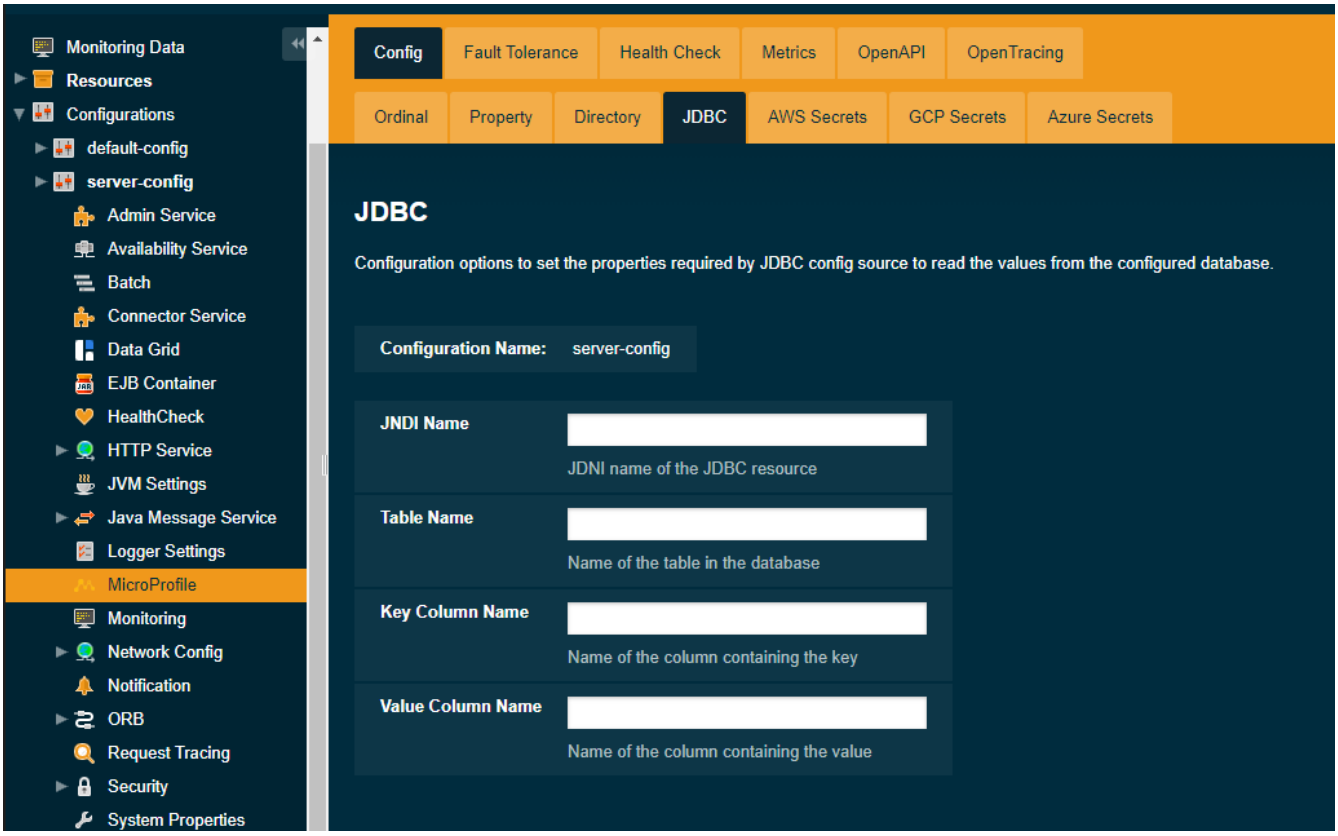
You can configure JDBC Config Source either via the admin console or the *asadmin* utility. You'll need the JNDI name of the database JDBC resources, name of a database table, name of the key column containing the key and name of the column containing the value.

The values from the key column will be used as the config property names and the values from the value column will be used as the config property value.

The type of the database columns for the *key* and *value* columns needs to be of type `*String*` or compatible.

From the Admin Console

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `JDBC`.



From here you configure the JNDI name of the database JDBC resources, name of the database table, name of the key column containing the key and name of the column containing the value.

From the Command Line

To configure the JDBC config source from the command line, use the following commands:

- `set-jdbc-config-source-configuration`.
- `get-jdbc-config-source-configuration`.

Usage

Once all required options are configured. You should be able to read configuration properties from a database table.

For example, let's look at the following diagram. It shows a table named Books with columns ISBN, Author and Title.

Books

ISBN	Authour	Title
9781973907985	Harper Lee	To Kill a Mockingbird
9780030779008	Charles Dickens	Great Expectations
9780345916419	Philip Pullman	The Subtle Knife
9780060120375	Aldous Huxley	Brave New World

If the key column name is set to `ISBN` and the value column name to `Title`. You can get the value of the Title column in relation to the ISBN column using the following command along with the ISBN value:

```
asadmin get-config-property --source jdbc --propertyName 9780030779008
Great Expectations
Command get-config-property executed successfully.
```

Currently, the JDBC config source only supports the `get-config-property` command and doesn't support the `set-config-property` and `delete-config-property` commands.

LDAP

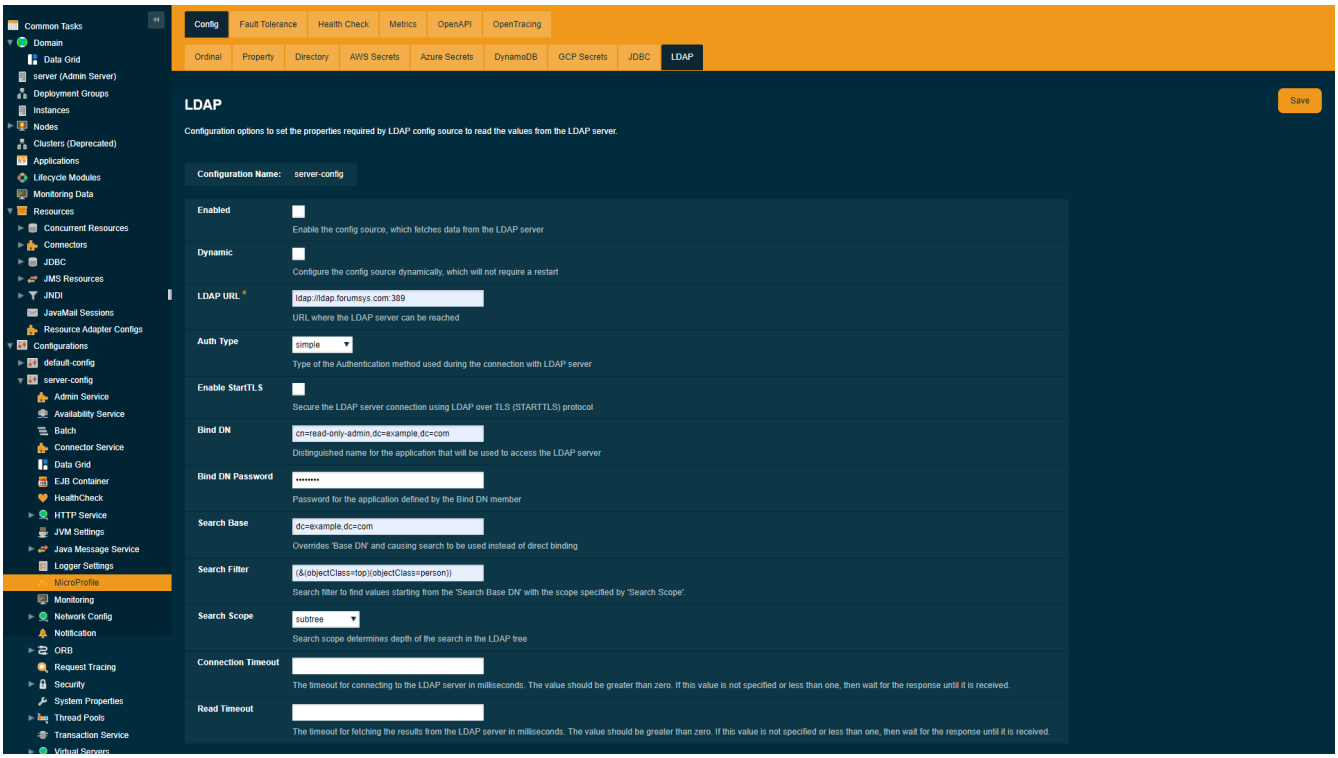
The LDAP configuration source reads properties from a predefined LDAP directory.

Configuration

The LDAP Config Source can be configured by using the Admin Console or `asadmin` commands.

From the Admin Console

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `LDAP`.



Using the Asadmin Commands

The following administration commands can be used to configure the MicroProfile LDAP config source:

- `set-ldap-config-source-configuration`.
- `get-ldap-config-source-configuration`.

Usage

Once all required options are configured, you should be able to read configuration properties from the LDAP directory.

```
asadmin> get-config-property --source ldap --propertyName sn
Read Only Admin
Command get-config-property executed successfully.
```

Currently, the LDAP config source only supports the `get-config-property` command and doesn't support the `set-config-property` and `delete-config-property` commands.

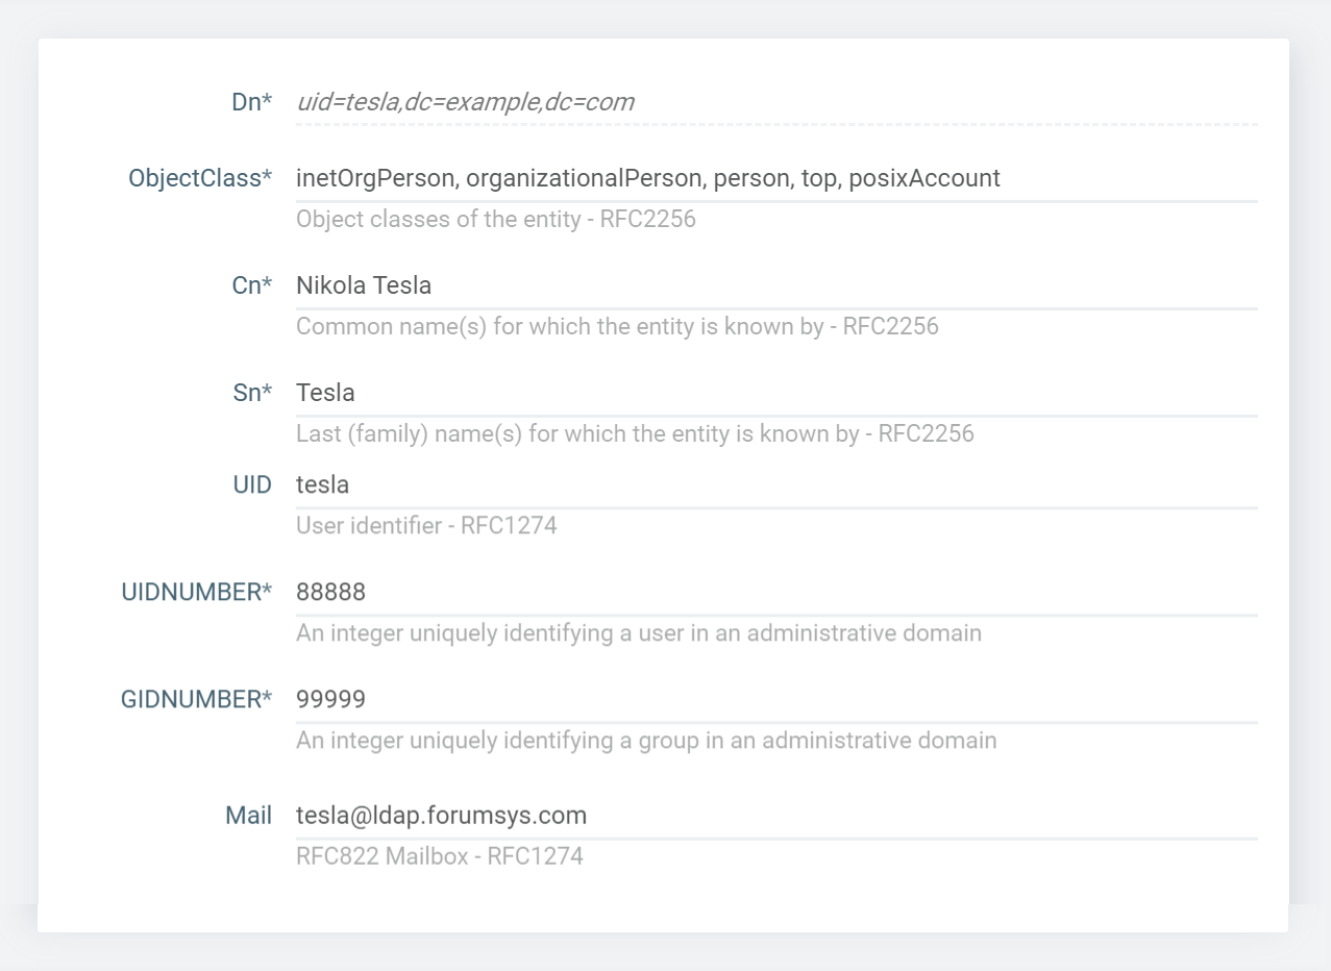
Finding User specific properties

If search filter and search base are not specified then properties fetched from the direct binding of `bindDn`.

```
asadmin set-ldap-config-source-configuration --enabled=true --dynamic=true
--url=ldap://ldap.forumsys.com:389 --authType=simple --bindDnPassword=password
--bindDn=cn=read-only-admin,dc=example,dc=com
```

```
asadmin get-config-property --source ldap --propertyName sn
Read Only Admin
Command get-config-property executed successfully.
```

Alternatively to fetch the user specific properties, search filter can be specified with attributes unique to specific user. For example, in the following configuration `uid` is used as user filter in the search query.



```
asadmin set-ldap-config-source-configuration --enabled=true --dynamic=true
--url=ldap://ldap.forumsys.com:389 --authType=simple --bindDNPassword=password
--bindDN=cn=read-only-admin,dc=example,dc=com --searchBase=dc=example,dc=com
--searchScope=subtree --searchFilter=(&(uid=tesla))
```

```
asadmin get-config-property --source ldap --propertyName UIDNUMBER
88888
Command get-config-property executed successfully.

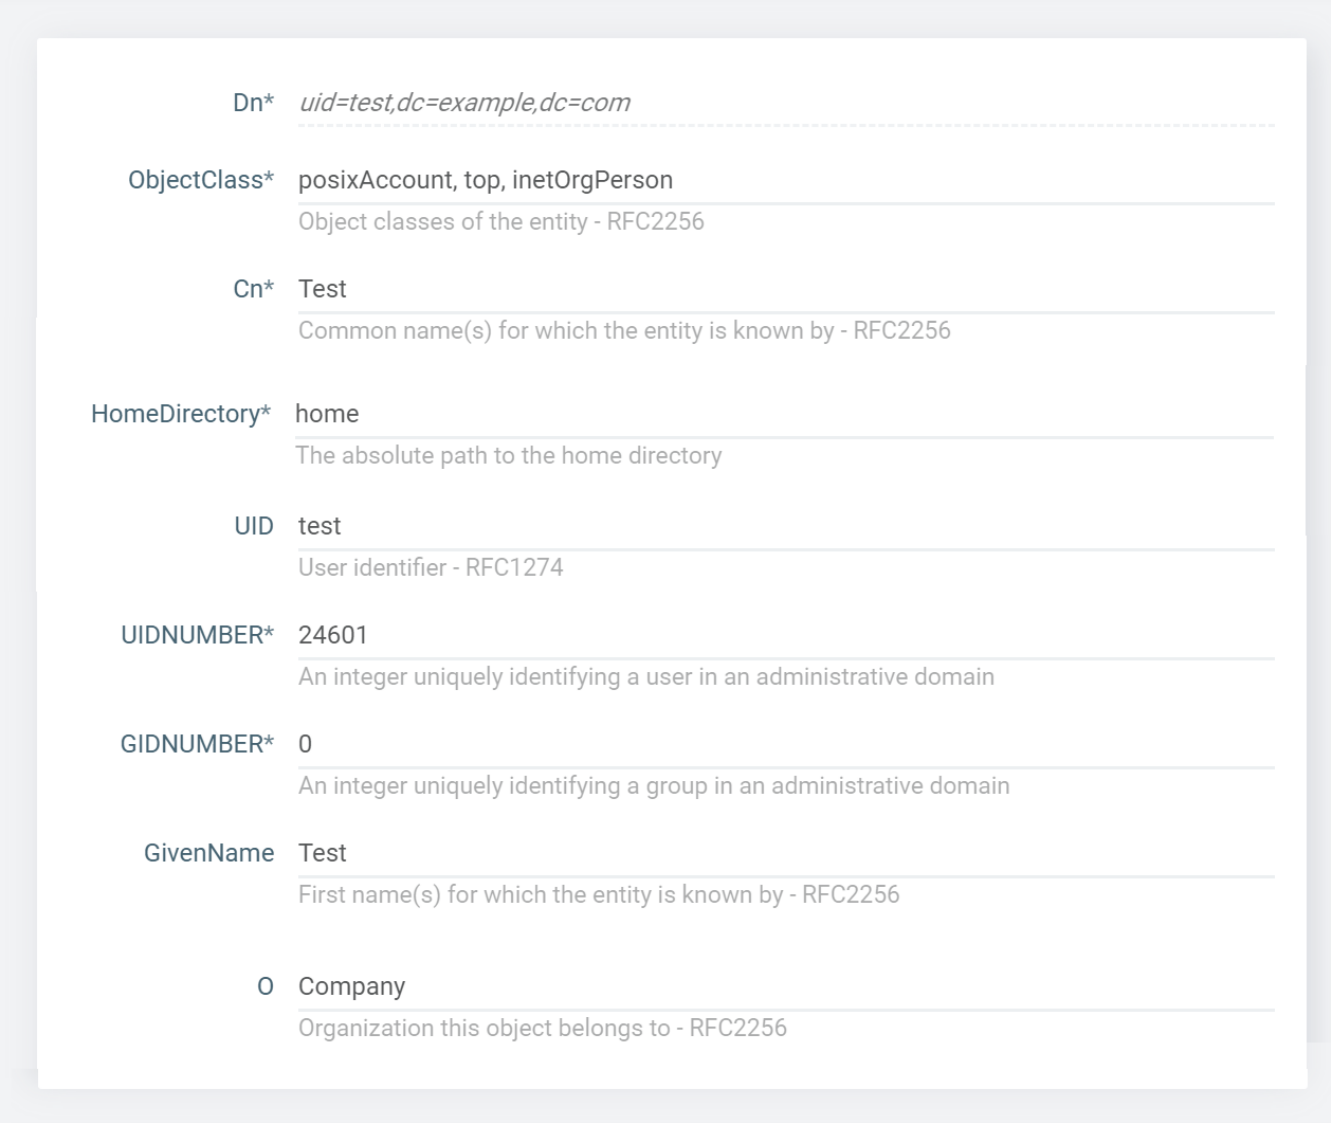
asadmin get-config-property --source ldap --propertyName GIDNUMBER
99999
Command get-config-property executed successfully.

asadmin get-config-property --source ldap --propertyName MAIL
tesla@ldap.forumsys.com
Command get-config-property executed successfully.

asadmin get-config-property --source ldap --propertyName sn
Tesla
Command get-config-property executed successfully.
```

Finding Group specific properties

To find properties from the group of users search filter is mandatory to specify. For e.g, In the following configuration `objectClass` is used as group filter.



```
asadmin set-ldap-config-source-configuration --enabled=true --dynamic=true
--url=ldap://ldap.forumsys.com:389 --authType=simple --bindDNPassword=password
--bindDN=cn=read-only-admin,dc=example,dc=com
 --searchBase=dc=example,dc=com --searchScope=subtree
--searchFilter=(&(objectClass=posixAccount)(objectClass=organizationalPerson))
```

```
asadmin get-config-property --source ldap --propertyName sn
Tesla,Test
Command get-config-property executed successfully.
```

TOML

The TOML Config Source takes configuration properties from a TOML configuration file.

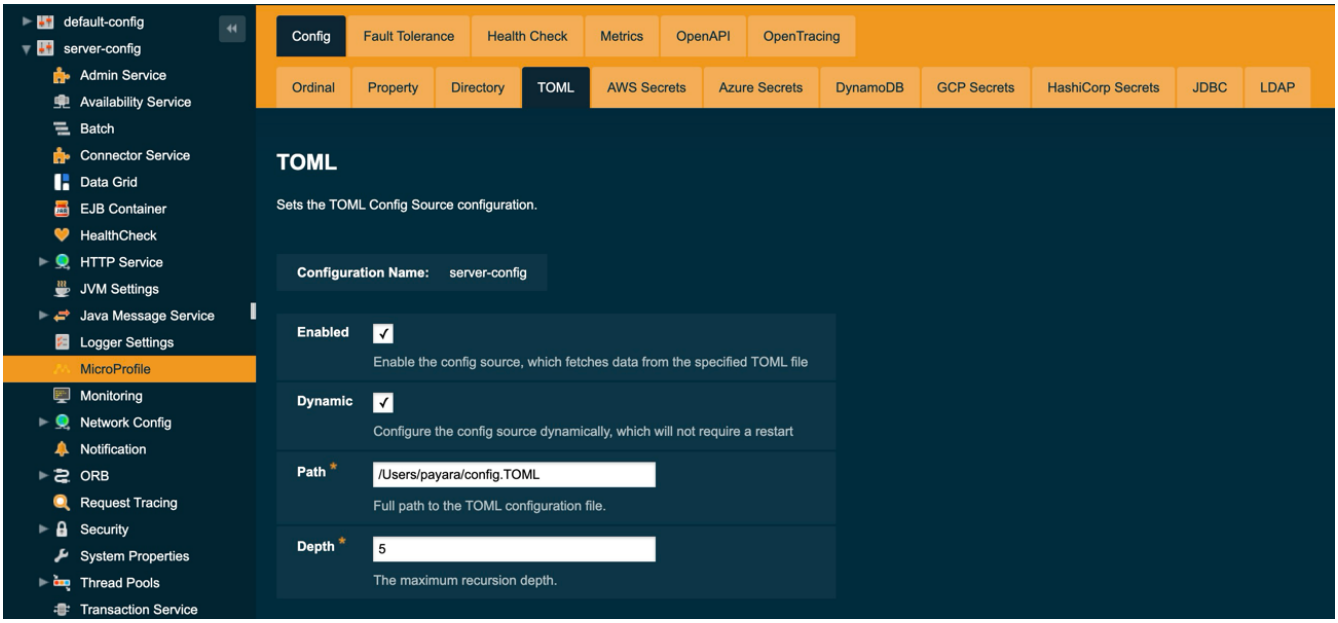
Configuration in Payara Server

You can configure TOML Config Source either via the admin console or the *asadmin* utility.

You'll need the path of the TOML configuration file and the maximum recursion depth.

From the Admin Console

To configure the config source from the admin console, go to `Configs` → `your-config` → `MicroProfile` → `Config` → `TOML`.



From here you can enter the path to the TOML configuration file and set the maximum recursion depth.

You can also decide whether to apply these changes dynamically or on the next server restart. If the config source is enabled or disabled dynamically it will take effect across the server immediately.

From the Command Line

To configure the TOML Config Source from the command line, use these commands:

- `set-toml-config-source-configuration`
- `get-toml-config-source-configuration`

Usage

Provided that all of the above sections are configured correctly, the properties can be injected into any applicable MicroProfile Config injection point as with any other Config Source. They can also be fetched using the asadmin utility.

To prevent `StackOverFlowException` issues, the `depth` parameter limits the recursion depth when reading properties from the TOML file. If the maximum recursion depth is reached, further properties will not be read.

Examples

Example TOML file

```
title = "TOML Example"

[owner]
name = "Tom Preston-Werner"
dob = 1979-05-27T07:32:00-08:00

[database]
enabled = true
ports = [ 8000, 8001, 8002 ]
```

Retrieving properties programmatically

```
Config config = ConfigProvider.getConfig();
String ownerName = config.getValue("owner.name", String.class);
```

Inject configuration properties

```
@Inject
@ConfigProperty(name="database.ports[0]")
private Optional<Integer> databasePort;
```

Fault Tolerance

The Payara Platform main-7 provides MicroProfile Fault Tolerance 4.0

Background

The Fault Tolerance API was created to help separate execution logic from execution. The execution can be configured with a number of fault tolerance policies.

The complete specification can be found on the Eclipse MicroProfile website.

Breaking changes introduced in MicroProfile Fault Tolerance 4.0 are listed in the official specification under Incompatible Changes

Additions to the Fault Tolerance Spec

In addition to the functionality detailed in the specification document, Payara Platform has implemented additional features like:

Configurable Executor Services

On Payara Server, the managed and scheduled managed executor pool used to generate threads for the service can be configured via the `set-fault-tolerance-configuration` Asadmin command.

The executor service is used to execute methods annotated with `@Asynchronous`, whereas the scheduled executor service is used by the `CircuitBreaker` and `Timeout` interceptors for their timeout operations (scheduling the circuit breaker to be set to half open, and just timing out respectively).

Alternative @Asynchronous Annotations

The Payara Platform configuration property `MP_Fault_Tolerance_Alternative_Asynchronous_Annotations` can be used to specify a comma separated list of fully qualified class names of those annotations that should have the same effect as the `@Asynchronous` defined in the Fault Tolerance specification.

These annotations do not have to be interceptor bindings.

For example:

```
MP_Fault_Tolerance_Alternative_Asynchronous_Annotations=jakarta.ejb.Asynchronous
```

Annotation Priority

As per the Fault Tolerance specification, interactions between annotations are handled effectively nesting computation in the following way (skipping handling for annotations not present):

1. `Asynchronous`
2. `Fallback`
3. `Retry`
4. `CircuitBreaker`
5. `Timeout`
6. `Bulkhead`
7. (calling annotated method; might be wrapped by other interceptors)

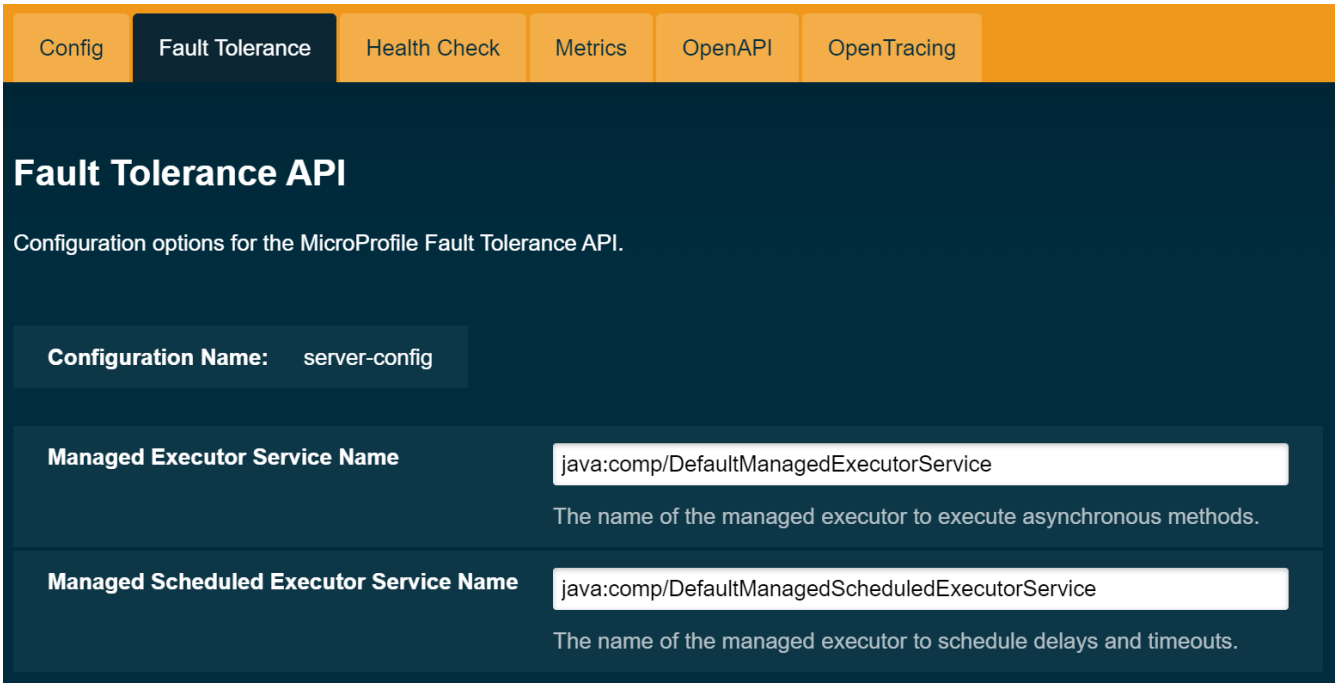
As specified the interceptor priority can be changed using the property `mp.fault.tolerance.interceptor.priority` affecting all annotations including alternative ones.

Fault Tolerance Configuration

On Payara Server the Fault Tolerance service can be configured by using the Admin Console or Asadmin CLI commands.

Using the Admin Console

To configure the Fault Tolerance in the Admin Console, go to Configuration → [instance-configuration (like `server-config`)] → MicroProfile → Fault Tolerance:



Using Asadmin Commands

Use the following commands to modify the configuration settings of the MicroProfile Fault Tolerance service:

- `set-fault-tolerance-configuration`
- `get-fault-tolerance-configuration`

Upgrading from Eclipse MicroProfile 3.x to 4.x

MicroProfile 4.0 brings with it a number of changes to MicroProfile Fault Tolerance. There are two incompatible changes with the previous version of MicroProfile Fault Tolerance.

Metric Names and Scopes Changed

The metrics added automatically by MicroProfile Fault Tolerance have been updated to take advantage of support for metric tags which were added to MicroProfile Metrics in version 2.0. As a result, some information which was previously contained in the metric name is now instead included in tags.

In addition, metrics have moved from the `application` scope to the `base` scope for consistency with other MicroProfile specifications. Note that this means:

- Metrics are now exported under `/metrics` and `/metrics/base`, instead of `/metrics` and `/metrics/application` as in previous versions.
- In the JSON format, when metrics are retrieved from `/metrics` they appear in the base object rather than the application object.
- In the OpenMetrics format, the names are prefixed with `base_` instead of `application_`.

There unfortunately is not a workaround for this change, users must simply ensure that any dashboard or application making use of these metrics must be updated to look at the new locations.

Example

Old format:

```
application:ft.<name>.timeout.callsTimedOut.total
```

New format:

```
base:ft.timeout.calls.total{method="<name>", timedOut="true"}
```

Lifecycle of CircuitBreakers and Bulkheads Specified

In previous versions of MicroProfile Fault Tolerance, the lifecycle of `CircuitBreaker` and `Bulkhead` annotations was not specified. These fault tolerance strategies hold state between invocations, so their lifecycle is important for correct functioning.

`CircuitBreaker` and `Bulkhead` are now treated as singletons identified by the annotated bean class and the guarded method. This means that if a `RequestScoped` bean has a method annotated with `CircuitBreaker` and/or `Bulkhead`, all invocations of that method will share the same `CircuitBreaker` and/or `Bulkhead` state, even though each request will have a different instance of the annotated bean.

There is unfortunately no workaround for this change in behaviour.

HealthCheck

The Payara Platform main-7 provides MicroProfile HealthCheck 4.0

Background

The Health Check API was created to allow easier probing of the state of computing nodes that live in a cloud infrastructure environment.

The complete specification can be found on the Eclipse MicroProfile website.

Breaking changes introduced in MicroProfile Health 4.0 are listed in the official specification under Incompatible Changes

REST Endpoints

The MicroProfile HealthCheck API defines the following list of REST endpoints that are available from the root context at `/health/${type}` by default:

Context	Type	Description
`/health/live`	Liveness	On invocation, all registered health checks annotated with `@Liveness` are performed and the results aggregated.

Context	Type	Description
`/health/ready`	Readiness	On invocation, all registered health checks annotated with `@Readiness` are performed and the results aggregated.
`/health/started`	Startup	On invocation, all registered health checks annotated with '@Startup' are performed and the results aggregated.
`/health`	Readiness + Liveness + Startup	On invocation, all registered health checks annotated with `@Liveness`, `@Readiness`, or `@Startup` are performed and the results aggregated.

On Payara Server, this root endpoint can be altered using the `set-microprofile-healthcheck-configuration` asadmin command to prevent collisions with other HTTP endpoints that might need to use the `health` context root.

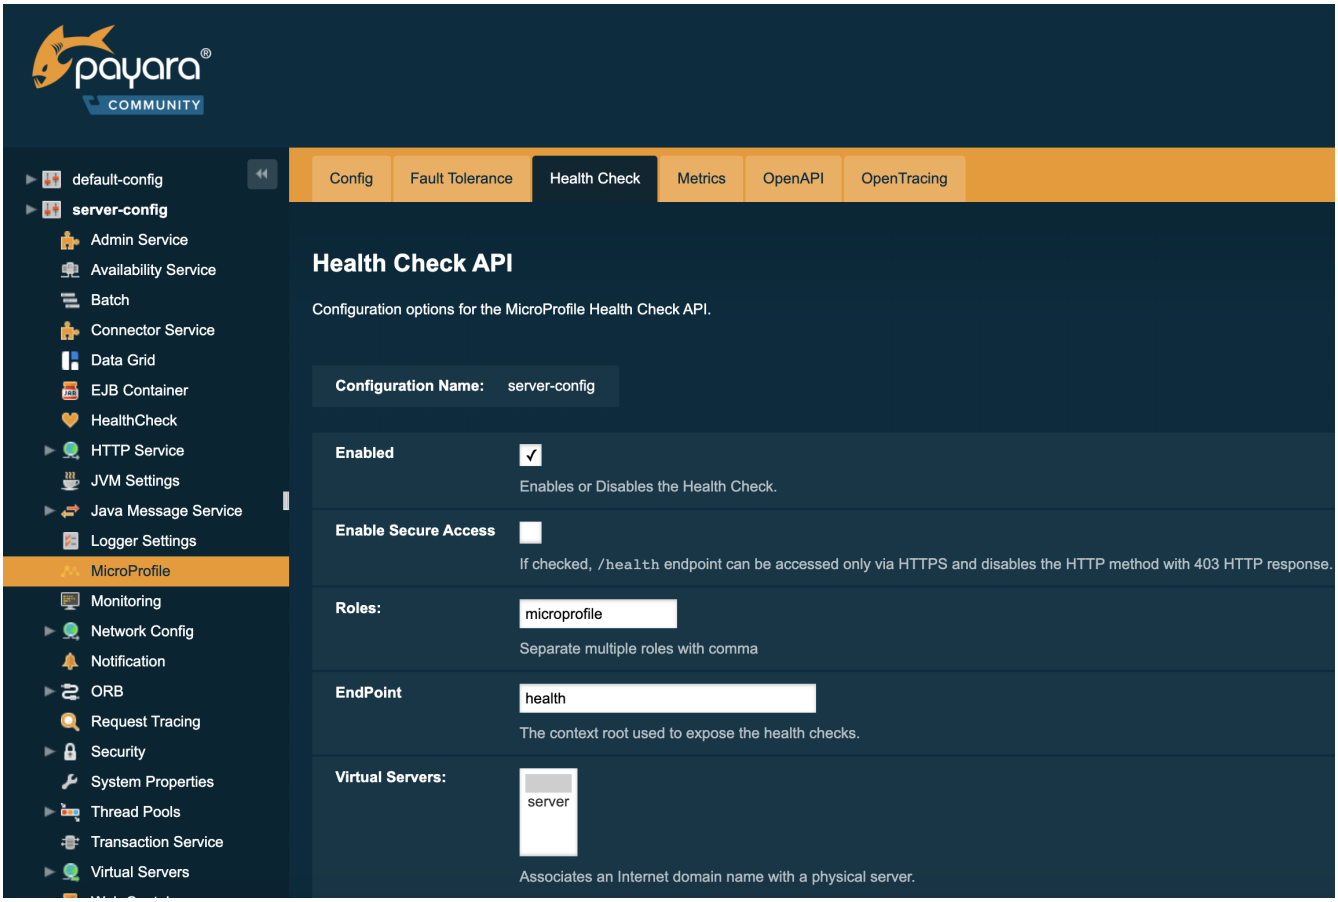
This endpoint will not be available until at least one application has been deployed.

Health Check Configuration

On Payara Server, the MicroProfile HealthCheck settings can be configured by using Admin Console or Asadmin commands.

Using the Admin Console

To configure the Health Check in the Admin Console, go to Configuration → [instance-configuration (like `server-config`)] → MicroProfile → Health Check:



Using Asadmin Commands

The following administration commands can be used to configure the MicroProfile Healthcheck service:

- `set-microprofile-healthcheck-configuration`
- `get-microprofile-healthcheck-configuration`

Changes made with this command will only be applied when the server or instance is restarted.

Security Configuration

By default, HealthCheck endpoints bind to the root context application which is the `default-web-module (also known as docroot) system application and thedefault-web-module` application, which is secured under the default realm (`file`) of the server.

If a user application is deployed in the empty context-root, then the security configuration of this application will be shared by the HealthCheck endpoints, so *exert extreme caution* when making these changes.

Upgrading from Eclipse MicroProfile 3.x to 4.x

MicroProfile 4.0 brings with it a number of changes to MicroProfile Health. The main incompatible change brought in by this upgrade is the removal of the deprecated `@Health` annotation.

There isn't a workaround for this, the annotation is simply gone: all health checks must be

registered as a `@Readiness`, `@Liveness`, or `@Startup` check.

JWT

The Payara Platform main-7 provides MicroProfile JWT Authentication 2.1.

Background

The JWT Authentication API was designed to provide application callers with the ability to authenticate themselves using a JWT token. A JWT token is essentially a string of JSON with fields for specifying the caller/username and the groups the caller is in.

To prevent tampering, the JSON token is cryptographically signed. Note that it's only signed, not fully encrypted. This means that the caller/username and the groups are in plain text, but because of the signature can't be changed.

The complete specification can be found on the Eclipse MicroProfile website.

Breaking changes introduced in MicroProfile JWT Authentication 2.1 are listed in the official specification under Incompatible Changes

The MicroProfile JWT Authentication specification currently does not define any means for preemptive authentication, that is, authenticating when the target resource (such as a JAX-RS end-point) is not protected / constrained by a security role.
Practically this means that if a JWT token is sent alongside a request to a public / unchecked resource, MicroProfile JWT implementations will ignore it. This limitation will be addressed in a later version of the JWT specification.

Jakarta Security and JWT

Payara Server and Payara Micro implement the JWT authentication mechanism as a normal Jakarta Security (JSR 375) authentication mechanism.

This specifically means that when MP JWT authentication is used on Payara Server or Payara Micro, there's an `HttpAuthenticationMechanism` CDI bean enabled that can be intercepted or decorated using the standard CDI APIs. Likewise, there's an `IdentityStore` CDI bean enabled, which can be intercepted or decorated too.

By providing additional `IdentityStore` beans, an application can, if needed, augment the JWT identity store, for instance by providing extra roles.

Vending tokens

A JWT token, like most API tokens, is typically vended from a website for use with the services provided by that site. For instance, from Google or Facebook can obtain such a token for usage with their respective APIs.

Though JWT tokens are more universal in format, they are still intended for use with a specific service (website / API). This is encoded in the **mandatory** `iss` ("issuer") field. The value of the field

can be anything that the intended service can recognize (see below).

For example:

```
{
    "iss": "fish.payara.example",
    "jti": "a-123",
    "sub": "24400320",
    "aud": "s6BhdRkqt3",
    "upn": "test",
    "groups": [
        "architect",
        "master",
        "leader",
        "dev"
    ]
}
```

A JWT also **must** be signed, and in the case of MicroProfile JWT this **must** be `RSASSA-PKCS-v1_5` using the SHA-256 hash algorithm.

One way to do this signing is by first generating an SSH keypair as follows:

1. Open a terminal
2. Generate the base key by entering: `openssl genrsa -out baseKey.pem`
3. From the base key generate the PKCS#8 private key: `openssl pkcs8 -topk8 -inform PEM -in baseKey.pem -out privateKey.pem -nocrypt`
4. And generate the public key: `openssl rsa -in baseKey.pem -pubout -outform PEM -out publicKey.pem`

Then put `privateKey.pem` on the root of the classpath (for instance, in a Maven project put it in `src/main/resources`) and use the following code to create the signed JSON token as a string:

```
@RequestScoped
public class TokenGenerator{

    public static String generateJWTString(String jsonResource) {
        byte[] byteBuffer = new byte[16384];
        currentThread().getContextClassLoader()
                       .getResource(jsonResource)
                       .openStream()
                       .read(byteBuffer);

        JSONParser parser = new JSONParser(DEFAULT_PERMISSIVE_MODE);
        JSONObject jwtJson = (JSONObject) parser.parse(byteBuffer);

        long currentTimeInSecs = (System.currentTimeMillis() / 1000);
        long expirationTime = currentTimeInSecs + 1000;
```

```
        jwtJson.put(Claims.iat.name(), currentTimeInSecs);
        jwtJson.put(Claims.auth_time.name(), currentTimeInSecs);
        jwtJson.put(Claims.exp.name(), expirationTime);

        SignedJWT signedJWT = new SignedJWT(new JWSHeader
                                            .Builder(RS256)
                                            .keyID("/privateKey.pem")
                                            .type(JWT)
                                            .build(), parse(jwtJson));

        signedJWT.sign(new RSASSASigner(readPrivateKey("privateKey.pem")));

        return signedJWT.serialize();
    }

    public static PrivateKey readPrivateKey(String resourceName){
        byte[] byteBuffer = new byte[16384];
        int length = currentThread().getContextClassLoader()
                                    .getResource(resourceName)
                                    .openStream()
                                    .read(byteBuffer);

        String key = new String(byteBuffer, 0, length).replaceAll("-----BEGIN
(.*)-----", "")
                                                      .replaceAll("-----END (.*)----",
"")
                                                      .replaceAll("\r\n", "")
                                                      .replaceAll("\n", "")
                                                      .trim();

        return KeyFactory.getInstance("RSA")
                         .generatePrivate(new
PKCS8EncodedKeySpec(Base64.getDecoder().decode(key)));
    }
}
```

The code here assumes the location of the raw JSON file on the classpath being passed in, the private key on the root of the classpath and the result as a string.

If other input/outputs are needed that should be easy to do using the above code as a starting point.

Accepting tokens

Public Key configuration

In order to validate the signature of a provided token is valid, an application that uses JWT Authentication has to provide the public key to the MicroProfile JWT Authentication implementation either using the standard MicroProfile Configuration options or using the vendor-specific option.

`mp.jwt.verify.publickey`

The `mp.jwt.verify.publickey` microprofile config property allows the Public Key text itself to be supplied as a string.

For e.g : `mp.jwt.verify.publickey=joer4fghieEM3UmZQcFRvNzM2fhMnJ6QV45ghRCdTQ1SnYwdXBkRVpjc54645jNJc65XltamJaUmtwZ1RSOEIxOWJfcl`

`mp.jwt.verify.publickey.location`

The `mp.jwt.verify.publickey.location` microprofile config property allows for an external or internal location of Public Key to be specified. The value may be a relative path or a URL.

For e.g : `mp.jwt.verify.publickey=/META-INF/publicKey.pem`

public key vendor-specific configuration

In Payara this is done by placing the public key such as generated above as `publicKey.pem` on the root of the application's classpath. For example, when using a Maven project as `src/main/resources/publicKey.pem`.

Vendor-specific option for supplying the public key will always take precedence.

Issuer configuration

Next to providing the public key, an application that uses JWT Authentication has to provide the issuer (corresponding to the `iss` field in the JSON token) it's willing to accept.

Issuer can be provided to the MicroProfile JWT Authentication implementation either using the standard MicroProfile Config option or using the vendor-specific option.

`mp.jwt.verify.issuer`

The `mp.jwt.verify.issuer` microprofile config property allows for the expected value of the `iss` claim to be specified.

issuer vendor-specific configuration

For the Payara Platform, this is done by placing a properties file named `payara-mp-jwt.properties` on the root of the application's classpath. For example, when using a Maven project as `src/main/resources/payara-mp-jwt.properties`. The properties file should contain the key `accepted.issuer` with as value the same value that of the `iss` field in the vended token, e.g. `fish.payara.example` as per the example JSON token shown above.

Vendor-specific option for supplying the issuer will always take precedence.

Namespaced claims configuration

Authentication services (like auth0, connect2id) offer the chance to add custom claims to JWT tokens but also enforce a namespaced format to avoid possible collisions with standard OpenID Connect claims.

In the Payara Platform, namespaced claims configuration is done by placing a properties file named `payara-mp-jwt.properties` on the root of the application's classpath.

For example, when using a Maven project as `src/main/resources/payara-mp-jwt.properties`. These properties file should contain the Boolean property `enable.namespace` and the optional property `custom.namespace`.

enable.namespace

If this is true, the default `https://payara.fish/mp-jwt/` namespace will be used and the parser will look out for namespaced claims.

For example:

If following JSON is the token payload and `enable.namespace` property is `true`:

```
{
  "https://payara.fish/mp-jwt/groups": ["admin", "read", "write"],
  "https://payara.fish/mp-jwt/upn": "test",
  "iss": "https://test.auth.com/",
  "sub": "5b2856bf8763ef356976dca3"
}
```

Then the JSON Parser search for namespace prefixed claims, remove the namespace from claim name, allow the processing of the token as usual.

custom.namespace

When the `custom.namespace` property is set, it will always take precedence over the default namespace and be used instead.

Disabling Type Claim Verification

The MicroProfile JWT Authentication specification currently mandates that the type claim (`typ`) of any authorization token parsed by the container is present and is set to the `JWT` value.

However, the current RFC document (RFC 7519) that defines the JWT standard states that this claim is **optional**:

> 5.1. "typ" (Type) Header Parameter
>
> The "typ" (type) Header Parameter defined by [JWS] and [JWE] is used by JWT applications to declare the media type [IANA.MediaTypes] of this complete JWT. This is intended for use by the JWT application when values that are not JWTs could also be present in an application data structure that can contain a JWT object; the application can use this value to disambiguate among the different kinds of objects that might be present.

> ...
>
> Use of this Header Parameter is OPTIONAL.

For this reason, some third-party token issuers may generate tokens that are not compatible with the MicroProfile JWT specification. The Payara Platform allows to set this verification off, so you can use the `disable.type.verification` custom property and set its value to `true` to this effect.

This property has to be defined in the `payara-mp-jwt.properties` configuration file described in the previous section.

Keep in mind that tokens which are missing their type claim and are propagated to other services running on other Eclipse MicroProfile runtimes might be rejected, as the specification mandates the inclusion of the claim.

Caching the Public Key

By default, the public key retrieved by the `mp.jwt.verify.publickey.location` configuration property will be cached in memory for 5 minutes after being read from either a local file or a remote location. You can modify this *"time-to-live"* which determines how long the key stays cached in memory in the case you are dealing with long-lived keys, this is done by setting the `publicKey.cache.ttl` custom property.

This property has to be defined in the `payara-mp-jwt.properties` configuration file described in the previous section.

If the public key is retrieved from a remote HTTP(S) location, and the server's response includes a `Cache-Control: max-age` header with a valid positive value, Payara will use that value as the cache duration instead of the `publicKey.cache.ttl` setting

The value of the `publicKey.cache.ttl` property is defined in milliseconds, so keep this in mind when modifying the property

Retaining the Cached Public Key on Retrieval Errors

When a public key is retrieved from a remote location as specified by the `mp.jwt.verify.publickey.location` configuration property, Payara caches it in memory for the duration defined by the `publicKey.cache.ttl` property (default 5 minutes). Once this time-to-live (TTL) period expires, the runtime will attempt to re-fetch the key from the remote location.

In certain environments, however, the remote public key location may become temporarily unavailable due to network interruptions or service downtime. In such cases, the cached key would normally be discarded after its TTL expires, potentially causing JWT verification failures even if the cached key itself remains valid.

To improve resilience in these scenarios, you can configure Payara to **retain the cached key for an**

additional period if the runtime cannot reach the remote location when attempting to refresh it. This behavior is controlled by the `publicKey.cache.retain-on-error-duration` custom property.

When this property is set, once the cached key expires and the system fails to fetch the updated key, the previously cached key will remain valid and continue to be used for the duration specified by this property. If the remote location becomes available again within this period, the cached key will be refreshed as normal. If the retain-on-error period also expires without a successful refresh, the cache will be invalidated and JWT verification will fail until the key can be fetched again.

This property must be defined in the `payara-mp-jwt.properties` configuration file described in the previous section.

The value of the `publicKey.cache.retain-on-error-duration` property is defined in **milliseconds**. For example, a value of `3600000` will retain the cached key for an additional 1 hour in the event of a remote key retrieval failure.

Activating JWT Authentication

An application activates the JWT authentication mechanism and identity store by annotating a class in the application, for instance, the JAX-RS `Application` class, with `@LoginConfig(authMethod = "MP-JWT")`.

Protecting Jakarta REST Services Endpoints

MicroProfile JWT Authentication specifies that Jakarta REST services endpoints are to be secured by using the `jakarta.annotation.security.RolesAllowed` annotation. Note that while this is a general annotation, for Jakarta EE it's only EJBs that interprets this.

The Jakarta REST Services specification itself does not specify that this annotation should work on resource classes or methods and hence most implementations do not support it out of the box. The Payara Platform supports this behaviour out of the box in a proprietary manner. This support holds for all types of authentication mechanisms, e.g. `BASIC`, and not just `JWT`.

For example:

```
@ApplicationScoped
@Path("/resource")
@Produces(TEXT_PLAIN)
public class Resource {

    @Inject
    private Principal principal;

    @GET
    @Path("/protected")
    @RolesAllowed("architect")
    public String protectedResource() {
        return
            "This is a protected resource \n" +
```

```
            "web username: " + principal.getName() + "\n";
    }
}
```

Accessing a Protected Endpoint

With the `generateJWTString()` method as presented above and the JWT token residing in a file called `jwt-token.json` on the classpath, a request to a JWT protected endpoint can be done as follows using the Jakarta REST Services client API:

```
public class Application{

    public static void main(String[] args){
        var response = newClient()
                       .target(
                           URI.create(new URL(base,
"resource/protected").toExternalForm()))
                       .request(TEXT_PLAIN)
                       .header(AUTHORIZATION, "Bearer " + generateJWTString("jwt-
token.json"))
                       .get(String.class);
    }
}
```

With `base` being the context where the application is deployed, e.g. `http://example.com/myapp`

Switching off @RolesAllowed Support

The out-of-the-box support of `@RolesAllowed` for Jakarta REST Services resources can be switched off by setting the `<jaxrs-roles-allowed-enabled>` tag in `WEB-INF/payara-web.xml` to `false`.

For more information see the documentation for the jaxrs-roles-allowed-enabled element.

Metrics

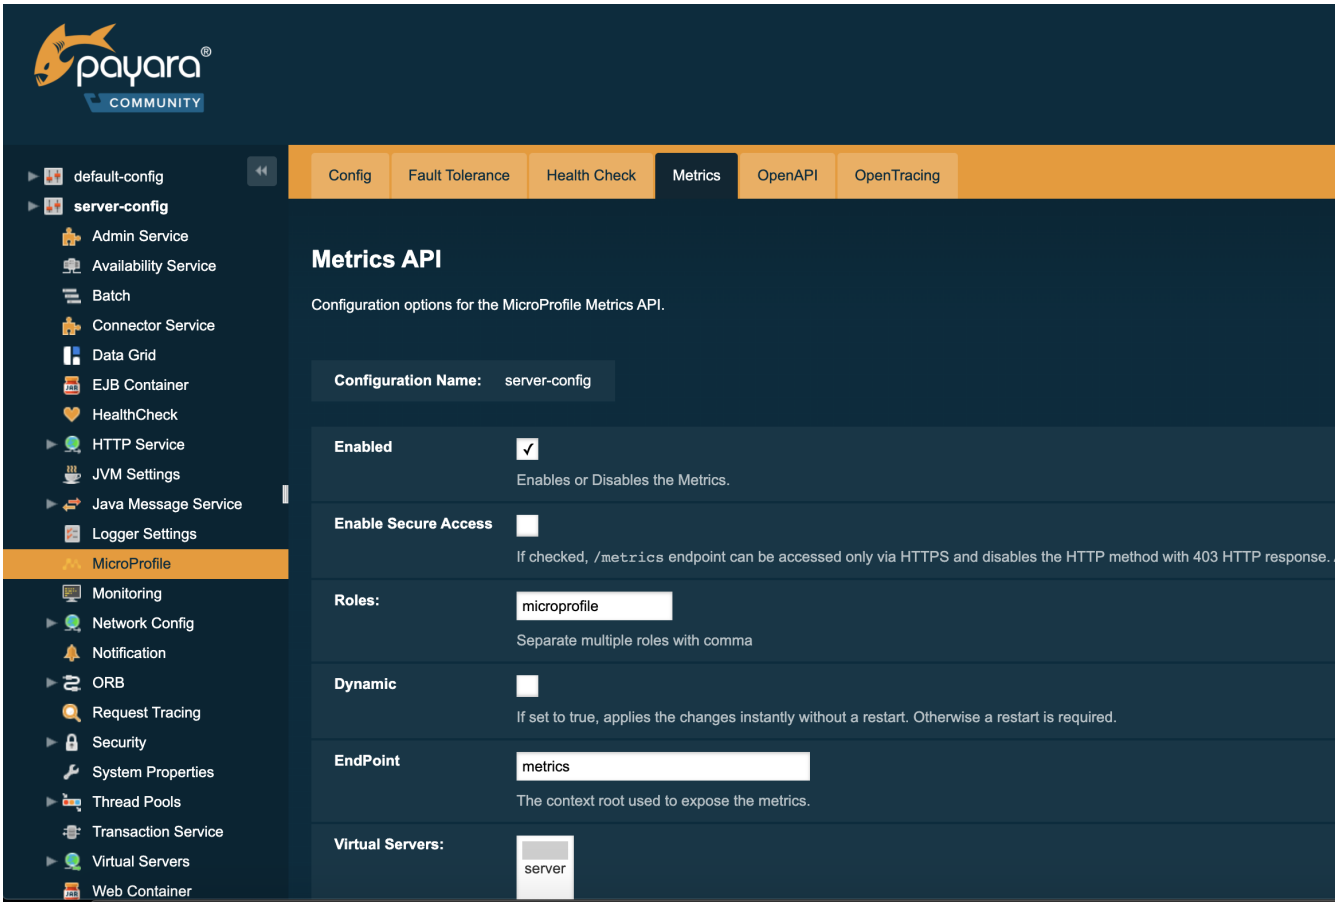
Metrics Configuration

On Payara Server, the MicroProfile Metrics service can be configured by using Admin Console or Asadmin commands.

Payara Micro doesn't have a convenient solution for its MicroProfile Metrics service configuration yet.

Using the Admin Console

To configure the Metrics in the Admin Console, go to Configuration → [instance-configuration (like `server-config`)] → MicroProfile → Metrics:



Using Asadmin Commands

Use the following commands to manipulate the configuration settings of the service:

- `set-metrics-configuration`
- `get-metrics-configuration`

Security Configuration Considerations

By default, the MicroProfile Metrics endpoint binds to the root context application which is the `default-web-module` (also known as **`docroot`**) system application and the`default-web-module` application, which is secured under the default realm (`file`) of the server domain.

If a user application is deployed in the empty **context-root**, then the security configuration of this application will be shared by the MicroProfile Metrics endpoint, so *exert extreme caution* when making these changes.

Metrics Rest Endpoint

MicroProfile Metrics specifies that all metrics are published at the endpoint `/metrics`. For both Payara Server and Payara Micro, this means that the endpoint can be found on the HTTP port (default `8080`). By visiting these endpoints in a browser, the Prometheus text format can be viewed directly.

Metric Scopes

The Metrics specification defines four *Scopes*, **Base**, **Vendor**, **Application** and **Custom** which

correspond to the following purposes:

Base

Base metrics are a set of optional metrics that a compliant server may provide. A server that provides this kind of metric can implement all, some of them or none of them. A reason to choose a different set of metrics is that the metrics libraries they are using in their implementation come with metrics with a similar purpose to the spec-described base metrics.

These metrics can be accessed under `/metrics?scope=base`.

These metrics must be tagged with `mp_scope=base`.

Vendor

Vendor metrics are specific to each implementation and are intended to offer metrics which are unique to each vendor.

These metrics can be accessed under `/metrics?scope=vendor`.

These metrics must be tagged with `mp_scope=vendor`.

Application

Application metrics are reserved for those metrics which are to be exposed from the application by using the developer API.

These metrics can be accessed under `/metrics?scope=application`.

These metrics must be tagged with `mp_scope=application`.

Custom Scopes

Applications may also define their own scope names by tagging metrics with a custom scope name (other than base, vendor or application).

These metrics can be accessed under `/metrics?scope=scope_name`.

These metrics must be tagged with `mp_scope=scope_name`.

For example:

```
@RequestScoped
public class Component{
    @Gauge(name = "gaugeMethod", unit = MetricUnits.NONE, scope = "mygauge")
    public long getGauge() {
        log.info("Private Gauge:"+getPrivateGauge());
        return gauge;
    }
}
```

Vendor Metrics

The Payara Platform supports exporting the JMX Beans and HealthCheck stats to the Vendor Metrics.

JMX MBeans

JMX MBeans can be exposed as **Custom Vendor Metrics** by the user by supplying a custom metrics.xml file in the `domain-dir/config/` directory with the following format:

```
<config>
    <base>
        ...
    </base>
    <vendor>
        <!--sample metadata-->
        <metadata>
            <tags>
                <tag>
                    <name>operatingSystem</name>
                    <value>Linux</value>
                </tag>
            </tags>
            <name>system.cpu.load</name>
            <mbean>java.lang:type=OperatingSystem/SystemCpuLoad</mbean>
            <type>gauge</type>
            <unit>none</unit>
            <displayName>System CPU Load</displayName>
            <description>Recent CPU usage for the whole system.</description>
        </metadata>
    </vendor>
</config>
```

Payara Server has a more extensive range of MBeans available than Payara Micro, but these *AMX* MBeans need to be enabled through the *Monitoring* section of the admin console before they will be usable.
Each of these AMX MBeans are also lazily loaded so, for example, JDBC connection pool MBeans will not be visible until an application that uses the connection pool is deployed.

Templating Metrics for AMX MBeans

It is possible to create a template for a metric based on AMX MBeans properties for multiple resource configurations or similar objects (like JDBC connection pools for example).

Simple Templating

You can use the `%s` placeholder to define a template in the metadata definition of the metric using the `mbean` element. The server will look for all MBeans that match the expression defined and will

generate metrics for each one of them.

You will need to use the `%s` placeholder in the name element as well to allow each metric to have a different name and avoid collisions.

Example

Here's a simple example of defining a custom metric definition template that will generate metrics for the number of free connections available to all JDBC connections pools:

```
<metadata>
     <tags>
        <tag>
            <name>name</name>
            <value>%s</value>
        </tag>
     </tags>
     <name>jdbc.connection.pool.numconnfree</name>
     <mbean>amx:pp=/mon/server-mon[server],type=jdbc-connection-pool-
mon,name=resources/%sPool/numconnfree#current</mbean>
     <type>counter</type>
     <unit>none</unit>
     <displayName>numconnfreePool</displayName>
     <description>The total number of free connections in the pool as of the last
sampling.</description>
</metadata>
```

Which will yield the following results:

```
# TYPE vendor_jdbc_connection_pool_numconnfree_total counter
# HELP vendor_jdbc_connection_pool_numconnfree_total The total number of free
connections in the pool as of the last sampling.
vendor_jdbc_connection_pool_numconnfree_total{name="resources/DerbyPool"} 0
vendor_jdbc_connection_pool_numconnfree_total{name="resources/H2Pool"} 0
vendor_jdbc_connection_pool_numconnfree_total{name="resources/__TimerPool"} 0 0
```

Instance Names

Payara provides the placeholder `${instance}`. It is replaced with the name of the Payara Server instance, where the metrics is running:

```
<metadata>
    <name>requestcount.${instance}</name>
    <mbean>amx:type=web-request-mon,pp=/mon/server-
mon[${instance}],name=clusterjsp/server/requestcount#count</mbean>
    <type>gauge</type>
    <unit>none</unit>
    <displayName>Request count for application</displayName>
```

```
</metadata>
```

Here's the sample output of this metric being queried on a server instance named `i1`:

```
vendor_requestcount_i1 1
```

Advanced Templating

If you need more control on the attributes of specific MBeans used in a metric definition, you can use the `${key}`, `${attribute}` and `${subattribute}` placeholders to define more fine-grained metrics.

These placeholders are used as follows:

`key`
: Used as a placeholder of the name (or part of the name) of an AMX MBean.

`attribute`
: Used as a placeholder for the name of an **attribute** of an AMX MBean.

`subattribute`
: Used as a placeholder for the name of a **sub-attribute** (or second-level attribute), which corresponds to the attribute of a `CompositeData` object.

You will need to use the `${key}`, `${attribute}` and `${subattribute}` placeholders in the `name` element as well to prevent name collisions between different templated metrics.

Example

Here's an example of defining a custom metric definition template with these placeholders that will generate a counter metric for each specific connection metric that is available to all JDBC connection pools:

```
<metadata>
     <name>jdbc.connection.pool.${key}Pool.${attribute}#${subattribute}</name>
     <mbean>amx:pp=/mon/server-mon[server],type=jdbc-connection-pool-
mon,name=resources/${key}Pool/${attribute}#${subattribute}</mbean>
     <type>counter</type>
     <unit>none</unit>
</metadata>
```

Which will yield the following results:

```
# TYPE
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnsuccessfullymatched#star
t_time counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnsuccessfullymatched#star
```

```
t_time 1540463722554
# TYPE vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconncreated#count
counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconncreated#count 0
# TYPE
vendor:jdbc_connection_pool_resources/_derby_pool_pool_connrequestwaittime#last_sample
_time counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_connrequestwaittime#last_sample
_time -1
# TYPE vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnused#start_time
counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnused#start_time
1540463106138
# TYPE
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnused#last_sample_time
counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnused#last_sample_time
1540463722554
# TYPE
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconntimedout#start_time
counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconntimedout#start_time
1540463722554
# TYPE
vendor:jdbc_connection_pool_resources/_derby_pool_pool_connrequestwaittime#start_time
counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_connrequestwaittime#start_time
1540463722554
# TYPE vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnfree#start_time
counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnfree#start_time
1540463106138
# TYPE
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnfailedvalidation#count
counter
vendor:jdbc_connection_pool_resources/_derby_pool_pool_numconnfailedvalidation#count 0
......
# TYPE
vendor:jdbc_connection_pool_resources/_h2_pool_pool_numconnsuccessfullymatched#start_t
ime counter
vendor:jdbc_connection_pool_resources/_h2_pool_pool_numconnsuccessfullymatched#start_t
ime 1540463722554
# TYPE vendor:jdbc_connection_pool_resources/_h2_pool_pool_numconncreated#count
counter
vendor:jdbc_connection_pool_resources/_h2_pool_pool_numconncreated#count 0
......
......
```

HealthCheck Stats

HealthCheck Services can be exposed as **Custom Vendor Metrics** by the user by supplying a custom metrics.xml file in the `domain-dir/config/` directory as well.

The following statistics are the integrated HealthCheck services metrics that are automatically exposed to the Microprofile Metrics service:

HealthCheck Service	Service ID	Attributes	Sub-Attributes
Stuck Threads	`healthcheck-stuck`	NA	`count`, `maxDuration`
Connection Pool	`healthcheck-cpool`	by default `H2Pool`, `__TimerPool`	`usedConnection`, `freeConnection`, `totalConnection`

Example

Here's an example of exposing the HealthCheck stats to the Microprofile Metrics endpoint:

```
<metadata>
    <name>thread.stuck.count</name>
    <service>healthcheck-stuck#count</service>
    <type>gauge</type>
    <unit>none</unit>
    <displayName>Stuck Thread Count</displayName>
    <description>Displays the stuck thread count which is blocked, and can't return to
the thread pool for a certain amount of time.</description>
</metadata>
```

Which will yield the following results:

```
# TYPE vendor_thread_stuck_count gauge
# HELP vendor_thread_stuck_count Displays the stuck thread count which is blocked, and
can't return to the threadpool for a certain amount of time.
vendor_thread_stuck_count 0
......
......
```

Health Check services need to be enabled first

Templating Metrics for HealthCheck Service

It is possible to create a template for a metric for multiple resource, attributes or sub-attributes configurations.

These placeholders are used as follows:

`attribute`

Used as a placeholder for the name of an **attribute** of an AMX MBean.

`subattribute`

Used as a placeholder for the name of a **sub-attribute** (or second-level attribute), which corresponds to the attribute of a `CompositeData` object.

You will need to use the `${attribute}` and `${subattribute}` placeholders in the `name` element as well to prevent name collisions between different templated metrics.

Example

Here's an example of defining a custom metric definition template with these placeholders that will generate a counter metric for each specific connection metric that is available to all JDBC connection pools:

```
<metadata>
    <name>connection.pool.${attribute}.${subattribute}</name>
    <service>healthcheck-cpool/${attribute}#${subattribute}</service>
    <type>counter</type>
    <unit>none</unit>
    <displayName>${attribute} ${subattribute}</displayName>
    <description>Displays the number of ${subattribute} in the Connection Pool
${attribute}.</description>
</metadata>
```

Which will yield the following results:

```
# TYPE vendor_connection_pool_H2Pool_freeConnection_total counter
# HELP vendor_connection_pool_H2Pool_freeConnection_total Displays the number of
freeConnection in the Connection Pool H2Pool.
vendor_connection_pool_H2Pool_freeConnection_total 0
# TYPE vendor_connection_pool_H2Pool_totalConnection_total counter
# HELP vendor_connection_pool_H2Pool_totalConnection_total Displays the number of
totalConnection in the Connection Pool H2Pool.
vendor_connection_pool_H2Pool_totalConnection_total 0
# TYPE vendor_connection_pool_H2Pool_usedConnection_total counter
# HELP vendor_connection_pool_H2Pool_usedConnection_total Displays the number of
usedConnection in the Connection Pool H2Pool.
vendor_connection_pool_H2Pool_usedConnection_total 0
# TYPE vendor_connection_pool___TimerPool_freeConnection_total counter
# HELP vendor_connection_pool___TimerPool_freeConnection_total Displays the number of
freeConnection in the Connection Pool __TimerPool.
vendor_connection_pool___TimerPool_freeConnection_total 0
# TYPE vendor_connection_pool___TimerPool_totalConnection_total counter
# HELP vendor_connection_pool___TimerPool_totalConnection_total Displays the number of
totalConnection in the Connection Pool __TimerPool.
vendor_connection_pool___TimerPool_totalConnection_total 0
# TYPE vendor_connection_pool___TimerPool_usedConnection_total counter
# HELP vendor_connection_pool___TimerPool_usedConnection_total Displays the number of
usedConnection in the Connection Pool __TimerPool.
```

```
vendor_connection_pool___TimerPool_usedConnection_total 0
......
......
```

OpenAPI

The Payara Platform main-7 provides MicroProfile OpenAPI 3.1

Background

OpenAPI was designed to provide a standard interface for documenting and exposing RESTful APIs. The MicroProfile OpenAPI API provides a set of interfaces and annotations to allow application developers to produce an OpenAPI document from their JAX-RS applications. OpenAPI is somewhat similar to the Swagger API, so many concepts in the API will be familiar.

The complete specification can be found on the Eclipse MicroProfile website.

Breaking changes introduced in MicroProfile OpenAPI 3.1 are listed in the official specification under Incompatible Changes

Version 3.1 of the OpenAPI specification does not define the behaviour of implementations where multiple applications are deployed to the same container. This limitation will be addressed in a later version of the OpenAPI specification. Payara Server allows you to see multiple applications in the OpenAPI document, see multiple applications.

REST Endpoint

MicroProfile OpenAPI specifies that an OpenAPI document should be published at the endpoint `/openapi` documenting a deployed application. For both Payara Server and Payara Micro, this means that the endpoint can be found on any HTTP port (e.g. `8080`) after deploying an application.

The OpenAPI document displayed will always be for the most recently deployed application, except in the special case of disabling the service.

By default, the OpenAPI document is displayed in YAML format, although this can be changed to JSON by changing the `Accept` header of the request. Alternatively if using a browser, this can also be done by specifying a `format` query parameter.

For example, `http://localhost:8080/openapi?format=json`. The valid values are `json` and `yaml`.

OpenAPI Configuration Sources

MicroProfile OpenAPI specifies several ways of configuring the data in the produced OpenAPI document. These are all provided by the OpenAPI API artifact:

```
<dependency>
    <groupId>org.eclipse.microprofile.openapi</groupId>
```

```
    <artifactId>microprofile-openapi-api</artifactId>
    <version>{mpOpenAPIVersion}</version>
    <scope>provided</scope>
</dependency>
```

Configuration Properties

The OpenAPI document generation process can be configured through the Config API. The following are the standard configuration properties as presented by the specification:

Property key	Description
`mp.openapi.model.reader`	Configuration property to specify the fully qualified name of the OASModelReader implementation.
`mp.openapi.filter`	Configuration property to specify the fully qualified name of the OASFilter implementation.
`mp.openapi.scan.disable`	Configuration property to disable annotation scanning. Default value is `false`.
`mp.openapi.scan.packages`	Configuration property to specify the list of packages to scan. For example, `mp.openapi.scan.packages=com.xyz.PackageA,com.xyz.PackageB`
`mp.openapi.scan.classes`	Configuration property to specify the list of classes to scan. For example, `mp.openapi.scan.classes=com.xyz.MyClassA,com.xyz.MyClassB`
`mp.openapi.scan.exclude.packages`	Configuration property to specify the list of packages to exclude from scans. For example, `mp.openapi.scan.exclude.packages=com.xyz.PackageC,com.xyz.PackageD`
`mp.openapi.scan.exclude.classes`	Configuration property to specify the list of classes to exclude from scans. For example, `mp.openapi.scan.exclude.classes=com.xyz.MyClassC,com.xyz.MyClassD`
`mp.openapi.servers`	Configuration property to specify the list of global servers that provide connectivity information. For example, `mp.openapi.servers=https://xyz.com/v1,https://abc.com/v1`
`mp.openapi.servers.path.`	Prefix of the configuration property to specify an alternative list of servers to service all operations in a path. For example, `mp.openapi.servers.path./airlines/ngs/{id}=https://xyz.io/v1`

Property key	Description
`mp.openapi.servers.operation.`	Prefix of the configuration property to specify an alternative list of servers to service an operation. Operations that want to specify an alternative list of servers must define an `operationId`, a unique string used to identify the operation. For example, `mp.openapi.servers.operation.getBooking=https://abc.io/v1`
`mp.openapi.schema.`	Prefix of the configuration property to specify an alternative list of servers to service an operation. Prefix of the configuration property to specify a schema for a specific class, in JSON format. The remainder of the property key must be the fully-qualified class name. The value must be a valid OpenAPI schema object, specified in the JSON format. The use of this property is functionally equivalent to the use of the `@Schema` annotation on a Java class, but may be used in cases where the application developer does not have access to the source code of a class. When a `name` key is provided with a string value, the schema will be added to the `schemas` collection in the `components` object of the resulting OpenAPI document using `name`'s value as the key. For example, in the case where an application wishes to represent a Java `Date` object in epoch-style milliseconds, the following configuration can be used (line escapes and indentation added for readability): `mp.openapi.schema.java.util.Date = { \ "name": "EpochMillis", \ "type": "number", \ "format": "int64", \ "description": "Milliseconds since January 1, 1970, 00:00:00 GMT" \ }`

In addition to the standard properties, the following properties have been added as extensions within the Payara Platform:

Property key	Description

`mp.openapi.extensions.scan.lib`	Configuration property that allows the server to scan packaged JAR files inside the WAR's library directory (`WEB-INF/lib`). If the WAR is inside EAR, the server also scans JAR files inside the EAR's `lib/` directory. Default value is `false`.

OASModelReader

`org.eclipse.microprofile.openapi.OASModelReader`

The OASModelReader interface can be implemented by an application developer. It must then be declared as a Config API variable in the form:

```
mp.openapi.model.reader=fish.payara.examples.OASModelReaderImpl
```

This class will be called at the beginning of the OpenAPI document generation, and will create the initial OpenAPI document.

OASFilter

`org.eclipse.microprofile.openapi.OASFilter`

The OASFilter interface can be implemented by an application developer. It must then be declared as a Config API variable in the form:

```
mp.openapi.filter=fish.payara.examples.OASFilterImpl
```

Each method in the implementation will be called on every appropriate element in the OpenAPI model. For example, the method `filterPathItem(PathItem pathItem)` will be called for every `PathItem` in the document. This class is called last, before the document is published.

Static Document

The MicroProfile OpenAPI supports using a static OpenAPI document to build from. This static file can be placed in either `META-INF` directory in a WAR file. Most often, this means putting the file in `src/main/resources/META-INF`.

The following file names are allowed for this file. The file given must also be in the specified format.

File Format	Allowed File Names
`yaml`	`openapi.yaml` `openapi.yml`
`json`	`openapi.json`

Annotations

The MicroProfile OpenAPI API provides many annotations to use to augment the OpenAPI document. These are detailed in the OpenAPI Specification. These annotations are applied before

the OASFilter.

Example

The following code could be used to give the corresponding operation an ID of "hello world".

```
import org.eclipse.microprofile.openapi.annotations.Operation;

@Path("/app")
public class AppResource{
    @GET
    @Operation(operationId = "hello world")
    public String helloWorld() {
        return "Hello World!";
    }
}
```

Here's an example of how the OpenAPI document of a sample application would look like

```
openapi: 3.0.0
info:
  title: A Test Application
  version: "1.0"
servers:
- url: http://localhost:8080/openapi-example-1.0
  description: Default Server.
- url: https://localhost:8181/openapi-example-1.0
  description: Default Server.
paths:
  /api/hello:
    get:
      operationId: hello-world
      responses:
        default:
          content:
            text/plain:
              schema:
                type: string
          description: Default Response.
      deprecated: false
endpoints:
  /openapi-example-1.0:
  - /api/hello
components: {}
```

Deployed Endpoints

When more than one application is deployed, a merge is done in the OpenAPI document. The resulting document will contain all application and path definitions present. To improve the its

readability, an `endpoints` attribute which lists all deployed endpoints grouped by their application context roots has been added to the document.

The `endpoints` attribute is an proprietary Payara Platform extension and it's not portable.

The following example shows an OpenAPI document generated when 2 different applications are deployed

```
openapi: 3.0.0
info:
  title: Deployed Resources
  version: 1.0.0
servers:
- url: http://localhost:8080/ClusteredSingleton
  description: Default Server.
- url: https://localhost:8181/ClusteredSingleton
  description: Default Server.
- url: http://localhost:8080/SimpleWAR
  description: Default Server.
- url: https://localhost:8181/SimpleWAR
  description: Default Server.
paths:
  /resources/javaee8:
    get:
      operationId: ping
      responses:
        default:
          content:
            '*/*':
              schema:
                type: object
          description: Default Response.
  /resources/randomNumberGen:
    get:
      operationId: randomNumberGen
      responses:
        default:
          content:
            '*/*':
              schema:
                type: integer
          description: Default Response.
  /rest/request:
    get:
      operationId: getXml
      responses:
        default:
          content:
            text/plain:
```

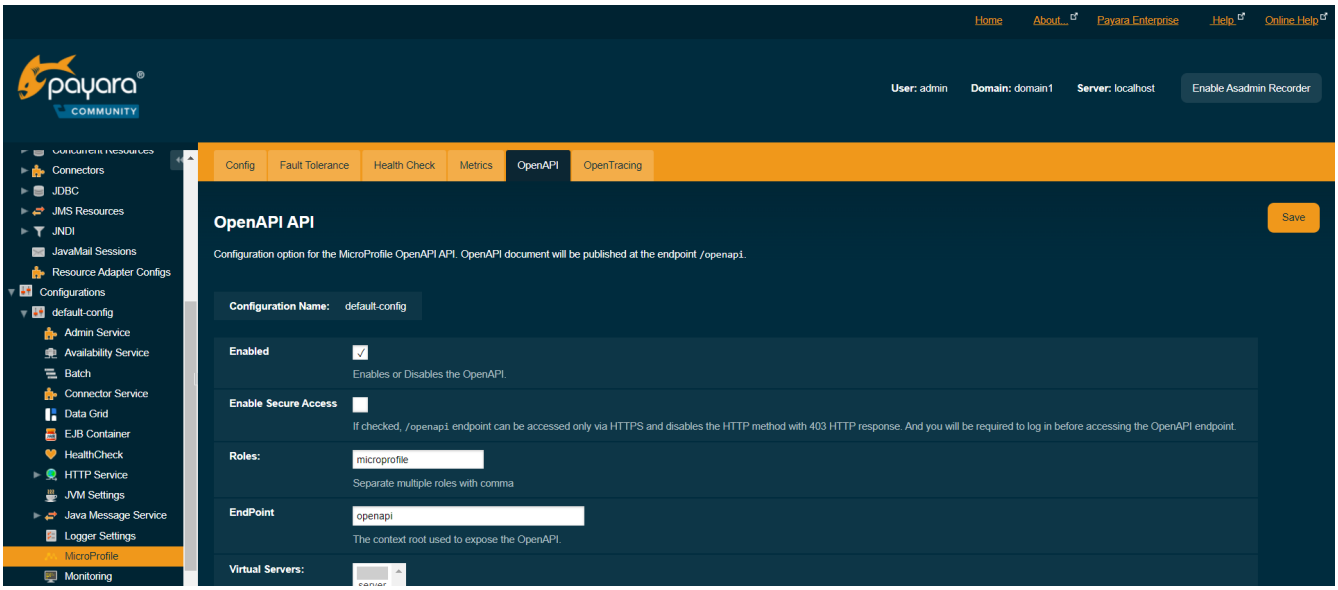
```
              schema:
                type: string
          description: Default Response.
    put:
      operationId: putXml
      requestBody:
        content:
          application/xml:
            schema:
              type: string
      responses:
        default:
          content:
            '*/*':
              schema:
                type: object
          description: Default Response.
endpoints:
  /ClusteredSingleton:
  - /resources/javaee8
  - /resources/randomNumberGen
  /SimpleWAR:
  - /rest/request
components: {}
```

OpenAPI Configuration

On Payara Server, MicroProfile OpenAPI settings can be configured by using the Admin Console or Asadmin CLI commands.

Using the Admin Console

To configure the OpenAPI in the Admin Console, go to Configuration → [instance-configuration (like `server-config`)] → MicroProfile → OpenAPI:



Using Asadmin Commands

Use the following commands to configure the settings of the MicroProfile OpenAPI service:

- `set-openapi-configuration`
- `get-openapi-configuration`

Security Configuration

By default, the OpenAPI endpoint binds to the root context application which is the `default-web-module (also known as docroot) system application and thedefault-web-module` application, which is secured under the default realm (`file`) of the server.

If a user application is deployed in the empty context-root, then the security configuration of this application will be shared by the OpenAPI endpoint, so exert extreme caution when making these changes.

Upgrading from MicroProfile 3.x to 4.x

MicroProfile 4.0 brings with it a number of changes to MicroProfile OpenAPI, among these changes are some which break previous behaviour. The breaking changes are primarily to do with the removal of a number of methods previously marked as deprecated from the API, and only affect the use of OpenAPI programmatically (there are no breaking changes pertaining to the use of the annotations).

- `Scopes` interface removed - Use `Map<String, ServerVariable>`.
- `ServerVariables` interface removed - Use `Map<String, ServerVariable>`.
- The following interfaces no longer extend `Map` - Ensure you are not using any of the methods or functionality gained from the `Map` class:
  - `APIResponses`
    - `get(Object key)` - Use `getAPIResponse(String)`.
    - `containsKey(Object key)` - Use `hasAPIResponse(String)`.
    - `put(String key, PathItem value)` - Use `addAPIResponse(String, APIResponse)`.
    - `putAll(Map<? extends String, ? extends APIResponse> m)` - Use `setAPIResponses(Map)`.
    - `remove(Object key)` - Use `removeAPIResponse(String)`.
  - `Callback`
    - `get(Object key)` - Use `getPathItem(String)`.
    - `containsKey(Object key)` - Use `hasPathItem(String)`.
    - `put(String key, PathItem value)` - Use `addPathItem(String, PathItem)`.
    - `putAll(Map<? extends String, ? extends PathItem> m)` - Use `setPathItems(Map)`.
    - `remove(Object key)` - Use `removePathItem(String)`.
  - `Content`
    - `get(Object key)` - Use `getMediaType(String)`.

        - `containsKey(Object key)` - Use `hasMediaType(String)`.
        - `put(String key, MediaType value)` - Use `addMediaType(String, MediaType)`.
        - `putAll(Map<? extends String, ? extends MediaType> m)` - Use `setMediaTypes(Map)`.
        - `remove(Object key)` - Use `removeMediaType(String)`.
    - `Path`
        - `get(Object key)` - Use `getPathItem(String)`.
        - `containsKey(Object key)` - Use `hasPathItem(String)`.
        - `put(String key, PathItem value)` - Use `addPathItem(String, PathItem)`.
        - `putAll(Map<? extends String, ? extends PathItem> m)` - Use `setPathItems(Map)`.
        - `remove(Object key)` - Use `removePathItem(String)`.
    - `SecurityRequirement`
        - `get(Object key)` - Use `getScheme(String)`.
        - `containsKey(Object key)` - Use `hasScheme(String)`.
        - `put(String key, List<String> value)` - Use `addScheme(String, List<String>)`.
        - `putAll(Map<? extends String, ? extends List<String> m)` - Use `setSchemes(Map)`.
        - `remove(Object key)` - Use `removeScheme(String)`.
- A number of methods have been removed from model interfaces, in addition to those above:
    - OASFactory
        - `createScopes` - use `Map<String, String>`.
        - `createServerVariables` - use `Map<String, ServerVariable>`.
    - OAuthFlow
        - `setScopes(Scopes scopes)` - Use `setScopes(Map)`.
        - `scopes(Scopes scopes)` - Use `scopes(Map)`.
    - OpenAPI
        - `path(String name, PathItem path)` - use `Paths#addPathItem(String, PathItem)` on `OpenAPI#getPaths`
    - PathItem
        - `readOperations` - use `Map#values()` on `PathItem#getOperations()`.
        - `readOperationsMap` - use `getOperations()`.
    - Schema
        - `getAdditionalProperties` - use `getAdditionalPropertiesSchema()` or `getAdditionalPropertiesBoolean()`.
        - `setAdditionalProperties(Schema additionalProperties)` - use `setAdditionalPropertiesSchema(Schema)`.
        - `setAdditionalProperties(Boolean additionalProperties)` - use `setAdditionalPropertiesBoolean(Boolean)`.

- `additionalProperties(Schema additionalProperties)` - use `additionalPropertiesSchema(Schema)`.
- `additionalProperties(Boolean additionalProperties)` - use `additionalPropertiesBoolean(Boolean)`.

- Server
  - `setVariables(ServerVariables variables)` - Use `setVariables(Map)`.
  - `variables(ServerVariables variables)` - Use `variables(Map)`.

OpenTelemetry and OpenTracing

The Payara Platform natively supports OpenTelemetry APIs as well as export of traces over the OTLP protocol. Natively in this context means, that deployment of an OpenTelemetry Agent is not necessary and may lead to duplicate traces.

All OpenTracing support in the Payara Platform is done by means of the OpenTracing Compatibility Layer.

The Payara Platform satisfies requirements of both MicroProfile OpenTracing 3.0 and MicroProfile Telemetry Tracing 1.1 provided appropriate [Technical Documentation-MicroProfile-OpenTelemetry and OpenTracing:::span-convention-settings] are applied.

OpenTelemetry implementation only covers the tracing aspect of OpenTelemetry, no metrics or logs are provided by default.
Manual instrumentation is needed to enable these.

Enabling OpenTelemetry

OpenTelemetry is enabled for a particular application when:

- It defines the MicroProfile configuration property `otel.sdk.disabled` with a value of `false` as defined by MicroProfile Telemetry Tracing
- The Request Tracing Service is enabled
- The `otel.sdk.disabled` System property is set to `false`
- The `OTEL_SDK_DISABLED` Environment variable is set to `false`

Configuring OpenTelemetry

When OpenTelemetry is enabled it proceeds to configure OpenTelemetry components by means of autoconfiguration, using the application's MicroProfile Config properties prefixed with `otel.` first, but also falling back to system properties and environment variables as described in the linked documentation.

If the configured component does not ship with Payara distribution, it can be added as a server or application library as described in [Technical Documentation-MicroProfile-OpenTelemetry and OpenTracing:::using-additional-components].

Default Settings

With no other configuration properties specified OpenTelemetry components will:

- Accept and propagate trace headers and baggage according to W3C recommendations Trace Context and Baggage
- Export traces via OTLP protocol to `http://localhost:4317`
- Respect parent trace's sampling decision and always sample local root traces (sampler setting `parentbased_always_on`)
- Will not export metrics or logs.

To easily receive traces in default configuration run the following Jaeger container and then access its UI at port `16686`:

```
docker run --name jaeger \
   -e COLLECTOR_OTLP_ENABLED=true \
   -p 16686:16686 \
   -p 4317:4317 \
   -p 4318:4318 \
   jaegertracing/all-in-one:latest
```

Span Convention Settings

In order to improve consistency among products our implementation offers several strategies of naming and tagging spans of Jakarta REST client and server calls.

These are configured by specifying the MicroProfile Config property `payara.telemetry.span-convention` for your application.

The following values are accepted:

- `opentelemetry` follows convention prescribed by OpenTelemetry semantic conventions for HTTP spans (default setting)
- `opentracing-http-path` satisfies MicroProfile OpenTracing setting for Operation Name Provider `http-path`
- `opentracing-class-method` corresponds to MicroProfile OpenTracing setting for Operation Name Provider `class-method`
- `microprofile-telemetry` satisfies span naming as tested by the MicroProfile Telemetry Tracing TCK

Span Name Examples

Let's assume `GET` request made to `/app/rest/resource/method`, where

- `/app` is application context root
- `/rest` is `@ApplicationPath` of Jakarta REST
- `/resource` is `@Path` annotation of class `example.Resource`

- `/method` is `@Path` annotation of method `restMethod`

The following span names will be created for this request for different Span Convention settings:

span-convention setting	Server Span Name
`opentelemetry`	`GET /app/rest/resource/method`
`opentracing-class-method`	`GET:example.Resource.restMethod`
`opentracing-http-path`	`GET:/resource/method`
`microprofile-telemetry`	`/app/rest/resource/method`

Suppressing Export Warning Message

When the export endpoint is not available in default setting the following error message is logged by logger `io.opentelemetry.exported.internal.grpc.OkHttpGrpcExporter`:

```
Failed to export spans. The request could not be executed. Full error message: Failed
to connect to `localhost/127.0.0.1:4317`
```

If you don't intend to run an **OTEL** endpoint on `localhost` or at all you need to configure the exporter by means of MP Config Properties, system properties, or environment variables:

- To turn off exports, set the `otel.traces.exporter` property to `none`
- To set the remote endpoint <code>otel.exporter.otlp.endpoint</code> to <code><a href="http://<collector-host>:<port&gt" class="bare">http://<collector-host>:<port&gt;</code>

Manual Tracing

To fine-tune spans and have better control about their boundaries you can use directly either the OpenTracing or OpenTelemetry APIs.

Dependencies

The appropriate versions of APIs are provided by link:/Technical Documentation/Ecosystem/Project Management Tools/Maven Bom.adoc[Payara BOM artifact,role=unresolved] matching the version of the Payara Platform distribution you are using.

Payara Platform provides the following APIs, and it is advised to mark them as `provided` dependencies in your application and don't package them with it:

- `io.opentelemetry:opentelemetry-sdk-extension-autoconfigure`
- `io.opentelemetry:opentelemetry-sdk`
- `io.opentelemetry:opentelemetry-sdk-common`
- `io.opentelemetry:opentelemetry-sdk-metrics`
- `io.opentelemetry:opentelemetry-sdk-logs`
- `io.opentelemetry:opentelemetry-api-logs`

- io.opentelemetry:opentelemetry-sdk-extension-autoconfigure-spi
- io.opentelemetry:opentelemetry-semconv
- io.opentelemetry:opentelemetry-opentracing-shim
- io.opentelemetry:opentelemetry-api
- io.opentelemetry:opentelemetry-context
- io.opentracing:opentracing-api
- io.opentracing:opentracing-noop
- io.opentelemetry:opentelemetry-exporter-otlp
- io.opentelemetry:opentelemetry-sdk-trace
- io.opentelemetry:opentelemetry-exporter-otlp-common
- io.opentelemetry:opentelemetry-exporter-common

Using OpenTelemetry Manually

```
import io.opentelemetry.api.trace.Tracer;

@RequestScoped
public class TracedComponent {

    @Inject
    Tracer tracer;

    public void tracedMethod() {
        var span = tracer.spanBuilder("tracedTask").startSpan();

        try (var scope = span.makeCurrent()) {
            // do work, add information to span
            if (span.isRecording()) {
                // compute expensive events or tags
                // only if the span is being sampled
            }
        } finally {
            span.setStatus(StatusCode.OK);
            span.end();
        }
    }
}
```

Using OpenTracing Manually

```
import io.opentracing.Tracer;

@RequestScoped
public class TracedComponent {
```

```
    @Inject
    Tracer tracer;

    public void tracedMethod() {
        var span = tracer.buildSpan("tracedTask").start();

        try (var scope = tracer.activateSpan(span)) {
            // do work, add information to span
        } finally {
            span.finish();
        }
    }
}
```

Using additional components

If your application requires OpenTracing components that are not shipped with the Payara Platform, it is possible to either put them in common libraries, or ship them with an application. Extension components can be even coded directly in the application code.

Provider components in library directory

Applies to Payara Server only.

Autoconfiguration can pick up components, which are placed in directory `domain_dir/lib` for example by means of the `asadmin add-library` command.

Example: adding export to log

1. Download opentelemetry-exporter-logging.jar
2. Run `asadmin add-library opentelemetry-exporter-logging.jar`
3. Use the component by defining `otel.traces.exporter=logging`

Provider components in application code

Applications can declare and use their own OpenTelemetry components such as exporters or samplers by writing against autoconfiguration SPI and placing appropriate Service Loader resource in the application

Example: Minimal logging exporter

src/main/resources/META-INF/services/io.opentelemetry.sdk.autoconfigure.spi.traces.ConfigurableSpanExporterProvider

```
fish.payara.example.LogExporter.Provider
```

src/main/java/fish/payara/example/LogExporter.java

```
public class LogExporter implements SpanExporter {
```

```
    private static final Logger LOGGER =
Logger.getLogger(LogExporter.class.getName());

    @Override
    public CompletableResultCode export(Collection<SpanData> spans) {
        spans.forEach(s -> LOGGER.info(s.toString()));
        return CompletableResultCode.ofSuccess();
    }

    @Override
    public CompletableResultCode flush() {
        return CompletableResultCode.ofSuccess();
    }

    @Override
    public CompletableResultCode shutdown() {
        return CompletableResultCode.ofSuccess();
    }

    // This is registered as SPI and creates configured exporter
    public static class Provider implements ConfigurableSpanExporterProvider {

        @Override
        public SpanExporter createExporter(ConfigProperties configProperties) {
            return new LogExporter();
        }

        @Override
        public String getName() {
            return "logs";
        }
    }
}
```

Relation to Request Tracing Service

All spans created by OpenTelemetry and OpenTracing APIs are passed into Request Tracing Service when they end. Propagated trace IDs are propagated into Request Tracing Service at the start of spans.

Sampling decisions of Request Tracing service are ***not*** taken into account when these traces are created, because the Request Tracing Service makes a tracing decision at the end of span rather than at the beginning.

This means that traces might get exported via **OTLP** but not passed to the notifiers configured in the Request Tracing Service, because the service might have taken the decision not to sample this particular trace.

Information that server's components put into Request Tracing Service is not available to

OpenTelemetry traces, as information does not flow in this direction.

However, more and more parts of Payara Server will gradually switch to using OpenTelemetry API natively and therefore this gap will eventually close.

OpenTracing

Payara Platform main-7 provides MicroProfile OpenTracing 3.0

Background

The Open Tracing API was created to allow easier tracing of the flow of a request in microservices environment across service boundaries.

The complete specification can be found on the Eclipse MicroProfile website.

Breaking changes introduced in MicroProfile OpenTracing 3.0 are listed in the official specification under Incompatible Changes

Support for MicroProfile Open Tracing is provided via compatibility layer for OpenTelemetry.

To achieve full compatibility in naming the spans with the spec a span convention needs to be configured as described in [Technical Documentation-MicroProfile-OpenTracing:::span-convention].

Text and Binary Carriers Support

The Payara Platform implementation of the `io.opentracing.Tracer` interface supports the following carriers:

- `TextMap` carriers with `HTTP_HEADERS` and `TEXT_MAP` formats

JAX-WS Support

The Payara Platform's MicroProfile implementation supports tracing of requests that are handled by SOAP Web Services implemented via the JAX-WS API. Since JAX-WS is only supported on Payara Server Full Profile, this support is not covered on Payara Micro.

OpenTracing Configuration

Span Naming Convention

By default, span names for JAX-RS endpoints follow recommendations set forth by OpenTelemetry Semantic Conventions. To have span names follow naming conventions defined by MicroProfile OpenTelemetry, following MicroProfile Config property must be set for application or globally for the server or domain:

```
payara.telemetry.span-convention=opentracing-class-method
```

All valid values for the property are documented in OpenTelemetry Span Convention Settings

Using Alternate OpenTracing Implementations

Currently, it is not possible to use other OpenTracing implementations in the Payara Platform.

It is however possible to deploy and configure other OpenTelemetry exporters (i.e. Zipkin) into the server or ship them with application.

Please consult OpenTelemetry Configuration.

Rest Client

Payara Platform main-7 provides MicroProfile Rest Client 3.0.1

Background

The MicroProfile Rest Client provides a type-safe approach to invoke RESTful services over HTTP. The aim of this specification is to provide a much more natural coding style, with the underlying MicroProfile implementation handling the communication between the client and service.

The complete specification can be found on the Eclipse MicroProfile website.

Breaking changes introduced in MicroProfile Rest Client 3.0.1 are listed in the official specification under Release Notes for MicroProfile Rest Client 3.0.1

The Payara Platform implementation of this specification is based on Jersey's MicroProfile Rest client, the interaction with client interfaces is translated into interaction with standard JAX-RS clients.

Jakarta CDI

Rest Client interfaces may be injected as CDI beans. To do this, you must first register your interface class by using the `@RegisterRestClient` annotation, and then use the `@RestClient` qualifier on the injected bean, like so:

```
@RegisterRestClient
public interface MyServiceClient {
    @GET
    @Path("/greet")
    Response greet();
}

@ApplicationScoped
public class MyService {
    @Inject
    @RestClient
    private MyServiceClient client;
}
```

The endpoint to connect to in such a case must either be configured directly in attribute `baseUri` of

the `@RegisterRestClient` annotation or via Microprofile Configuration properties.

Asynchronous Communication

It is possible for Rest Client interface methods to be declared asynchronous, by having return type of `CompletionStage<?>`. This allows the thread invoking the interface method to proceed while the effective client communication occurs on another thread.

The thread pool used in this call can be configured via the `RestClientBuilder.executorService` method. If this setting is not configured, a default, server-managed thread pool will be provided.

Providers

The `RestClientBuilder` interface extends the `Configurable` interface of the JAX-RS API, allowing users to register custom providers while at the object's instantiation. The following provider types are supported:

- `ClientRequestFilter`
- `ClientResponseFilter`
- `MessageBodyReader`
- `MessageBodyWriter`
- `ParamConverter`
- `ReaderInterceptor`
- `WriterInterceptor`
- `ResponseExceptionMapper`

See the full documentation (linked below) for more information on available registration methods.

SSL Configuration

On a per-client basis, or via Microprofile Configuration properties, the following aspects of secure client communication can be set:

- Truststore, listing trusted certificates and authorities — by default the one used by the Payara Platform is used
- Keystore for setting up mutual SSL trust
- Hostname verifier, useful for suppressing validity checks for whitelisted host names

Programmatically it is also possible to provide an implementation of the `javax.net.ssl.SSLContext` class to have major control over all aspects of this secure communication channel.

SSL Context configuration

You can define the certificate alias rest client will use with one of the following approaches:

During REST client call

Property	Public API Constant	Description
`fish.payara.jaxrs.client.certificate.alias`	`PayaraConstants.REST_CLIENT_CERTIFICATE_ALIAS`	The alias name of the certificate

The name of the property is defined as a constant in the `fish.payara.security.client.PayaraConstants` class.

Example

Here's an example of how to set up the property when executing a new MP Rest Client call:

```
public class Component{
    public void executeRestClientCall(){
        RestClientBuilder.newBuilder()
                         .baseUri(new URI("https://localhost:8080/service"))
                         .property(PayaraConstants.REST_CLIENT_CERTIFICATE_ALIAS,
"someAliasName")
                         .build(Service.class);
    }
}
```

On MicroProfile Configuration

Property	Public API Constant	Description
`payara.certificate.alias`	`PayaraConstants.MP_CONFIG_CLIENT_CERTIFICATE_ALIAS`	The alias name of the certificate

You can define the alias globally as a MicroProfile Config property, either in an application-specific config source only for a single application, or with a global config source for all applications. In this case you don't need to add it during every single Rest Client call.

For this to work, you need to include the certificate with the given alias in the default Payara Server keystore.

Proxy Configuration

MicroProfile Rest Client 2.0 introduced support for configuring proxy servers via MicroProfile Config properties and the `RestClientBuilder` API. On a vanilla installation however, Payara Platform will not use these settings thus they will be ignored. This is due to Jersey, the JAX-RS client and underlying implementation of MicroProfile Rest Client, which by default, doesn't support the configuration of proxies on a per-client basis (only via a global JVM-level system property).

However, Jersey supports proxy configuration on a per-client basis when using non-default "connectors" (the means by which Jersey performs the actual network call)

If you wish to make use of this feature, you must perform a number of steps to configure Payara

Server to use of one of these non-default Jersey connectors.

Below are instructions for how to configure Payara Server to make use of Apache HTTP Client connector.

Create a RestClientListener

To configure Jersey to use Apache HTTP Client as its connector, a `RestClientListener` must be used to register the connector for each new client. You can add one to your application by simply registering as a custom JAX-RS provider.

Below is a simple example of registering the Jersey Apache HTTP Client Connector:

```
public class RestClientApacheHttpClientListener implements RestClientListener {

    @Override
    public void onNewClient(Class<?> aClass, RestClientBuilder restClientBuilder) {
        restClientBuilder.register(new ApacheConnectorProvider());
    }
}
```

The `ApacheConnectorProvider` class can be found in the `org.glassfish.jersey.connectors:jersey-apache-connector` library, please refer to the Payara BOM artefact for the specific version of the Jersey connector to use.

Add Apache HTTP Client Dependencies

In addition to the above, you will also need to add the following dependencies to the Payara Server domain (if applicable):

- `org.apache.httpcomponents:httpclient-osgi:4.5.13`
- `org.apache.httpcomponents:httpcore-osgi:4.4.14`
- `commons-logging:commons-logging:1.2`

These can be included with your application or added to the server via the `add-library` command:

```
asadmin add-library httpclient-osgi-4.5.13.jar httpcore-osgi-4.4.14.jar commons-
logging-1.2.jar
```

If you haven't bundled the library in your application, you will also need to add the `org.glassfish.jersey.connectors:jersey-apache-connector` dependency to Payara Server:

```
asadmin add-library jersey-apache-connector-${jersey.version}.jar
```

Telemetry

Payara Platform main-7 provides MicroProfile Telemetry 1.1.

The aim of the spec is to adopt OpenTelemetry into MicroProfile applications, so they can benefit from distributed tracing.

OpenTelemetry thus becomes the primary observability API in Payara Platform.

OpenTelemetry defines more types of signals. As of version main-7 and in line with MicroProfile spec, support is only provided for Tracing aspects for the API.

For more details about configuration of OpenTelemetry refer to OpenTelemetry documentation for application development.

Ecosystem

Overview

The Payara Foundation not only provides application servers in the form of Payara Server and Payara Micro; there are also satellite projects which complement and enhance the developer experience.

These include:

link:/Technical Documentation/Ecosystem/Project Management Tools/Maven Plugin.adoc[Payara Micro Maven Plugin,role=unresolved]

A plugin for Apache Maven is available for Payara Micro.

link:/Technical Documentation/Ecosystem/Project Management Tools/Maven Archetype.adoc[Payara Micro Maven Archetype,role=unresolved]

An archetype for Apache Maven is available for Payara Micro.

link:/Technical Documentation/Ecosystem/Project Management Tools/Gradle Plugin.adoc[Payara Micro Gradle Plugin,role=unresolved]

A plugin for Gradle is available for Payara Micro.

Payara Starter

An archetype is available for Payara Platform.

link:/Technical Documentation/Ecosystem/IDE Integration/Eclipse Plugin/Overview.adoc[Payara Tools Eclipse Plugin,role=unresolved]

A plugin for using Payara is available for Eclipse.

link:/Technical Documentation/Ecosystem/IDE Integration/Apache NetBeans IDE/Overview.adoc[Payara Tools for Apache NetBeans,role=unresolved]

The tools for using Payara are available in the Apache NetBeans.

link:/Technical Documentation/Ecosystem/IDE Integration/IntelliJ Plugin/Overview.adoc[Payara IntelliJ IDEA Plugin,role=unresolved]

A plugin for using Payara is available for IntelliJ IDEA.

link:/Technical Documentation/Ecosystem/IDE Integration/VSCode Extension/Overview.adoc[Payara Visual Studio Code Extension,role=unresolved]

An extension for using Payara is available for Visual Studio Code.

link:/Technical Documentation/Ecosystem/Connector Suites/Arquillian Containers/Overview.adoc[Cloud Connectors,role=unresolved]

Cloud Connectors are a collection of JCA adapters which can interact with popular message brokers, including:

- Amazon SQS
- Apache Kafka
- Azure Service Bus
- MQTT

Arquillian Containers

Arquillian containers help perform integration tests for application servers. There are various containers available for Payara:

- Payara Micro Managed
- Payara Server Remote
- Payara Server Managed
- Payara Server Embedded

Project Management Tools

Maven Bom

The Payara Platform consists of many artifacts and it depends on lots of APIs as well as their implementations. Having matching versions of these dependencies will prevent classloading issues at runtime. To this effect, the Payara Platform's Bill Of Materials (BOM) artifact collects all of these versions for the following categories:

- Payara Platform Distribution artifacts
- Payara Platform Client libraries

- Jakarta EE, Eclipse Microprofile and OSGi APIs
- Arquillian Container Adapters
- Implementations and libraries included in Payara Server (see the list below)

Quick Start

To make use of the BOM, you need to list the artifact in `dependencyManagement` section of your project in scope `import`. Some of the artifacts are Payara-specific patch versions which are available in our repository payara-artifacts.

Add following snippet to your Maven project:

```
<dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>fish.payara.api</groupId>
            <artifactId>payara-bom</artifactId>
            <version>main-7</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
    </dependencies>
</dependencyManagement>

<!-- Some of the referenced APIs in POM are Payara's patched versions.
      These are published in following repo: -->
<repositories>
    <repository>
        <id>payara-patched-externals</id>
        <name>Payara Patched Externals</name>
        <url>https://nexus.payara.fish/repository/payara-artifacts/</url>
        <releases>
            <enabled>true</enabled>
        </releases>
        <snapshots>
            <enabled>false</enabled>
        </snapshots>
    </repository>

</repositories>
```

An example application utilizing the BOM can be seen in repository Payara Examples/. See the ecosystem/payara-bom/bom-import/ subproject for more details.

BOM Contents

The following is a summary of all dependencies included in the BOM, grouped by category.

Payara Platform Distributions

Distribution artifacts do not define a Maven scope and are therefore imported in `compile` scope.

Artifact	Example usage	Note
Payara Server	`<dependency> <groupId>fish.payara.distributions</groupId> <artifactId>payara</artifactId> <type>zip</type> </dependency>`	Also available are `payara-ml`, `payara-web`, `payara-web-ml`
Payara Micro	`<dependency> <groupId>fish.payara.extras</groupId> <artifactId>payara-micro</artifactId> </dependency>`	
Payara Embedded	`<dependency> <groupId>fish.payara.extras</groupId> <artifactId>payara-embedded-all</artifactId> </dependency>`	Also available `payara-embedded-web`
EJB HTTP Client	`<dependency> <groupId>fish.payara.extras</groupId> <artifactId>ejb-http-client</artifactId> </dependency>`	

Artifact	Example usage	Note

Appclient	`<dependency>`
	`<groupId>fish.payara.server.appclient</groupId>`
	`<artifactId>payara-client</artifactId>`
	`</dependency>`	

Payara Public API	`<dependency>`
	`<groupId>fish.payara.api</groupId>`
	`<artifactId>payara-api</artifactId>`
	`</dependency>`	

Standard APIs

Standard APIs are defined in `provided` scope, as they already include classes that are present in the server's runtime.

Artifact	Example usage	Note

Jakarta EE	`<dependency>`
	`<groupId>jakarta.platform</groupId>`
	`<artifactId>jakarta.jakartaee-api</artifactId>`
	`</dependency>`
		Also available `jakarta.jakartaee-web-api`, and all individual API artifacts.

Eclipse Microprofile	`<dependency>`
	`<groupId>org.eclipse.microprofile</groupId>`
	`<artifactId>microprofile</artifactId>`
	`<type>pom</type>`
	`</dependency>`
		Individual APIs are also declared.

Artifact	Example usage	Note
OSGi	`<dependency> <groupId>org.osgi</groupId> <artifactId>osgi.core</artifactId> </dependency>`	Also available are `org.cmpn`, `osgi.annotation`, `org.osgi.dto`, and `osgi.enterprise`

Test Frameworks and Other Tools

Arquillian is the recommended way to run integration tests written for Payara Server. Payara Platform provides multiple connectors fitting the deployment scenarios. These artifacts are declared in scope `test`.

Payara Server includes the H2 database, so their matching versions are also declared, but in their default scope.

Artifact	Example usage
Arquillian container - Remote	`<dependency> <groupId>fish.payara.arquillian</groupId> <artifactId>arquillian-payara-server-remote</artifactId> </dependency>`
Arquillian container - Embedded	`<dependency> <groupId>fish.payara.arquillian</groupId> <artifactId>arquillian-payara-server-embedded</artifactId> </dependency>`
Arquillian container - Managed	`<dependency> <groupId>fish.payara.arquillian</groupId> <artifactId>arquillian-payara-server-managed</artifactId> </dependency>`

Artifact	Example usage

Arquillian container - Payara Micro Managed	`<dependency>`
	`<groupId>fish.payara.arquillian</groupId>`
	`<artifactId>arquillian-payara-micro-managed</artifactId>`
	`</dependency>`

Arquillian container - Payara Micro Remote	`<dependency>`
	`<groupId>fish.payara.arquillian</groupId>`
	`<artifactId>arquillian-payara-micro-remote</artifactId>`
	`</dependency>`

Arquillian container - Payara Micro Remote Deployer	`<dependency>`
	`<groupId>fish.payara.arquillian</groupId>`
	`<artifactId>payara-micro-deployer</artifactId>`
	`</dependency>`

Payara Arquillian Client Dependencies	`<dependency>`
	`<groupId>fish.payara.arquillian</groupId>`
	`<artifactId>payara-client-ee9</artifactId>`
	`</dependency>`

H2 Database	`<dependency>`
	`<groupId>com.h2database</groupId>`
	`<artifactId>h2</artifactId>`
	`<scope>test</scope>`
	`</dependency>`

Libraries and API implementations

This is a non-exhaustive list of dependencies. By default all are declared in their respective default scopes, but it is more correct to use them with scope `provided` if they are already present in the server's internal modules.

Artifact	Example usage	Note
Jersey	`<dependency> <groupId>org.glassfish.jersey.core</groupId> <artifactId>jersey-client</artifactId> <scope>test</scope> </dependency> <dependency> <groupId>org.glassfish.jersey.inject</groupId> <artifactId>jersey-hk2</artifactId> <scope>test</scope> </dependency>`	Example: JAX-RS clients in tests. All artifacts of the Jersey BOM are imported.
Hibernate Validator	`<dependency> <groupId>org.hibernate.validator</groupId> <artifactId>hibernate-validator</artifactId> <scope>test</scope> </dependency>`	
EclipseLink - JPA Metamodel generator	`<dependency> <groupId>org.eclipse.persistence</groupId> <artifactId>org.eclipse.persistence.jpa.modelgen.processor</artifactId> </dependency>`	The only dependency that is `provided` scoped, as it is an annotation processor.

Artifact	Example usage	Note
EclipseLink	`<dependency> <groupId>org.eclipse.persistence</groupId> <artifactId>org.eclipse.persistence.jpa</artifactId> <scope>provided</scope> </dependency>`	
Hazelcast	`<dependency> <groupId>com.hazelcast</groupId> <artifactId>hazelcast</artifactId> <scope>provided</scope> </dependency>`	The `hazelcast-kubernetes` dependency is also available.
Jackson	`<dependency> <groupId>com.fasterxml.jackson.datatype</groupId> <artifactId>jackson-datatype-jdk8</artifactId> </dependency>`	All artifacts of the Jackson BOM are imported.
Yasson	`<dependency> <groupId>org.eclipse</groupId> <artifactId>yasson</artifactId> <scope>test</scope> </dependency>`	

Artifact	Example usage	Note
Tyrus	<dependency> <groupId>org.glassfish.tyrus</groupId> <artifactId>tyrus-client</artifactId> <scope>test</scope> </dependency> <dependency> <groupId>org.glassfish.tyrus</groupId> <artifactId>tyrus-container-grizzly-client</artifactId> <scope>test</scope> </dependency>	

Maven Plugin

The Payara Maven Plugins provide seamless integration with Maven, enabling developers to start, stop, and deploy Jakarta EE applications on Payara Server and Payara Micro. These plugins streamline development, support automated deployment, and enhance workflow efficiency.

Plugins

- Payara Server Maven Plugin - The Payara Server Maven Plugin allows developers to start, stop, and deploy applications to Payara Server directly from Maven, streamlining the development and deployment process.
- Payara Micro Maven Plugin - The Payara Micro Maven Plugin enables seamless integration with Payara Micro, providing goals to start, stop, and package lightweight, microservice-based Jakarta EE applications.

Payara Server Maven Plugin

Payara Server provides a Maven plugin that can start and stop the server and deploy Jakarta EE applications.

The plugin requires JDK 17 or higher.

Configurable Goals

`start`

Aim: This goal starts Payara Server with the specified configuration. **Usage**: `mvn payara-server:start`

Example:

```
<plugin>
    <groupId>fish.payara.maven.plugins</groupId>
    <artifactId>payara-server-maven-plugin</artifactId>
    <version>${payara.server.maven.plugin.version}</version>
    <executions>
        <execution>
            <goals>
                <goal>start</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <payaraServerVersion>7.2025.1</payaraServerVersion>
        <javaHome>/path/to/Java/Executable</javaHome>
        <contextRoot>myApp</contextRoot>
    </configuration>
</plugin>
```

Common Configuration:

The following properties allow customization of local and remote deployments:

Property Name	System Property	Environment Variable	Default Value	Description
contextRoot	payara.context.root	PAYARA_CONTEXT_PATH	*none*	Defines the context root of an application.
adminPort	payara.admin.port	PAYARA_ADMIN_PORT	*none*	Admin port for Payara server administration.
httpPort	payara.http.port	PAYARA_HTTP_PORT	*none*	HTTP port for accessing deployed applications.
httpsPort	payara.https.port	PAYARA_HTTPS_PORT	*none*	HTTPS port for accessing deployed applications securely.
protocol	payara.protocol	PAYARA_PROTOCOL	*none*	Protocol to be used for server communication (e.g., HTTP or HTTPS).
adminPassword	payara.admin.password	PAYARA_ADMIN_PASSWORD	*none*	Password for the Payara admin user.
adminPasswordFile	payara.admin.password.file	PAYARA_ADMIN_PASSWORD_FILE	*none*	Path to the file containing the Payara admin password.
adminUser	payara.admin.user	PAYARA_ADMIN_USER	*none*	Username for Payara server administration.
instanceName	payara.instance.name	PAYARA_INSTANCE	*none*	Name of the Payara server instance.

Property Name	System Property	Environment Variable	Default Value	Description
daemon	payara.daemon	PAYARA_DAEMON	false	Starts Payara Server in separate JVM process and continues with the maven build.
immediateExit	payara.immediate.exit	PAYARA_IMMEDIATE_EXIT	false	If Payara Server is executed in daemon mode, the executor thread will wait for the ready message before shutting down its process. By setting `immediateExit` to `true` you can skip this and instantly interrupt the executor thread.
autoDeploy	payara.auto.deploy	PAYARA_AUTO_DEPLOY	false	Enables automatic compilation and deployment upon saving files.
keepState	payara.keep.state	PAYARA_KEEP_STATE	false	Persists session state across multiple redeployments.
liveReload	payara.live.reload	PAYARA_LIVE_RELOAD	false	Triggers a browser refresh for an up-to-date view after each redeployment.
browser	payara.browser	PAYARA_BROWSER	System default browser	Specifies the browser used for live reload. If not explicitly set, Payara selects the best available browser based on the system: Chrome (if installed), then Firefox, followed by the system default—Edge on Windows, Safari on macOS, and Firefox on Linux.
trimLog	payara.trim.log	PAYARA_TRIM_LOG	false	Refactors log format for improved readability.
hotDeploy	payara.hot.deploy	PAYARA_HOT_DEPLOY	false	Enables the Hot Deploy mode.
webappDirectory			${project.build.directory}/${project.build.finalName}	The directory where the web application is built.

Property Name	System Property	Environment Variable	Default Value	Description
debug	payara.debug	PAYARA_DEBUG	false	Enables debugging mode. If true, the server waits for a debugger to attach.
debugPort	payara.debug.port	PAYARA_DEBUG_PORT	*none*	The port for remote debugging.
httpConnectionTimeout	payara.http.connection.timeout	PAYARA_HTTP_CONNECTION_TIMEOUT	3000	Socket connection timeout (in milliseconds).
httpReadTimeout	payara.http.read.timeout	PAYARA_HTTP_READ_TIMEOUT	3000	Socket read timeout (in milliseconds).

Local Configuration:

The following properties allow customization of deployments to local instance.

Property Name	System Property	Environment Variable	Default Value	Description
javaHome	payara.java.home	PAYARA_JAVA_HOME	Environment Variable `JAVA_HOME` or `JDK_HOME`	Absolute path to the java executable.
payaraServerVersion	payara.server.version	PAYARA_SERVER_VERSION	`6.2025.6`	By default, start mojo fetches payara-server with version `6.2025.6`.
payaraServerPath	payara.server.path	PAYARA_SERVER_PATH	*none*	Absolute path to the Payara server installation directory.
artifactItem			*none*	Defines payara-server artifact with its coordinates. Specified artifact should be available in local maven repository.
domainName	payara.domain.name	PAYARA_DOMAIN_NAME	`domain1`	Payara server domain to be used.
exploded	payara.exploded	PAYARA_EXPLODED	false	If true, deploys the application in an exploded (unpacked) format.
commandLineOptions			*none*	Defines a list of command line options that will be passed onto payara-server.

Property Name	System Property	Environment Variable	Default Value	Description
javaCommandLine Options			*none*	Defines a list of command line options that will be passed to `java` executable. Command line options can either be defined as key-value pairs or just as list of values. key-value pairs will be formatted as `key=value`.

Remote Configuration:

The following properties allow customization of deployments to remote instance.

Property Name	System Property	Environment Variable	Default Value	Description
remote	payara.remote	PAYARA_REMOTE	false	If true, connects to a remote Payara server instance.
hostName	payara.host.name	PAYARA_HOST_NAME	*none*	Hostname or IP address of the Payara server.

`dev`

Aim: The dev goal is designed to streamline development by enabling `exploded`, `autoDeploy`, `liveReload`, `keepState`, and `trimLog` to true, which facilitates automatic compilation and deployment when saving files, resulting in faster iterations and a more efficient development workflow.

Usage:

```
mvn payara-server:dev
```

The `dev` goal is an extended goal of `start` and is pre-configured for developing web applications in development mode which is equivalent to starting the Payara Server instance using the following command:

```
mvn payara-server:start -DautoDeploy=true -DliveReload=true -Dexploded=true
-DkeepState -DtrimLog=true
```

Features in Dev Mode:

1. **Auto Deploy**: The AutoDeploy feature enables automatic compilation and deployment of the application upon saving files within the project structure. Enabled by setting `autoDeploy=true`.

   The AutoDeploy feature relies on Java's WatchService to monitor changes in source directories, enabling continuous build and reload using Maven's Invoker. It dynamically modifies Maven goals based on file modifications, supports asynchronous execution for concurrent build tasks,

and includes specifics for tracking changes in source, resources, and test directories.

2. **Live Reload**: The LiveReload feature automatically refreshes the browser upon redeployment.
    - `liveReload` Property: Enables or disables automatic browser refresh on redeployment. The `liveReload` property is set to `true` by default in the `dev` goal and `false` in the `start` goal.
    - `browser` Property: The `browser` property offers seamless configuration. If not specified, the system prioritizes Chrome and Firefox, gracefully falling back to Edge on Windows, Safari on macOS, or Firefox on other platforms. This improvement simplifies setup - no need to worry about specifying a browser; it adapts based on your system.
    - Cached Last Accessed URL: The last accessed Payara Server URL is stored in the `payara-maven-config.properties` file within the system's temporary directory. This ensures accessibility across application restarts, and eliminating the need for users to manually navigate back to the last accessed URL. This streamlined approach enhances the overall user experience by maintaining continuity and reducing manual intervention after each restart.
3. **Persistent Session State**: The `keepState` property allows for the persistence of session state across multiple re-deployments during the development process. Enabled by default in the `dev` goal and disabled in the `start` goal.
4. **Readable Logging**: The `trimLog` property refactors the log format for improved readability. Enabled by default in the `dev` goal and disabled in the `start` goal.

All listed features are enabled by default in the `dev` mode.

Supported Keywords

The Payara Server Maven plugin provides a built-in CLI interface that accepts specific keywords to interact with a running Payara Server instance. These commands can be used via terminal input.

- `asadmin <command>` Executes the specified `asadmin` subcommand. This is only available when the server manager is an instance of a local server.

```
Example:
[source,shell]
----
asadmin list-applications
----
```

- `deploy` Deploys the current application to the running server instance.
- `undeploy` Undeploys the current application from the running server instance.
- `exit` Exits the CLI session and terminates the running Payara server process.
- AI Agent Query

```
If the AI agent is enabled in the plugin configuration, the CLI accepts **any
natural language query**.
The query will be interpreted by the AI and responded to accordingly, based on the
```

```
current context.
```

The predefined keywords (`asadmin`, `deploy`, `undeploy`, `exit`) will take precedence over AI interpretation if matched.

AI Agent (Experimental)

The AI Agent is an experimental feature in the Payara Server Maven plugin that brings intelligent automation and observability to Jakarta EE application development. It is enabled by default in `dev` mode and disabled in other modes for safety. To enable it manually, set the `payara.ai.agent` system property or the `PAYARA_AI_AGENT` environment variable to `true`.

Capabilities

The AI Agent enhances the developer experience by interpreting natural language instructions and extracting contextual insights from the running server. Key features include:

- Generating and explaining `asadmin` **commands** from plain English instructions.
- Querying server configuration and runtime state via the **Domain REST endpoints** and **JMX MBeans**.
- Executing **safe, read-only** `asadmin` **commands**, such as listing deployed applications or viewing JDBC connection pool status.
- Parsing and summarizing **server logs** and key configuration files like `domain.xml` to surface relevant insights.
- Offering intelligent prompts and auto-completions for common server administration and troubleshooting tasks.

Configuration Properties

The AI Agent can be customized using the following properties:

Property Name	System Property	Environment Variable	Default Value	Description
API Key	payara.ai.api.key	PAYARA_AI_API_KEY	*none*	API Key for accessing the AI provider's services.
Provider Location	payara.ai.provider.location	PAYARA_AI_PROVIDER_LOCATION	*none*	Endpoint or URL of the AI provider. For example, for `OLLAMA`, the location is `http://localhost:11434`.
Provider	payara.ai.provider	PAYARA_AI_PROVIDER	`OPEN_AI`	Name of the AI service provider. Supported values: `OPEN_AI`, `CUSTOM_OPEN_AI`, `GOOGLE`, `DEEPINFRA`, `DEEPSEEK`, `GROQ`, `MISTRAL`, `OLLAMA`, `ANTHROPIC`, `LM_STUDIO`, `GPT4ALL`.

Property Name	System Property	Environment Variable	Default Value	Description
Model	payara.ai.model	PAYARA_AI_MODEL	`gpt-4o-mini`	The AI model to be used (e.g., `gpt-4`, `claude-3-opus`, etc.).
Temperature	payara.ai.temperature	PAYARA_AI_TEMPERATURE	*none*	Controls the randomness of AI responses. Range: 0.0 (deterministic) to 1.0 (creative).
Top-P	payara.ai.top.p	PAYARA_AI_TOP_P	*none*	Controls diversity via nucleus sampling. An alternative to temperature.
Stream	payara.ai.stream	PAYARA_AI_STREAM	*none*	Enable streaming responses if supported by the provider.
Timeout	payara.ai.timeout	PAYARA_AI_TIMEOUT	*none*	Timeout in milliseconds for requests made to the AI provider.
Log Requests	payara.ai.log.requests	PAYARA_AI_LOG_REQUESTS	*none*	Log outgoing AI requests.
Log Responses	payara.ai.log.responses	PAYARA_AI_LOG_RESPONSES	*none*	Log incoming AI responses.
Repeat Penalty	payara.ai.repeatPenalty	PAYARA_AI_REPEAT_PENALTY	*none*	Controls penalty for repeated tokens in generated content.
Organization ID	payara.ai.organizationId	PAYARA_AI_ORGANIZATION_ID	*none*	AI provider organization ID, if required (e.g., OpenAI).
Top-K	payara.ai.topK	PAYARA_AI_TOP_K	*none*	Limit the next token sampling to the top-K most likely tokens.
Max Tokens	payara.ai.maxTokens	PAYARA_AI_MAX_TOKENS	*none*	Maximum number of tokens for a request.
Max Completion Tokens	payara.ai.maxCompletionTokens	PAYARA_AI_MAX_COMPLETION_TOKENS	*none*	Maximum number of tokens to generate in a completion.
Max Output Tokens	payara.ai.maxOutputTokens	PAYARA_AI_MAX_OUTPUT_TOKENS	*none*	Maximum number of tokens expected in AI response.
Presence Penalty	payara.ai.presencePenalty	PAYARA_AI_PRESENCE_PENALTY	*none*	Penalty for including new topics in completions.
Frequency Penalty	payara.ai.frequencyPenalty	PAYARA_AI_FREQUENCY_PENALTY	*none*	Penalty for repeating existing words/tokens in the input.

Property Name	System Property	Environment Variable	Default Value	Description
Custom Headers	payara.ai.customHeaders	PAYARA_AI_CUSTOM_HEADERS	*none*	Comma-separated custom headers to include in requests.
Seed	payara.ai.seed	PAYARA_AI_SEED	*none*	Seed value for deterministic output from the AI provider.
Allow Code Execution	payara.ai.allowCodeExecution	PAYARA_AI_ALLOW_CODE_EXECUTION	*none*	Allow executing code snippets in the AI responses.
Include Code Execution Output	payara.ai.includeCodeExecutionOutput	PAYARA_AI_INCLUDE_CODE_EXECUTION_OUTPUT	*none*	Include the result of code execution in AI output.
Max Retries	payara.ai.maxRetries	PAYARA_AI_MAX_RETRIES	*none*	Maximum number of retries on failure when querying the AI provider.
Chat History	payara.ai.chat.history	PAYARA_AI_CHAT_HISTORY	false	Enable context history in chat-based AI requests.
Chat History Limit	payara.ai.chat.history.limit	PAYARA_AI_CHAT_HISTORY_LIMIT	3	Number of previous interactions retained in chat history.

Usage Context

The AI Agent operates best during development, local testing, or in isolated environments. It is **not recommended for use in production** due to its access to sensitive runtime data and its experimental nature. By integrating AI-driven insights into the Payara tooling, the AI Agent aims to streamline operations, accelerate diagnostics, and boost developer productivity.

As this is an experimental feature, usage and API compatibility may change in future versions.

Payara Micro Maven Plugin

Payara Micro has a Maven plugin which can start and stop Payara Micro and create an Uber JAR bundle of the application and Payara Micro.

The plugin requires JDK 8 or higher and the latest version is currently `1.4.0`

Configurable Goals

`bundle`

Aim: This goal bundles the attached project's artifact into an Uber JAR with the specified configurations. By default, this goal is attached to the install phase. **Usage**: `mvn payara-micro:bundle`

Example:

```
<plugin>
    <groupId>fish.payara.maven.plugins</groupId>
    <artifactId>payara-micro-maven-plugin</artifactId>
    <version>${payara.micro.maven.plugin.version}</version>
    <executions>
        <execution>
            <goals>
                <goal>bundle</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <startClass>my.custom.start.class.Main</startClass>
        <deployArtifacts>
            <artifactItem>
                <groupId>org.mycompany</groupId>
                <artifactId>my-project</artifactId>
                <version>1.0</version>
                <type>ear</type>
            </artifactItem>
        </deployArtifacts>
        <customJars>
            <artifactItem>
                <groupId>org.primefaces</groupId>
                <artifactId>primefaces</artifactId>
                <version>6.0</version>
            </artifactItem>
        </customJars>
    </configuration>
</plugin>
```

Table 203. Configuration tags

Element	System Property	Environment Variable	Default	Notes
`autoDeployArtifact`	payara.auto.deploy.artifact	PAYARA_AUTO_DEPLOY_ARTIFACT	true	If the extension of the produced artifact is `WAR`, it will be copied automatically to the `MICRO-INF/deploy` directory when this property is set to `true`.
`autoDeployContextRoot`	payara.auto.deploy.context.root	PAYARA_AUTO_DEPLOY_CONTEXT_ROOT	*none*	Sets context root of the deployed artifact if `autoDeployArtifact` is `true`. `autoDeployContextRoot` has the higher precedence compared to the `autoDeployEmptyContextRoot`.

Element	System Property	Environment Variable	Default	Notes
`autoDeployEmptyContextRoot`	payara.auto.deploy.empty.context.root	PAYARA_AUTO_DEPLOY_EMPTY_CONTEXT_ROOT	`true`	Sets context root of the deployed artifact to `/` if `autoDeployArtifact` is `true`. If set to false, context root is derived from `project.build.finalName`. If `autoDeployContextRoot` is specified, `autoDeployEmptyContextRoot` will be ignored.
`startClass`	payara.start.class	PAYARA_START_CLASS	(optional):	Replaces the `Start-Class` definition that resides in the `MANIFEST.MF` file with the provided class.
`appendSystemProperties`	payara.append.system.properties	PAYARA_APPEND_SYSTEM_PROPERTIES	`true`	Appends all system properties defined into the `payara-boot.properties` file.
`payaraMicroVersion`	payara.micro.version	PAYARA_MICRO_VERSION	`main-7`	By default, bundle mojo fetches Payara Micro with version main-7. Note: `payaraVersion` is deprecated and has been replaced by `payaraMicroVersion` to stay in sync with the Payara Server Maven Plugin.
`deployArtifacts`			*None*	Can contain a list of artifactItems, which defines the dependencies with their GAVs to be copied under MICRO-INF/deploy folder.
`customJars`			*None*	Can contain a list of artifactItems, which defines the dependencies with their GAVs to be copied under MICRO-INF/lib folder.
`uberJarClassifier`	payara.uber.jar.classifier	PAYARA_UBER_JAR_CLASSIFIER	`microbundle`	Specifies the maven artifact classifier to use for the generated uber-jar.

The `bundle` goal always searches for domain configuration files in `src/main/resources` to copy in to the `MICRO-INF/domain` directory of the Uber jar. The files which are currently included are:

- `domain.xml`

- `hazelcast-config.xml`
- `keystore.jks`
- `login.conf`
- `logging.properties`
- `metrics.xml`

Additionally, boot command scripts will be included if they exist in `src/main/resources` and transferred to the `MICRO-INF` directory of the Uber jar artifact.

`pre-boot-commands.txt`

Provides a file of asadmin commands to run before booting the server.

`post-boot-commands.txt`

Provides a file of asadmin commands to run after booting the server.

`post-deploy-commands.txt`

Provides a file of asadmin commands to run after all deployments have completed.

`start`

Aim: This goal starts Payara Micro with the specified configuration. **Usage**: `mvn payara-micro:start`

Example:

```
<plugin>
    <groupId>fish.payara.maven.plugins</groupId>
    <artifactId>payara-micro-maven-plugin</artifactId>
    <version>${payara.micro.maven.plugin.version}</version>
    <executions>
        <execution>
            <goals>
                <goal>start</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <useUberJar>true</useUberJar>
        <payaraMicroAbsolutePath>/path/to/payara-micro.jar</payaraMicroAbsolutePath>
        <payaraVersion>{page-version}</payaraVersion>
        <artifactItem>
            <groupId>fish.payara.extras</groupId>
            <artifactId>payara-micro</artifactId>
            <version>{page-version}</version>
        </artifactItem>
        <daemon>true</daemon>
        <javaPath>/path/to/Java/Executable</javaPath>
        <deployWar>true</deployWar>
        <contextRoot>myApp</contextRoot>
        <javaCommandLineOptions>
```

```
            <option>
                <value>-Xdebug</value>
            </option>
            <option>
                <key>-Xrunjdwp:transport</key>
                <value>dt_socket,server=y,suspend=y,address=5005</value>
            </option>
        </javaCommandLineOptions>
        <commandLineOptions>
            <option>
                <key>--domainconfig</key>
                <value>/path/to/domain.xml</value>
            </option>
            <option>
                <key>--autoBindHttp</key>
                <value>true</value>
            </option>
        </commandLineOptions>
    </configuration>
</plugin>
```

If you want to execute the payara-micro plugin along with maven-toolchains-plugin, you need to execute the plugin as: `mvn toolchains:toolchain payara-micro:start`. See [Technical Documentation-Ecosystem-Project Management Tools-Maven Plugin-Payara Micro Maven Plugin:::using-toolchains] for more information.

Table 204. Configuration tags

Element	System Property	Environment Variable	Default	Notes
`useUberJar`	payara.use.uber.jar	PAYARA_USE_UBER_JAR	false	Use the created uber-jar that resides in the target folder. The name of the JAR artifact will be resolved automatically by evaluating its final name, artifact ID and version. This configuration element has the higher precedence compared to `payaraMicroAbsolutePath`, `payaraVersion` and `artifactItem`.
`uberJarClassifier`	payara.uber.jar.classifier	PAYARA_UBER_JAR_CLASSIFIER	`microbundle`	Specifies the maven artifact classifier to use for the Uber JAR.

Element	System Property	Environment Variable	Default	Notes
`payaraMicroPath`	payara.micro.path	PAYARA_MICRO_PATH	*none*	Absolute path to the Payara Micro executable. Note: Parameter `payaraMicroAbsolutePath` is deprecated and has been replaced by `payaraMicroPath` to stay in sync with the Payara Server Maven Plugin.
`payaraMicroVersion`	payara.micro.version	PAYARA_MICRO_VERSION	`main-7`	By default, bundle mojo fetches Payara Micro with version main-7. Note: `payaraVersion` is deprecated and has been replaced by `payaraMicroVersion` to stay in sync with the Payara Server Maven Plugin.
`artifactItem`			*none*	Defines payara-micro artifact with its coordinates. Specified artifact should be available in local maven repository.
`daemon`	payara.daemon	PAYARA_DAEMON	false	Starts Payara Micro in separate JVM process and continues with the maven build.
`immediateExit`	payara.immediate.exit	PAYARA_IMMEDIATE_EXIT	false	If Payara Micro is executed in daemon mode, the executor thread will wait for the ready message before shutting down its process. By setting `immediateExit` to `true` you can skip this and instantly interrupt the executor thread.

Element	System Property	Environment Variable	Default	Notes
`javaHome`	payara.java.home	PAYARA_JAVA_HOME	`java`	Absolute path to the java executable. This has higher priority to the java executable identified via the Maven toolchain. Note: Parameter `javaPath` is deprecated and has been replaced by `javaHome` to stay in sync with the Payara Server Maven Plugin.
`deployWar`	payara.deploy.war	PAYARA_DEPLOY_WAR	false	If the attached project is of type WAR, it will automatically be deployed if `deployWar` is set to `true`.
`contextRoot`	payara.context.root	PAYARA_CONTEXT_ROOT	*none*	Defines the context root of an application.
`javaCommandLineOptions`			*none*	Defines a list of command line options that will be passed to `java` executable. Command line options can either be defined as key-value pairs or just as list of values. key-value pairs will be formatted as `key=value`.
`commandLineOptions`			*none*	Defines a list of command line options that will be passed onto payara-micro.
`hotDeploy`	payara.hot.deploy	PAYARA_HOT_DEPLOY	false	Enables the Hot Deploy mode.
`autoDeploy`	payara.auto.deploy	PAYARA_AUTO_DEPLOY	false	Enables automatic compilation and deployment upon saving files.
`liveReload`	payara.live.reload	PAYARA_LIVE_RELOAD	false	Triggers a browser refresh for an up-to-date view after each redeployment.
`browser`	payara.browser	PAYARA_BROWSER	none	Specifies the browser for live reload. Adapted based on the system if not specified.
`keepState`	payara.keep.state	PAYARA_KEEP_STATE	false	Persists session state across multiple redeployments.

Element	System Property	Environment Variable	Default	Notes
trimLog	payara.trim.log	PAYARA_TRIM_LOG	false	Refactors log format for improved readability.

`stop`

Aim: This goal stops Payara Micro with the specified configuration. By default, this goal tries to find the currently executing Payara Micro instance by checking the running JAR.

If an `artifactItem` is defined, it will take precedence for identifying currently running instances. If `processId` is defined, this takes the highest precedence and the given `processId` will immediately kill the executing Payara Micro instance.

Usage: `mvn payara-micro:stop`

Example:

```
<plugin>
    <groupId>fish.payara.maven.plugins</groupId>
    <artifactId>payara-micro-maven-plugin</artifactId>
    <version>${payara.micro.maven.plugin.version}</version>
    <executions>
        <execution>
            <goals>
                <goal>stop</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <processId>32333</processId>
        <artifactItem>
            <groupId>fish.payara.extras</groupId>
            <artifactId>payara-micro</artifactId>
            <version>{page-version}</version>
        </artifactItem>
    </configuration>
</plugin>
```

If you want to execute the payara-micro plugin along with maven-toolchains-plugin, you need to execute the plugin as: `mvn toolchains:toolchain payara-micro:start`. See [Technical Documentation-Ecosystem-Project Management Tools-Maven Plugin-Payara Micro Maven Plugin:::using-toolchains] for more information.

Table 205. Configuration tags

Element	System Property	Environment Variable	Default	Notes
`processId`	payara.process.id	PAYARA_PROCESS_ID	*none*	Process id of the running Payara Micro instance.
`artifactItem`			*none*	Defines payara-micro artifact with its coordinates. This information is used to identify the process id of the running Payara Micro instance.
`useUberJar`	payara.use.uber.jar	PAYARA_USE_UBER_JAR	`false`	Use the name of the created uber-jar that resides in target folder to identify the process id of the running Payara Micro instance.
`uberJarClassifier`	payara.uber.jar.classifier	PAYARA_UBER_JAR_CLASSIFIER	`microbundle`	Specifies the maven artifact classifier of the generated uber-jar to identify the process id of the running Payara Micro instance.
`maxStopTimeoutMillis`	payara.max.stop.timeout.millis	PAYARA_MAX_STOP_TIMEOUT_MILLIS	5000	Defines the maximum timeout in milliseconds to wait for the process of Payara Micro instance to stop.

`reload`

Aim: This goal reloads the Payara Micro application with the specified configuration. By default, this goal performs the vanilla deployment of the application without restarting the Payara Micro instance.

If `hotDeploy` is set to true then the Hot Deploy functionality will be enabled.

Usage: `mvn payara-micro:reload`

This goal is specifically designed for integration with the IDEs and Editors. Payara Micro instance allows IDEs to deploy the application in Hot Deploy mode by reusing the existing application instance and updating its classloader and internal components relative to the modified source.
This can lead to significant savings of time when an application is redeployed and boost developer productivity even more.

Table 206. Configuration tags

Element	System Property	Environment Variable
Default	Notes	`hotDeploy`
payara.hot.deploy	PAYARA_HOT_DEPLOY	false
Enables the Hot Deploy mode.	`sourcesChanged`	payara.sources.changed
PAYARA_SOURCES_CHANGED	*none*	Defines a list (comma separated) of the absolute paths to the source file which need to be reloaded via the Hot Deploy feature.
`metadataChanged`	payara.metadata.changed	PAYARA_METADATA_CHANGED
false	If set to true, reloads deployment descriptors metadata in Hot Deploy mode	`keepState`
payara.keep.state	PAYARA_KEEP_STATE	false

`dev`

Aim: The dev goal is designed to streamline development by enabling `deployWar`, `exploded`, `autoDeploy`, `liveReload`, `keepState`, and `trimLog` to true, which facilitating auto compilation and deployment on saving files resulting in rapid compilation, and deployment for an efficient development workflow.

Usage:

```
mvn payara-micro:dev
```

The `dev` goal is an extended goal of `start` and is pre-configured for developing web applications in development mode which is equivalent to starting the Payara Micro instance using the following command:

```
mvn payara-micro:start -DautoDeploy=true -DliveReload=true -DdeployWar=true
-Dexploded=true -DkeepState -DtrimLog=true
```

Features in Dev Mode:

1. **Auto Deploy**: The AutoDeploy feature enables automatic compilation and deployment of the application upon saving files within the project structure. Enabled by setting `autoDeploy=true`.

   The AutoDeploy feature relies on Java's WatchService to monitor changes in source directories, enabling continuous build and reload using Maven's Invoker. It dynamically modifies Maven goals based on file modifications, supports asynchronous execution for concurrent build tasks, and includes specifics for tracking changes in source, resources, and test directories.

   The AutoDeploy feature has a limitation and is not supported for `pom.xml`, `pre-boot-commands.txt`, `post-boot-commands.txt`, or `post-deploy-commands.txt`.

2. **Restart on modifying boot command scripts**: The restart functionality in `dev` mode enables a seamless instance restart upon modifications to the boot command scripts `pre-boot-commands.txt`, `post-boot-commands.txt`, or `post-deploy-commands.txt`, offering a quick server restart option for improved development efficiency.

   Modifying the `pom.xml` is not supported in this context, as limitations may arise when restarting with a modified `pom.xml`, potentially conflicting with previously passed properties via the command line.

3. **Live Reload**: The LiveReload feature automatically refreshes the browser upon redeployment.
   - `liveReload` Property: Enables or disables automatic browser refresh on redeployment. The `liveReload` property is set to `true` by default in the `dev` goal and `false` in the `start` goal.
   - `browser` Property: The `browser` property offers seamless configuration. If not specified, the system prioritizes Chrome and Firefox, gracefully falling back to Edge for Windows, Safari for macOS, or Firefox for other platforms. This improvement simplifies setup - no need to worry about specifying a browser; it adapts based on your system.
   - Cached Last Accessed URL: The last accessed Payara Micro URL is stored in the `payara-maven-config.properties` file within the system's temporary directory. This ensures accessibility across application restarts, eliminating the need for users to manually navigate to the last accessed URL. This streamlined approach enhances the overall user experience by maintaining continuity and reducing manual intervention after each restart.
4. **Persistent Session State**: The `keepState` property allows for the persistence of session state across multiple re-deployments during the development process. Enabled by default in the `dev` goal and disabled in the `start` goal.
5. **Readable Logging**: The `trimLog` property refactors the log format for improved readability. Enabled by default in the `dev` goal and disabled in the `start` goal.

   All listed features are enabled by default in the `dev` mode.

Using Toolchains

The Maven Toolchains provide a way for plugins to discover what JDK (or other tools) are to be used during the build and Payara Micro Maven Plugin also supports using toolchains with its configuration.

In order to use the toolchains with either `payara-micro:start` or `payara-micro:stop`, first toolchains plugin should be defined as:

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-toolchains-plugin</artifactId>
    <version>1.1</version>
    <executions>
        <execution>
            <goals>
                <goal>toolchain</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <toolchains>
            <jdk>
                <version>1.8</version>
                <vendor>oracle</vendor>
            </jdk>
        </toolchains>
    </configuration>
</plugin>
```

`toolchains.xml` is the file for configuring each toolchain, and it should reside under the `.m2` folder. A sample would be as:

```
<?xml version="1.0" encoding="UTF8"?>
<toolchains>
    <toolchain>
        <type>jdk</type>
        <provides>
            <version>1.7</version>
            <vendor>oracle</vendor>
        </provides>
        <configuration>

<jdkHome>/Library/Java/JavaVirtualMachines/jdk1.7.0_80.jdk/Contents/Home</jdkHome>
        </configuration>
    </toolchain>
    <toolchain>
        <type>jdk</type>
        <provides>
```

```
            <version>1.8</version>
            <vendor>oracle</vendor>
        </provides>
        <configuration>

<jdkHome>/Library/Java/JavaVirtualMachines/jdk1.8.0_131.jdk/Contents/Home</jdkHome>
        </configuration>
    </toolchain>
</toolchains>
```

The version and the vendor defined in the plugins section should match one of the entries defined in the toolchains.xml file. After configuring the toolchain, the plugin can be executed with `start` and `stop` goals as:

```
mvn toolchains:toolchain payara-micro:start
mvn toolchains:toolchain payara-micro:stop
```

Maven Archetype

Payara Micro has a Maven archetype which can create a sample Payara Micro application quickly.

Create a project

To generate a new project from the archetype, run the following command :

```
$ mvn archetype:generate -DarchetypeGroupId=fish.payara.maven.archetypes
-DarchetypeArtifactId=payara-micro-maven-archetype -DarchetypeVersion=1.0.1
-DgroupId=fish.payara.micro -DartifactId=micro-sample -Dversion=1.0-SNAPSHOT
-Dpackage=fish.payara.micro.sample -Darchetype.interactive=false
```

Maven will ask for the project detail confirmation. Press enter or press Y.

```
Confirm properties configuration:
groupId: fish.payara.micro
artifactId: micro-sample
version: 1.0-SNAPSHOT
package: fish.payara.micro.sample
autoBindHttp: true
javaeeVersion: 8.0
payaraMicroVersion: 5.182
 Y: :
```

Now Maven will start creating the project structure and will display the following :

```
[INFO] ----------------------------------------------------------------------------
[INFO] Using following parameters for creating project from Archetype: payara-micro-
```

```
maven-archetype:1.0.1
[INFO] ----------------------------------------------------------------------------
[INFO] Parameter: groupId, Value: fish.payara.micro
[INFO] Parameter: artifactId, Value: micro-sample
[INFO] Parameter: version, Value: 1.0-SNAPSHOT
[INFO] Parameter: package, Value: fish.payara.micro.sample
[INFO] Parameter: packageInPathFormat, Value: fish/payara/micro/sample
[INFO] Parameter: payaraMicroVersion, Value: 5.182
[INFO] Parameter: package, Value: fish.payara.micro.sample
[INFO] Parameter: version, Value: 1.0-SNAPSHOT
[INFO] Parameter: javaeeVersion, Value: 8.0
[INFO] Parameter: groupId, Value: fish.payara.micro
[INFO] Parameter: artifactId, Value: micro-sample
[INFO] Parameter: autoBindHttp, Value: true
[INFO] Project created from Archetype in dir: D:\micro-sample
[INFO] ------------------------------------------------------------------------
[INFO] BUILD SUCCESS
[INFO] ------------------------------------------------------------------------
[INFO] Total time: 9.067 s
[INFO] Final Memory: 15M/196M
[INFO] ------------------------------------------------------------------------
```

Run the project

```
$ mvn package payara-micro:start
```

Gradle Plugin

Payara Micro has a Gradle plugin which can start and stop Payara Micro and create an Uber JAR bundle of the application and Payara Micro .

The plugin requires JDK 8 or higher and the latest plugin version is currently `1.1.0`

Installation

To use it, simply add the following script to your `build.gradle`:

```
plugins {
  id "fish.payara.micro-gradle-plugin" version "1.1.0"
}
```

Configuration Example

```
payaraMicro {
    payaraVersion = 'main-7'
    deployWar = false
    useUberJar = true
```

```
    daemon = false
    commandLineOptions = [port: 2468]
    javaCommandLineOptions = [Dtest: 'test123', ea:true]
}
```

Plugin Tasks

`microBundle`

Aim: This task bundles the attached project's artifact into an Uber JAR with the specified configurations. **Usage**: `gradle microBundle`

Table 207. Configuration tags

Element	Default	Notes
`javaPath`	java	Absolute path to the java executable
`payaraVersion`	main-7	By default `microBundle` task fetches payara-micro with version main-7

`microStart`

Aim: This task starts Payara Micro with the specified configuration. **Usage**: `gradle microStart`

Table 208. Configuration tags

Element	Default	Notes
`useUberJar`	false	Use created uber-jar that resides in target folder. The name of the JAR artifact will be resolved automatically by evaluating its final name, artifact ID and version. This configuration element has the higher precedence compared to `payaraMicroAbsolutePath` and `payaraVersion`.
`payaraMicroAbsolutePath`	*none*	Absolute path to payara-micro executable.
`payaraVersion`	main-7	By default `microStart` task fetches Payara Micro with version main-7.
`daemon`	false	Starts Payara Micro in separate JVM process and continues with the Gradle build.
`immediateExit`	false	If Payara Micro is executed in daemon mode, the executor thread will wait for the ready message before shutting down its process. By setting `immediateExit` to `true` you can skip this and instantly interrupt the executor thread.
`javaPath`	`java`	Absolute path to the java executable.
`deployWar`	false	If the attached project is of type WAR, it will automatically be deployed to Payara Micro if `deployWar` is set to `true`.
`javaCommandLineOptions`	*none*	Defines a list of command line options that will be passed to `java` executable. Command line options can either be defined as key-value pairs or just as list of values. key-value pairs will be formatted as `key=value`.

Element	Default	Notes
`commandLineOptions`	*none*	Defines a list of command line options that will be passed onto Payara Micro.
`hotDeploy`	false	Enables the hot reload mode.

`microStop`

Aim: This task stops Payara Micro with the specified configuration. By default this task tries to find out currently executing Payara Micro instance based on project GAV. If `processId` is defined, it will take precedence and the given `processId` will immediately kill the executing Payara Micro instance. **Usage**: `gradle microStop`

Table 209. Configuration tags

Element	Default	Notes
`processId`	*none*	Process id of the running Payara Micro instance.
`useUberJar`	false	Use created uber-jar that resides in build\libs folder. The name of the jar artifact will be resolved automatically by evaluating its final name.

`microReload`

Aim: This task reloads the Payara Micro application with the specified configuration. By default, this task performs the vanilla deployment of the application without restarting the Payara Micro instance. If `hotDeploy` is set to true then the Hot Reload functionality will be enabled. **Usage**: `gradle microReload`

This task is specifically designed for integration with the IDEs and Editors. Payara Micro instance allows IDEs to deploy the application in Hot Deploy mode by reusing the existing application instance and updating its classloader and internal components relative to the modified source. This can lead to significant savings of time when an application is redeployed and boost developer productivity even more.

Table 210. Configuration tags

Element	Default	Notes
`hotDeploy`	false	Enables the hot reload mode.
`sourcesChanged`	*none*	Defines a list(comma separated) of the absolute paths to the source file which need to be reloaded via the Hot Reload feature.
`metadataChanged`	false	If set to true, reloads deployment descriptors metadata in hot deploy mode

Maven Regex Profile Activation

The Maven Regex Profile Activation extension allows activating profiles by checking that a property matches a given regular expression, rather than an exact value.

Usage

The Regex Profile Activator Maven Extension can be found on Maven Central and can be included in your project using the following Maven coordinates:

```
<dependency>
    <groupId>fish.payara.maven.extensions</groupId>
    <artifactId>regex-profile-activator</artifactId>
    <version>${version}</version>
</dependency>
```

You can find the latest artifact version from here.

Example

This extension is now active in your build, and you can activate profiles using a regex string beginning and ending with a `/`.

Example usage of Maven Regex Profile Activation in a `pom.xml` file

```
<profile>
    <id>test-profile</id>
    <activation>
        <property>
            <name>myproperty</name>
            <value>/abra.+/</value>
        </property>
    </activation>
</profile>
```

The profile above will be active when built with `-Dmyproperty=abracadabra`, or anything else is matching the regex.

In order to release the artifact you will need to sign the source, javadoc and artifact JARs. To do this, build the project with the `sign` profile:

```
mvn install -Dsign
```

Payara Starter

Introduction

Payara Starter is a web application and command line tool designed to accelerate Jakarta EE development by simplifying the creation of new application projects. It supports the creation of

both Maven and Gradle projects, allowing developers to focus on coding their application components in a faster way as they don't have to deal with the complexities of setting up their projects.

- Website
- GitHub Repository
- Maven Central Repository for Payara Starter Archetype

Key Features of Payara Starter

- Build System Flexibility: Supports Maven and Gradle as Project Management tools for seamless integration with preferred build systems.
- Customizable Project Details: Define crucial project specifics upfront, aligning with organizational naming conventions.
- Java and Jakarta EE Version Control: Allows the selection of specific versions to ensure compatibility and leverage the latest features.
- MicroProfile Integration: Includes options to integrate MicroProfile APIs for building resilient, scalable services.
- Payara Platform Compatibility: Effortlessly works with the Payara Platform, ensuring readiness for deployment.
- Docker Support: Facilitates Docker compatibility, streamlining containerization for agile deployment.
- Unit Test Templates: Optionally includes test templates, encouraging best testing practices from project initiation.
- Advanced Security Configuration: Optional advanced security setup for robust authentication via Jakarta Security, facilitating secure application development from the start.

Supported Jakarta EE Profiles

Payara Starter supports various Jakarta EE profiles:

- Platform: `jakarta.platform:jakarta.jakartaee-api`
- Web Profile: `jakarta.platform:jakarta.jakartaee-web-api`
- Core Profile: `jakarta.platform:jakarta.jakartaee-core-api`

Generating a New App using Payara Starter

You can generate a new application using Payara Starter in two ways:

Command Line Using Archetype

To generate a new application using the Payara Starter archetype from the command line, use the following Maven command:

```
mvn archetype:generate -DarchetypeGroupId=fish.payara.starter
```

```
-DarchetypeArtifactId=payara-starter-archetype -DarchetypeVersion=1.0-beta4 <other
options>
```

This command generates a new application based on specified options. Adjust properties according to your project requirements.

Payara Starter Archetype Parameter

The Payara Starter Archetype has a robust set of parameters that allows the customization of various aspects during the application generation process. Below is a table detailing each parameter, its default value, and additional notes:

Element	Default Value	Notes
`build`	`maven`	Specifies the preferred build system for the project. Options include: `maven`, `gradle`.
`groupId`	`fish.payara`	Specifies the Group ID for the generated project.
`artifactId`	`hello-world`	Determines the Artifact ID for the generated project.
`version`	`0.1-SNAPSHOT`	Sets the version of the generated project.
`package`	`fish.payara`	Defines the base package name for the project.
`javaVersion`	`21`	Sets the Java version for the project. Available options: • 8 • 11 • 17 • 21 Keep in mind that versions older than `11` are not supported in Payara Platform main-7

Element	Default Value	Notes
`jakartaEEVersion`	`10`	Specifies the targeted Jakarta EE version. Valid options: • 8 • 9 • 9.1 • 10 For compatibility with the Payara Platform main-7, versions older than `10` are not supported.
`profile`	`full`	Specifies the Jakarta EE profile options: 'core', 'web', or 'full'.
`platform`	`server`	Specifies the target distribution where the application will be deployed Options include: • `server` for Payara Server. • `micro` for Payara Micro.
`payaraVersion`	`main-7`	Sets the targeted Payara version. Retrieved from Maven Central.
`addConcurrentApi`	`false`	Includes support for the Concurrent API if `true`.
`addResourceApi`	`false`	Includes support for the Resource API if `true`.
`addJBatchApi`	`false`	Includes support for the JBatch API if `true`.
`addMicroprofileApi`	`true`	Includes support for the MicroProfile API if `true`.
`addJcache`	`false`	Includes support for the JCache if `true`.
`addPayaraApi`	`true`	Includes support for the Payara Public API if `true`.
`deployWar`	`true`	Automatically deploys the WAR file if `true`. Applicable only for Payara Micro deployments.
`autoBindHttp`	`true`	Enables automatic HTTP binding. Applicable only for Payara Micro deployments.

Element	Default Value	Notes
`contextRoot`	`/`	Sets the web context root for the deployed artifact. Applicable only for Payara Micro deployments.
`includeTests`	`false`	Includes a set of generated Unit tests if `true`. Currently limited to Maven projects.
`docker`	`false`	Enables Docker compatibility.
`mpConfig`	`false`	Enables support for the MicroProfile Config API.
`mpOpenAPI`	`false`	Enables support for MicroProfile OpenAPI.
`mpFaultTolerance`	`false`	Enables support for MicroProfile Fault Tolerance.
`mpMetrics`	`false`	Enables support for MicroProfile Metrics.
`auth`	`none`	Specifies the authentication type for the application. Available choices: • `none` • `formAuthFileRealm` • `formAuthDB` • `formAuthLDAP`

Web application at `start.payara.fish`

Visit start.payara.fish to use the web application for generating applications via a graphical interface.

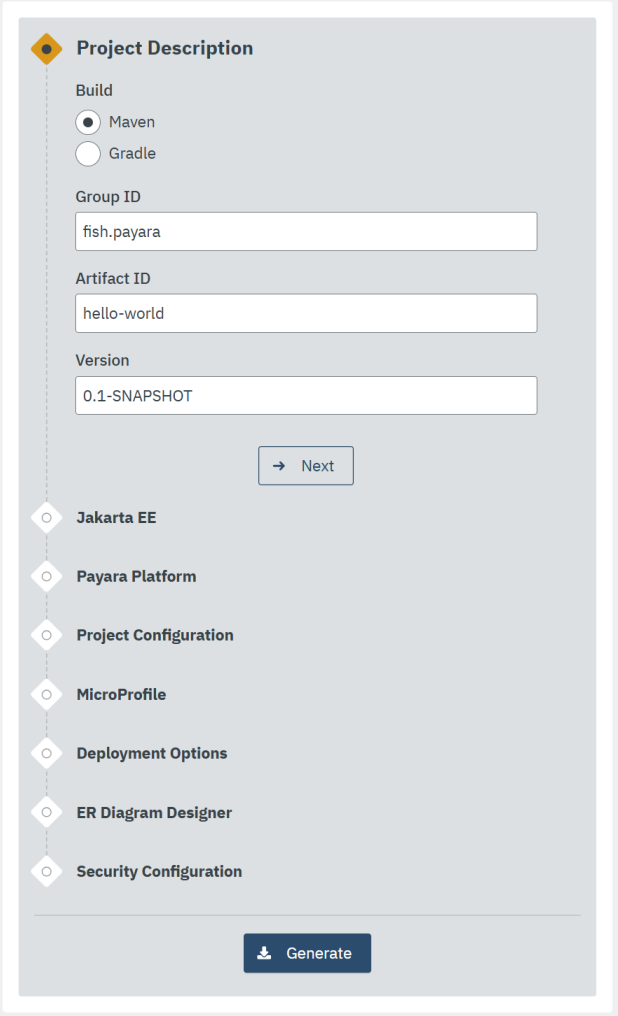
Using the Payara Starter Web Application

Payara Starter provides a convenient web application that allows you to generate Jakarta EE projects via a graphical interface.

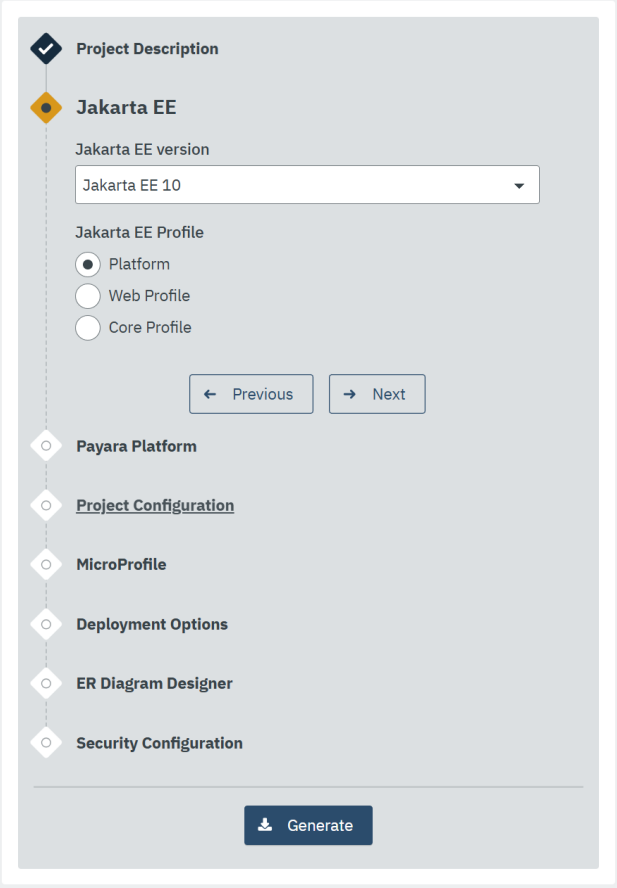
Follow these steps to use the web application:

1. Access the web application:
    - Visit the Payara Starter web application at https://start.payara.fish.
2. Fill in the **Project Details**:
    - On the web application's landing page, you'll find a user-friendly interface to input project details.
    - Enter the required information, such as **Group ID**, **Artifact ID**, and other relevant details.

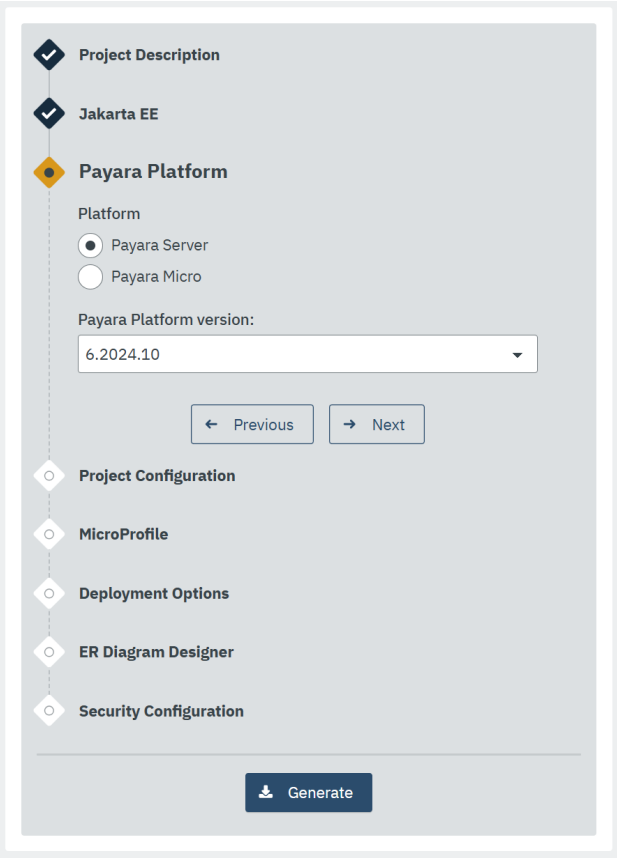
      You can customize these based on your project requirements:



3. Choose the **Build System** and **Jakarta EE Version**:
    - Select your preferred build system (Maven or Gradle) from the provided options.
    - Choose the desired Jakarta EE version that aligns with your project's compatibility requirements.



4. Configure any **Additional Options**:
    - The web application allows you to configure additional options such as MicroProfile integration, Payara Platform version, and more.
    - Customize these options based on your project needs.



5. Review and Generate:
    - Review the summary of your selected options to ensure they match your project requirements.
    - Click the **Generate** button to initiate the project generation process.
6. Download the Generated Project:
    - Once the generation process is complete, the web application triggers the download of the generated project archive.
    - Download the project archive, and you can then proceed to import it into your preferred Integrated Development Environment (IDE).

The web application simplifies the project creation process but may not expose all configuration options available through the command-line archetype generation. If you need better control of how the application is generated, we recommend using the starter archetype instead.

Sample Generated Jakarta REST Resource

Here's an example of a generated Jakarta REST resource using Payara Starter:

```
package fish.payara.hello;

import jakarta.ws.rs.GET;
import jakarta.ws.rs.Path;
import jakarta.ws.rs.QueryParam;
import jakarta.ws.rs.core.Response;

@Path("hello")
public class HelloWorldResource {

    @GET
    public Response hello(@QueryParam("name") String name) {
        if ((name == null) || name.trim().isEmpty()) {
            name = "world";
        }
        return Response.ok(name).build();
    }
}
```

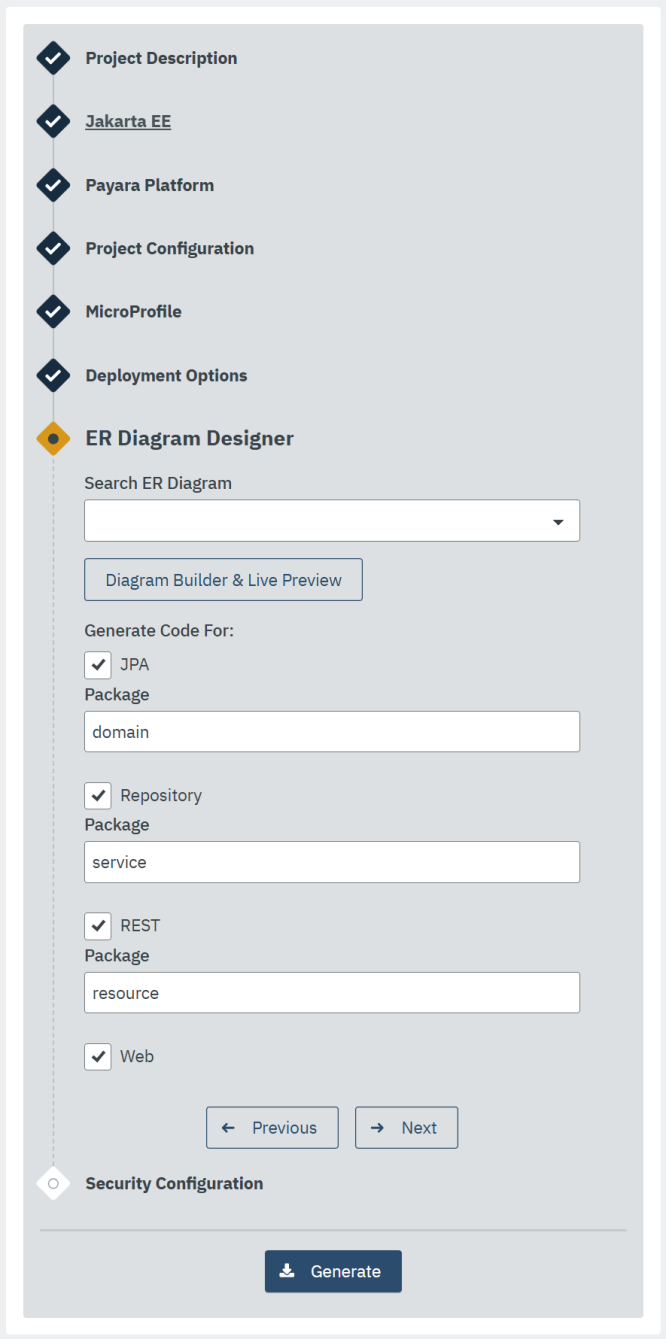
This sample demonstrates a simple REST endpoint named `hello` that accepts a query parameter `name` and responds with a greeting message.

Feel free to adjust archetype parameters to tailor the generated application to your project requirements.

ER Diagram Designer with Generative AI Support

Payara Starter start.payara.fish enables developers to streamline the creation of full-stack

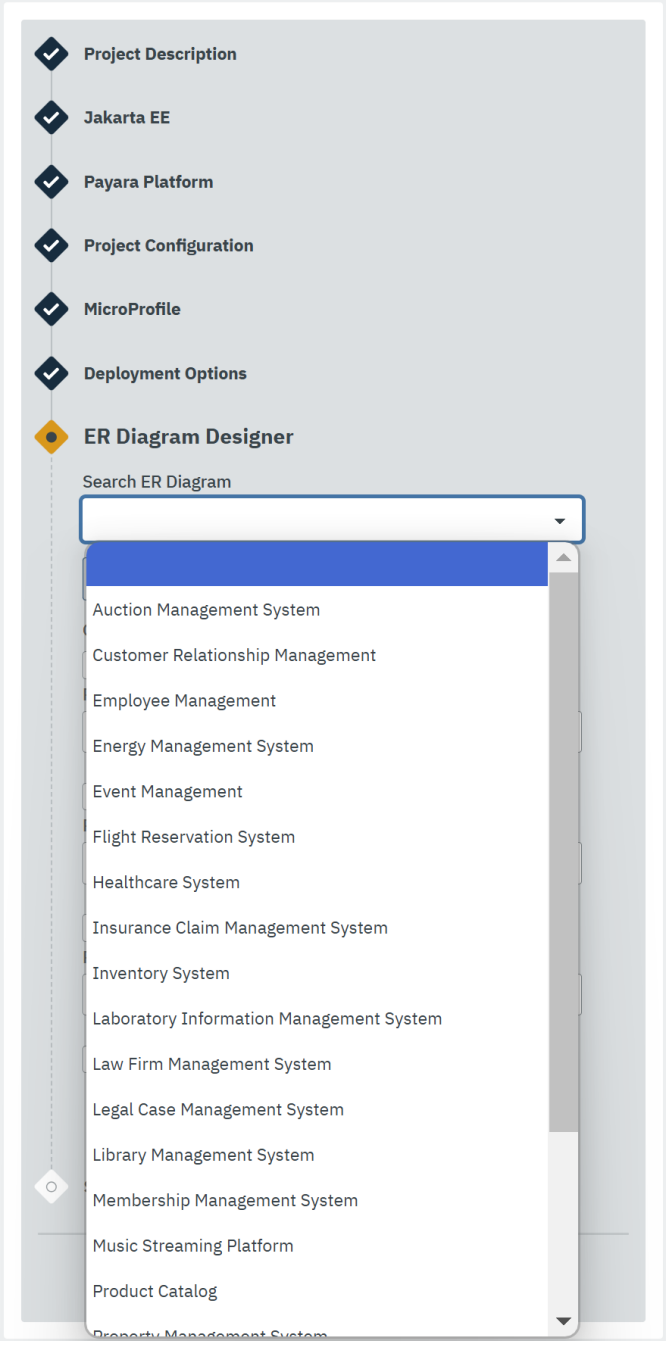
applications by leveraging Entity-Relationship (ER) diagrams. Generative AI enhances this process by automating the generation and customization of diagrams based on inputs and requirements. Developers can visualize, interact, and modify these diagrams in real time, making Payara Starter a more powerful tool for application design and development.



Features of ER Diagram Designer

Default ER Diagrams

The Payara Starter website includes default ER diagrams, stored in Mermaid format, which users can modify as a starting point for their own designs.



Automated ER Diagram Generation

Payara Starter automates ER diagram generation by leveraging Generative AI based on user-provided descriptions. Users can create accurate and well-structured diagrams with minimal effort.

Real-time Diagram Design via Free-text Support

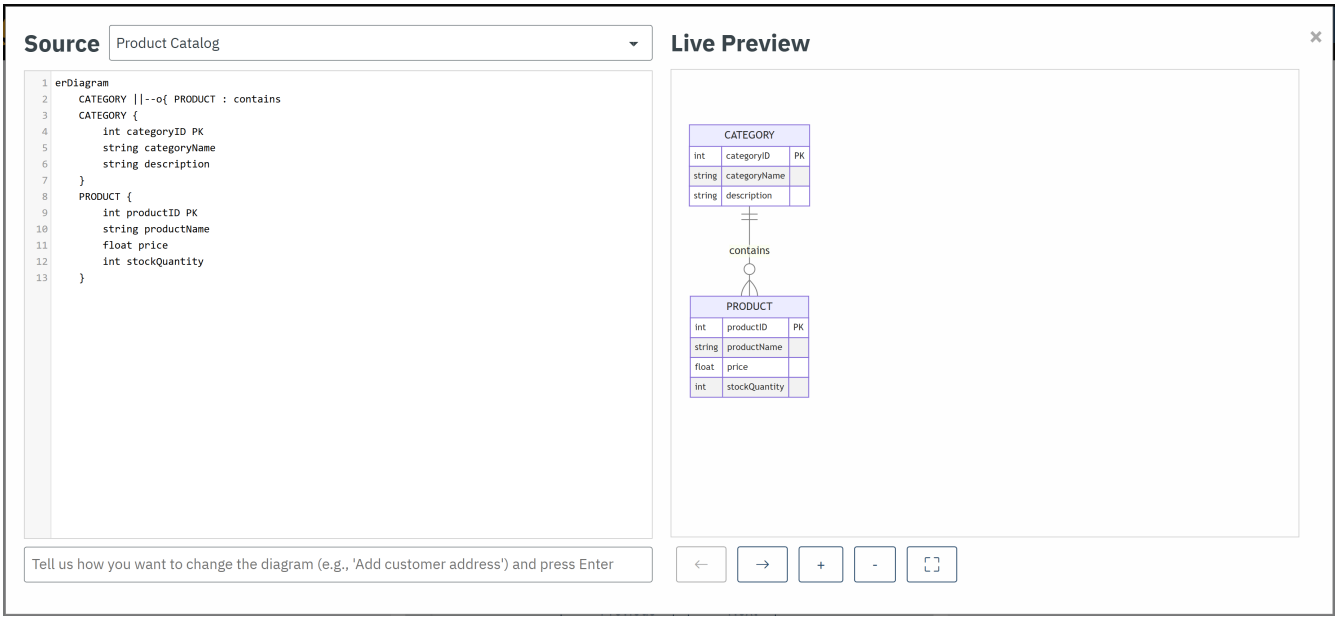
Through **Real-time Diagram Design via Free-text Support**, users can interact with Generative AI to refine and enlarge existing diagrams based on their specific requirements. This feature allows users to quickly modify or create new diagrams using free-form text commands.

Generative AI is a helpful assistant for designing diagrams, but it is not perfect.
Not all instructions will be understood as intended, and some results may differ from user expectations.

Instructions and Examples

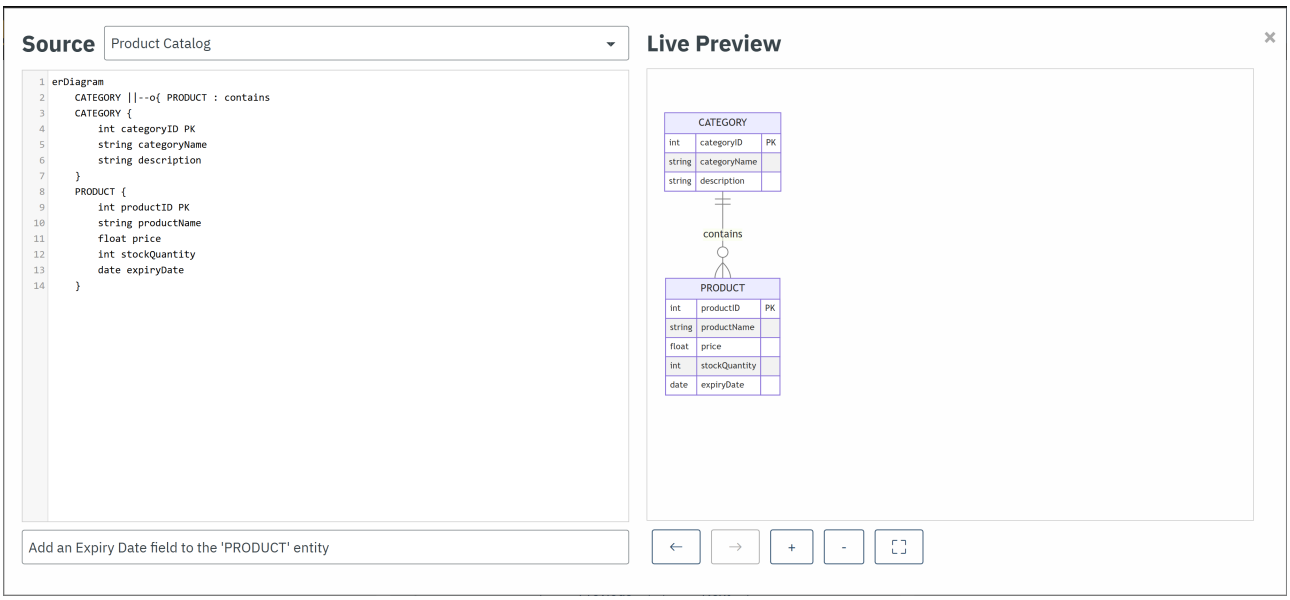
To get the best results, users should provide clear, concise commands. Below are a few sample scenarios to illustrate how users can modify their diagrams.

Starting from this default diagram:



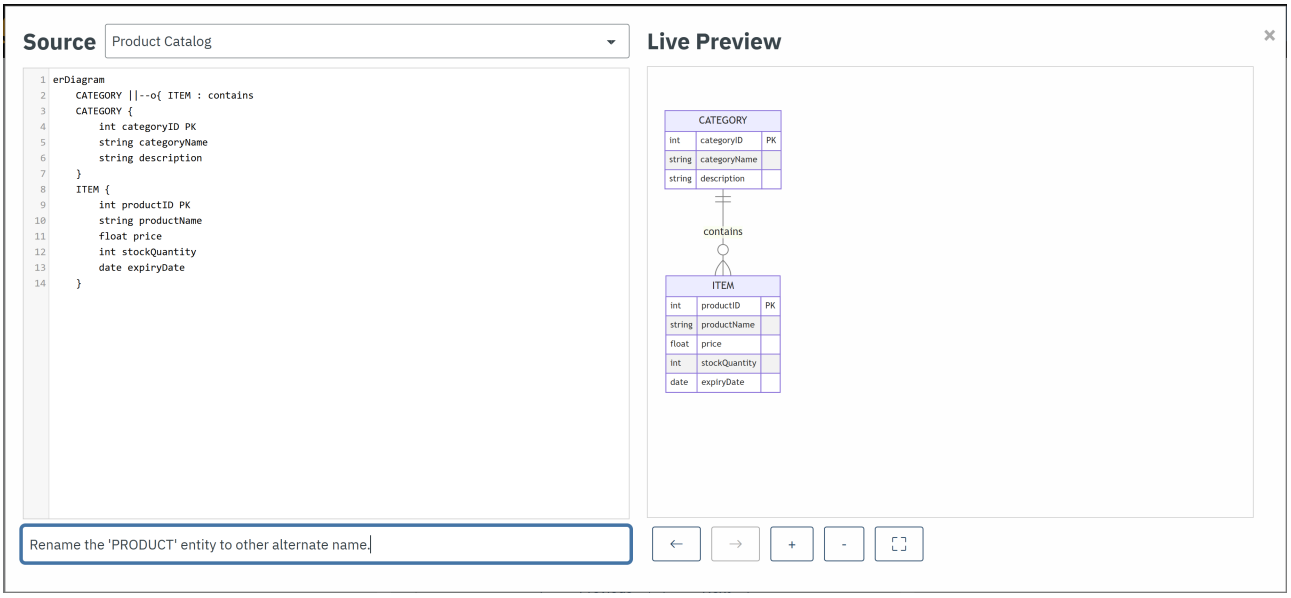
1. **Adding a new Field**: The following command prompts the AI to include a new attribute named `expiryDate` in the existing `PRODUCT` entity.

   Command: *Add an Expiry Date field to the* `PRODUCT` *entity*.



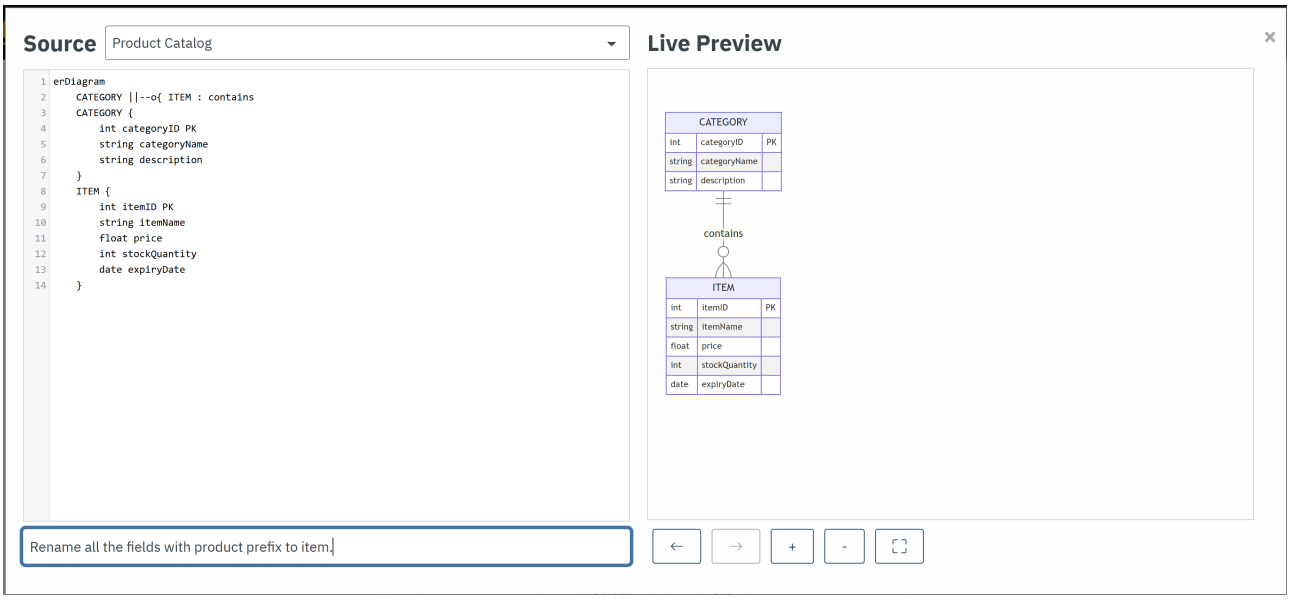
2. **Change an Entity Name**: The following command directs the AI to change the name of the `PRODUCT` entity, allowing for a new designation that may better reflect its purpose or context within the application.

   Command: *Rename the* `PRODUCT` *entity to other alternate name.*



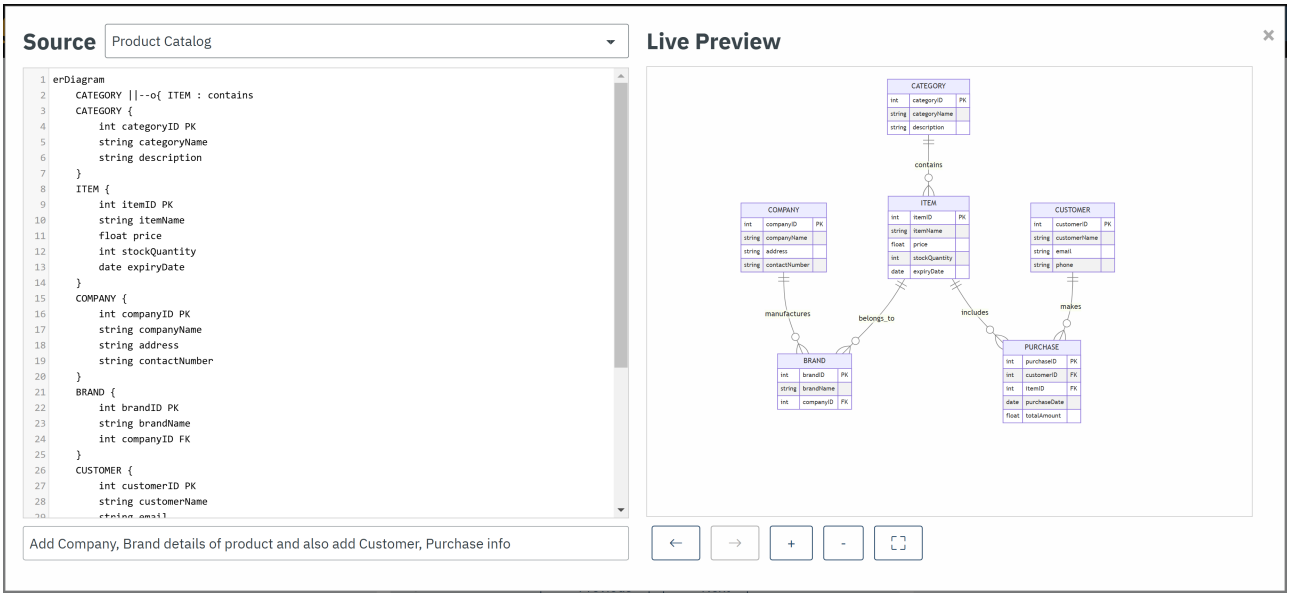
3. **Modify a Field**: The following command results in the AI updating the names of all fields that begin with `product`, replacing that prefix with `item`, thus standardizing or rebranding the fields for consistency.

   Command: *Rename all the fields with* `product` *prefix to `item`.*



4. **Enhance the diagram by adding more entities and relationship**: The following command instructs the AI to enrich the diagram by introducing new entities (`Company`, `Brand`, `Customer`, `Purchase`) and defining relationships between them, thus expanding the data model to cover more aspects of the application domain.

   Command: *Add* `Company`, `Brand` *details of product and also add* `Customer`, `Purchase` *info.*



Users should review and modify the diagram after the AI-assisted prototype is generated.
For more complex designs or detailed customizations, manual changes may be necessary to ensure the final entity relationship model meets all requirements.
The AI is designed to speed up the process of generating diagram prototypes, but the user is responsible for creating the complete and accurate design of the application's business mode in its source code.

Interactive Auto-Pilot Mode

An innovative autopilot mode allows users to dynamically enlarge or shrink the number of entities in the ER diagram using (+/-) buttons, providing a quick way to modify complexity without detailed configuration.

Enlarge (+)

Adds additional entities or relationships to the diagram based on the current context. For example, clicking the `+` button might introduce a related table, such as an `Order` entity linked to an existing `Customer` entity, along with predefined attributes or relationships.

Shrink (-)

Removes entities or relationships from the diagram to simplify its structure. For instance, clicking the `-` button could remove auxiliary entities that are not critical to the application's initial design.

This feature helps users quickly prototype or refine their diagrams by adjusting the scope and complexity of the database structure, without requiring manual edits to every detail.

Live Diagram Panel

The Payara Starter interface includes a split panel where the Mermaid source code appears on the left, and a live visual representation of the ER diagram is shown on the right. Any changes made in the source or through Generative AI interactions update the visualization immediately.

Users can freely modify the ER diagram by editing the Mermaid source code directly in the left

panel. These modifications are instantly reflected in the live preview, offering full control over the diagram's structure and appearance.

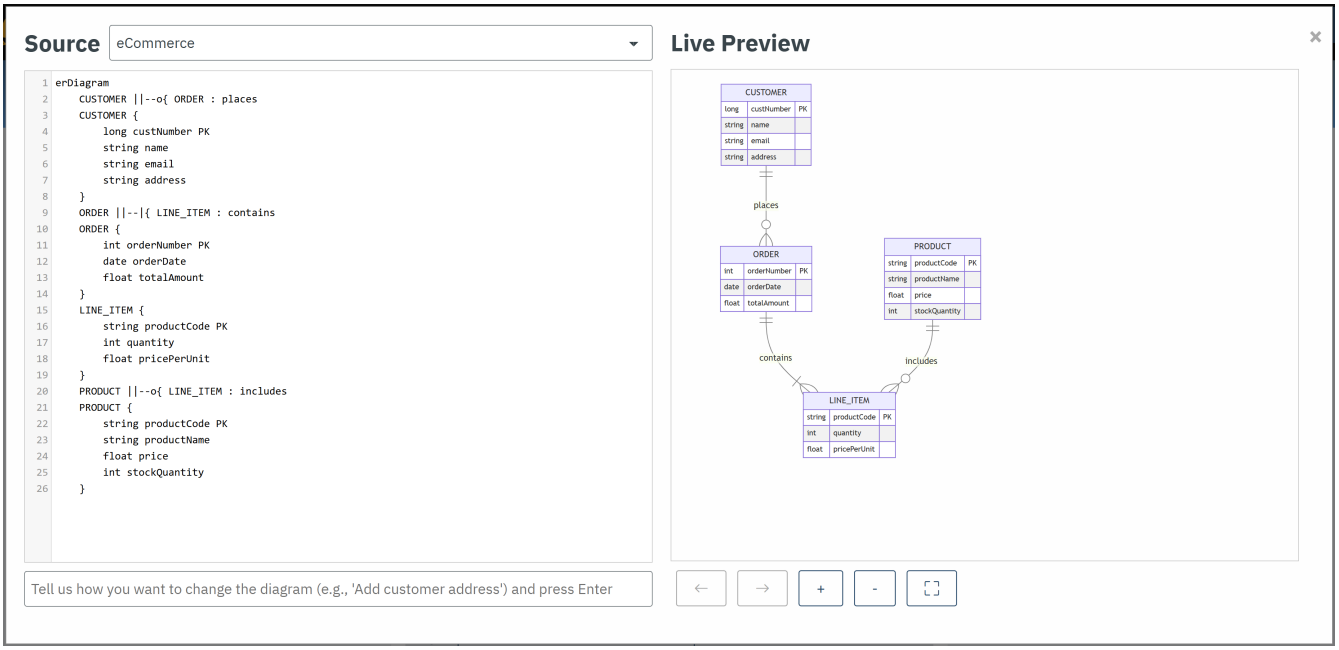
Full-Stack Application Generation

Once finalized, Payara Starter uses the ER diagram to automatically generate corresponding JPA entities and REST endpoints, making it easy to move from design to implementation.

Using the ER Diagram

Open the existing or Generate a new ER Diagram:

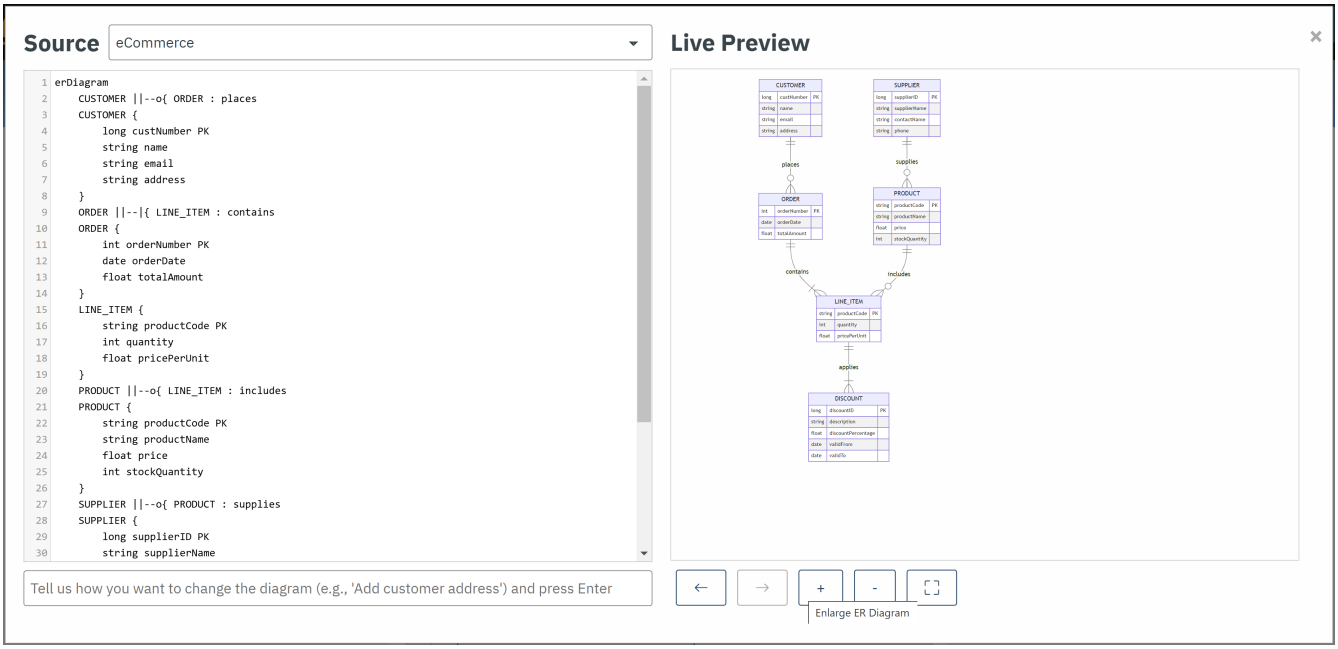
Open the ER Diagram panel within the Payara Starter application interface. Select from the default diagrams or start a new diagram by pressing the **Diagram Builder & Live Preview** button and entering a description.



Enhance the Diagrams

Use the Real-time Diagram Design via Free-text support to interact with OpenAI. Type specific requests or commands, such as *"Add an Order entity"* or *"Make Customer and Order related"* and receive real-time updates to your diagram.

In autopilot mode, use the (+/-) buttons to quickly enlarge or shrink the diagram.



Generate the Full-Stack Application

Once the ER diagram meets your requirements, you can initiate the full-stack application generation. Payara Starter uses the diagram structure to create JPA entities, repository services, REST endpoints, and optionally web pages.

Optional Features and Dependencies

During the generation process, you can customize the output to include or exclude specific components. Note the cascading dependencies between components:

JPA Entities

If skipped, all other components (repository services, REST endpoints, and web pages) will also be skipped. Only the ER diagram will be saved to the root of the project.

Repository Services

If skipped, the generation of REST endpoints and web pages will also be skipped.

REST Endpoints

If skipped, web pages will also be skipped.

Web Pages

Can only be generated if repository services and REST endpoints are included.

This flexibility allows developers to tailor the generated application to meet their specific project needs while ensuring structural coherence.

IDE Integration

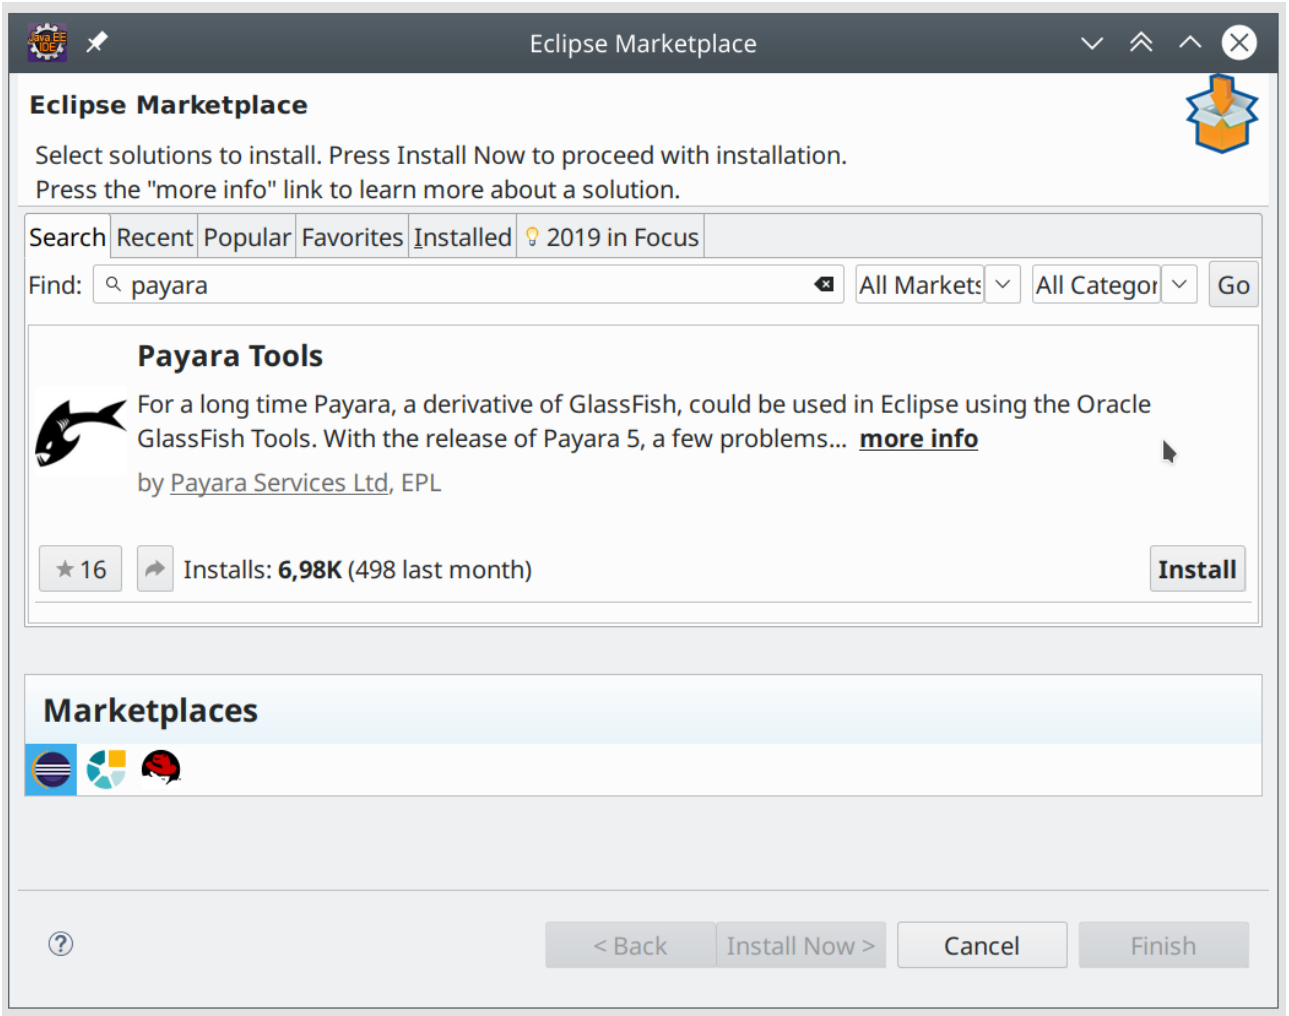
Eclipse Plugin

Overview

The Payara Tools plugin enables integration between Payara Server and Payara Micro into the Eclipse IDE. The Payara Tools plugin is available from the Eclipse Marketplace.

Installing Payara Tools Eclipse Plugin

1. Go to **Help → Eclipse Marketplace...**
2. On the Marketplace window, type **"Payara"** and click the **Go** button on the right side.
3. Click the **Install** button.



4. Read and accept the license agreement.
5. You will see a **Security Warning**, click **Install Anyway**.
6. Finally, you will need to restart Eclipse.

Payara Platform Tools

- Payara Server - The Payara Eclipse plugin enables developers to easily configure Payara Server and manage applications from the Eclipse IDE.
- Payara Micro - Payara Eclipse plugin provides the support to create, run and debug Payara Micro applications from the Eclipse IDE. Payara Micro is the microservices-ready version of Payara Server.

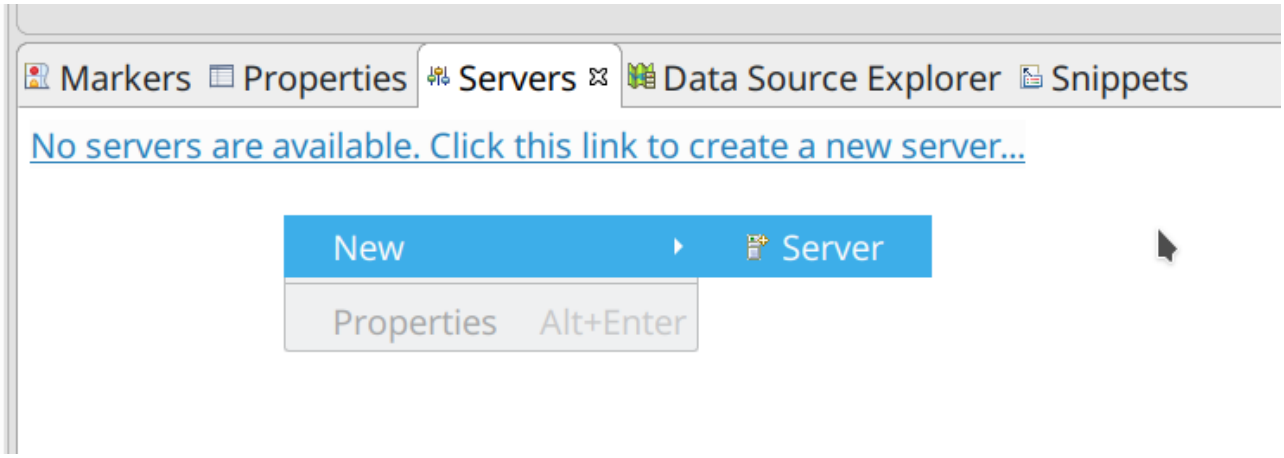
Payara Server

Using the Payara Tools Eclipse plugin, you can integrate Payara Server within the Eclipse IDE and perform the following tasks:

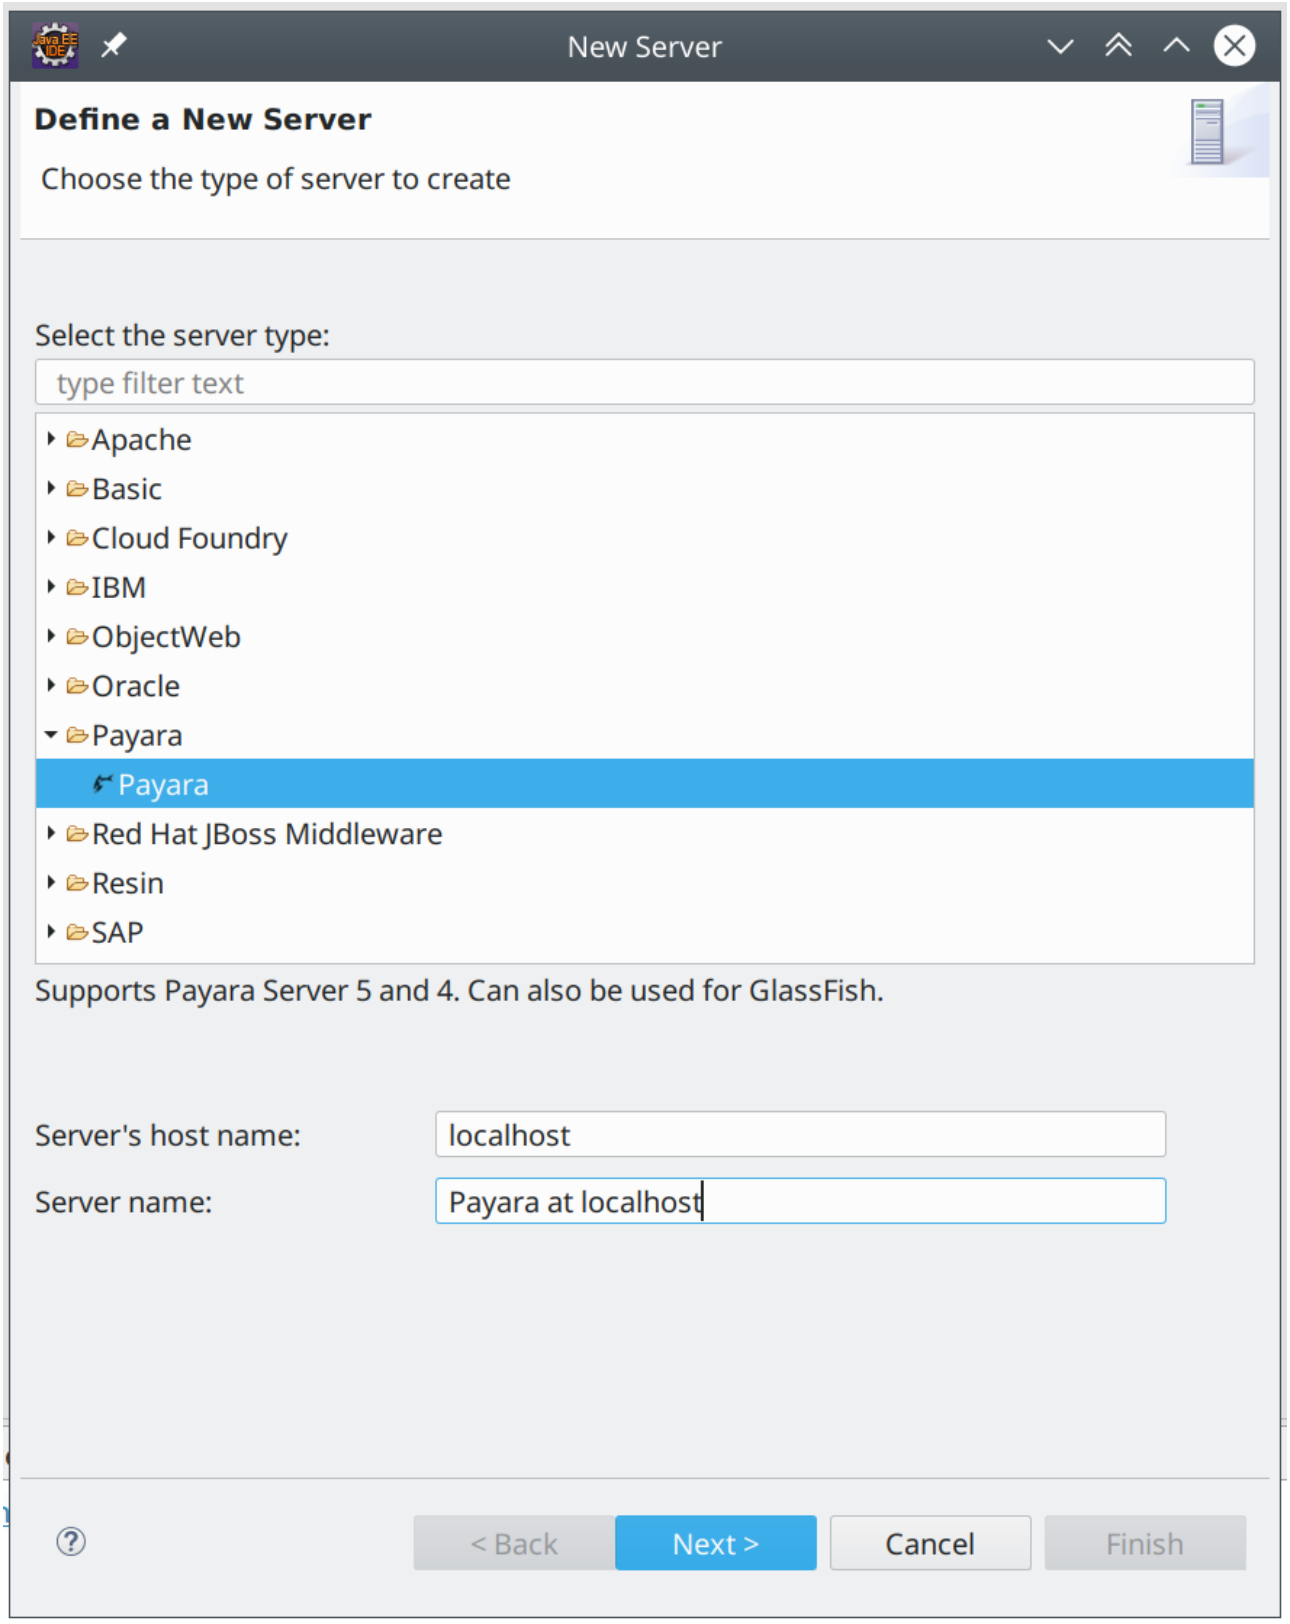
- Start and stop the Payara Server from within the IDE
- Define the Java runtime to be used by Payara Server
- Deploy an application from within the IDE
- Launch the admin console within the IDE
- View the server logs from the IDE
- Auto Publish & Hot Deploy your application

Adding Payara Server to Eclipse IDE

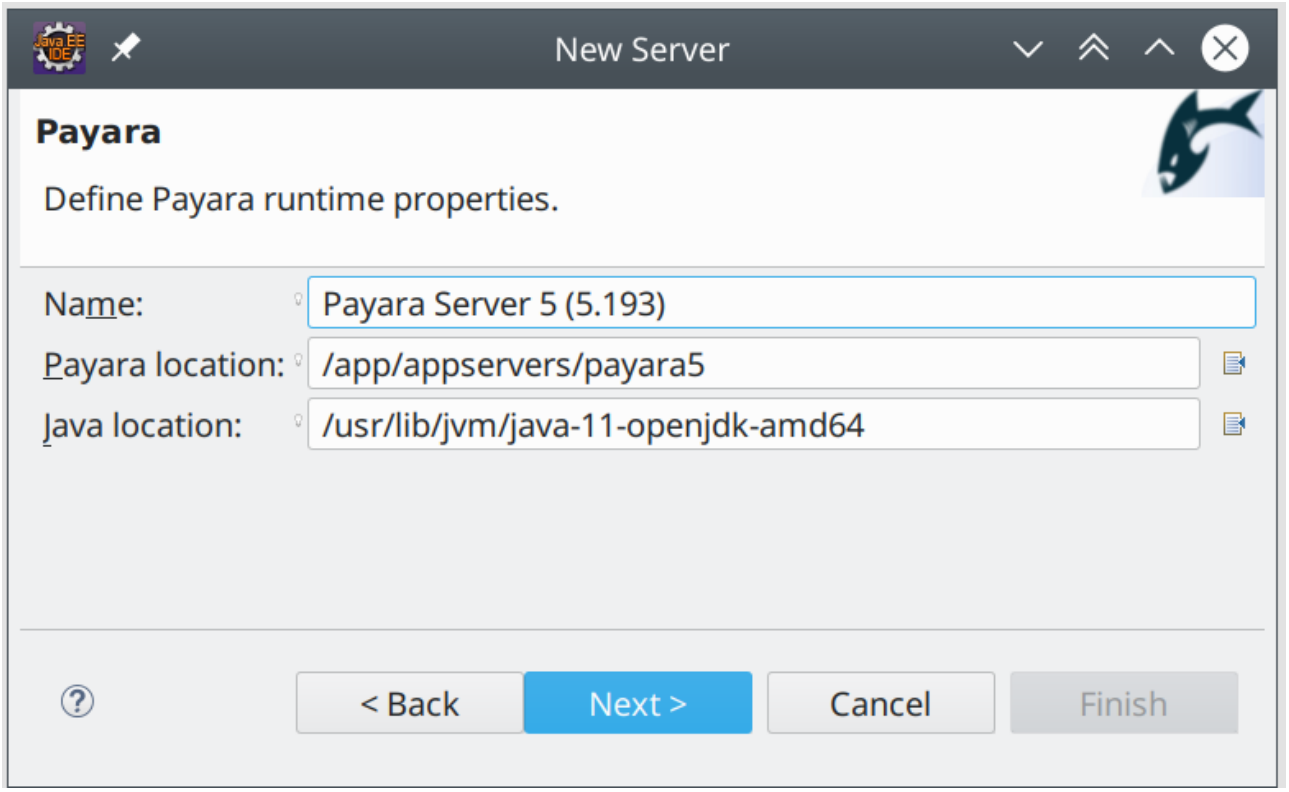
1. Open the **Servers** view (if not visible, it should be under menu **Window** → **Show View** → **Servers**).



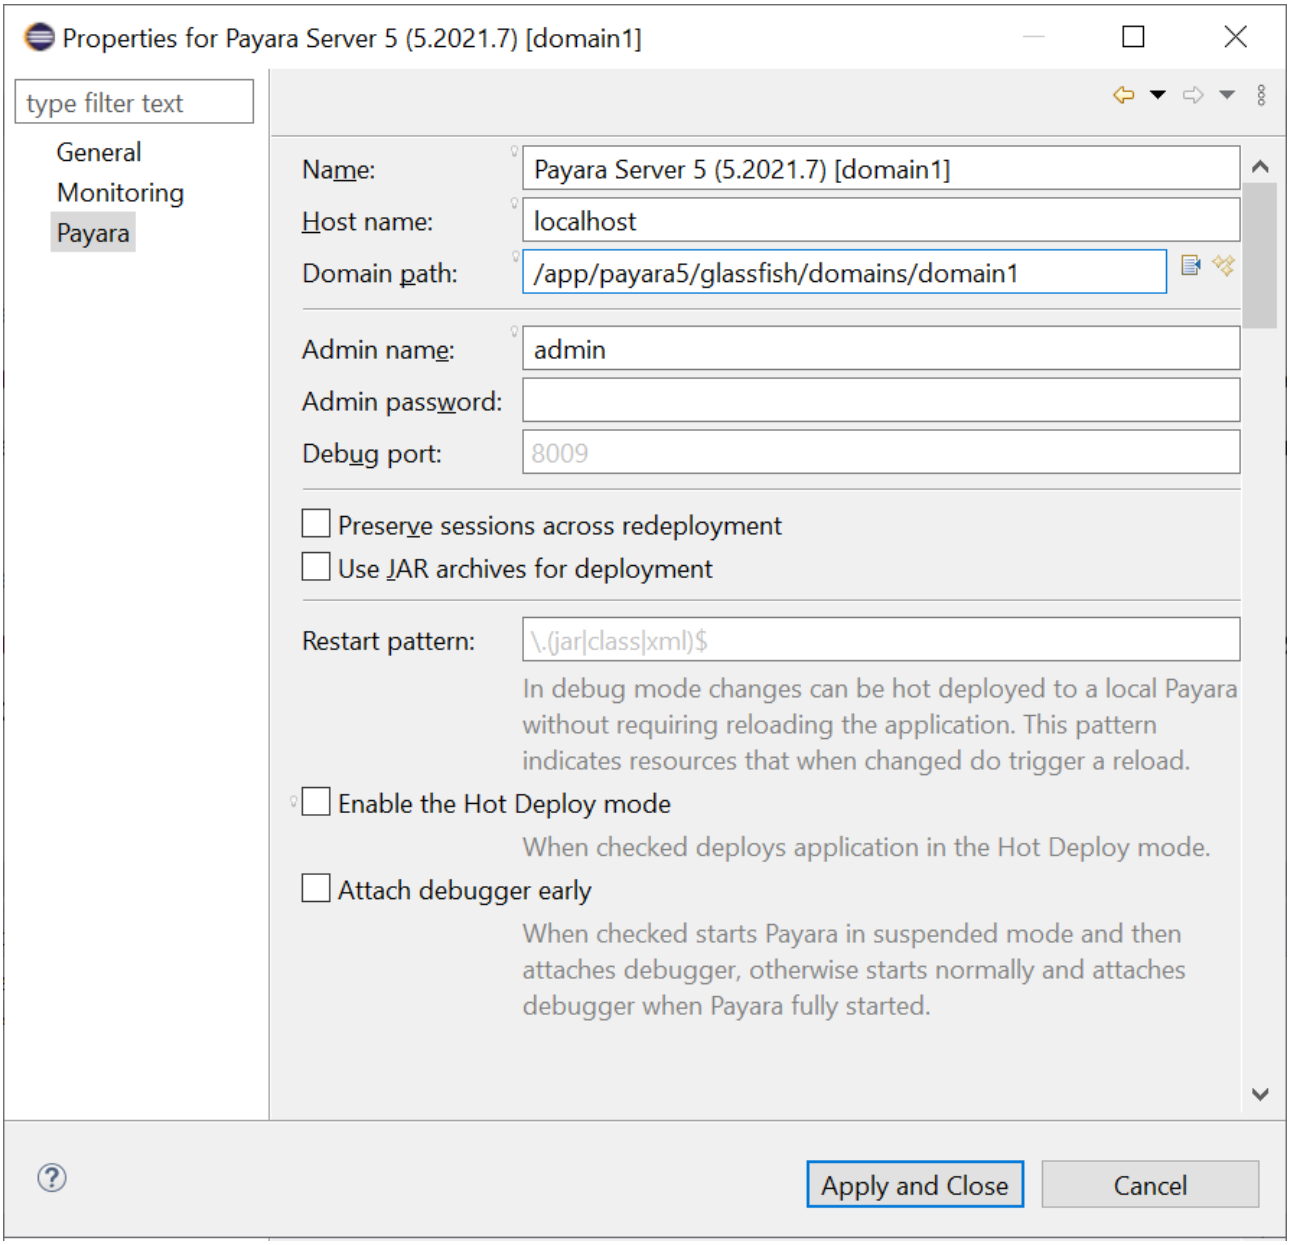
2. Select **Payara** → **Payara** and set the **Host name** and some comprehensible **Server name**.



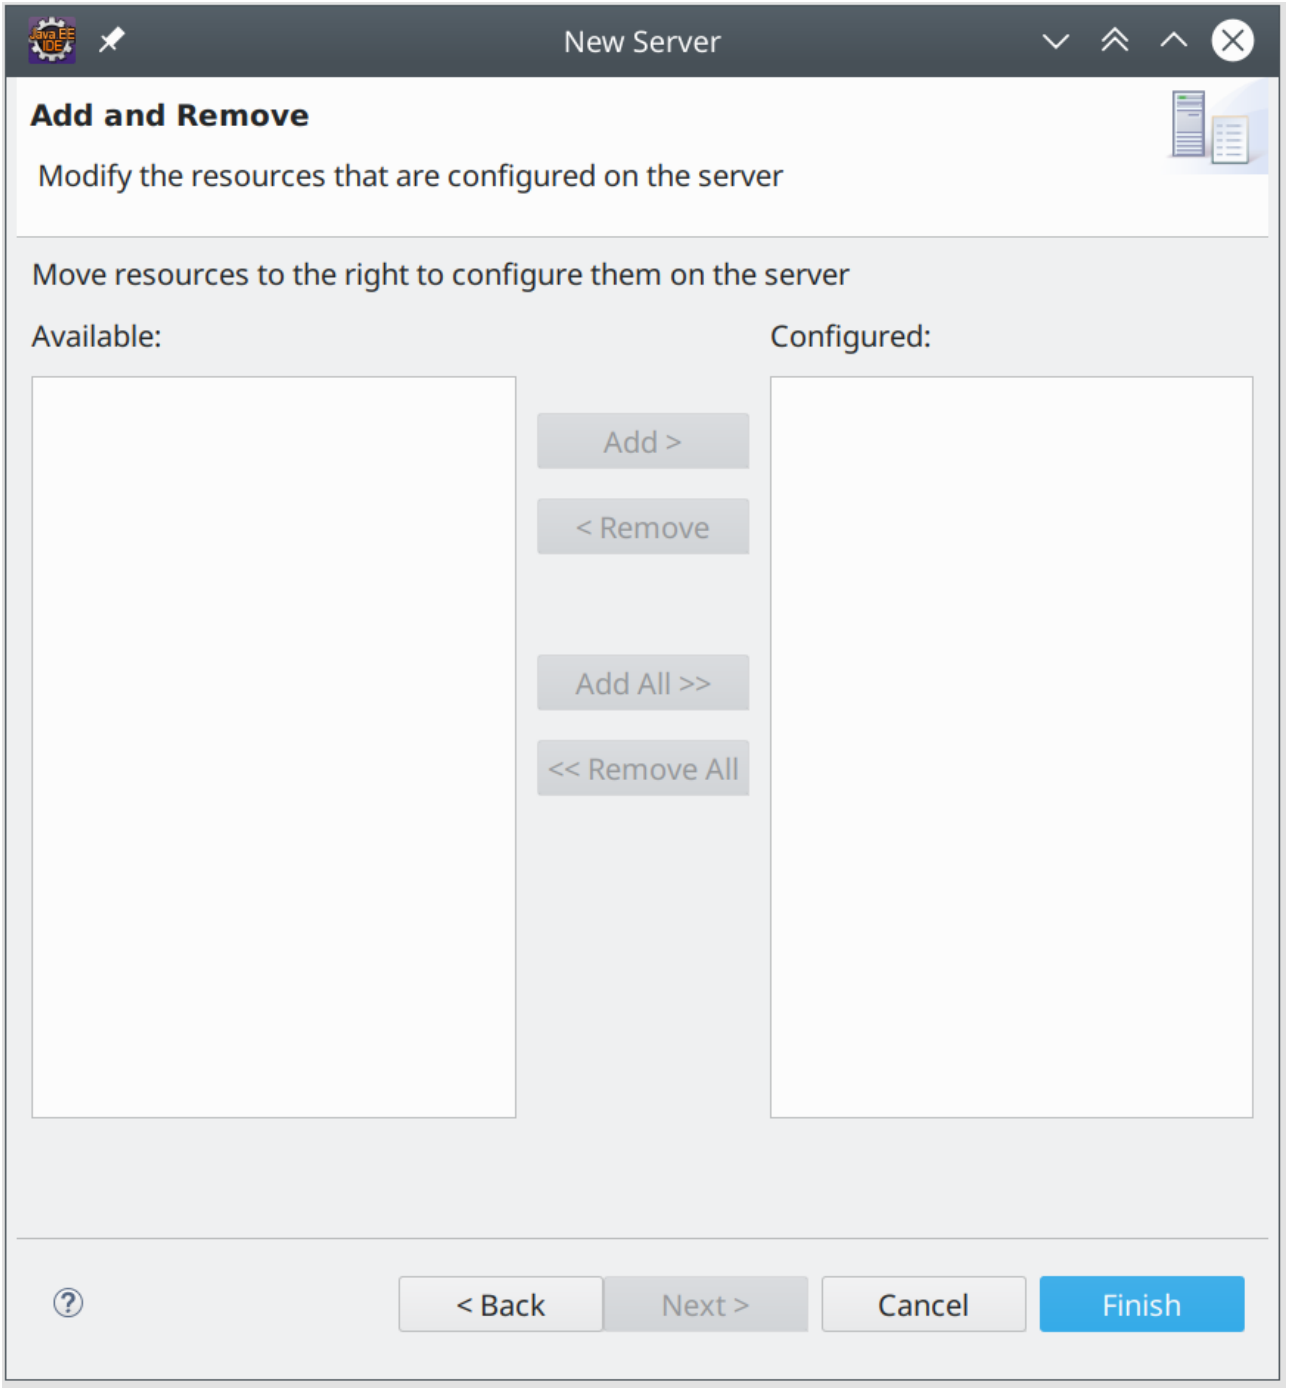
3. Then click **Next** to another window with server runtime configuration.



4. Then click **Next** again to window with the configuration of the domain. In this example we use domain without configured admin user and the server is not started in debug mode.

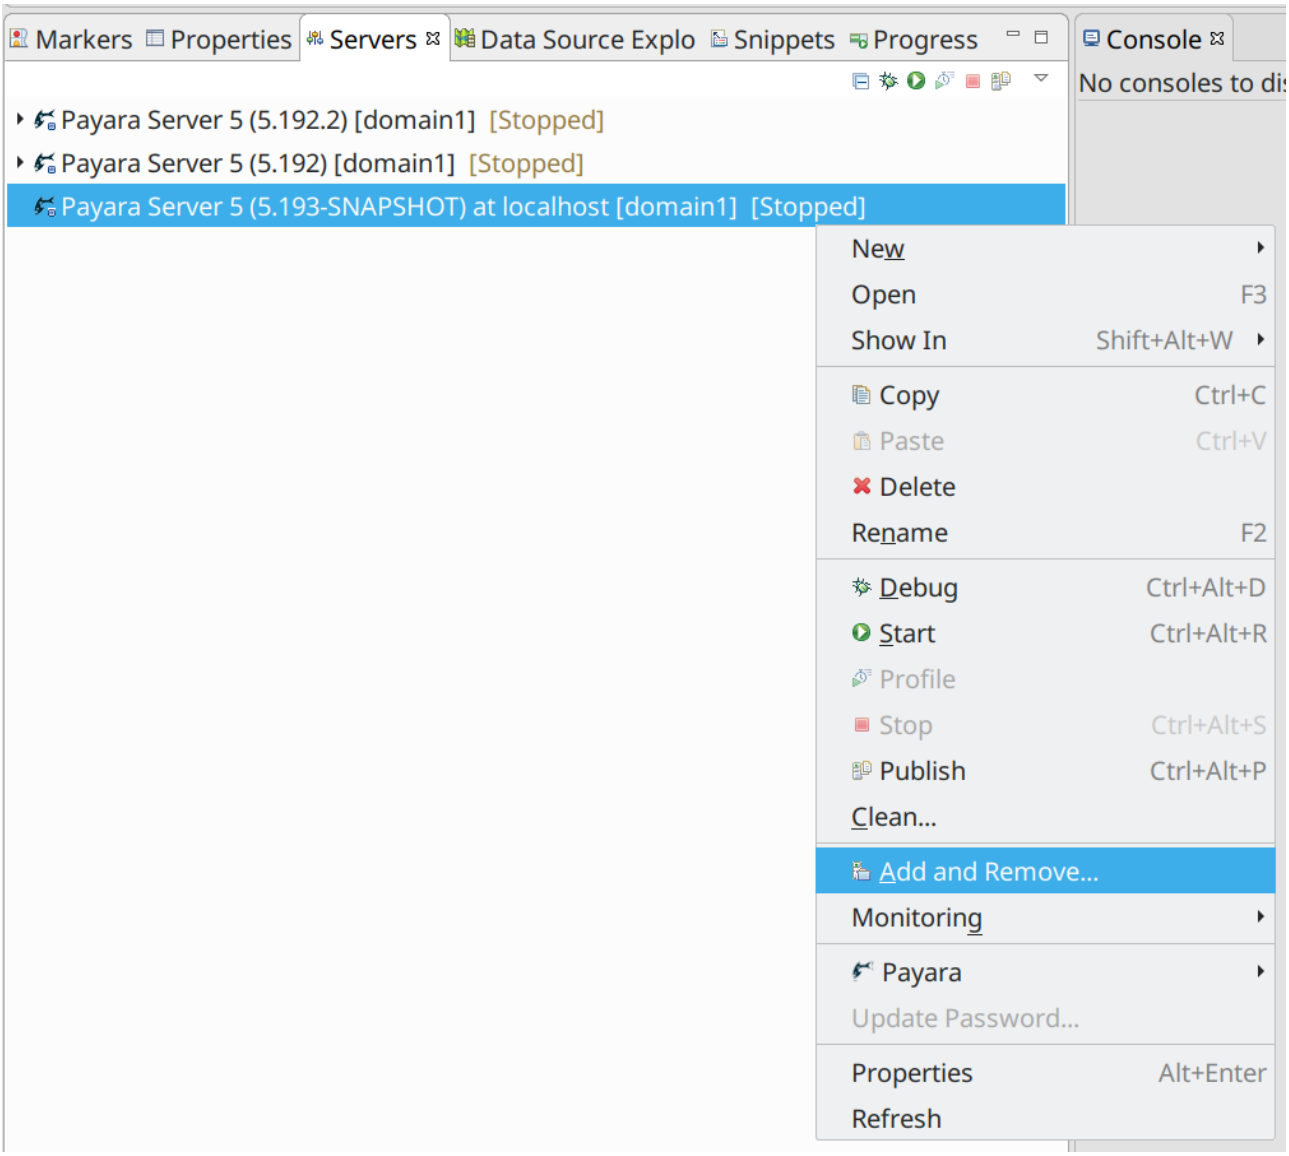


5. In the last step you can select resources which will be deployed on the server. Here we don't have any deployable projects in the workspace yet, so both panels are empty.

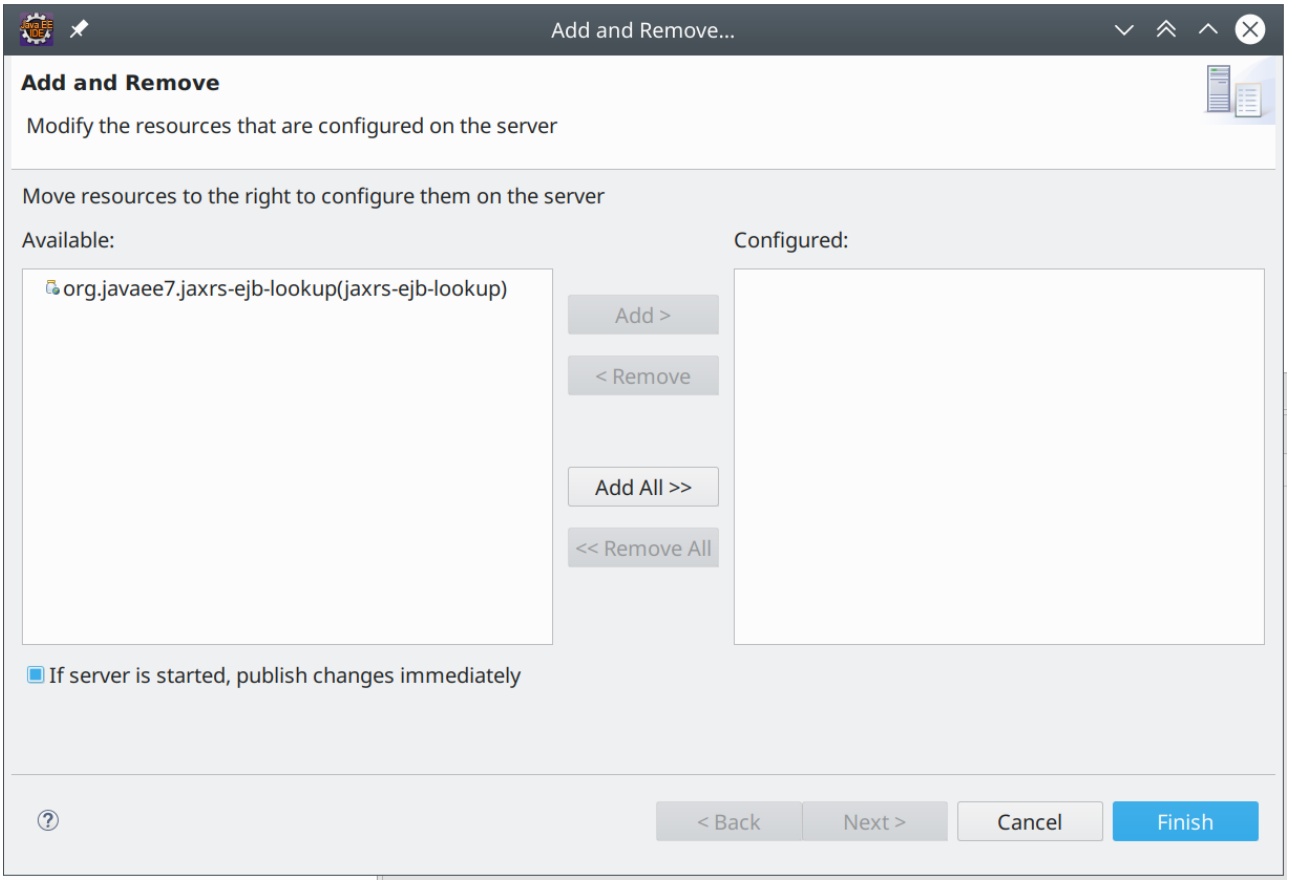


Adding Resources to Server

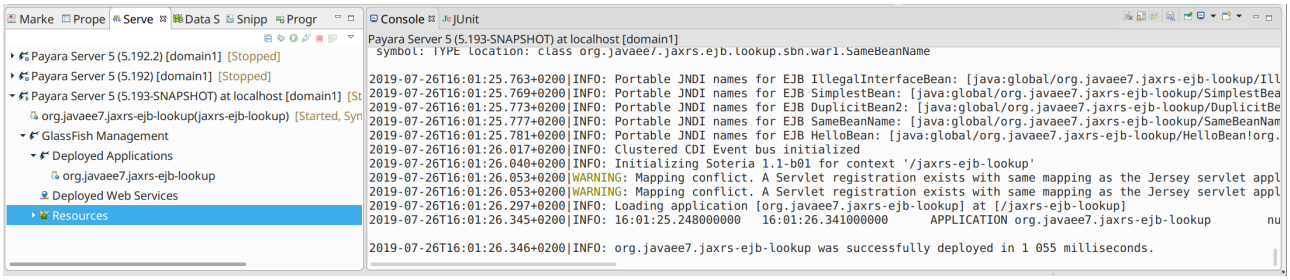
1. First import or create some project, deployable to the **Payara Server**. Here we use one of the Java EE 7 Samples .
2. Right-click the target server in the **Servers** view and click **Add and Remove...**



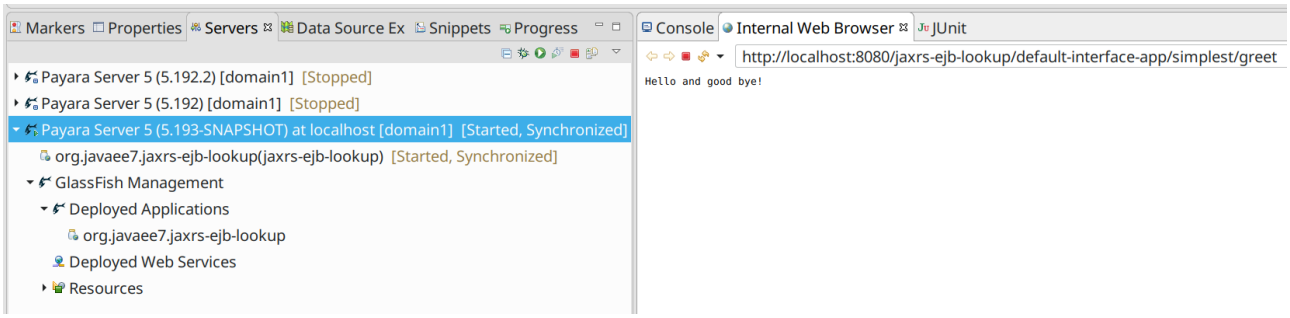
3. Select resources you want to be managed by the **Payara Tools**, add them to the right panel and click **Finish**.



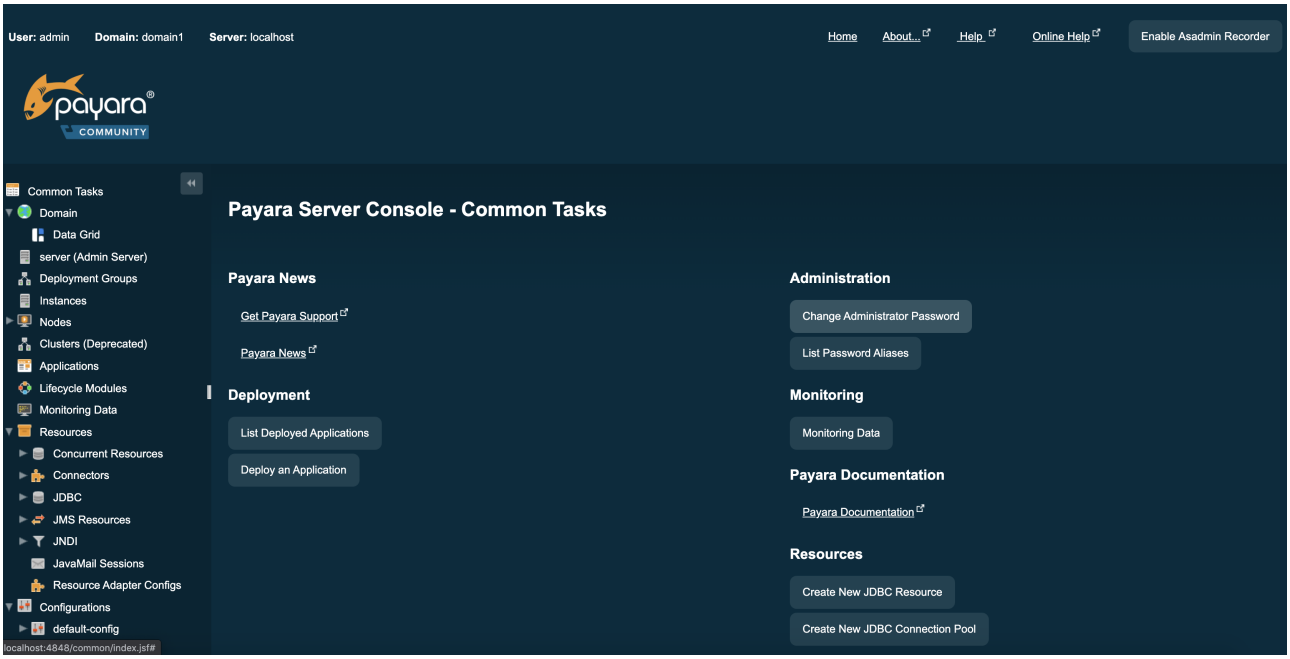
4. Now you can watch the deployment of the application in the **Console** view.

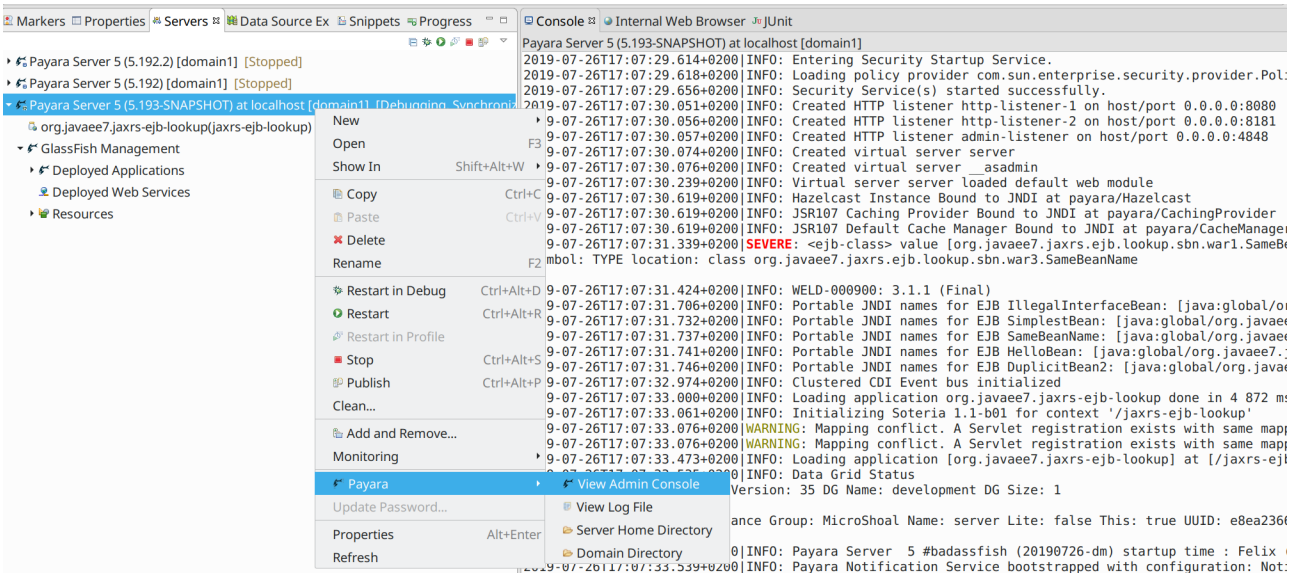


5. If the deployment was successful, you can use the application. Here we simply opened the internal Eclipse's browser and sent the HTTP GET request - and the application responded.



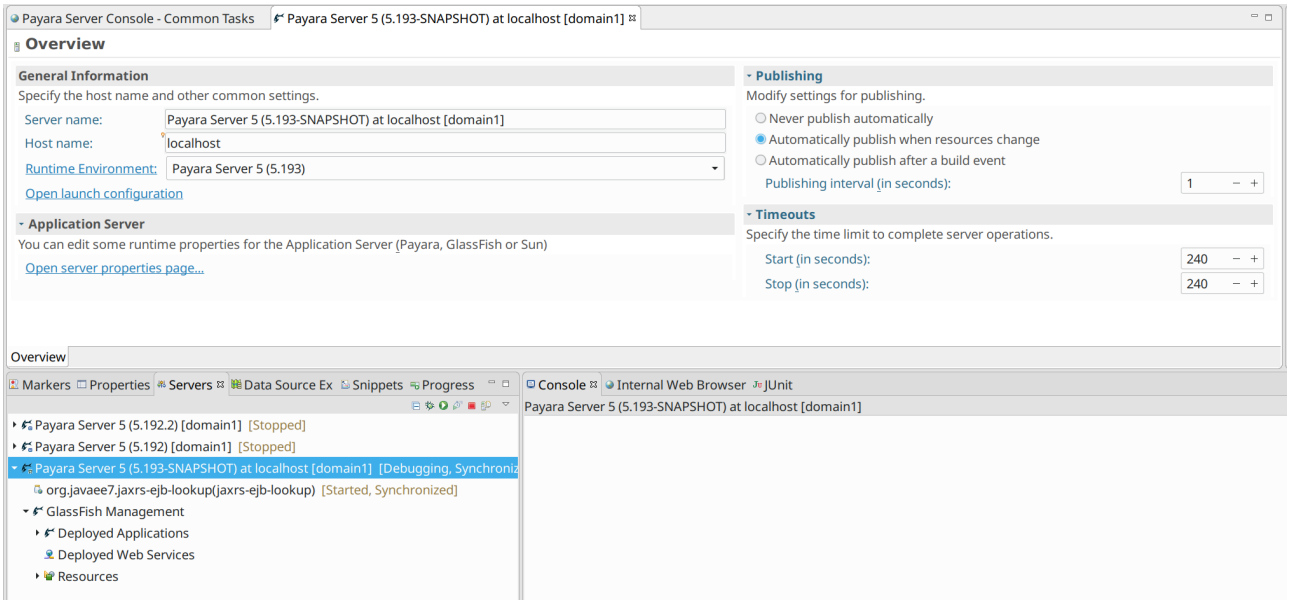
6. You can also access the administration console directly from the Eclipse Browser. Just right-click the target server in the **Servers** view and click **Payara → View Admin Console**





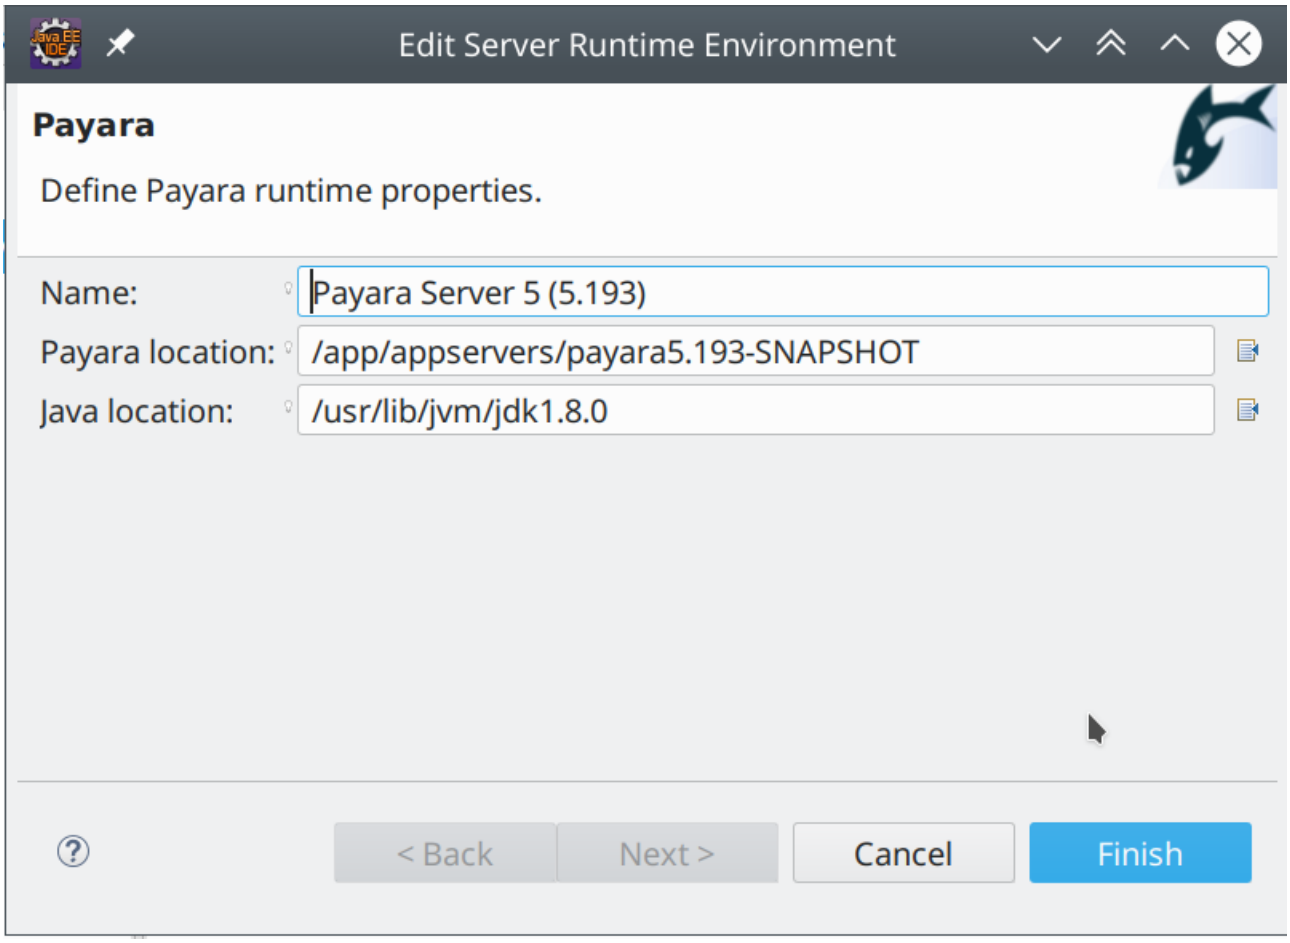
Runtime Reconfiguration

1. In the **Servers** view double-click the server you want to reconfigure. The **Server Overview** will open.



2. Click on **Runtime Environment** and you will see well known window.

Changing the runtime may result in unusable state of the server because of incompatible configuration.



Deploy Applications in a Local Docker Container

The Payara Server tools for Apache NetBeans include Docker integration, making it seamless to deploy exploded applications to a Payara Server instance running within a local Docker container.

To take advantage of this feature, follow these steps below:

1. Register a new Payara Server instance by performing the following:
    a. Open the **Servers** view (if not visible, it should be under menu **Window** → **Show View** → **Servers**).
    b. Select **Payara** → **Payara** and set the **Host name** and some comprehensible **Server name**.
    c. Then click **Next** to another window with server runtime configuration and browse and locate the Payara Server installation directory with the same version as the one running in the Docker container.
    d. Then click **Next** again to window with the configuration of the domain. Enter the domain name, host, and necessary credentials.
    e. For Docker integration, choose the "Docker Volume" option and provide the `HOST_PATH` (e.g., `D:/test`) and `CONTAINER_PATH` (e.g., `/mnt/test`) mapping details.

    This mapping should align with the exploded application path or parent path of exploded application.

    f. In the last step you can select resources which will be deployed on the server. You may add them later.
2. Run the Payara Server Docker container using the following command:

```
docker run -p 8080:8080 -p 4848:4848 -p 9009:9009 -v HOST_PATH:CONTAINER_PATH
payara/server-full:{page-version}
```

    Replace `HOST_PATH` with the actual host path and `CONTAINER_PATH` with the desired container path.

    The `HOST_PATH` points to the location on your host machine, and `CONTAINER_PATH` is the corresponding location inside the container.

3. Create your web application and deploy it to the registered Payara Server instance.

Deploy Applications in a WSL Environment

Another noteworthy feature is the integration of the Payara Server Tools with Windows Subsystem for Linux (WSL).

This integration empowers developers to manage and deploy exploded applications to a Payara Server instance running within WSL.

Here's how you can make use of this feature:

1. Start the Payara Server instance within WSL:
    a. Run the following command to start the server:

```
./asadmin start-domain
```

b. Set a password for the admin user:

```
./asadmin change-admin-password
```

c. Enable secure admin:

```
./asadmin enable-secure-admin
```

d. Restart the Payara Server domain:

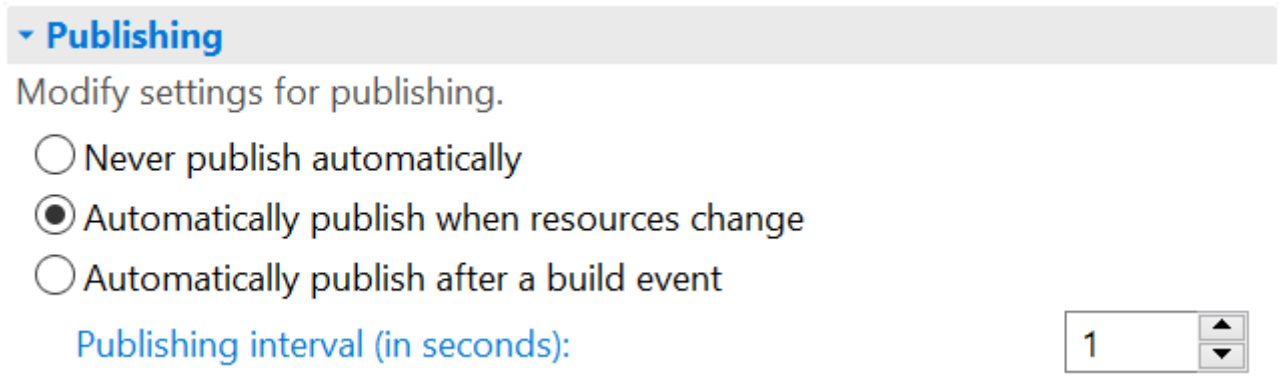
```
./asadmin restart-domain
```

e. Fetch the IP address of WSL environment using the command `hostname -I` and enter it in the `host name` field in the Eclipse IDE settings.

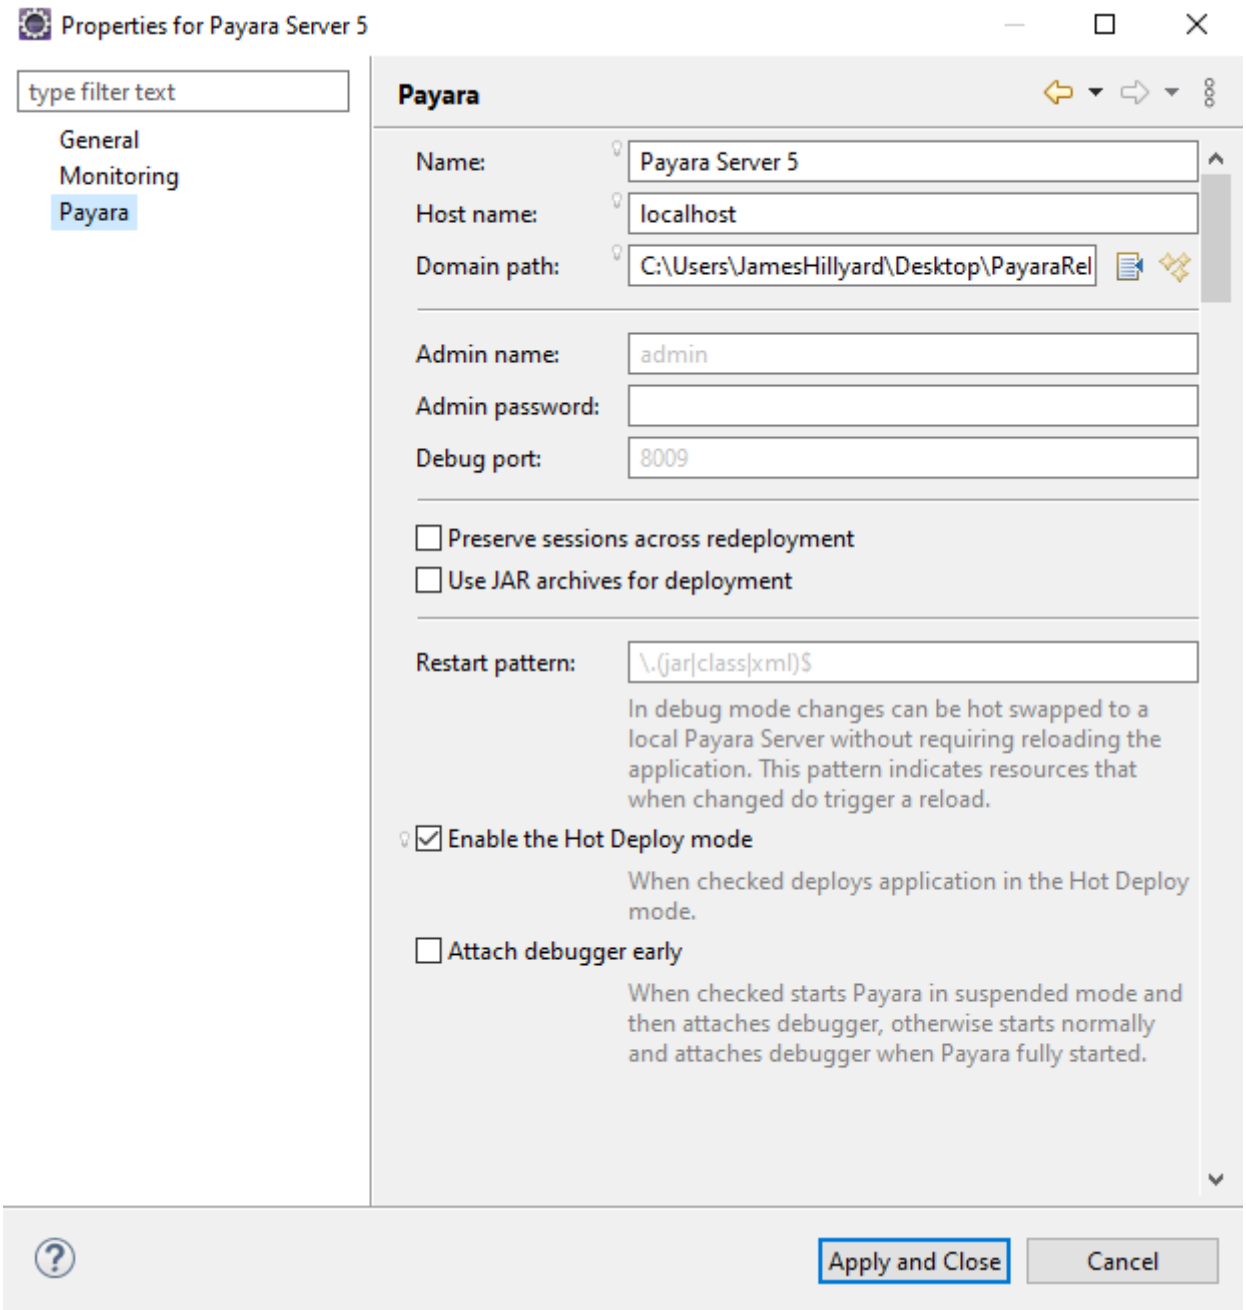
2. Register the WSL-based Payara Server instance in VS Code:
   a. Open the **Servers** view (if not visible, it should be under menu **Window** → **Show View** → **Servers**).
   b. Select **Payara** → **Payara** and set the **Host name** and some comprehensible **Server name**.
   c. Then click **Next** to another window with server runtime configuration and browse and locate the Payara Server installation directory with the same version as the one running in the Docker container.
   d. Then click **Next** again to window with the configuration of the domain. Enter the domain name, host name (fetched via the command `hostname -I` in WSL instance), and necessary credentials.
   e. For WSL integration, choose the "WSL" instance type.
   f. In the last step you can select resources which will be deployed on the server. You may add this setting later.
3. Create your web application and deploy it to the registered Payara Server instance.

Hot Deploy and Auto Deploy Settings

To enable **Auto Deploy** from the Eclipse IDE, open The **Server** panel, double-click the server name and expand the **Publishing** section to reconfigure the setting.



Hot Deploy mode can be enabled from the Payara Server properties page to boost the deployment performance which reuses the existing application instance relative to the modified source:



See Also

Hot Deploy and Auto Deploy

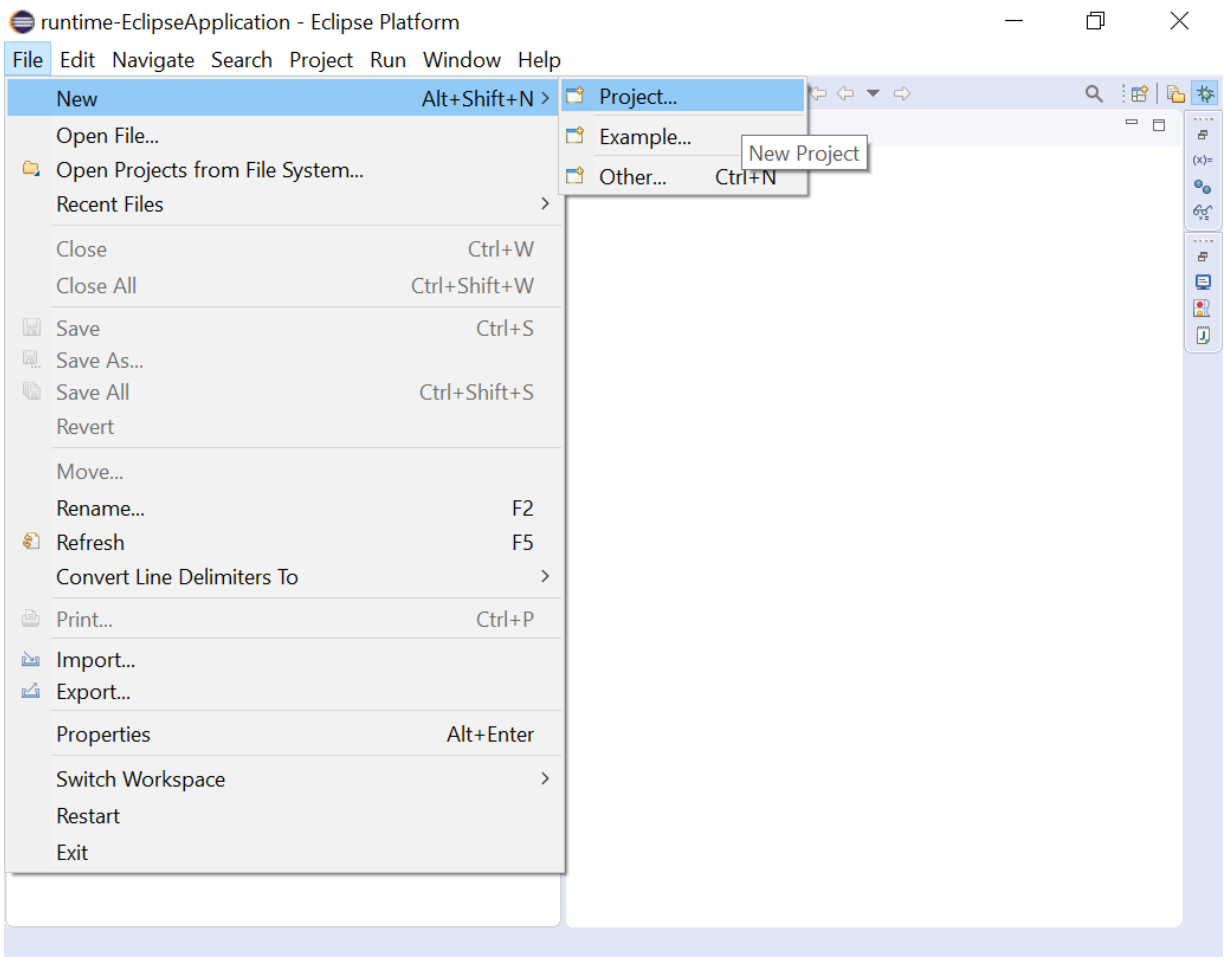
Payara Micro

Using the Payara Eclipse Tools, you can integrate Payara Server within the Eclipse IDE and perform the following tasks:

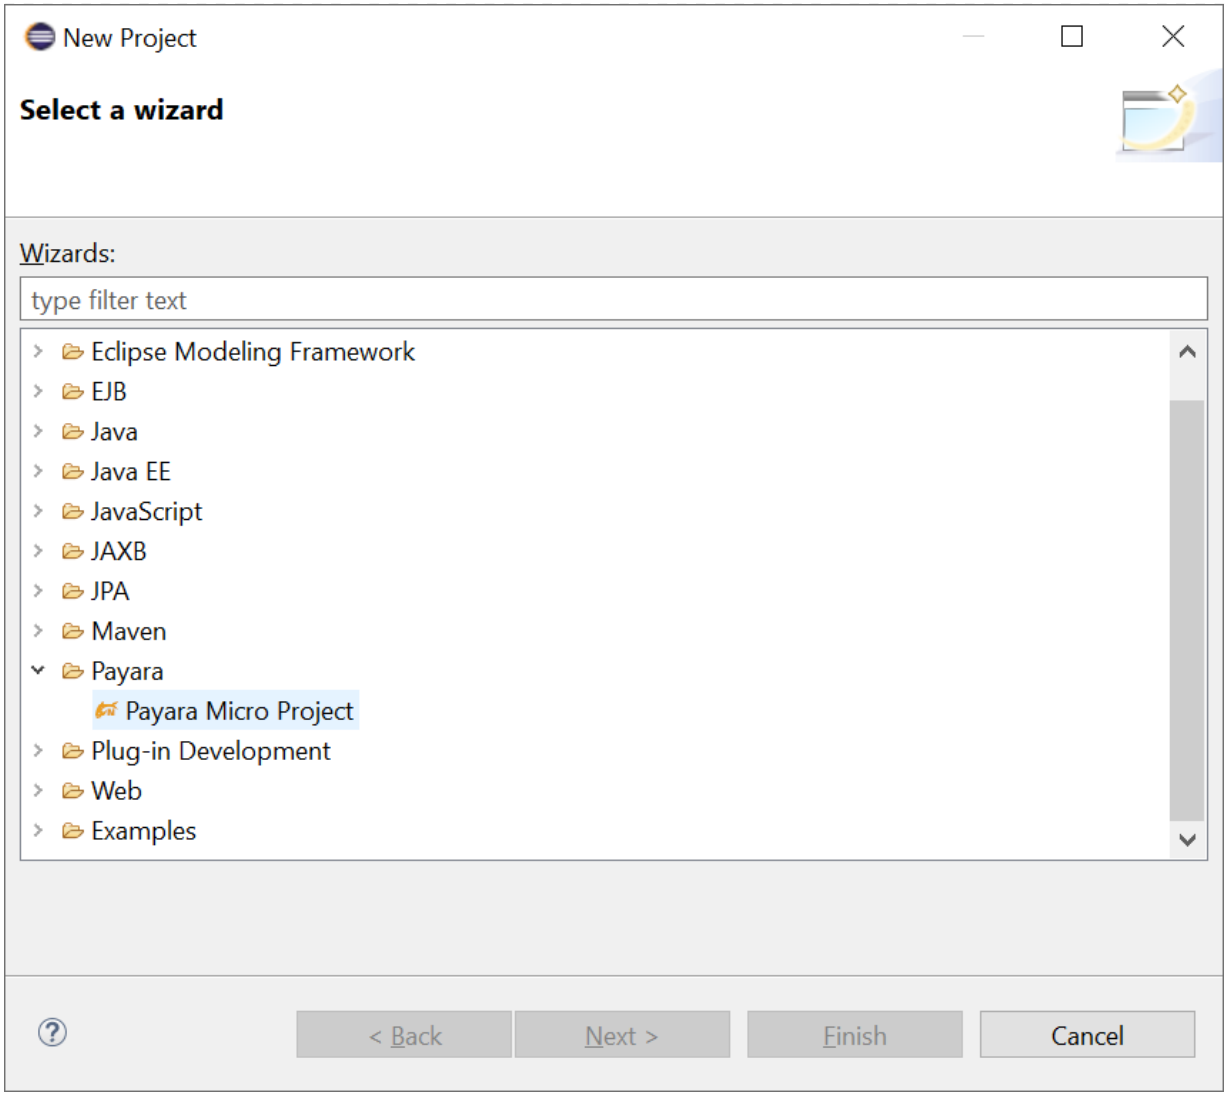
- Run Payara Micro from within the IDE
- Control Payara Micro properties from within the IDE
- Deploy applications to Payara Micro within the IDE
- Auto Publish & Hot Deploy your application

====== Creating A New Payara Micro Maven Application

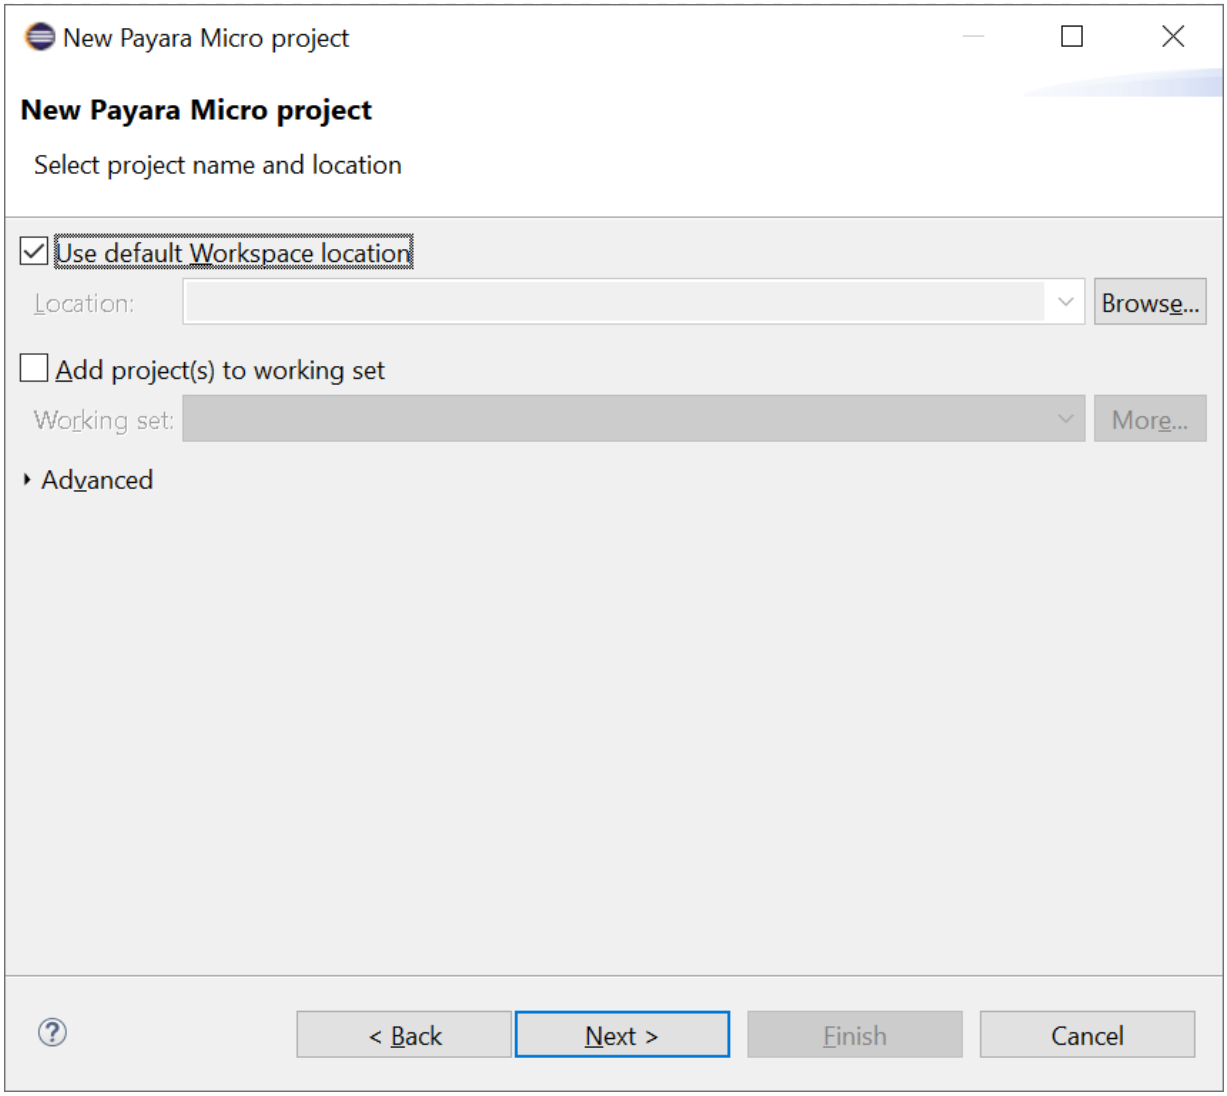
1. Simply start up Eclipse IDE and then Choose **File** > **New** > **Project** from the main menu or press Ctrl+N to get the list of available projects:



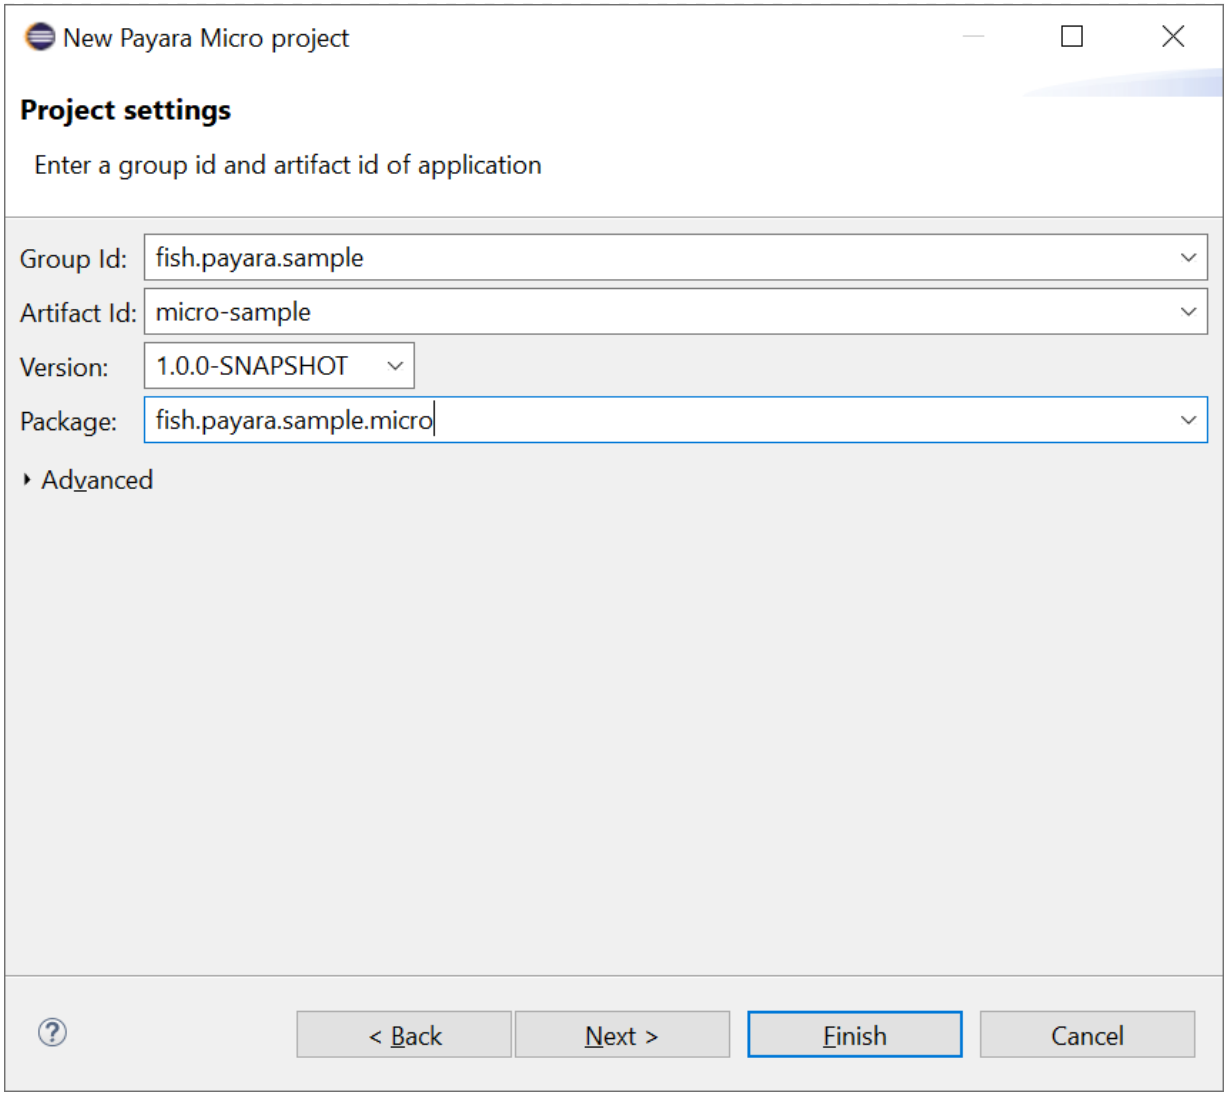
2. Now, select the Payara Micro Project type to create the application:



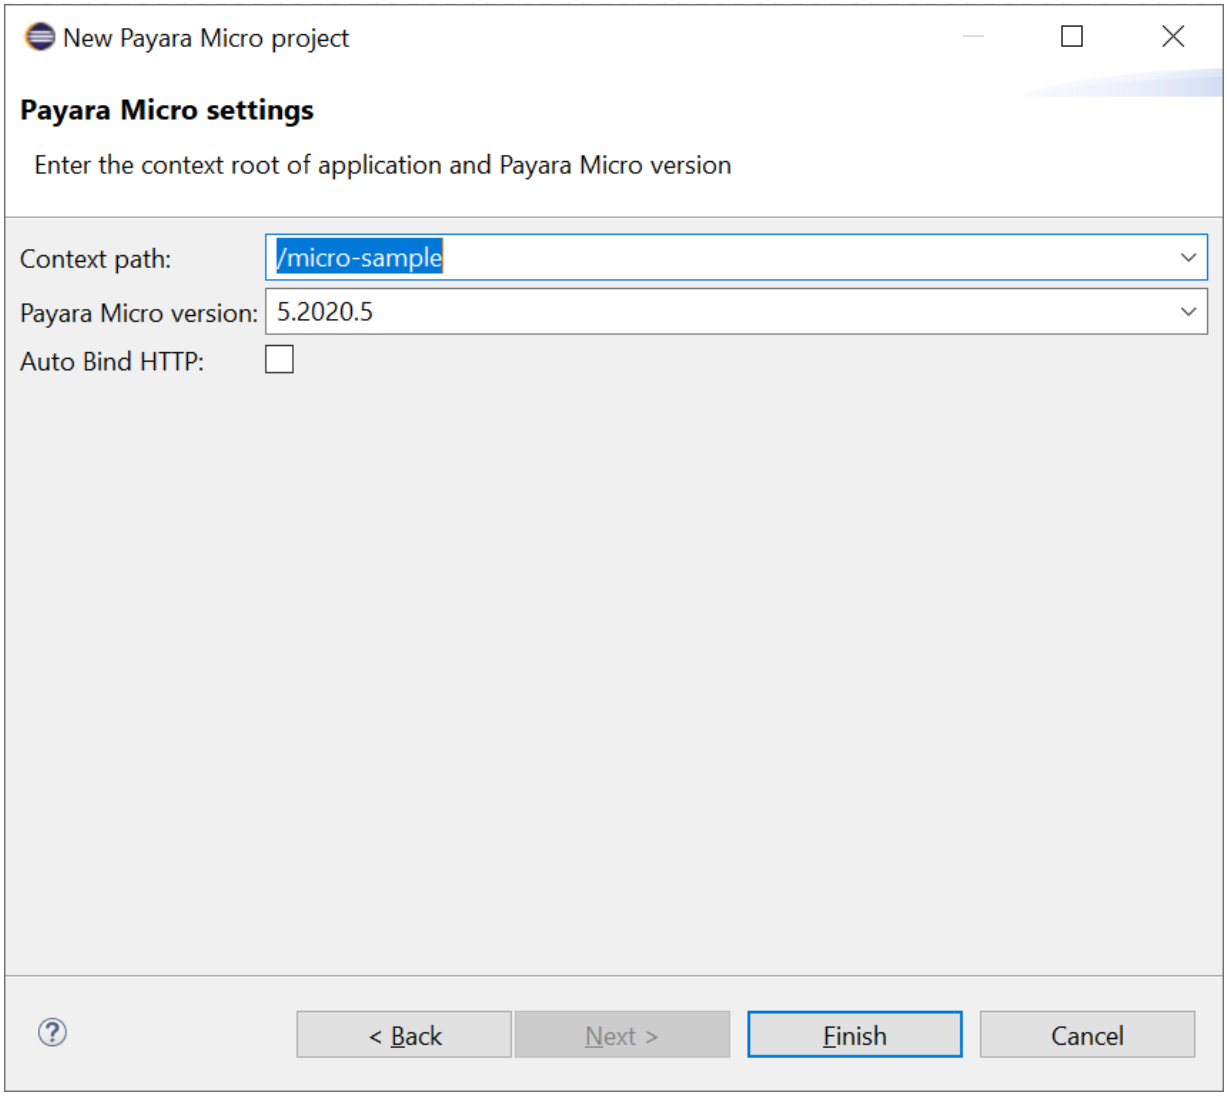
3. Select the destination folder, where the project will be generated. You may also use the default workspace location:



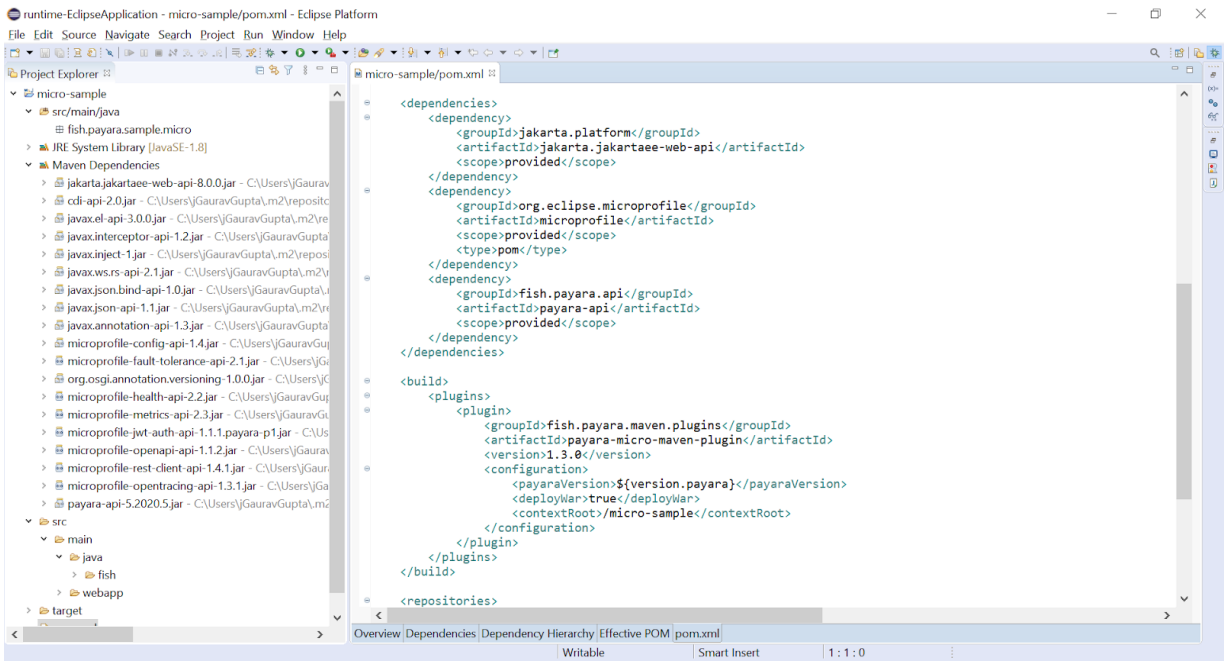
4. Enter the groupId, artifactId, etc to set up the project, and then click **Next**:



5. Enter the Payara Micro application settings e.g context path of the application and Payara Micro version and click the **Finish** button:



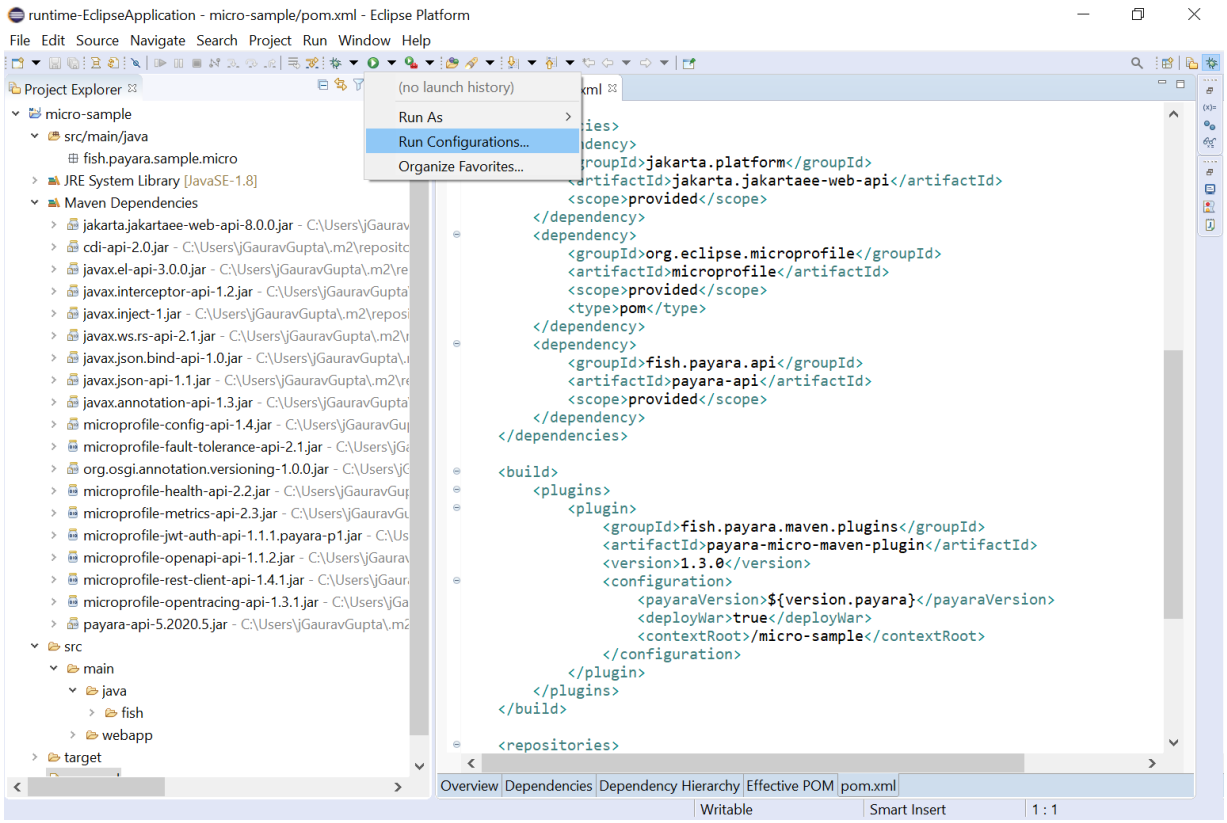
6. The IDE creates the Payara Micro application using the Payara Micro maven archetype. As you can see, the project has a basic structure with `src\main\java` and `src\main\webapp` folders:



====== Running The Payara Micro Application

Eclipse IDE needs a run configuration to build the artifacts and run/debug the Payara Micro application.

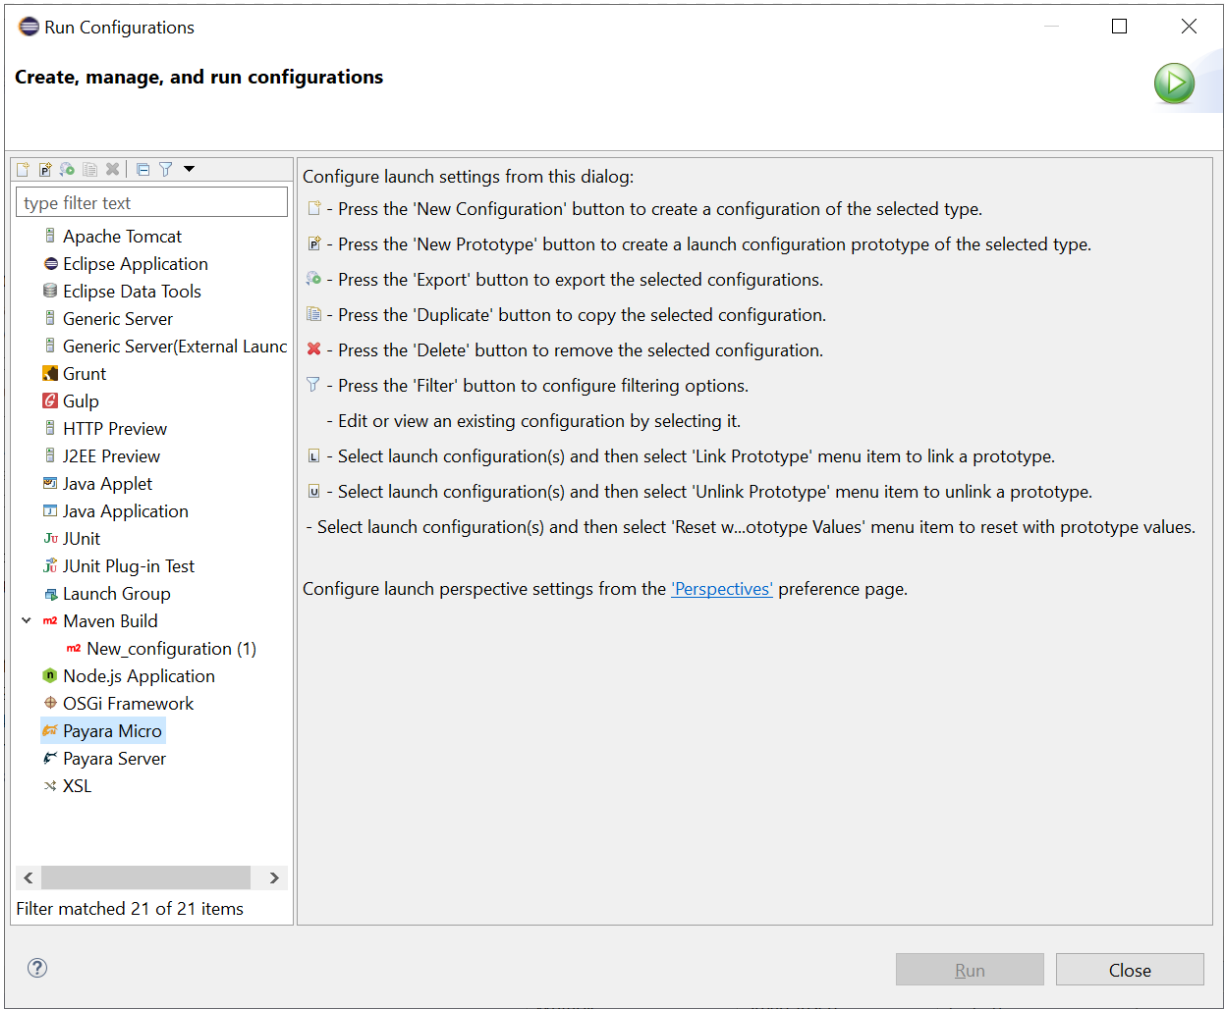
1. To create the Payara Micro Run configuration, select the **Run** > **Run Configurations...** from the main menu or toolbar:



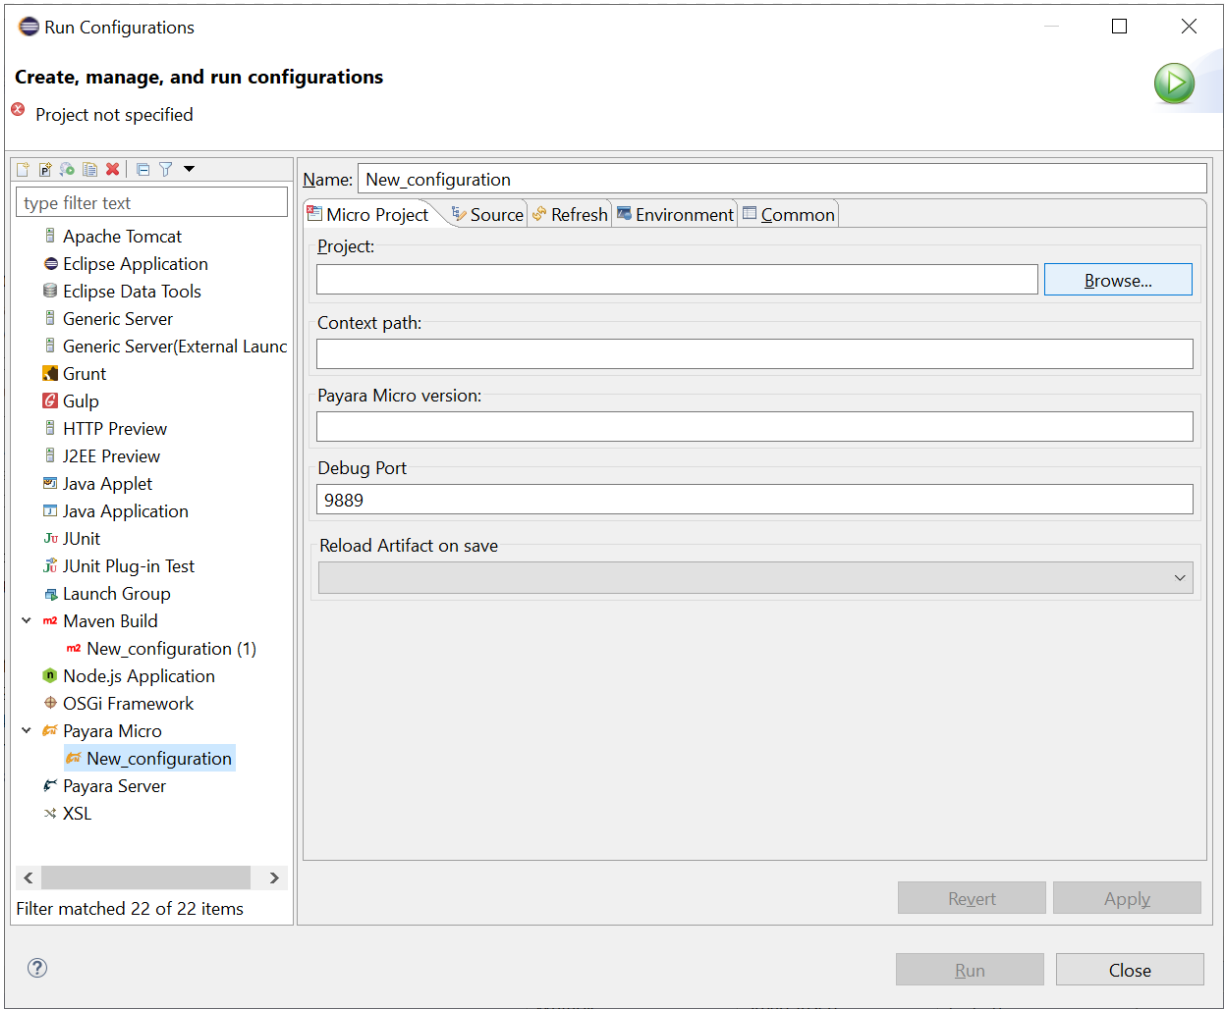
2. The Payara Micro Run configuration dialog allows you to specify Payara Micro settings and environment variables.

Payara Micro setting specified by **payara-micro-maven-plugin** in the **pom.xml** takes precedence over the **Run Configuration**.

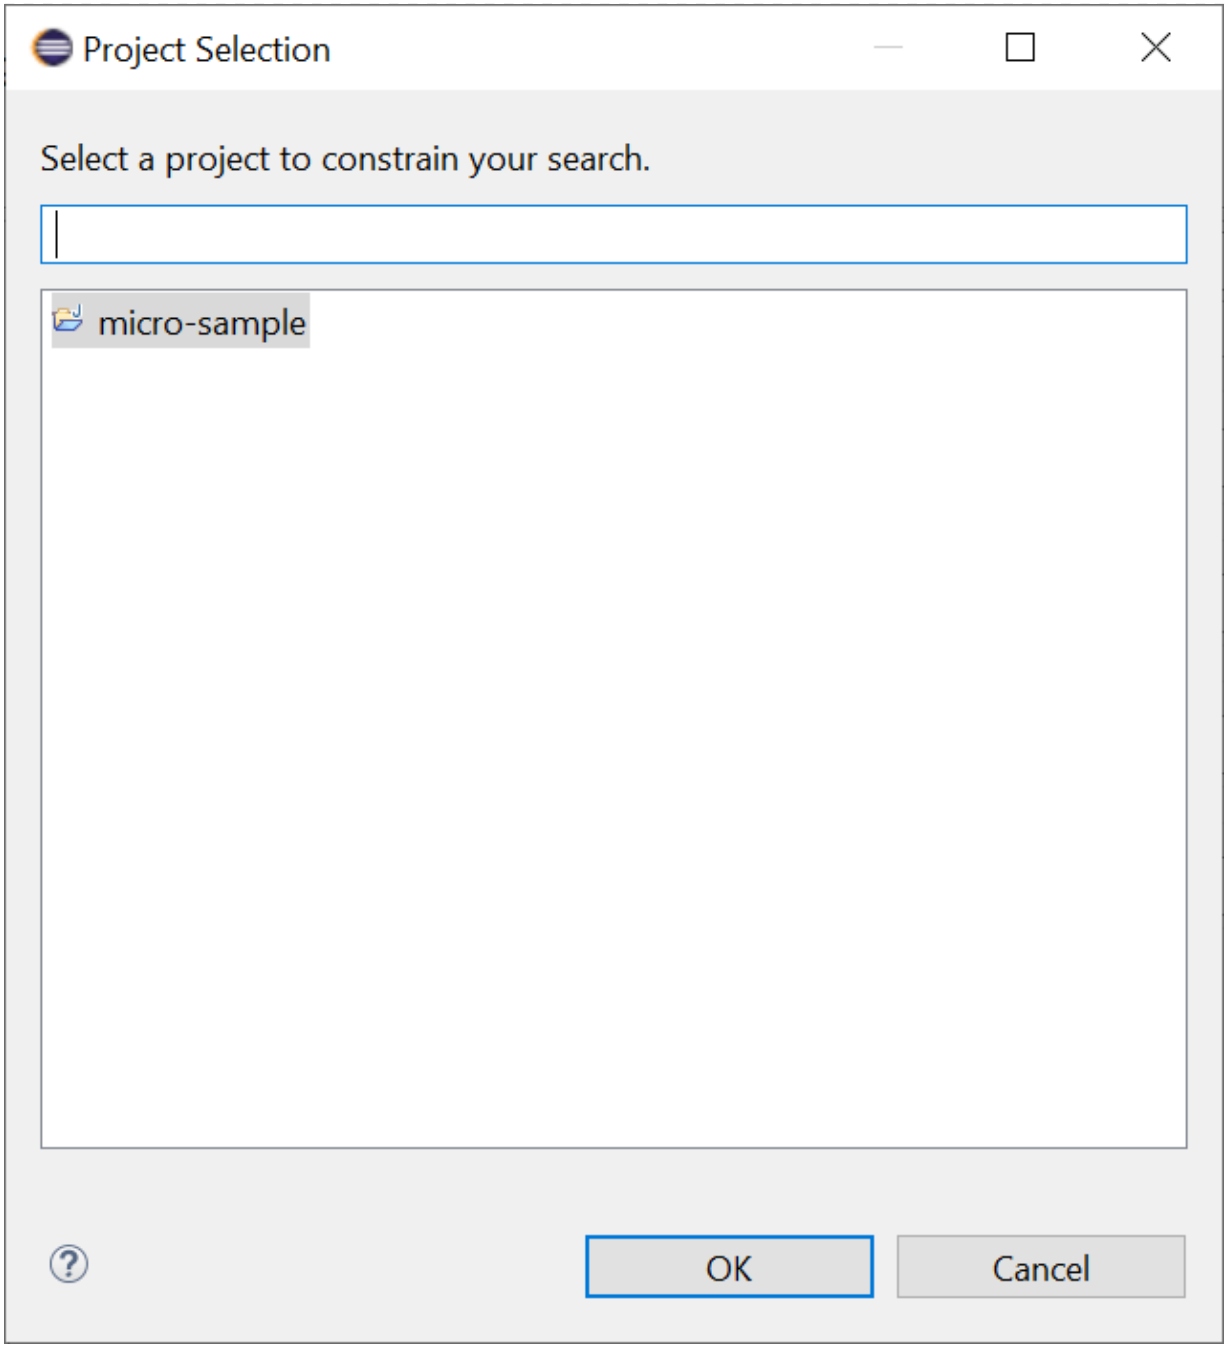
3. Select Payara Micro and double click it or click on the **New configuration** button to create a new configuration :



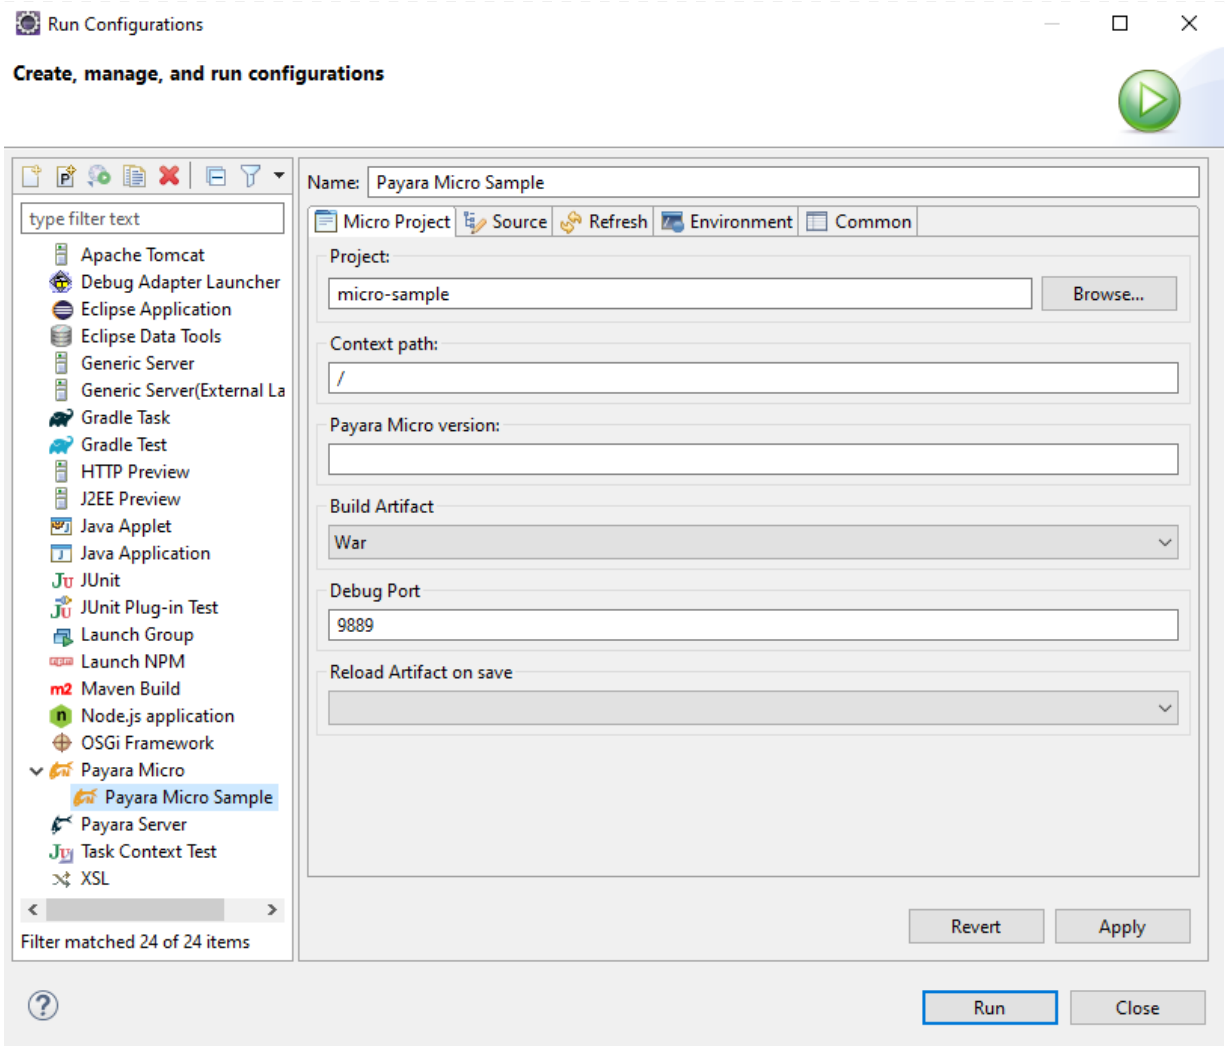
4. Associate the workspace project with the run configuration:



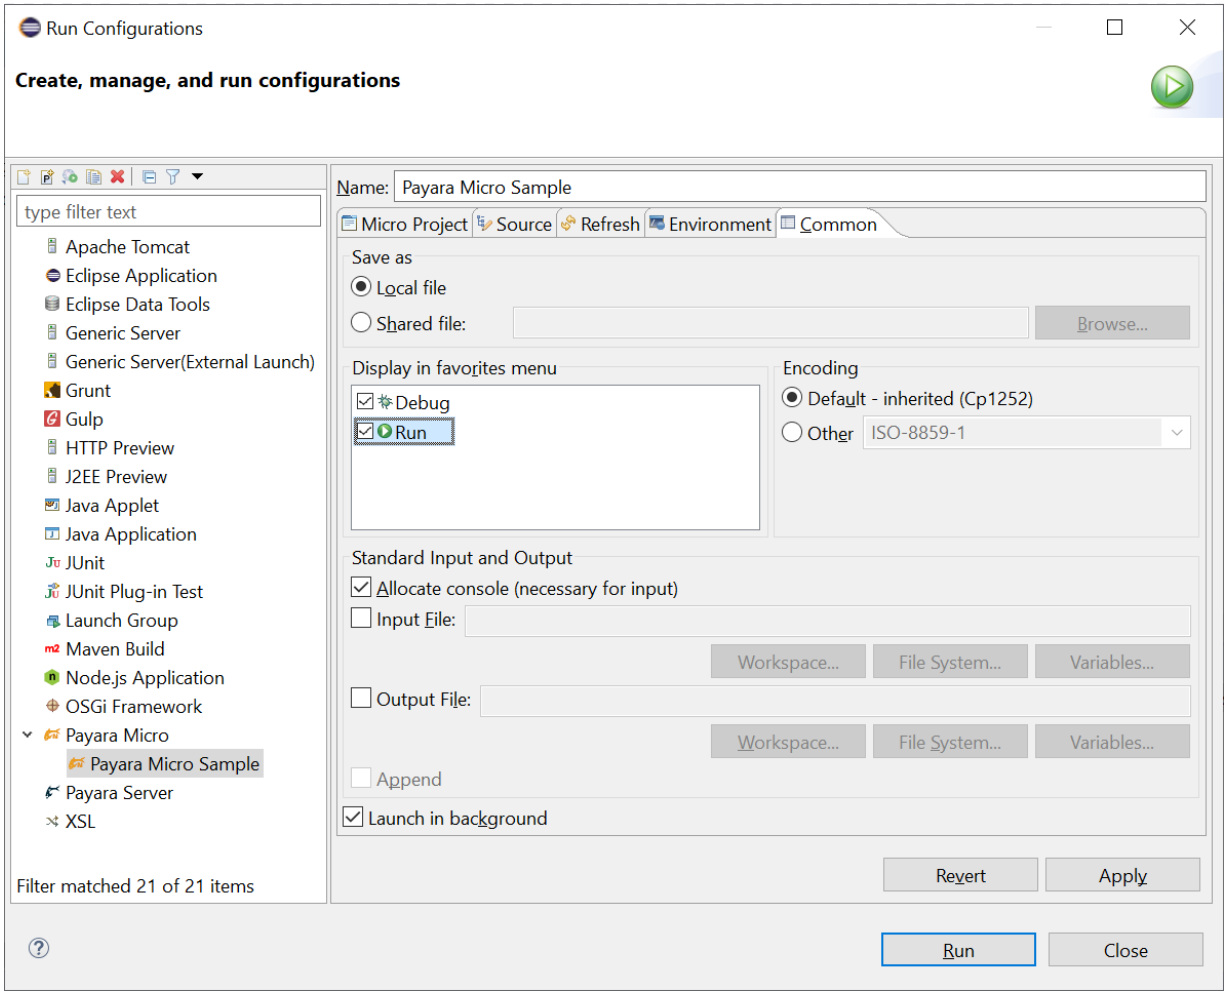
5. Click the browse button and select the project from the **Project Selection** dialog:



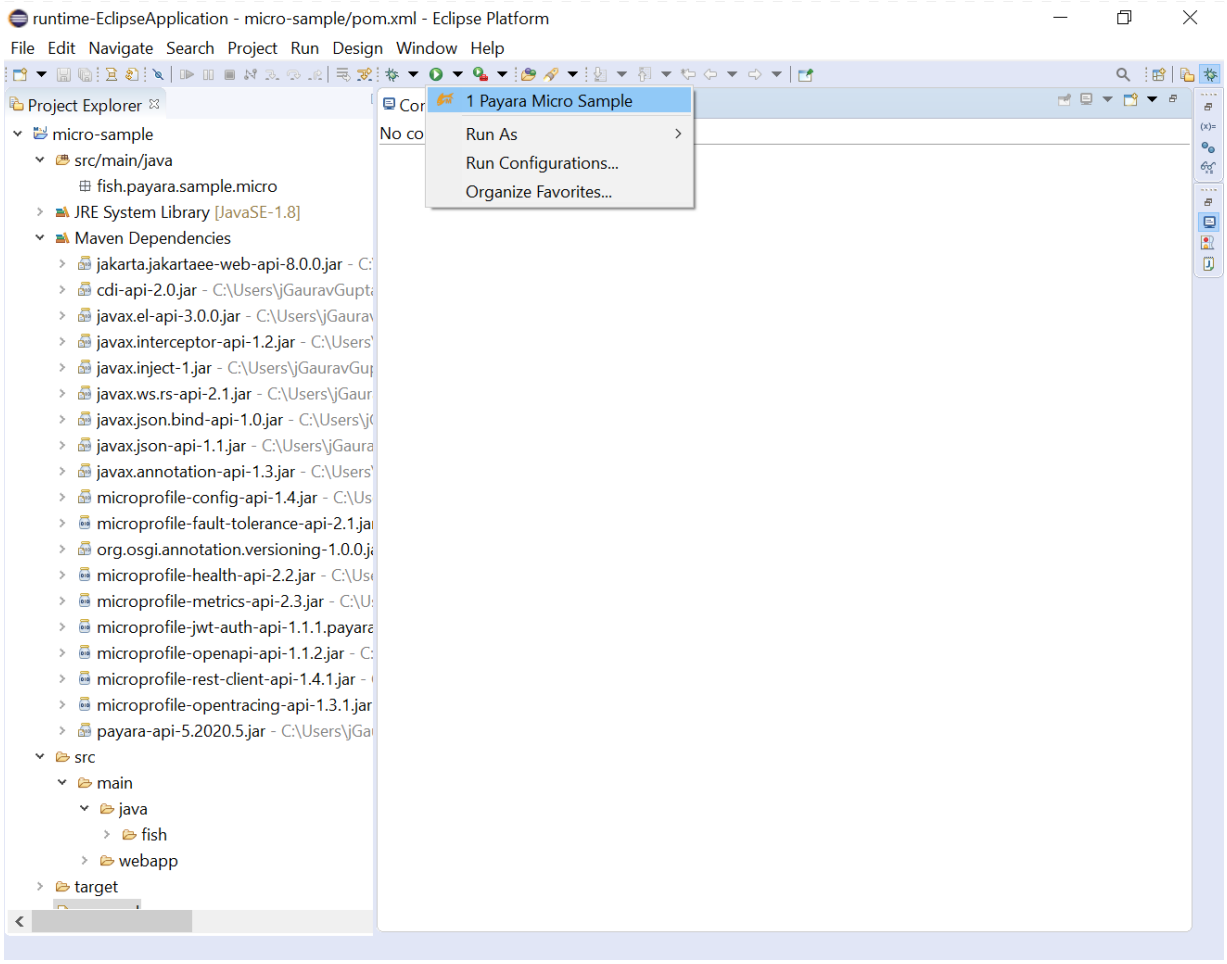
6. Enter the configuration name and choose the **Build Artifact** type



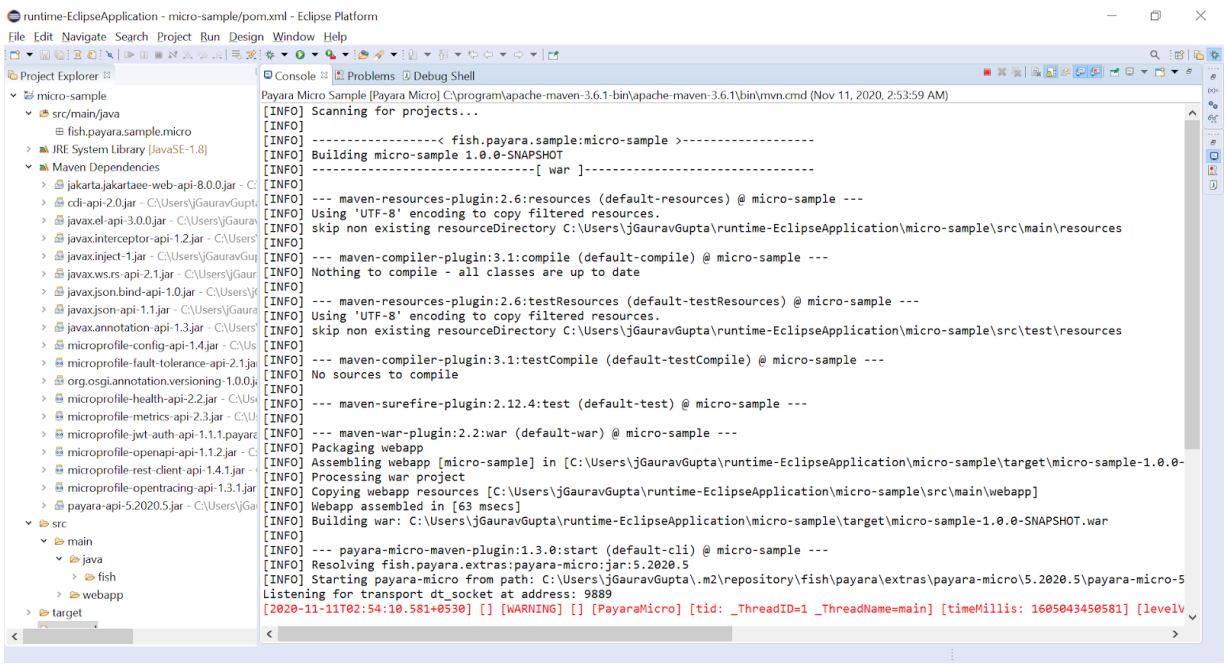
7. Add the configuration to **Run and Debug** menu and press the **Apply** button to save the configuration:

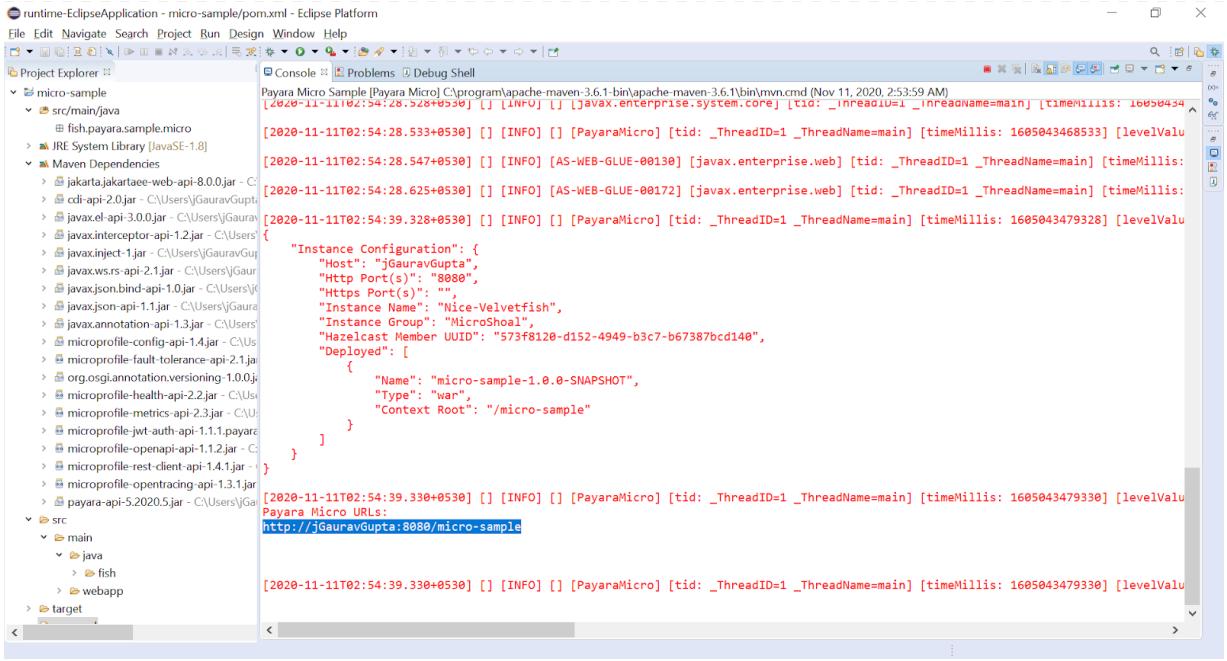


8. To start the Payara Micro instance, run the **Payara Micro Sample** configuration from the toolbar or main menu:



9. After running the Micro application, you may see the log in the OUTPUT window:

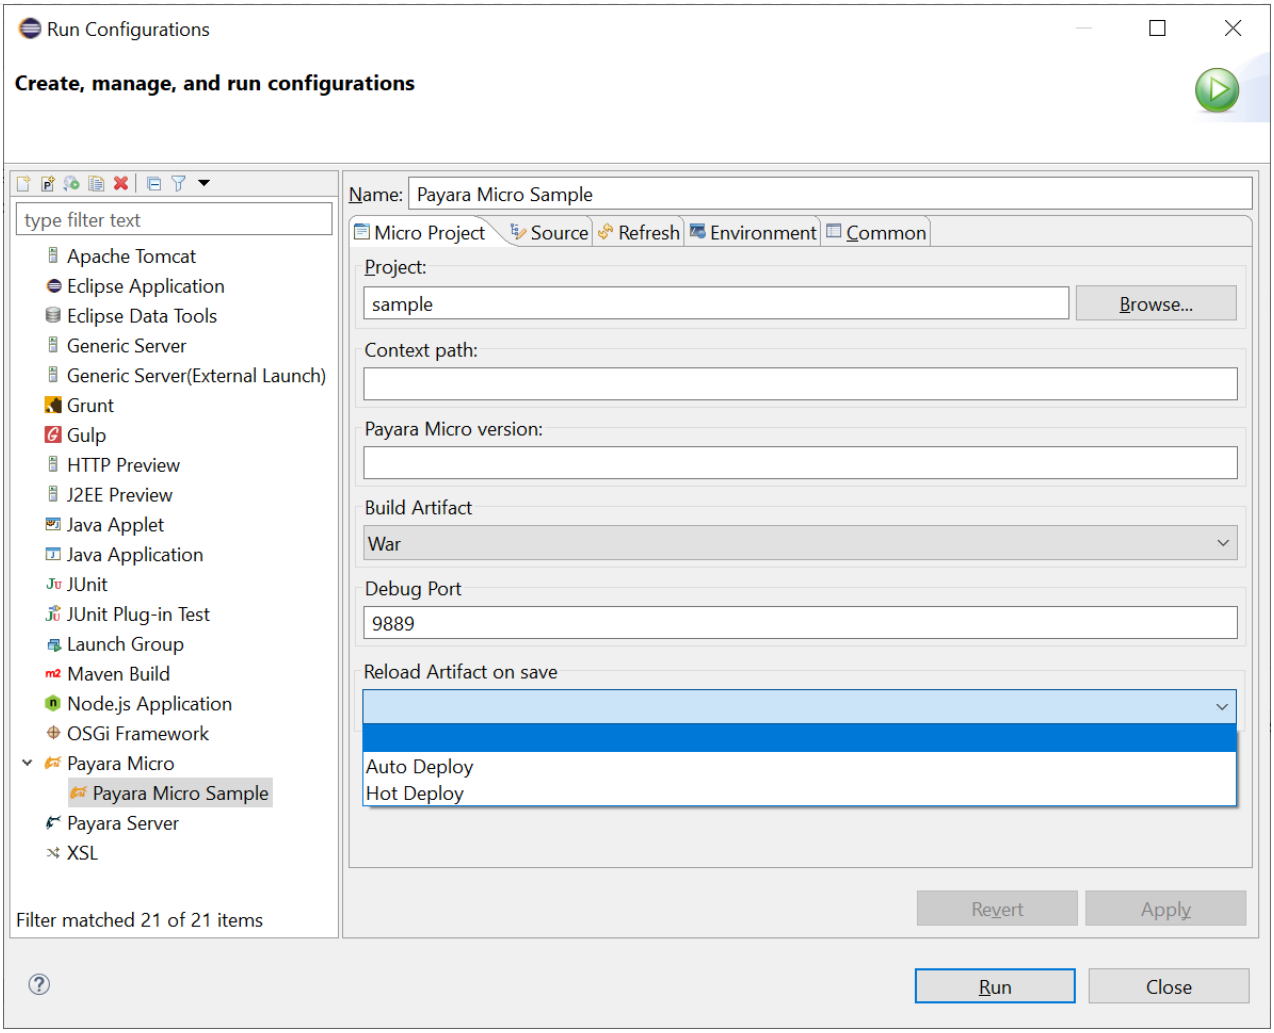




Similarly, to debug the Payara Micro application and attach the debugger to the application, instead of pressing the Run button, you can instead click **Debug** from similar locations and select the Payara Micro Sample configuration.

====== Hot Deploy and Auto Deploy Settings

To enable the **Auto Deploy** or **Hot Deploy** features for Payara Micro on the Eclipse IDE, modify your run configurations **Reload Artifact** action from the drop-down list:



====== See Also Hot Deploy and Auto Deploy

====== Building Eclipse Plugin

The Payara Tools Eclipse IDE Plugin source code is available in the Eclipse Plugin repository.

====== Prerequisites Before building the Payara Tools Eclipse plugin, you will need to configure your local environment. Subsequent builds will not require these steps.

Clone the ecosystem-eclipse-plugin repository

You must first clone the repository where the plugin source code is stored. Eclipse Plugin repository

Set the `JAVA_HOME` environment variable

An environment variable named JAVA_HOME must be created and point to a valid JDK 17 installation.

Install Apache Maven

Apache Maven is the build tool for the Payara Tools Eclipse IDE Plugin and must be configured locally. Visit Apache Maven Installation to install Maven.

====== Build Payara Tools To build Payara Tools for Eclipse, navigate to the root directory of the cloned repository and run the following command:

```
mvn clean install
```

This command will initiate the build process for the Payara Tools Eclipse plugin using Maven.

The build job will create both a zip and exploded-directory format. The zip format of this build can be found in the `[project_root]/releng/fish.payara.eclipse.update/target` directory, and the exploded-directory format can be found in the `[project_root]/releng/fish.payara.eclipse.update/target/repository` directory.

====== Install Payara Tools into Eclipse After Payara Tools for Eclipse has been compiled successfully, you need to add it into the Eclipse IDE.

Adding Payara Tools to Eclipse

1. Navigate to Help → Install New Software…
2. Click Add → Archive…
3. Select the zip format in `[project_root]/releng/fish.payara.eclipse.update/target`
4. Select the Eclipse Payara Tools checkbox
5. Click Next → Finish
6. Select Install Anyway
7. Restart Eclipse when prompted

[Installing Payara Tools] | *../_images/eclipse-plugin/Install Payara Tools.gif*

====== Removing Payara Tools from Eclipse Removing Payara Tools from Eclipse after installing using the method above is the same as removing any plugin from Eclipse.

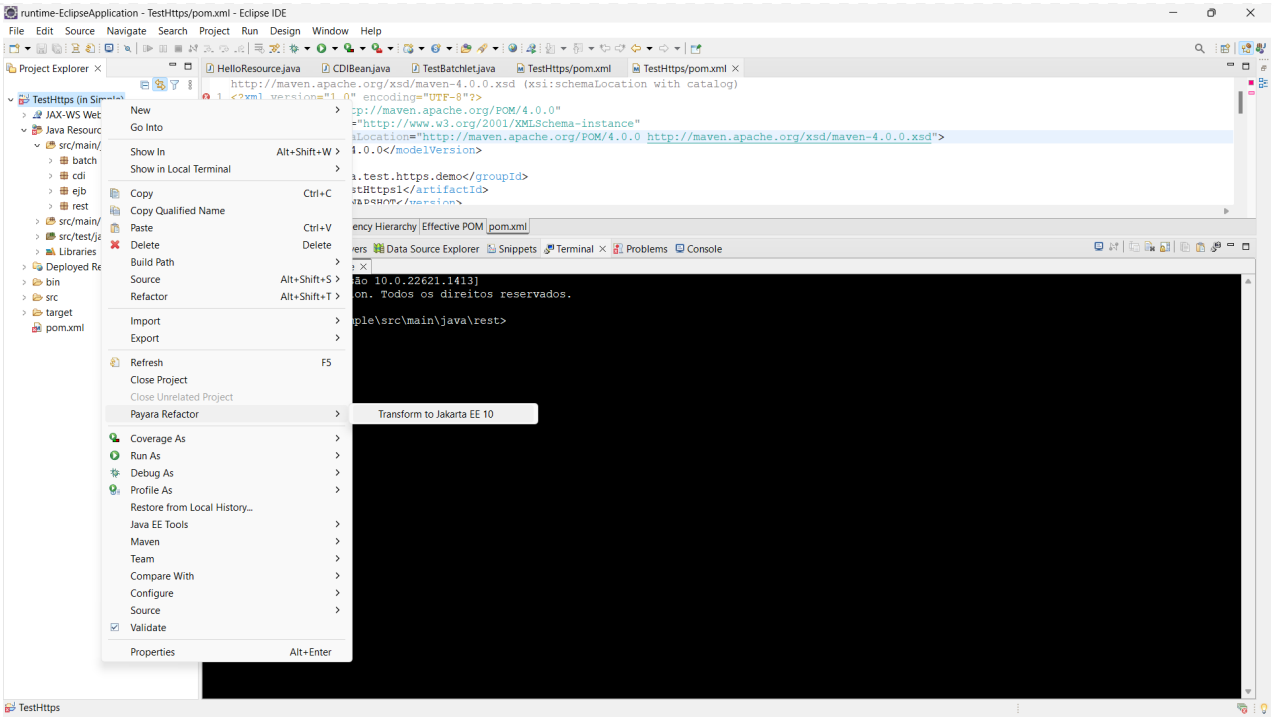
Removing Payara Tools from Eclipse

1. Navigate to Help → Eclipse Marketplace
2. Open the Installed tab
3. Locate Payara Tools and click Uninstall

====== Transform to Jakarta-EE10

Using the `Payara Tools plugin`, you can transform whole projects or single files from Java EE 8 to Jakarta EE 10.

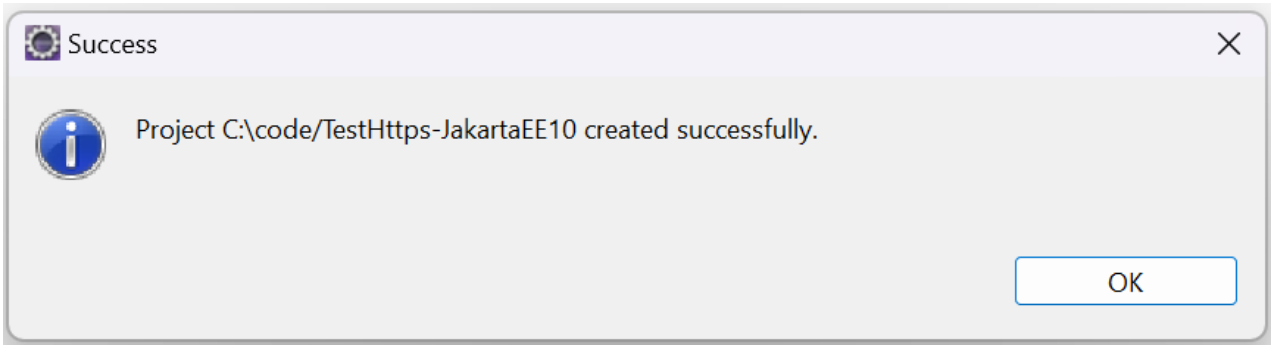
====== Refactor a Java EE 8 Project to Jakarta EE 10 To refactor a Java EE 8 based **Maven** project right click on root project folder and choose **Payara Refactor→Transform to Jakarta EE 10**:



The plugin will open a dialog to choose the destination folder where the new project will be created:

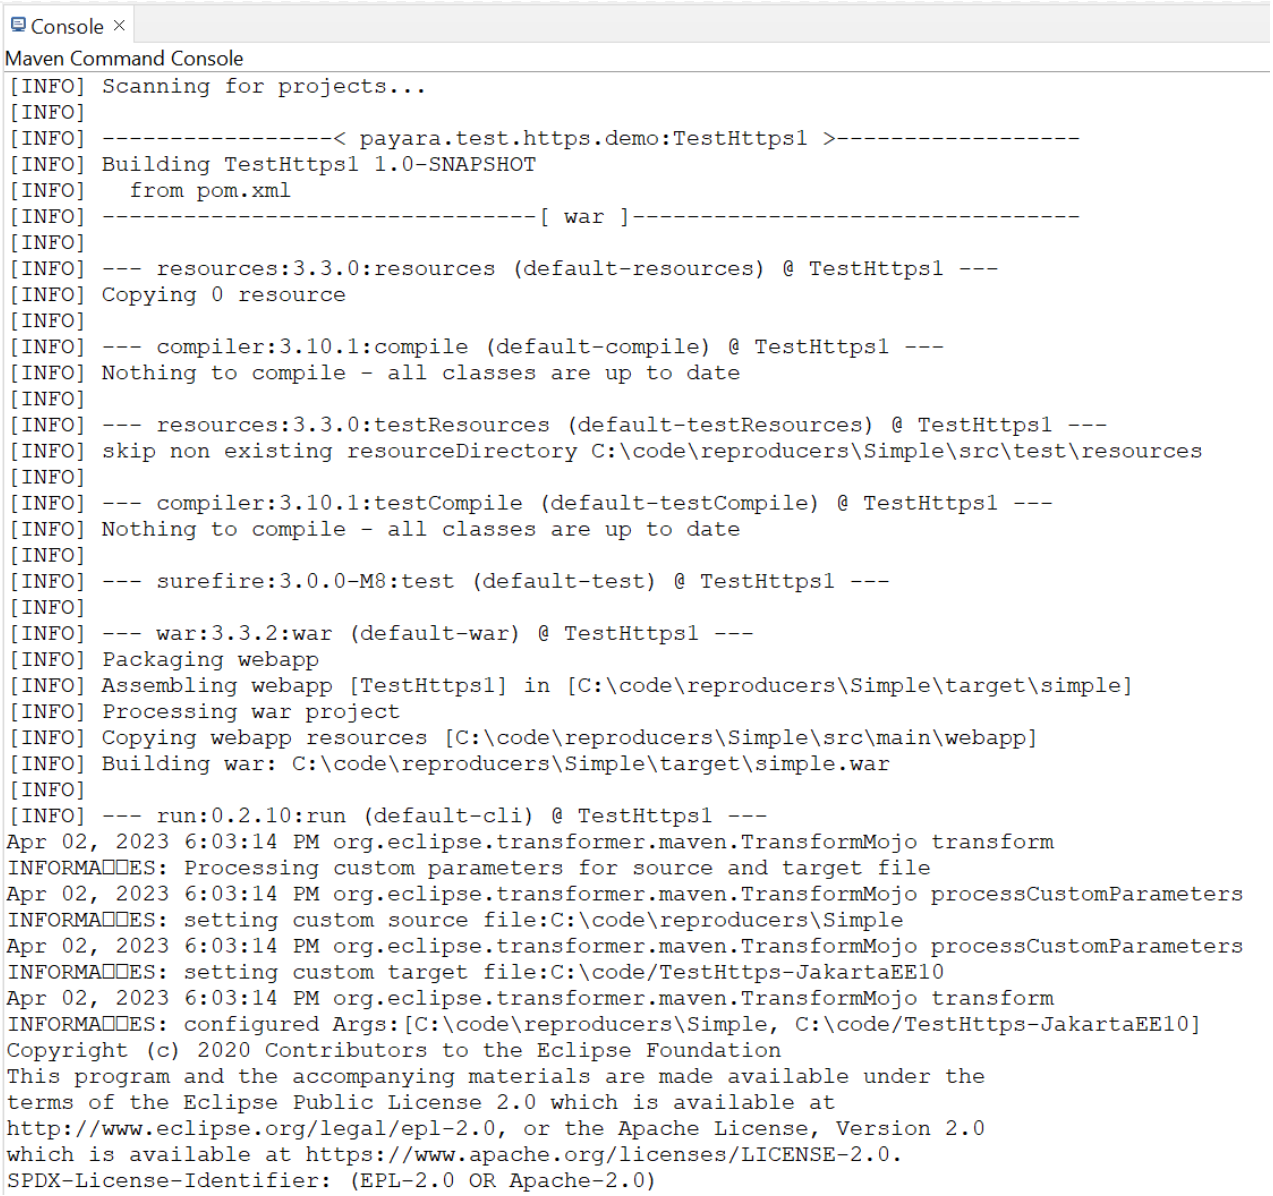
[Choose Project Destination Folder] | *../_images/eclipse-plugin/transform-to-jakarta/choose-new-project-dest-folder.png*

After choosing the `Destination Directory`, a confirmation message will appear indicating that the project was generated.

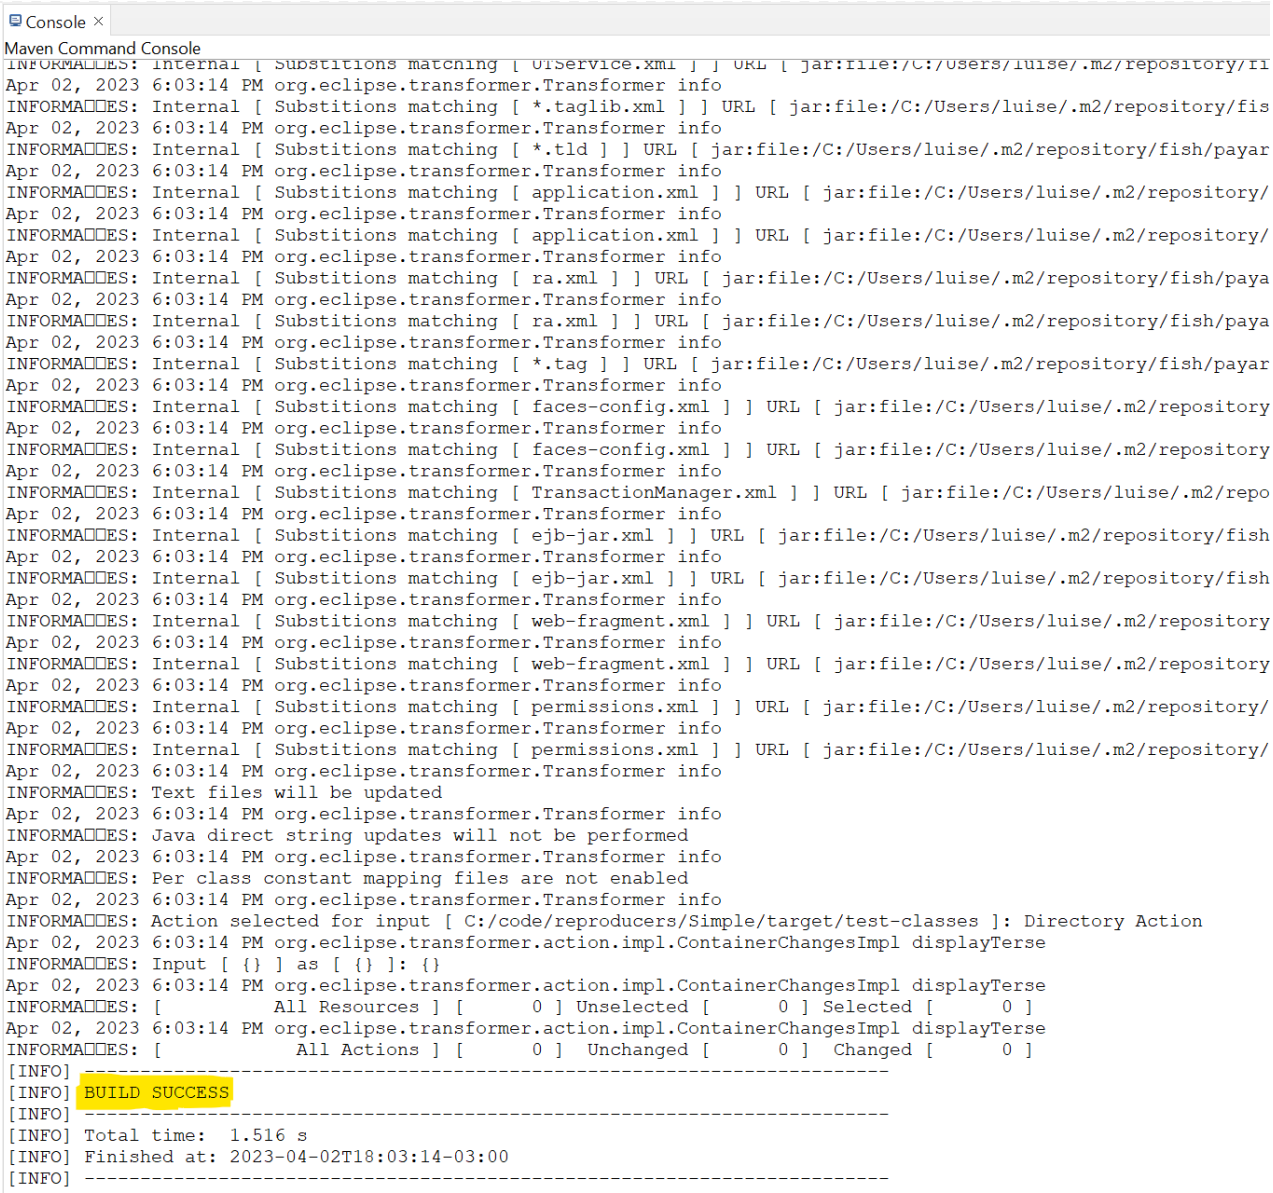


You can see the output of the generation process in the Eclipse console.

The Maven plugin that executes the transformation process will print its output to the IDE's console:



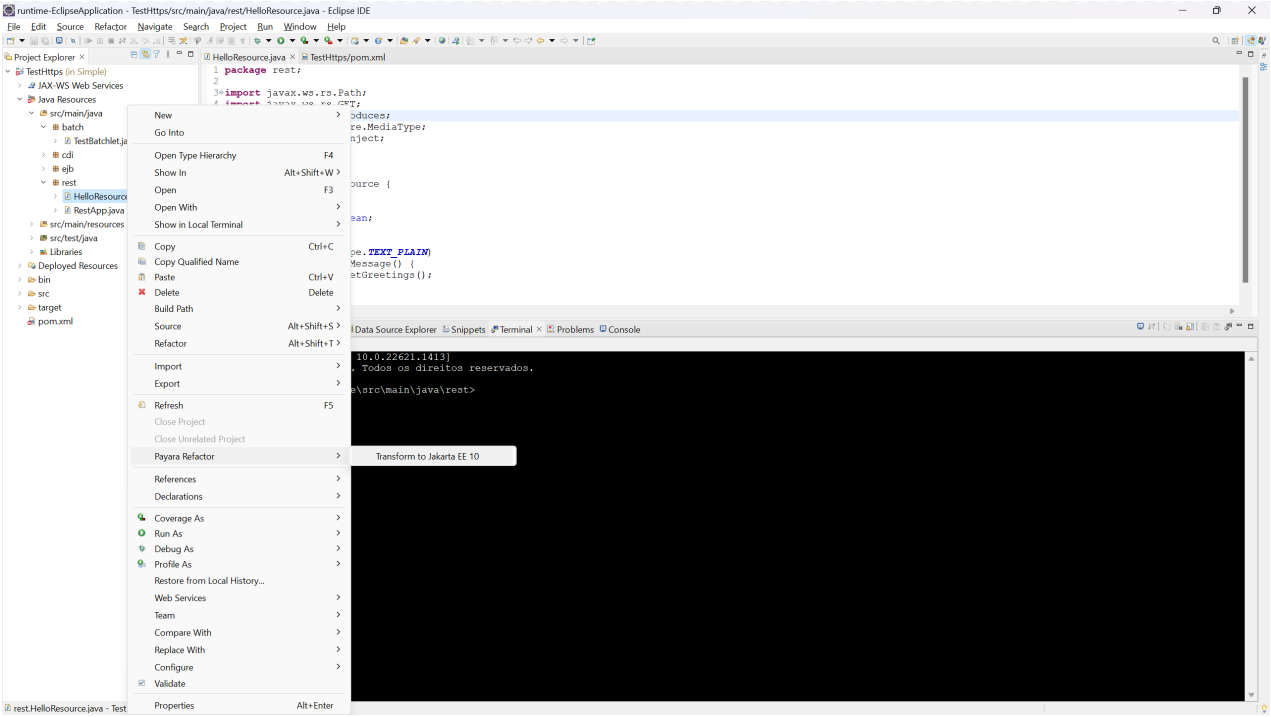
A maven `BUILD SUCCESS` message should be logged in the IDE's console.



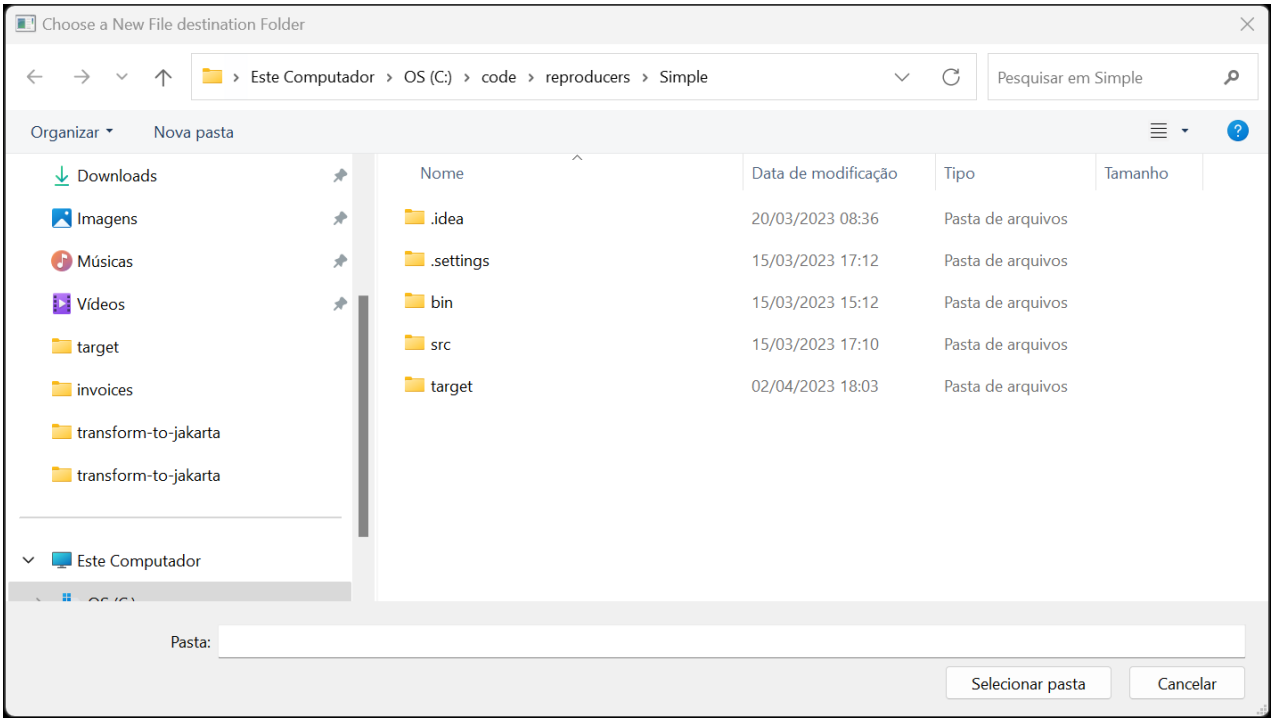
When the whole project is transformed, the plugin adds `JakartaEE10` at the end of the project name. In our example, `demo-JakartaEE10` project was created from `demo` project.

====== Transform a Single File

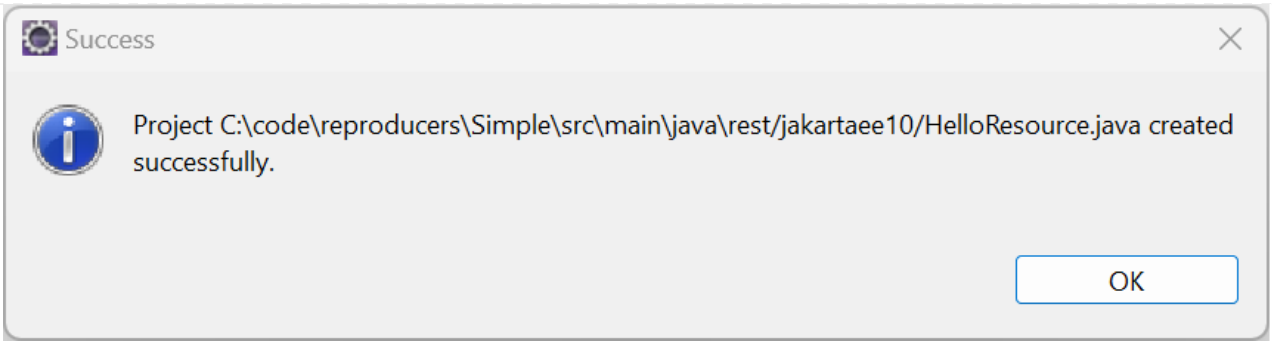
To refactor a `Java EE 8 file` right click on it and choose **Payara Refactor→Transform to Jakarta EE 10** option:



The plugin will open a dialog to choose the destination package where the new file will be created:



After choosing the `Destination Package`, a confirmation message will appear indicating that the file was generated.



You can see the output of the generation process in the Eclipse console.

The output of the Maven plugin that executes the transformation code can be reviewed in the IDE's console:

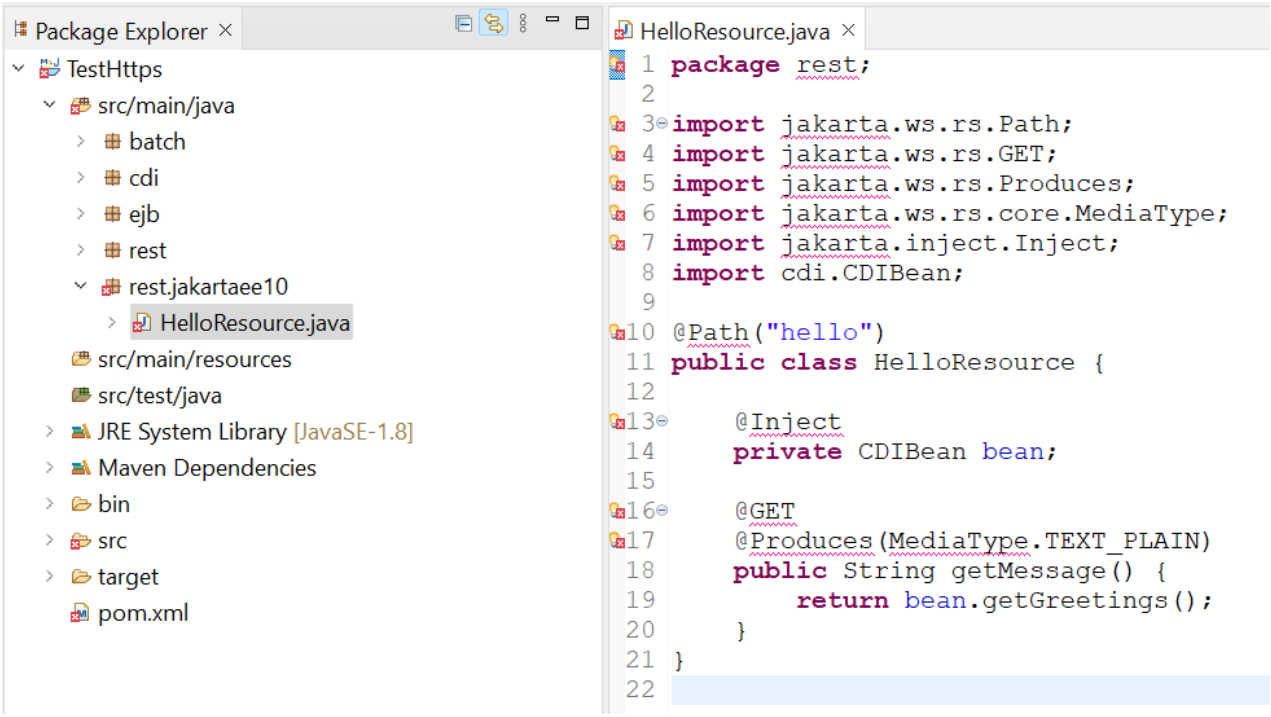
The new file will be located in the chosen destination package.



When a single file is transformed, a `jakartaee10` package containing the new file will be created in the destination package.

===== IntelliJ Plugin

====== Overview

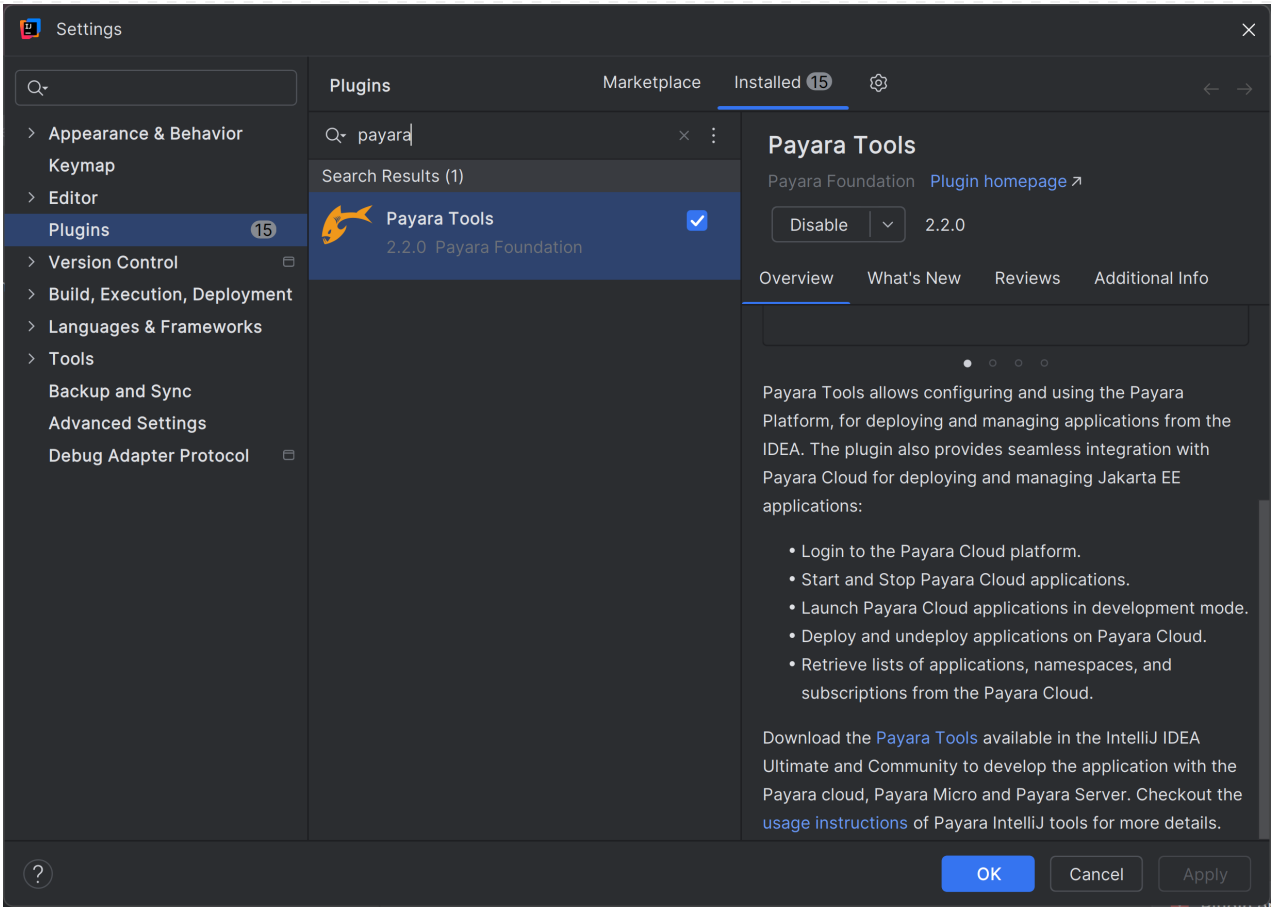
The Payara IntelliJ Ultimate Tools enables Payara Server, Payara Micro and Payara Cloud integration with IntelliJ IDEA Ultimate Edition. The Payara IntelliJ Ultimate Tools plugin is available in the JetBrains Plugins Marketplace.

If you are developing an application on IntelliJ IDEA Community Edition, you should install the Payara IntelliJ Community Tools plugin which enabled integration of Payara Micro with IntelliJ IDEA Community Edition. The Payara IntelliJ Community Tools Plugin is also available in the JetBrains Plugins Marketplace.

If you are using IntelliJ IDEA Ultimate, you should only install the `Payara IntelliJ Ultimate Tools` plugin. This contains support for both Payara Server and Payara Micro.

====== Installing Payara Tools

1. Open IntelliJ IDEA and navigate to **File** > **Settings** > **Plugins**
2. In the Plugins dialog, switch to the **Marketplace** tab
3. Search for **Payara**
4. Click the **Install** button for **Payara Tools**
5. Click **OK** to apply the changes and restart IntelliJ IDEA if prompted



====== Payara IntelliJ Tools features

- Payara Server - The Payara IntelliJ Ultimate Tools enables developers to easily configure Payara Server and manage applications from IntelliJ IDEA.
- Payara Micro - The Payara IntelliJ Ultimate Tools provide support to create, run and debug Payara Micro applications from IntelliJ IDEA. Payara Micro is the microservices-ready version of the Payara Server.

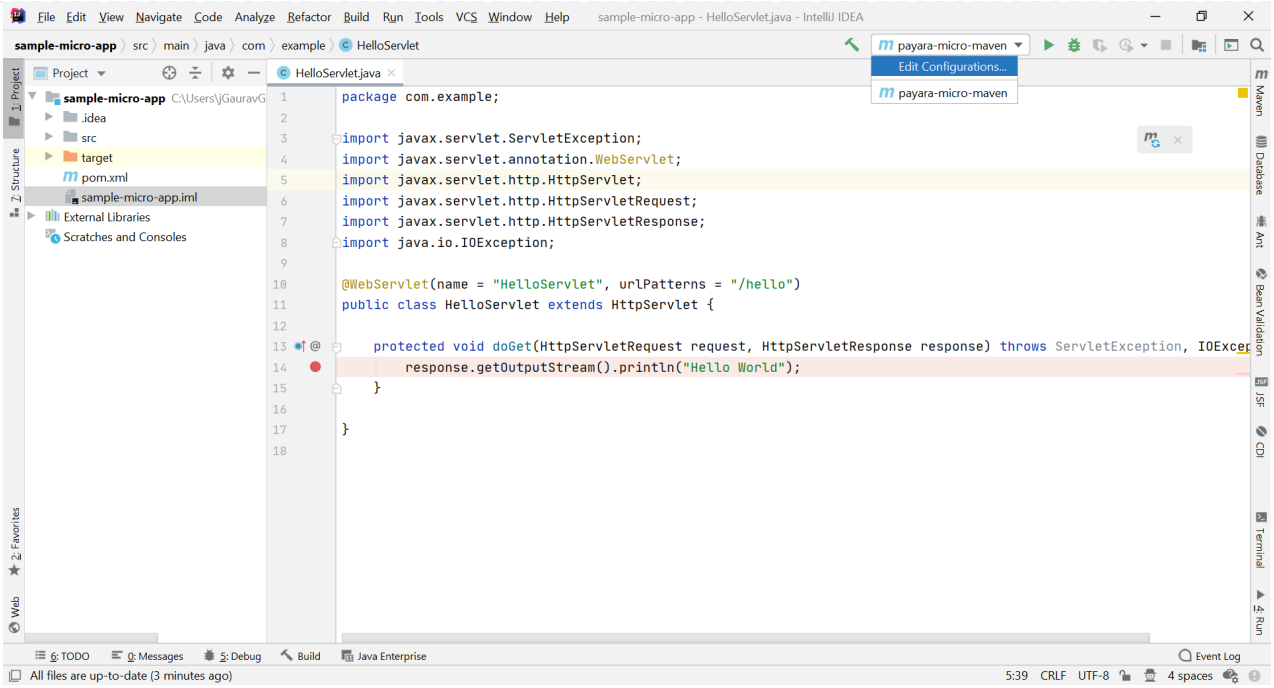
====== Payara Server

This is only available in the `Payara IntelliJ Ultimate Tools` plugin which is exclusive to IntelliJ IDEA Ultimate

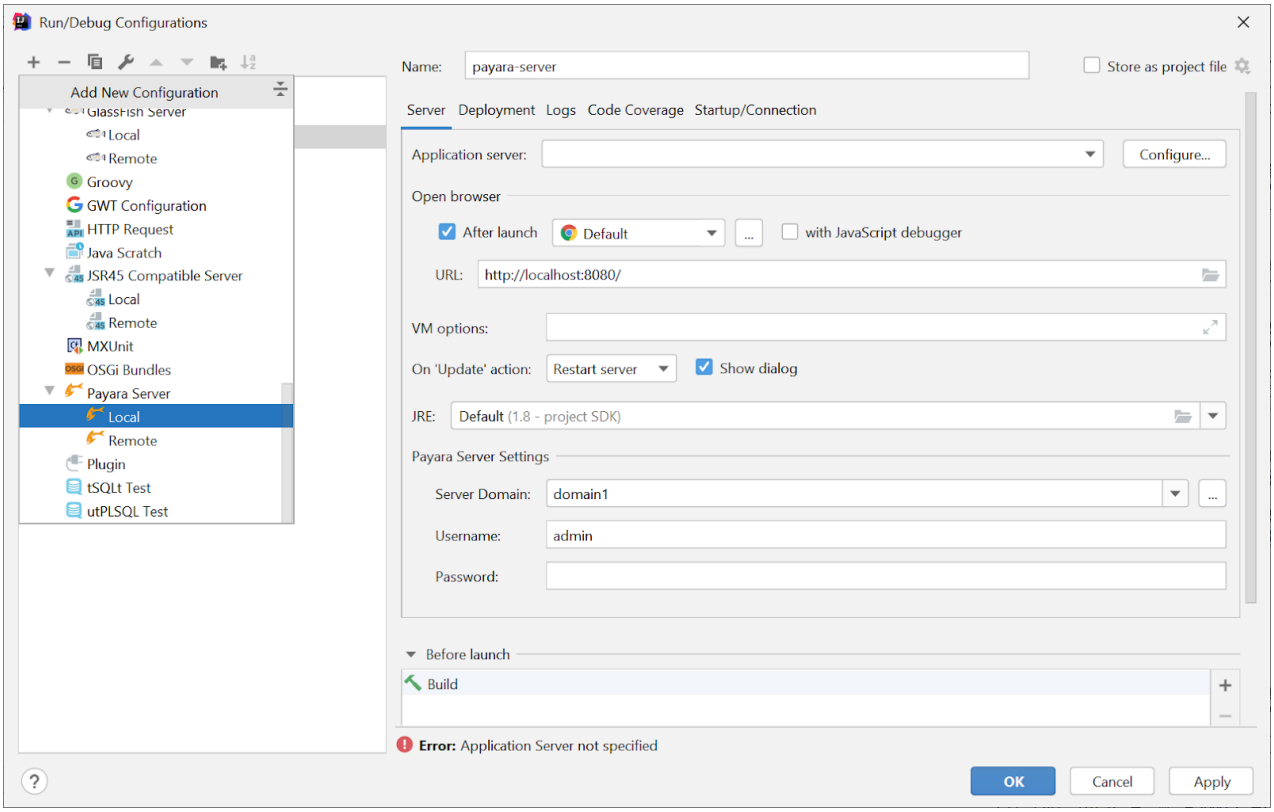
Using the Payara IntelliJ Ultimate Tools plugin, you can integrate Payara Server within the IntelliJ IDEA and perform the following tasks:

- Start and stop the Payara Server from within the IDE
- Define the Java runtime to be used by Payara Server
- Deploy an application from within the IDE

====== Managing Payara Server from the IntelliJ IDE To manage Payara Server from the IntelliJ idea, first create the new **Payara Server configuration** by selecting the **Edit Configuration** option:



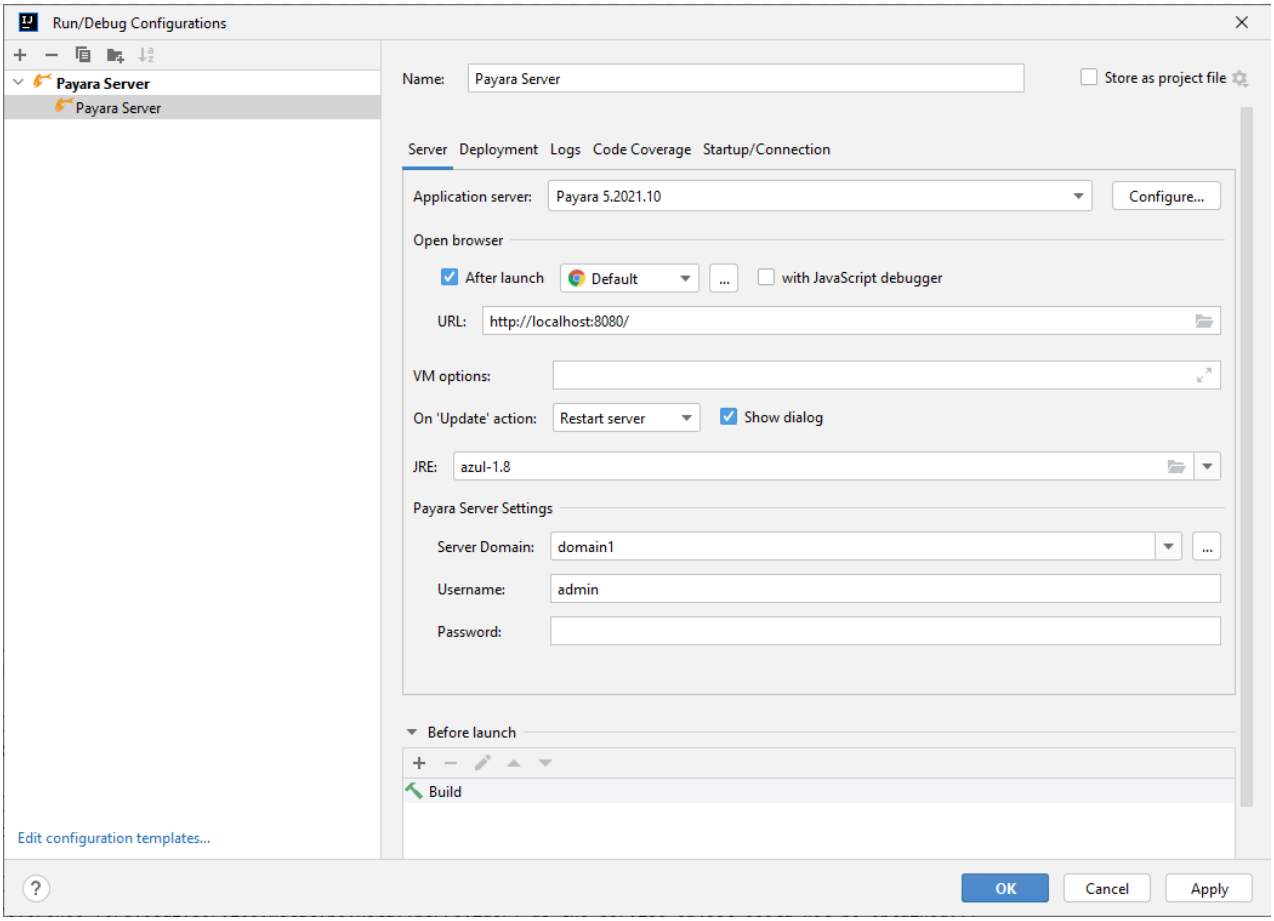
In the **Run/Debug Configurations** dialog, click +, expand the **Payara Server** node, and select **Local**:



To add the Payara Server to the configuration, click the **Configure...** button and set it to the Payara Server's installation path you would like to add to the IDE.

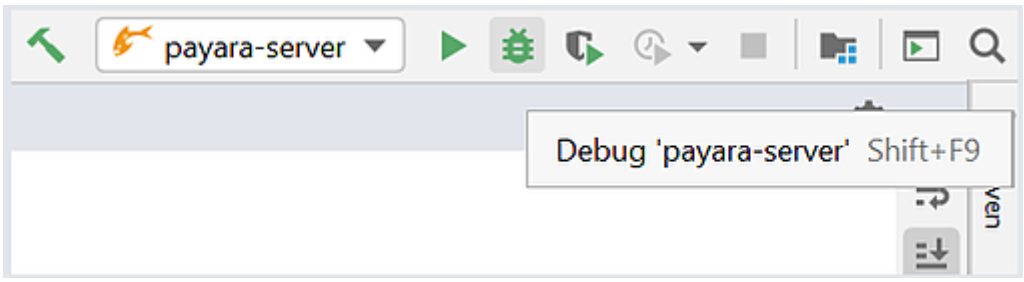
Specify the path to the JRE or JDK version you would like Payara Server to run on.

Finally, fix the debugger related warning by pressing the **Fix** button, which updates the debugger settings in the domains.xml of the selected Payara Server's domain.



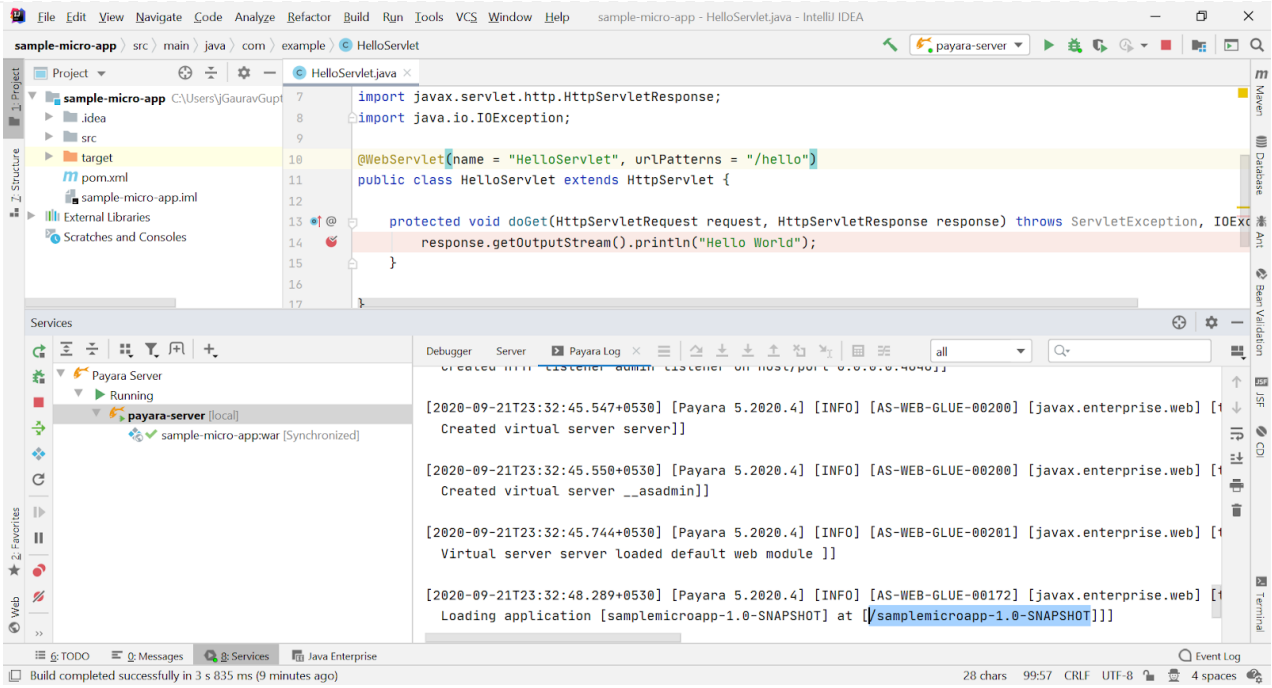
For now, ignore the `No artifacts marked for deployment` warning and click **OK** to save the configuration

Click the **Run or Debug** button from top-right panel to start Payara Server, or start Payara Server in debug mode, which would allow you to debug deployed applications



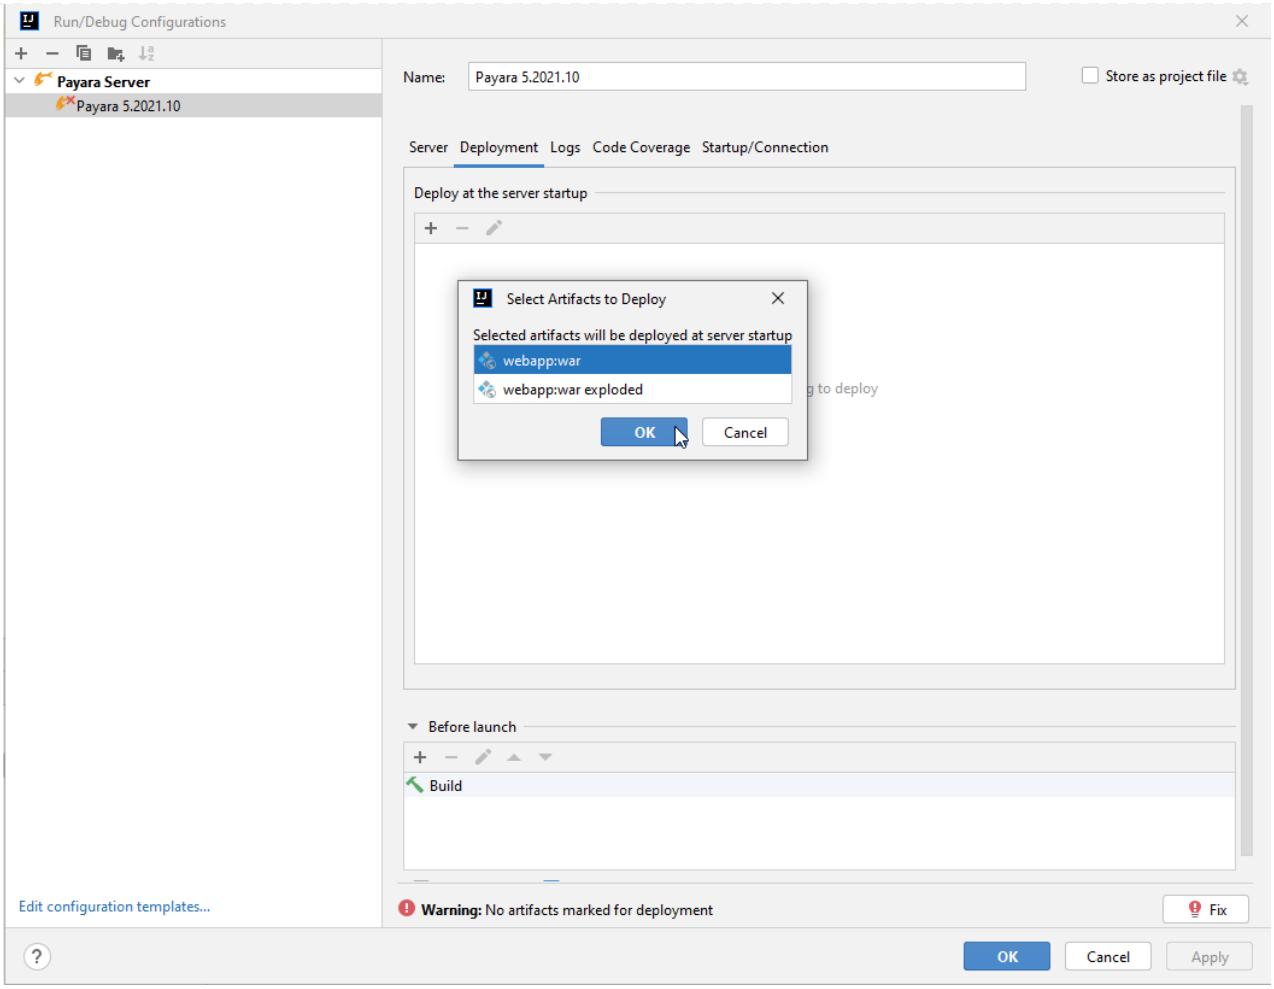
You can see the server log in the **Run** > **Payara Log** window.

You can filter logs by level with the dropdown menu on the right of the `Payara Log`



====== Deploying an Application to Payara Server from IntelliJ To deploy an application to Payara Server you must further edit the run configuration you are using to run Payara Server from IntelliJ.

1. Select the Run Configurations drop down menu
2. Click on **Edit Configurations**
3. Choose the Payara Server configuration to which you want to deploy the application.
4. In the configuration settings, navigate to the **Deployment** section and click on the + button.
5. Select **Artifact...** then choose the non-exploded format of your application's name.
6. Click **OK**



After application deployed to the Payara Server, IntelliJ starts a web browser and opens the application context root in the web browser.

====== Deploy Applications in a Local Docker Container

The Payara Server tools for IntelliJ IDEA include Docker integration, making it seamless to deploy exploded applications to a Payara Server instance running within a local Docker container.

1. Run the Payara Server Docker container using the following command:

   ```
   docker run -p 8080:8080 -p 4848:4848 -p 9009:9009 -v HOST_PATH:CONTAINER_PATH
   payara/server-full:{page-version}
   ```

   Replace `HOST_PATH` with the actual host path and `CONTAINER_PATH` with the desired container path that must be the exploded application path or parent path of application.

   The `HOST_PATH` points to the location on your host machine, and `CONTAINER_PATH` is the corresponding location inside the container.

2. Open Intellij IDEA Ultimate and first create the new **Payara Server configuration** by selecting the **Edit Configuration** option:
3. In the **Run/Debug Configurations** dialog, click `+`, expand the **Payara Server** node, and select **Remote**.

4. To add the Payara Server to the configuration, click the **Configure...** button and set it to the Payara Server's installation path with the same version as the one running in the Docker container.
5. For Docker integration, choose the "Docker Volume" option and provide the `HOST_PATH` (e.g., `D:/test`) and `CONTAINER_PATH` (e.g., `/mnt/test`) mapping details.

   This mapping should align with the exploded application path or parent path of exploded application.
6. Navigate to the **Deployment** section and click on the `+` button to select **Artifact...**.
7. Click **OK**
8. Click the **Run or Debug** button from top-right panel to deploy the application to the registered Payara Server docker instance.

====== Deploy Applications in a WSL Environment

Another noteworthy feature is the integration of the Payara Server Tools with Windows Subsystem for Linux (WSL).

This integration empowers developers to manage and deploy exploded applications to a Payara Server instance running within WSL.

Here's how you can make use of this feature:

1. Start the Payara Server instance within WSL:
   a. Run the following command to start the server:

   ```
   ./asadmin start-domain
   ```

   b. Set a password for the admin user:

   ```
   ./asadmin change-admin-password
   ```

   c. Enable secure admin:

   ```
   ./asadmin enable-secure-admin
   ```

   d. Restart the Payara Server domain:

   ```
   ./asadmin restart-domain
   ```
2. Register the WSL-based Payara Server instance in the IntelliJ IDEA:
   a. Open Intellij IDEA Ultimate and first create the new **Payara Server configuration** by selecting the **Edit Configuration** option:

b. In the **Run/Debug Configurations** dialog, click `+`, expand the **Payara Server** node, and select **Remote**.

c. To add the Payara Server to the configuration, click the **Configure…** button and set it to the Payara Server's installation path running within WSL on your Windows machine.

d. For WSL integration, choose the "WSL" option and make sure **Use SSL Connection** option is checked.

e. Enter the host (fetched via the command `hostname -I` in WSL instance) and the necessary credentials.

f. Navigate to the **Deployment** section and click on the + button to select **Artifact…**.

g. Click **OK**

h. Click the **Run or Debug** button from top-right panel to deploy the application to the registered Payara Server WSL environment.

====== Payara Server Maven Plugin

Using the Payara Tools and Payara Server Maven Plugin, you can integrate Payara Server within the IntelliJ IDEA to streamline development workflows. This integration allows you to:

- Start and stop the Payara Server from within the IDE
- Define the Java runtime to be used by Payara Server
- Deploy an application from within the IDE
- Configure pre-launch Maven tasks for automatic build and deployment

====== Managing Payara Server using Maven Plugin from IntelliJ IDEA . To manage Payara Server using the Maven plugin from IntelliJ IDEA, first create the new **Payara Server configuration** by selecting the **Edit Configuration** option: image::intellij-plugin/payara-server-maven-plugin/create-configuration.png[Create Configuration]

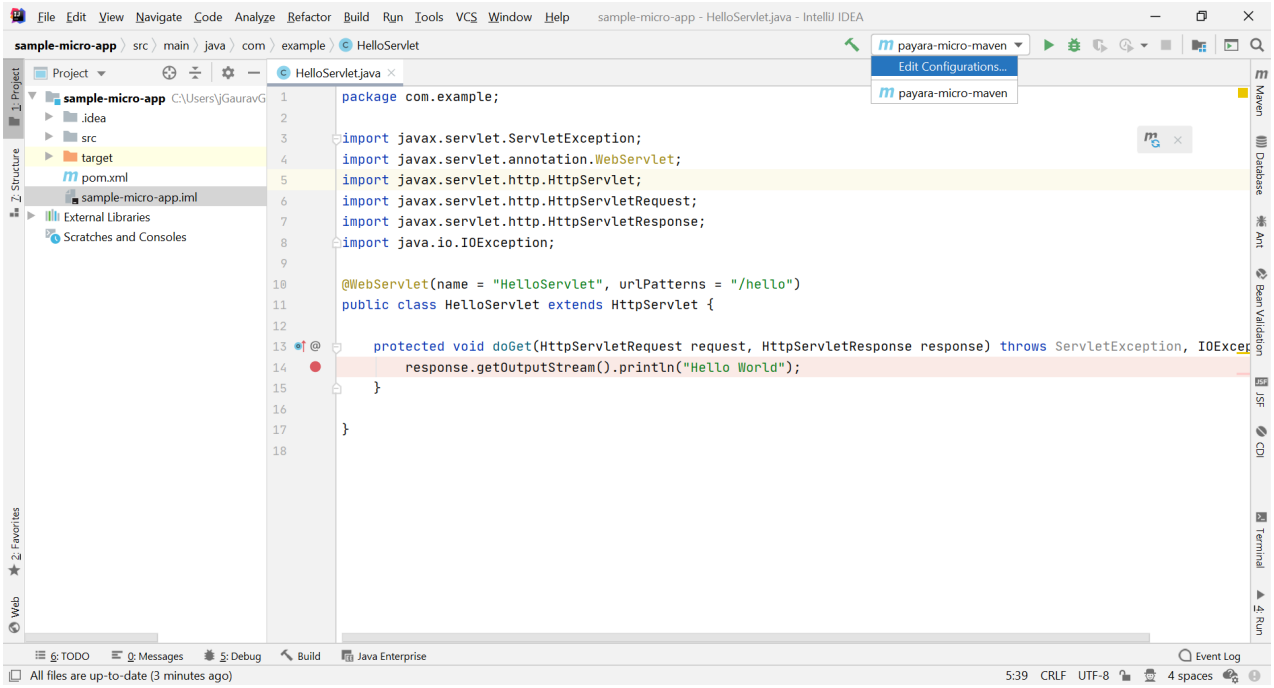
1. In the **Run/Debug Configurations** dialog, click +, select the **Payara Server**: image::intellij-plugin/payara-server-maven-plugin/create-server-configuration.png[Create Server configuration]
2. In the newly created configuration:
   a. Set the goal to `dev` to deploy the application in development mode using the Payara Server Maven Plugin or `start` to start the server without dev mode.
   b. Specify the JDK or JRE path that Payara Server should use.
3. Optionally, configure the application's context path or deployment format (e.g., exploded). image::intellij-plugin/payara-server-maven-plugin/app-configuration.png[App configuration]
4. To add the Payara Server to the configuration, click the **Payara Server Settings** > **Payara Home** and set it to the Payara Server's installation path you would like to add to the IDE. image::intellij-plugin/payara-server-maven-plugin/payara-configuration.png[Payara configuration]
5. Configure environment variables and system properties required by the server and Maven

plugin. image::intellij-plugin/payara-server-maven-plugin/env-server-properties.png[Env and Server properties]

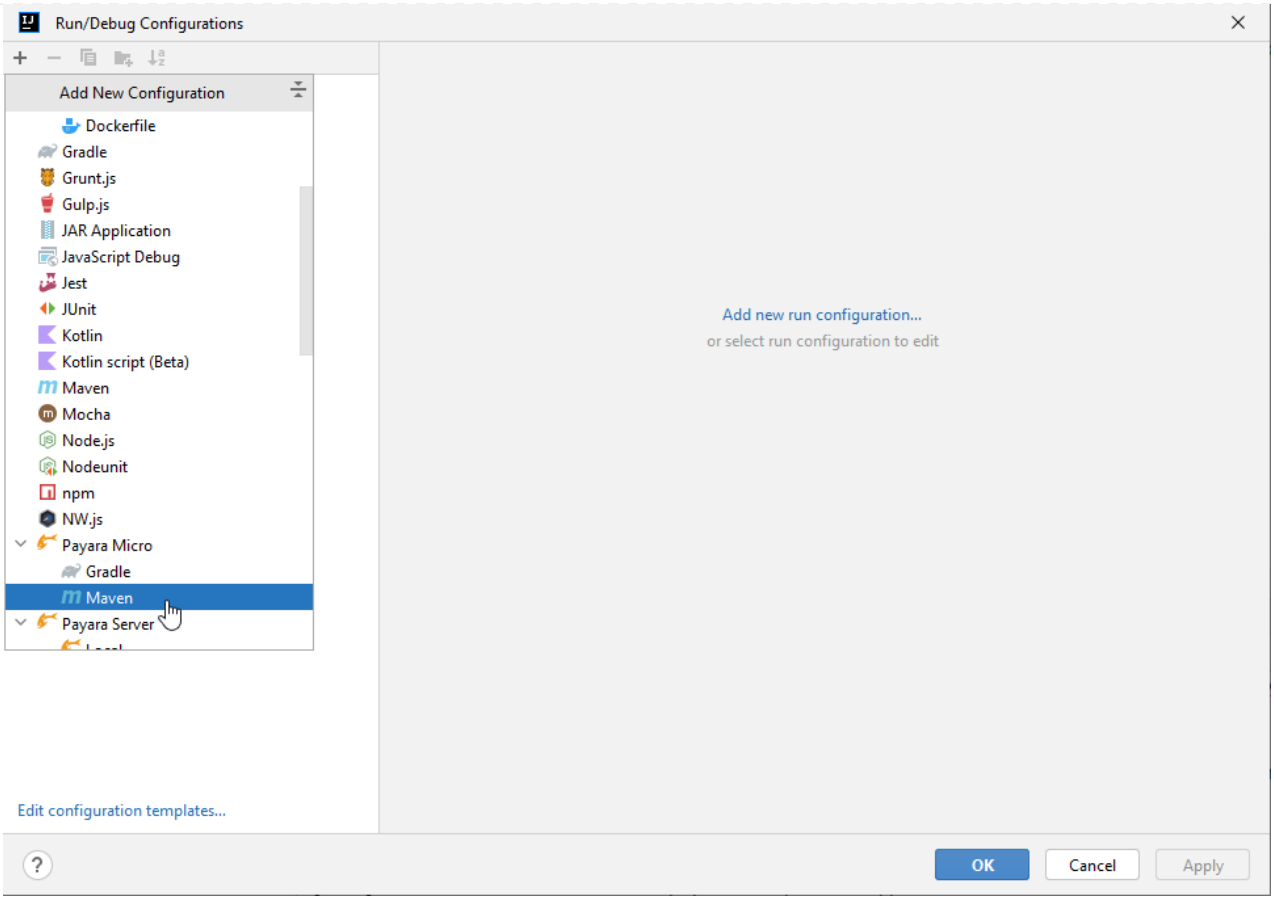
6. Define additional Maven properties used by the Payara Server Maven Plugin during the build and deployment process. image::intellij-plugin/payara-server-maven-plugin/maven-properties.png[Maven properties]
7. Specify Maven tasks to run before launching the server. image::intellij-plugin/payara-server-maven-plugin/before-launch-task.png[Before Launch Task]
8. Click the **Run or Debug** button from top-right panel to start Payara Server, or start Payara Server in debug mode, which would allow you to debug deployed applications image::intellij-plugin/payara-server-maven-plugin/run-server.png[Start the Payara Server]
9. You can see the server log in the **application build console** window. image::intellij-plugin/payara-server-maven-plugin/server-log.png[Payara Server log]
10. After application deployed to the Payara Server, IntelliJ starts a web browser and opens the application context root in the web browser.

====== Payara Micro

====== Run Payara Micro from IntelliJ To run Payara Micro from IntelliJ, you need to first configure Payara Micro as a run configuration.

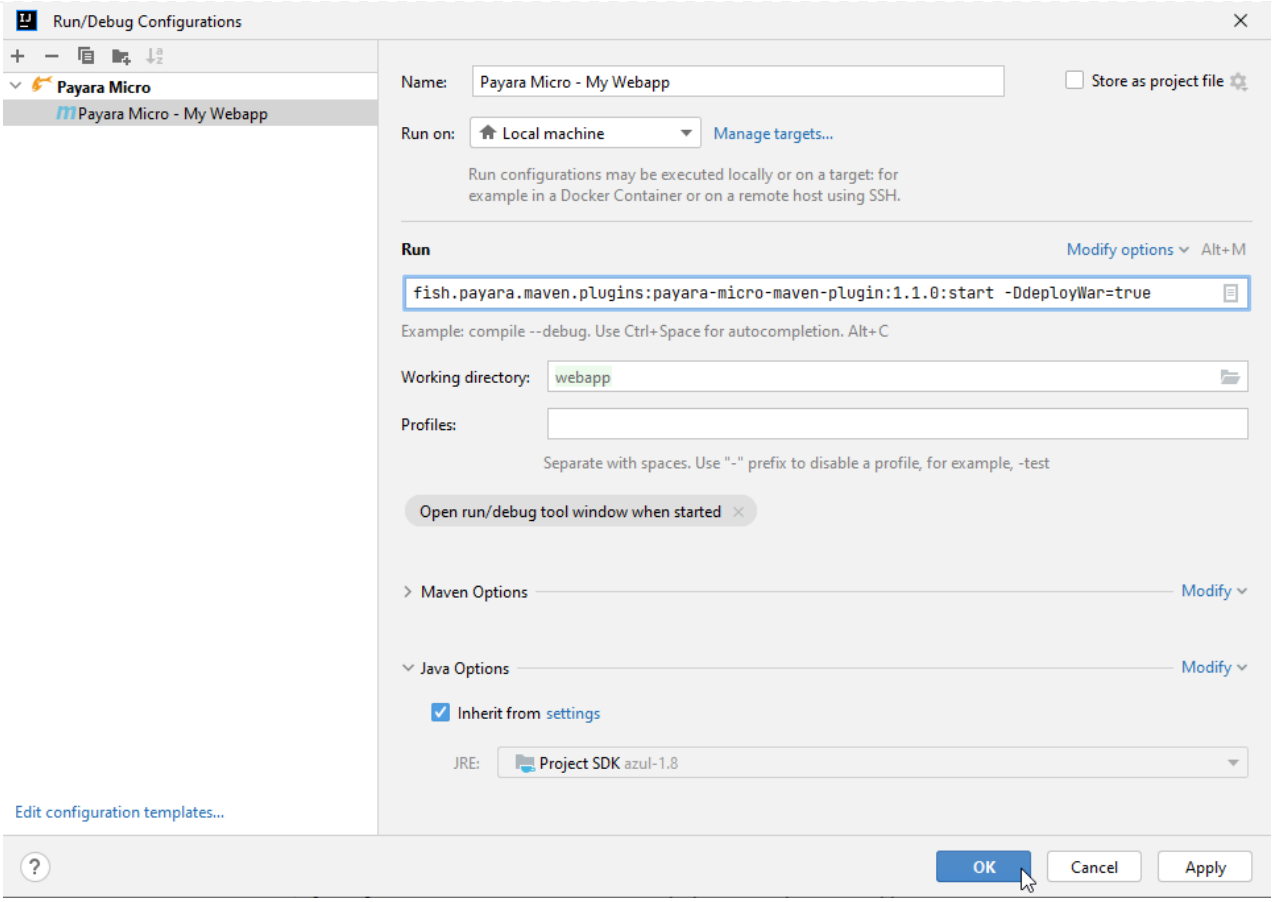


In the **Run/Debug Configurations** dialog, click +, expand the **Payara Micro** node, and select **Maven** or **Gradle**:



This run configuration will be configured by default to deploy the project you are currently working on. If you wish to modify which application is deployed, edit the `Working Directory` option. Otherwise the default settings are correct, and click **OK**.

Due to a known issue within the IntelliJ IDEA Payara plugin, you must modify the default `Run` option by removing the leading and trailing quotation marks, `"`.

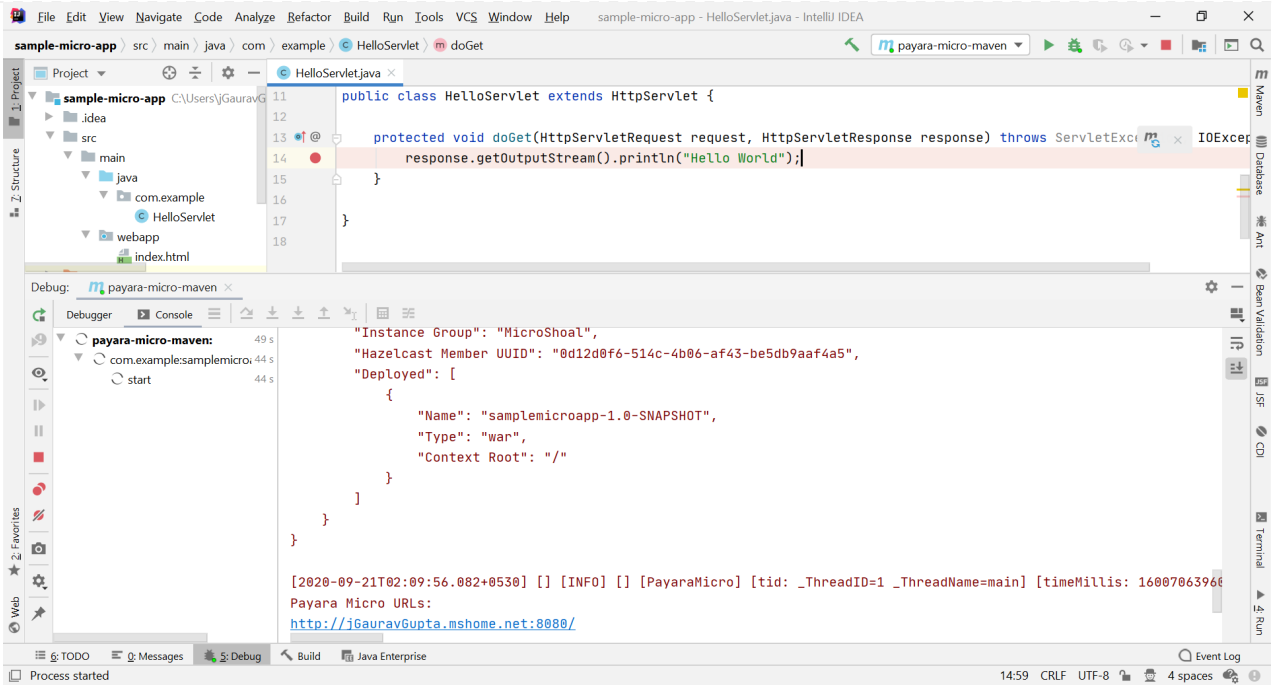


To run Payara Micro with your application compiled and deployed, just click **Run**. You can view the Payara Micro log in the **Run** window then select your run configurations name.

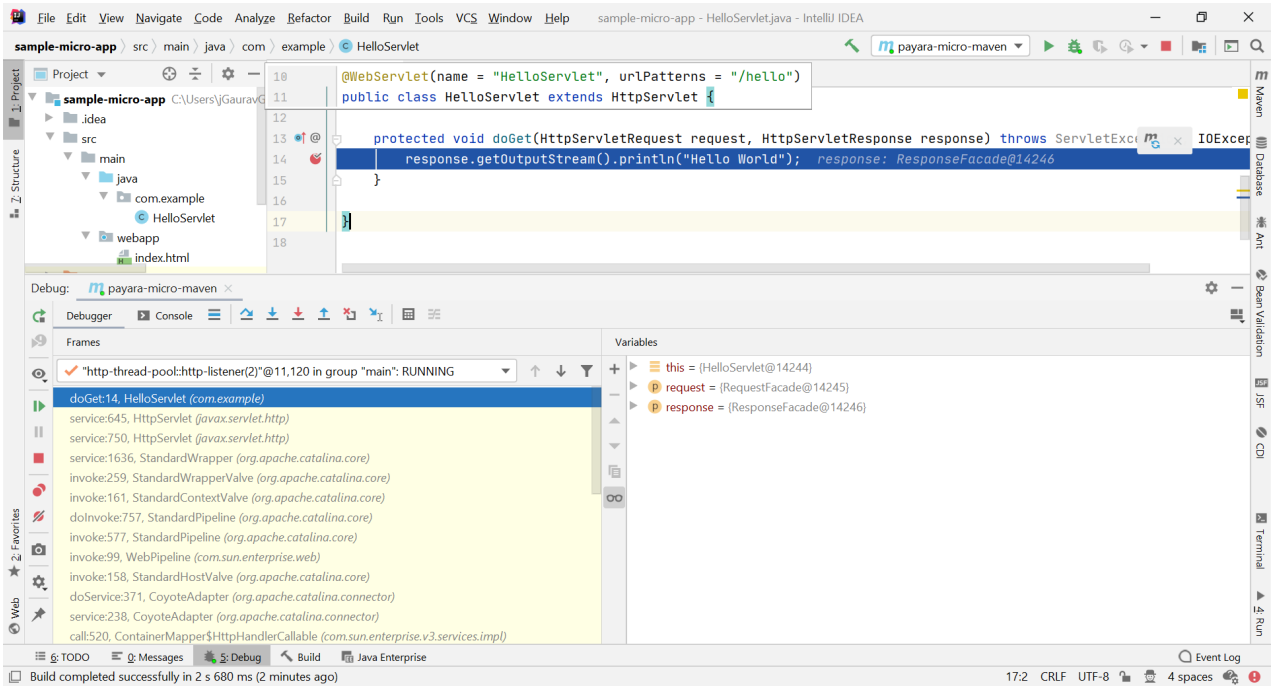
====== Debugging the Payara Micro Application

Instead of pressing the **Run** button, you can instead click **Debug** to automatically start the micro instance and attach the debugger to the application

After debugging the Payara Micro application, you can see the Payara Micro log in the **Debug** window then select your run configurations name.



After the debugger session starts and the application hits the breakpoint, the code execution is paused at the line where the breakpoint was placed, showing a list of running threads and the stacktrace:



====== Building IntelliJ Plugin

The process of building and testing the IntelliJ IDEA IDE Plugin, is the same for both the Ultimate and Community versions of the plugin. After cloning the appropriate repository, the following steps can be applied to either plugin.

The Payara IntelliJ Community Tools source code is available in the Ecosystem IntelliJ Community repository.

The Payara IntelliJ Ultimate Tools source code is available in the Ecosystem IntelliJ Ultimate repository.

====== Prerequisites Before building the Payara IntelliJ Tools, you will need to configure your local environment. Subsequent builds will not require these steps.

Clone the relevant repository

You must first clone the appropriate repository for the IntelliJ IDEA plugin you are trying to build.

JDK 11

JDK 11 is required to build and test the IntelliJ IDEA plugin.

Install Gradle

Gradle is the build tool for the Payara IntelliJ Tools. You can either download and configure Gradle locally or use the Gradle wrapper in the source code.

====== Build Payara IntelliJ Tools To build the Payara IntelliJ Tools, run the following command from the root directory where the project was cloned:

If you installed Gradle

1. `gradle build`

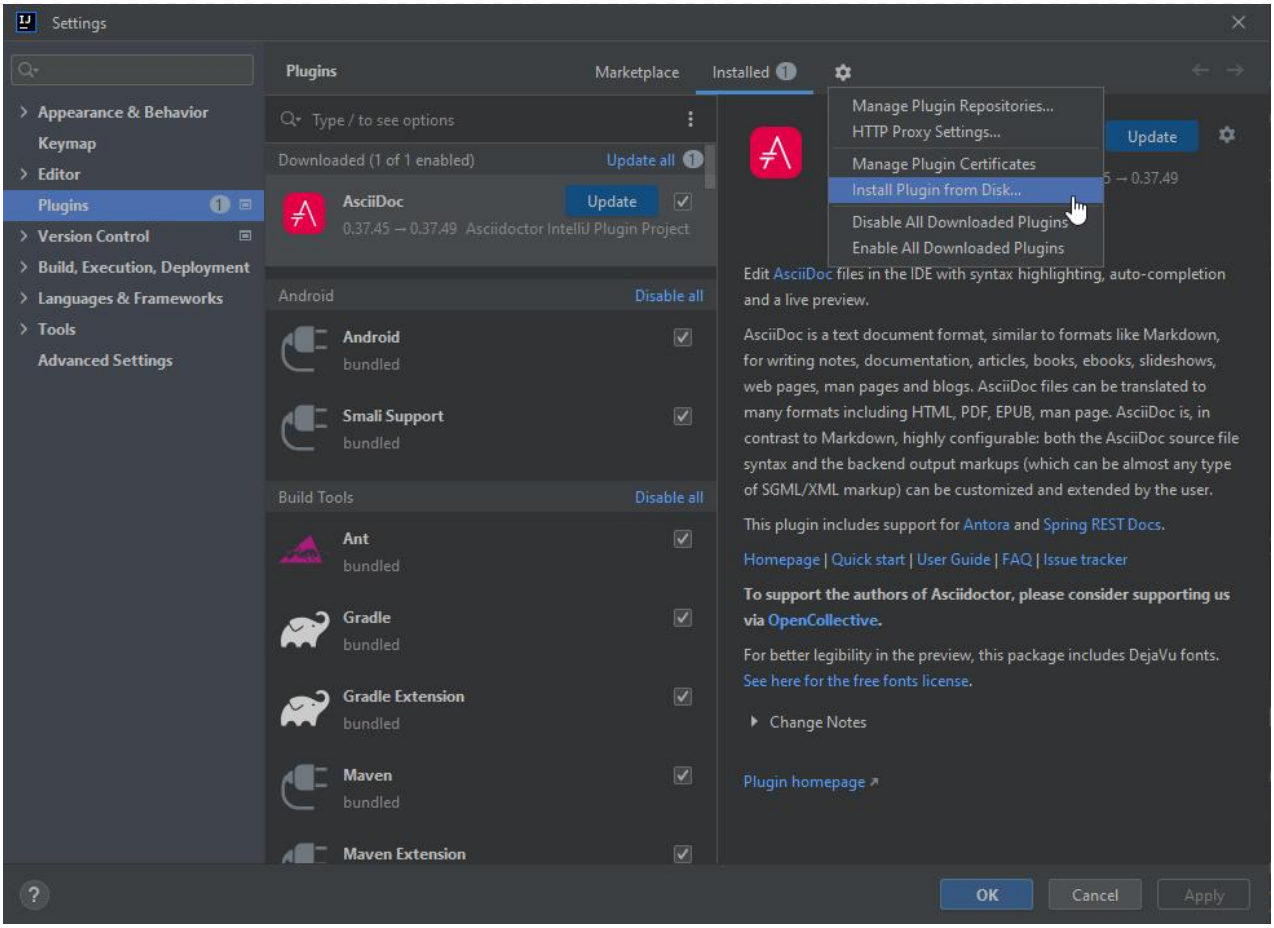
If you are using the Gradle wrapper

1. `./gradlew build`

After a successful build, the final ZIP distribution will be located in the `/build/distributions` directory. This ZIP file can be installed into IntelliJ IDEA.

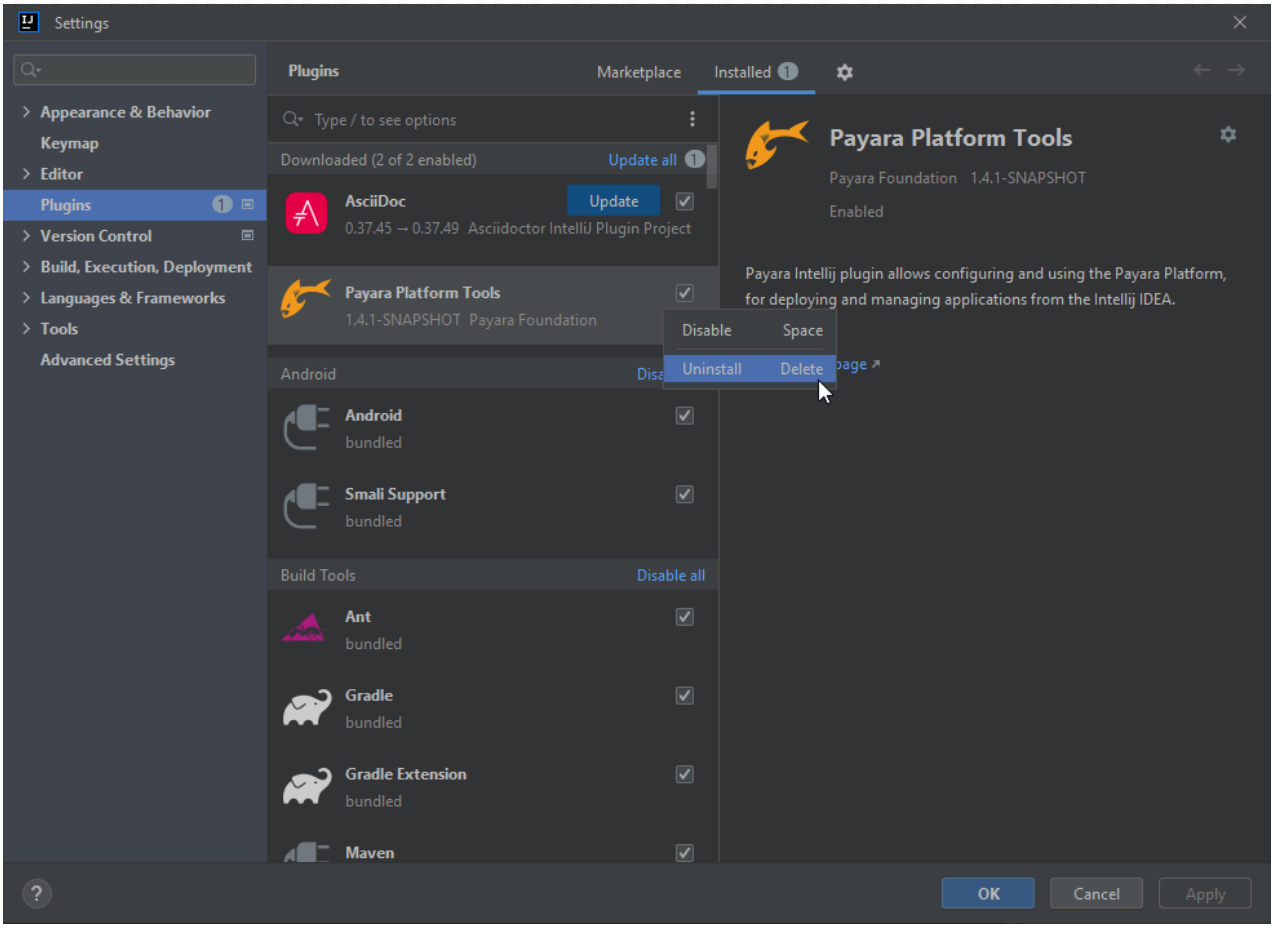
====== Install Payara Tools into IntelliJ IDEA After the Payara Tools plugin has been built, you can install it in IntelliJ IDEA as follows:

1. Open the **Settings** menu (`Ctrl + Alt + S`)
2. Open the `Plugins` panel
3. Click the ⚙ cog icon and select `Install Plugin from Disk`
4. Select the compiled ZIP file from the `/build/distributions` directory



====== Removing Payara Tools from IntelliJ IDEA To uninstall the plugin:

1. Open the **Settings** menu (`Ctrl + Alt + S`)
2. Open the `Plugins` panel
3. Right-click the **Payara Tools** plugin
4. Click **Uninstall**



====== Test Payara Tools

Instead of manually installing the plugin each time, you can run a test instance of IntelliJ IDEA with the plugin pre-installed using the following:

If you installed Gradle

1. `gradle runIde`

If you are using the Gradle wrapper

1. `./gradlew runIde`

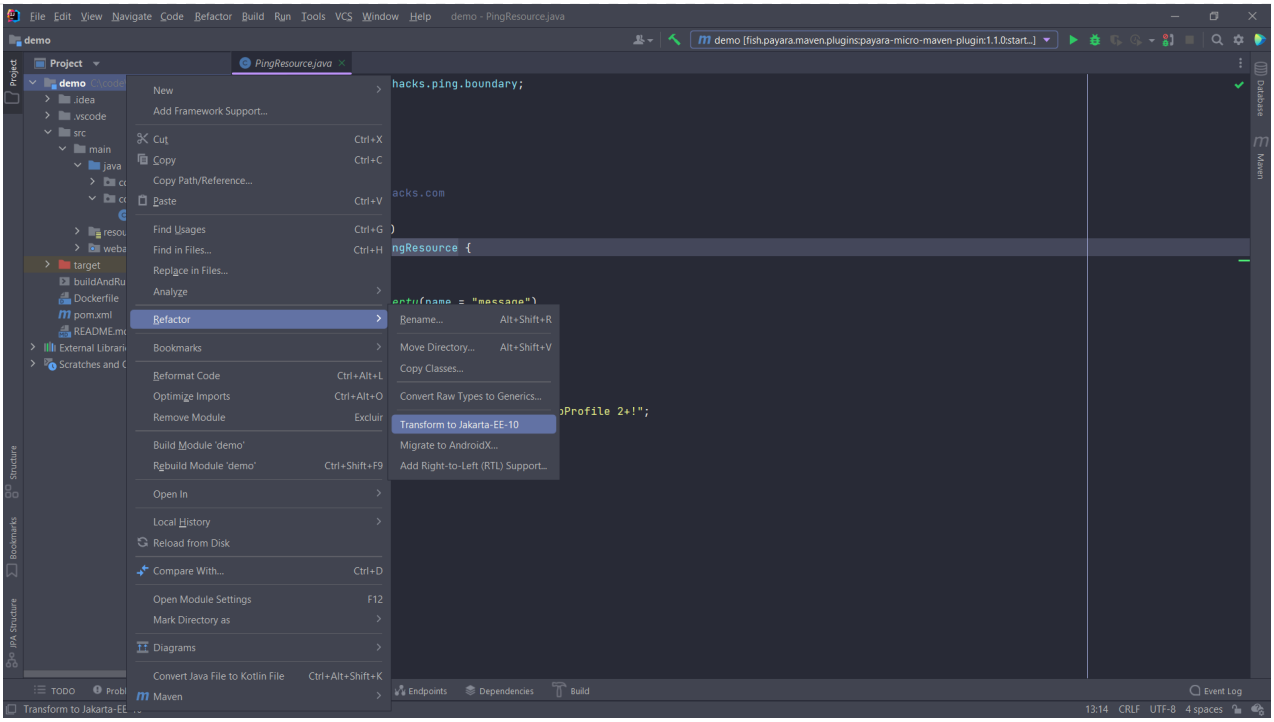
This will launch a sandboxed IntelliJ IDEA environment with the plugin enabled for testing purposes.

====== Transform to Jakarta-EE10

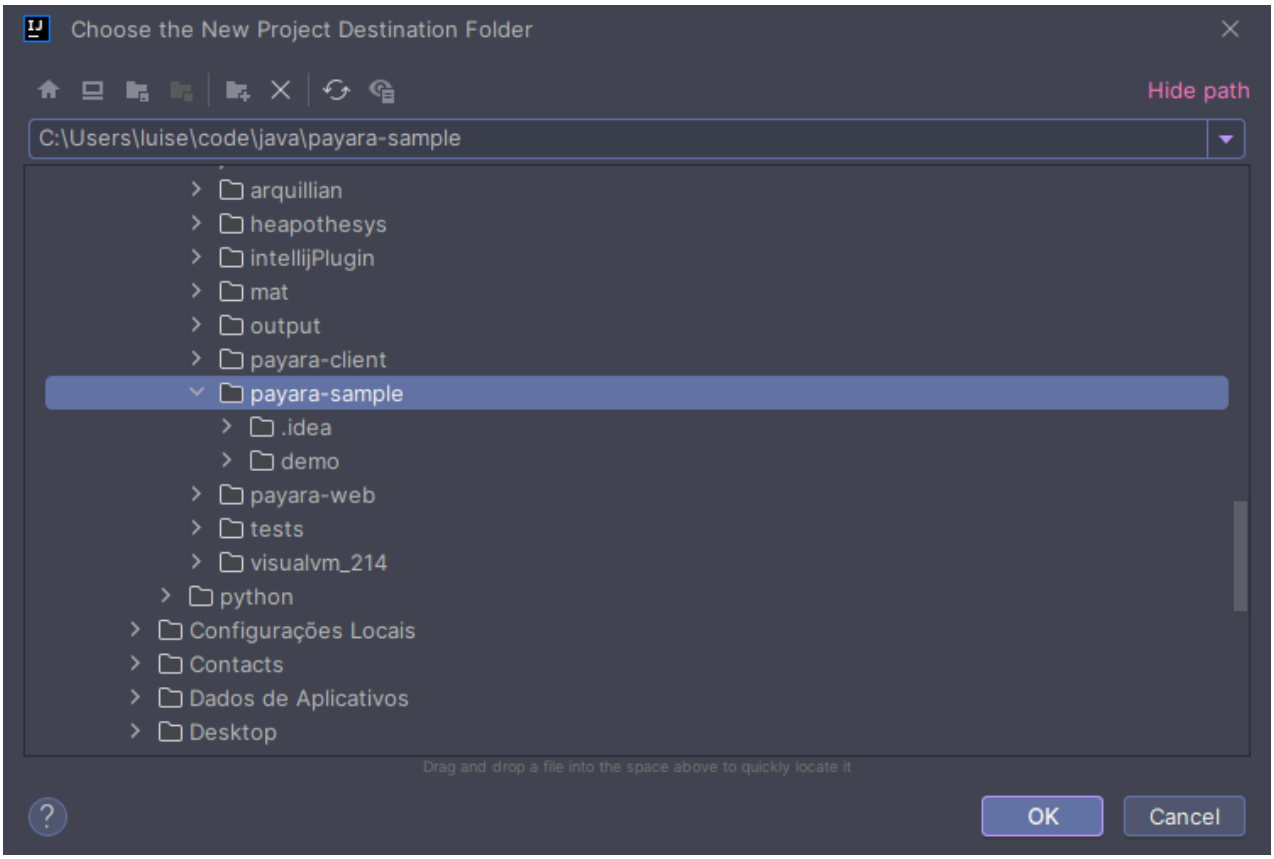
Using the `Payara IntelliJ Ultimate Tools` and `Payara IntelliJ Community Tools` plugins, you can transform whole projects or just a file from Java EE 8 to Jakarta EE 10.

This feature is available in both **Community** and **Ultimate** editions of the plugin.

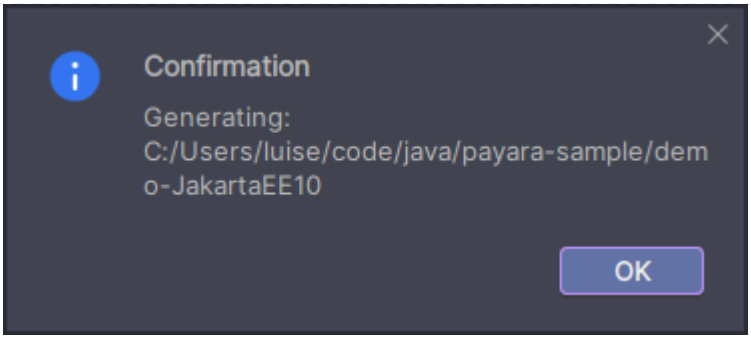
====== Refactor a Java EE 8 Project to Jakarta EE 10 To refactor a Java EE 8 based **Maven** project right click on root project folder and choose **Refactor → Transform to Jakarta EE 10**:



The plugin will open a dialog to choose the destination folder where the new project will be created:

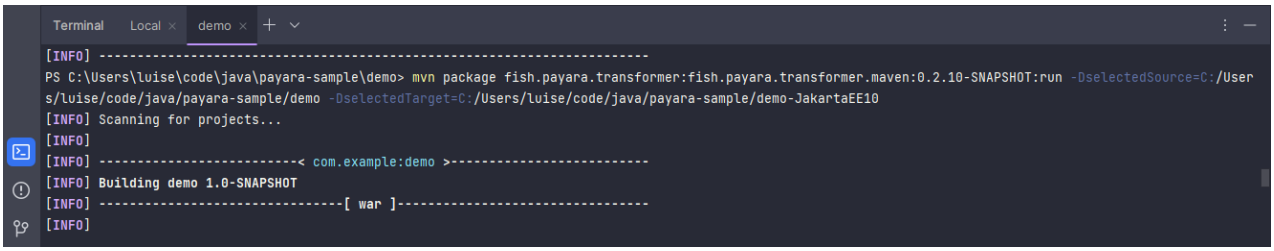


After choosing the `Destination Directory`, a confirmation message will appear indicating that the project is being generated.

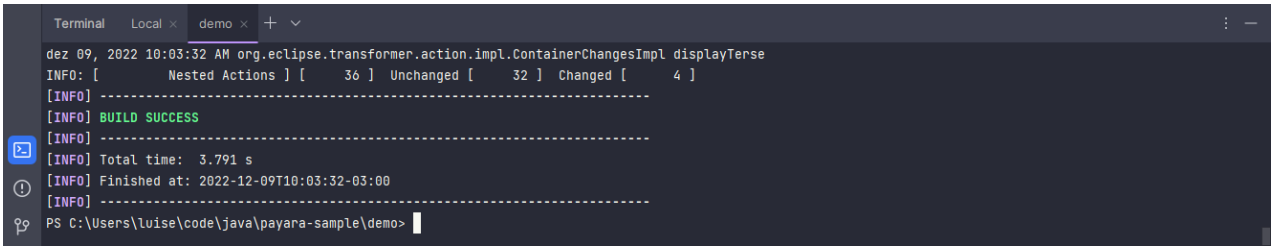


You can see the output of the generation process in the IntelliJ console.

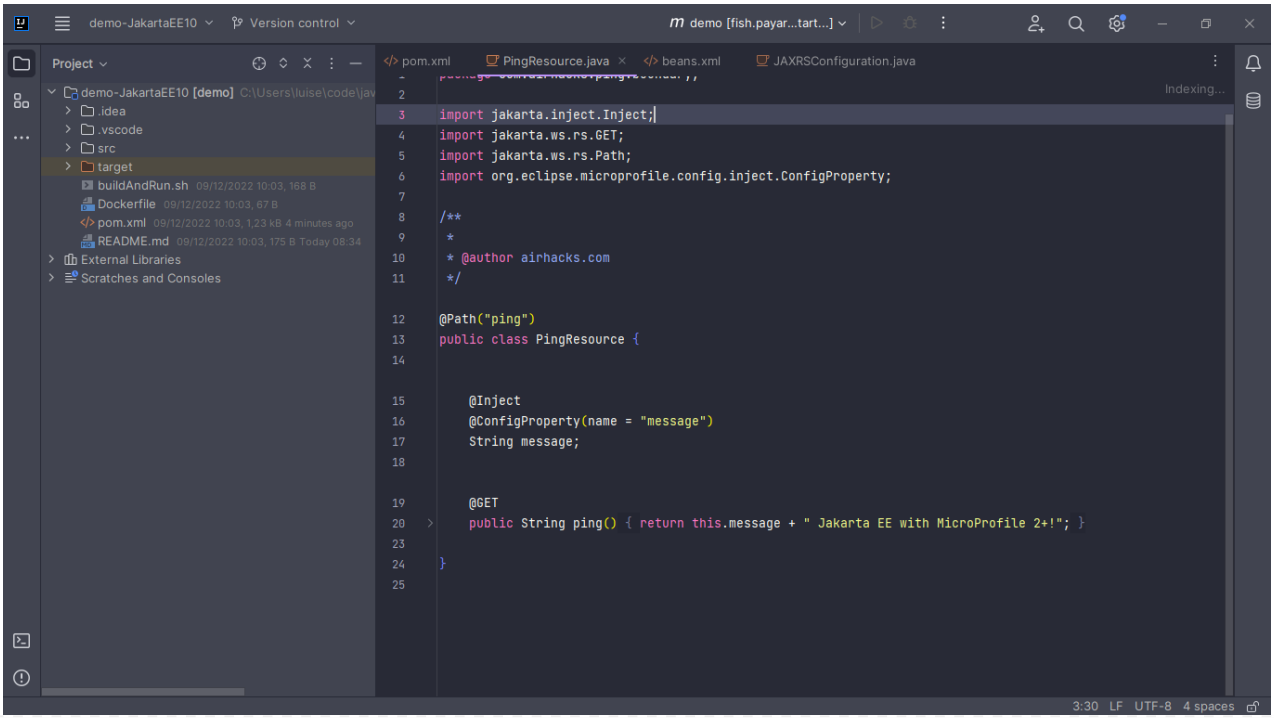
The Maven plugin that executes the transformation process will print its output to the IDE's console:



After the creation, a Maven `BUILD SUCCESS` message should be logged in the IDE's console.



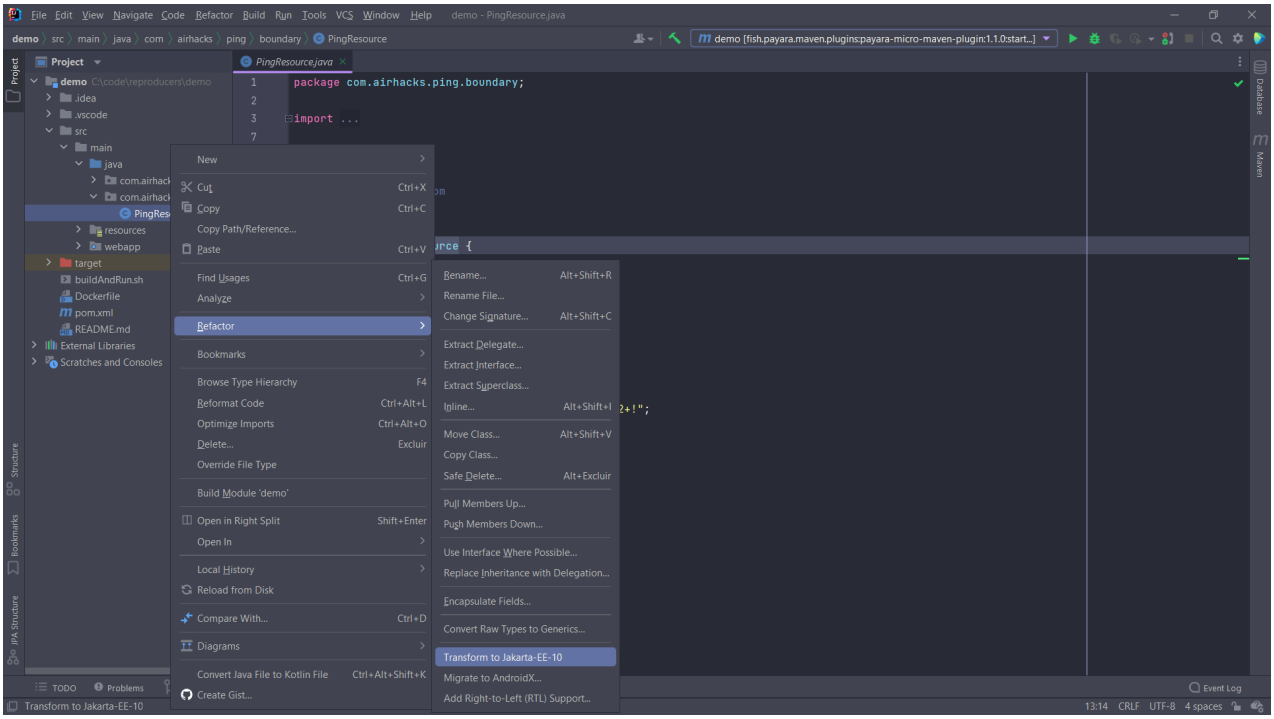
The new project with suffix `-JakartaEE10` is opened in a new IntelliJ instance which loads the project from the Destination Directory previously selected.



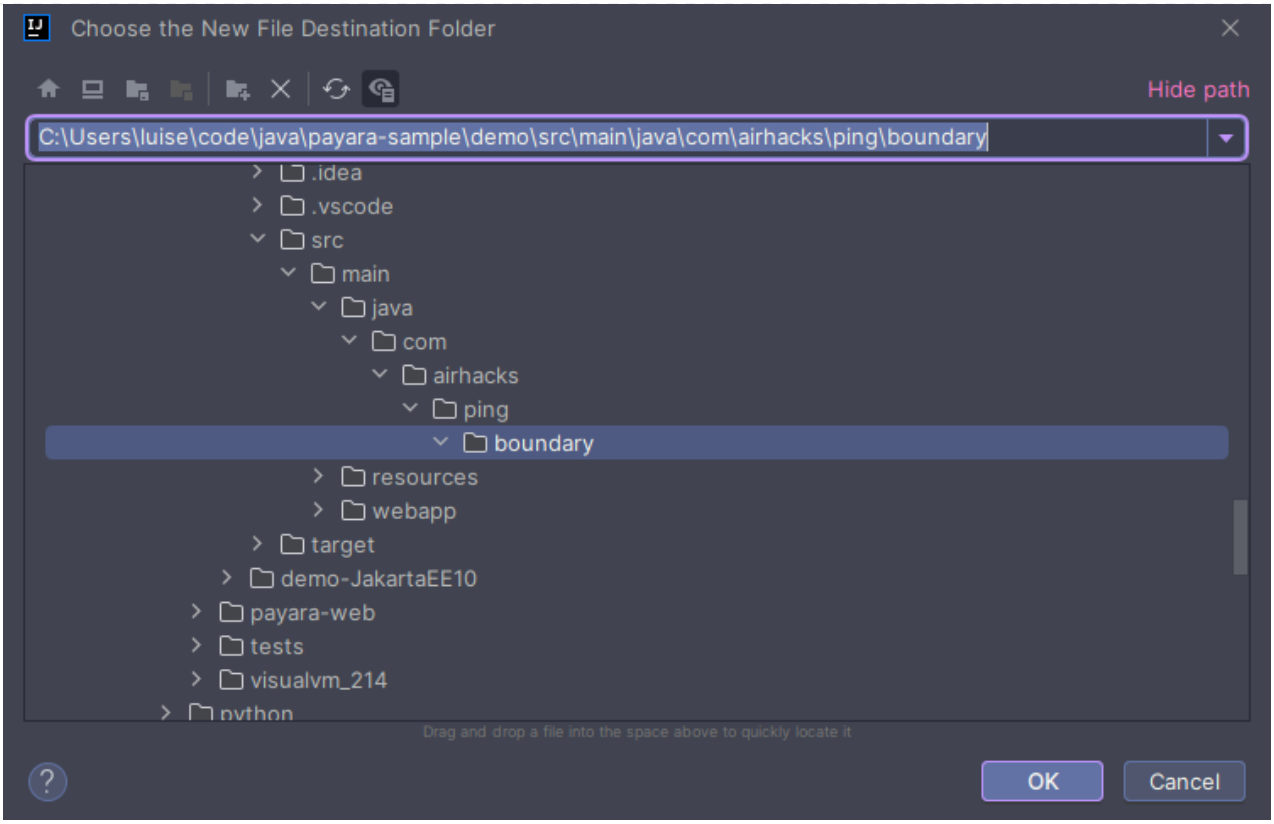
When the whole project is transformed, the plugin adds `-JakartaEE10` at the end of the project name. In our example, `demo-JakartaEE10` project was created from a named `demo`.

====== Transform a Single File

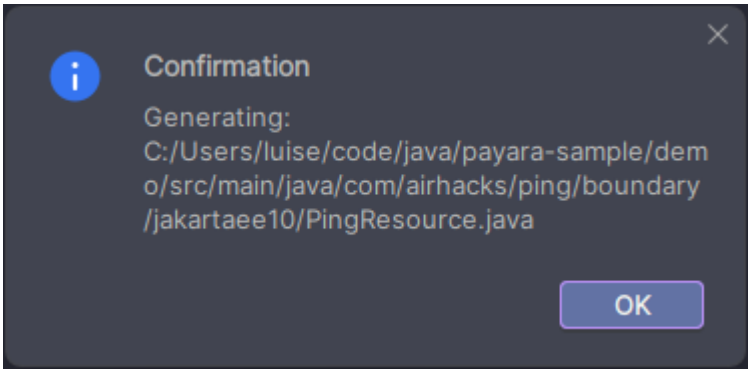
To refactor a `Java EE 8 file` right click on it and choose **Refactor → Transform to Jakarta EE 10** option:



The plugin will open a dialog to choose the destination package where the new file will be created:



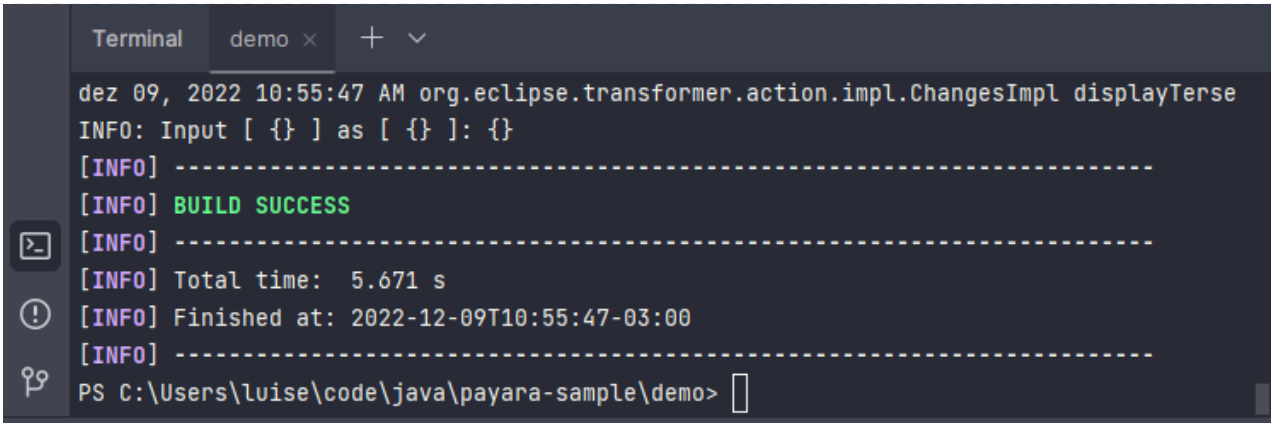
After choosing the `Destination Package`, a confirmation message will appear indicating that the file is being generated.



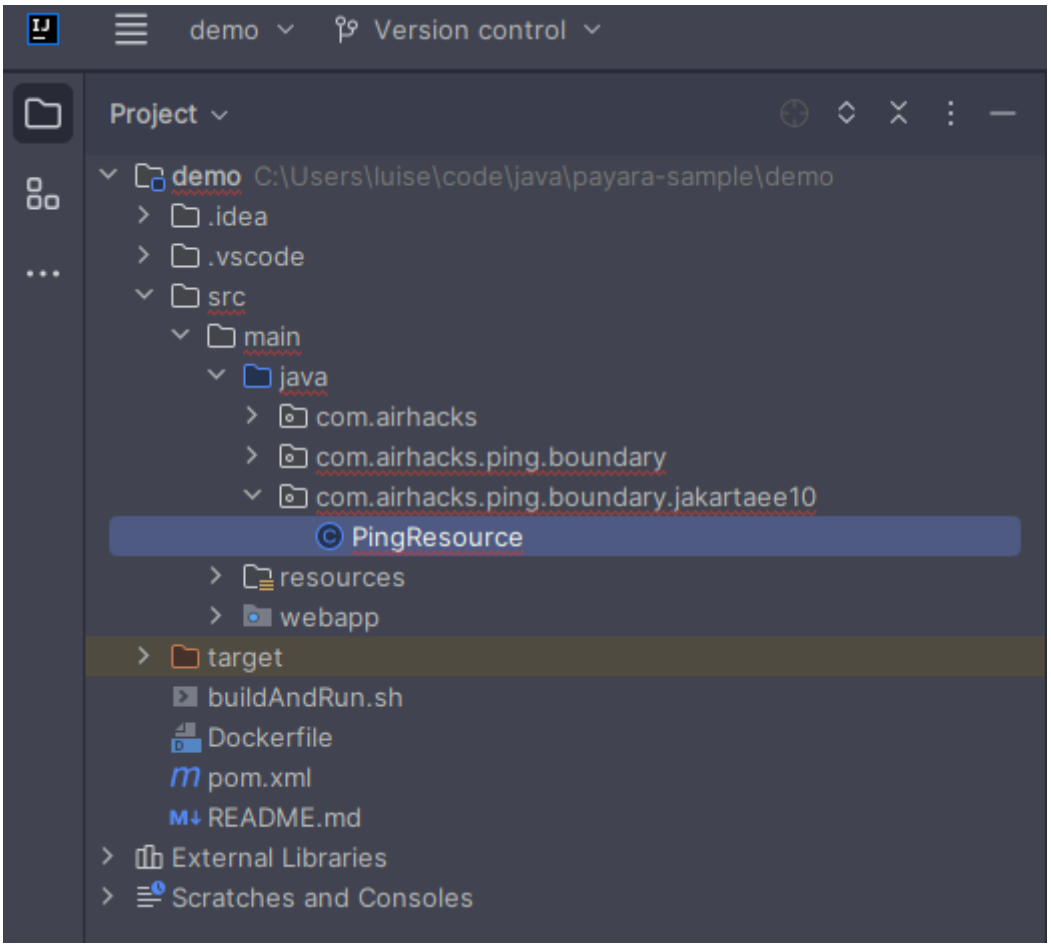
You can see the output of the generation process in the IntelliJ console.

The output of the Maven plugin that executes the transformation code can be reviewed in the IDE's console:

After the new file is created, a `BUILD SUCCESS` message from the Maven plugin will be logged in the IDE's console.



The new file will be located in the chosen destination package.



When a single file is transformed, a new package containing the transformed file will be created in the destination package with the suffix `-jakartaee10`.

===== Apache NetBeans IDE

====== Overview

Apache NetBeans IDE 16 and higher provides out-of-the-box support for the Payara Platform to integrate Payara Server and Payara Micro into the Apache NetBeans IDE's interface.

Therefore, there is no need to manually install the Payara Tools plugin.

====== Tools * Payara Server - Apache NetBeans enables developers to download the latest

version of Payara Server that can be easily configured and added as a recognised server in NetBeans IDE. This means you can easily deploy and manage applications from the NetBeans IDE.

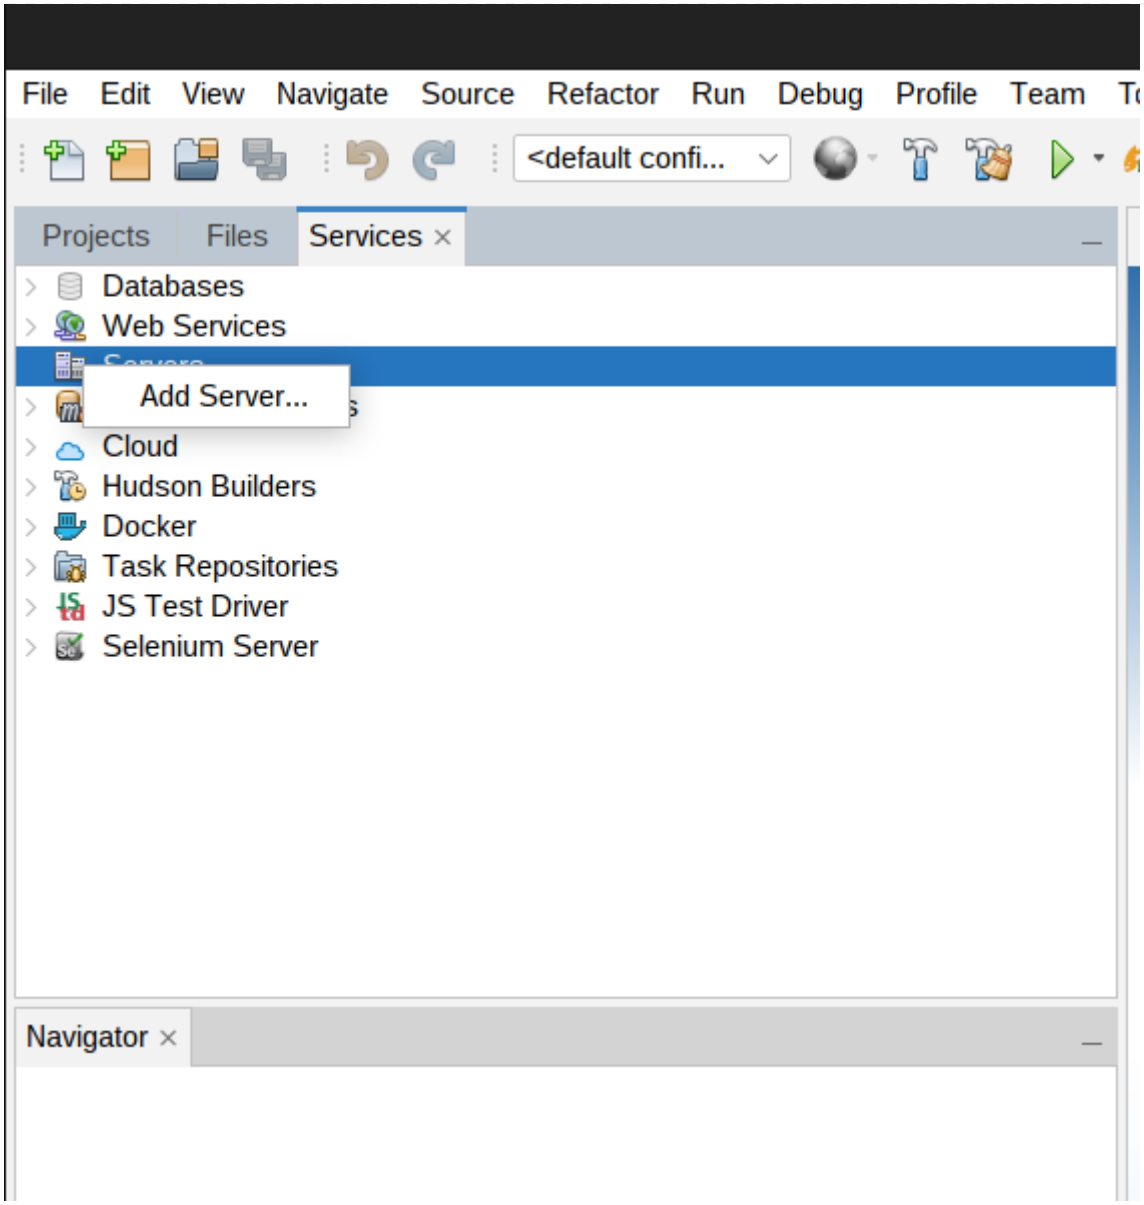
- Payara Micro - Apache NetBeans IDE also provides first-class support to create and run Payara Micro maven web applications from the NetBeans interface. Payara Micro is the microservices-ready version of Payara Server.

====== Payara Server

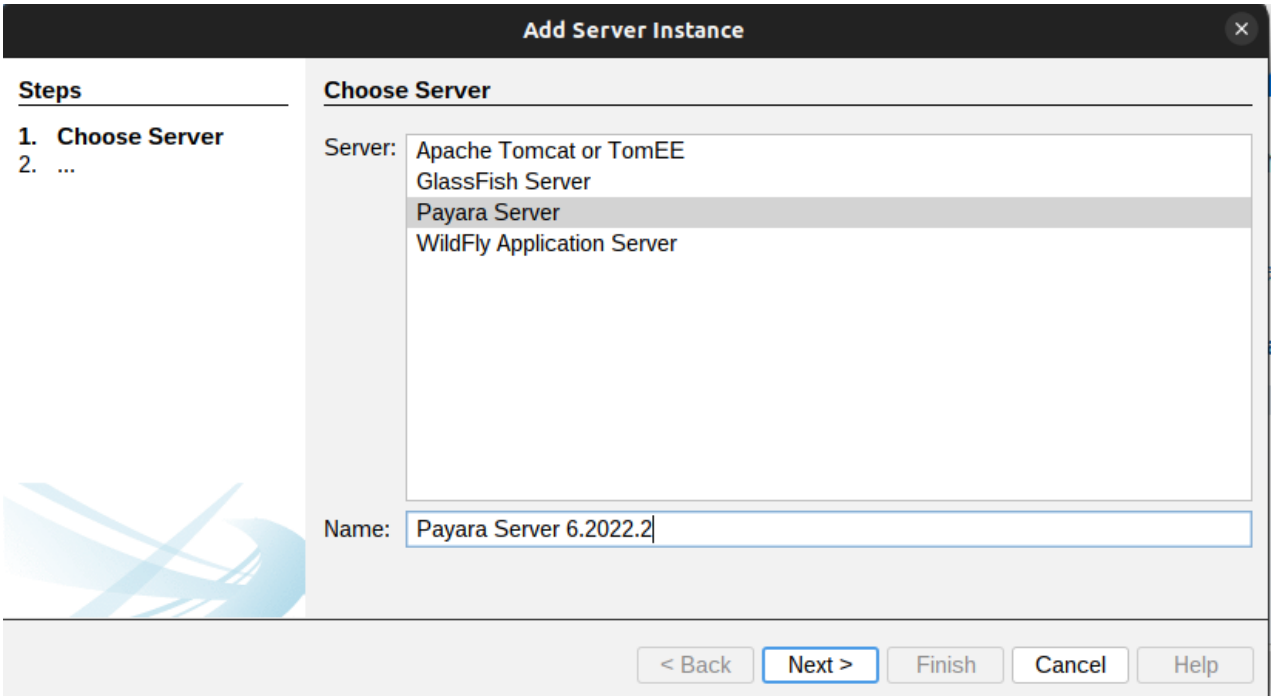
The Apache NetBeans IDE has built-in integration with Payara Server and allows you to easily perform the following tasks:

- Start and stop the Payara Server from within the IDE
- Define the Java runtime to be used by Payara Server
- Deploy an application from within the IDE
- Auto Publish & Hot Deploy your application

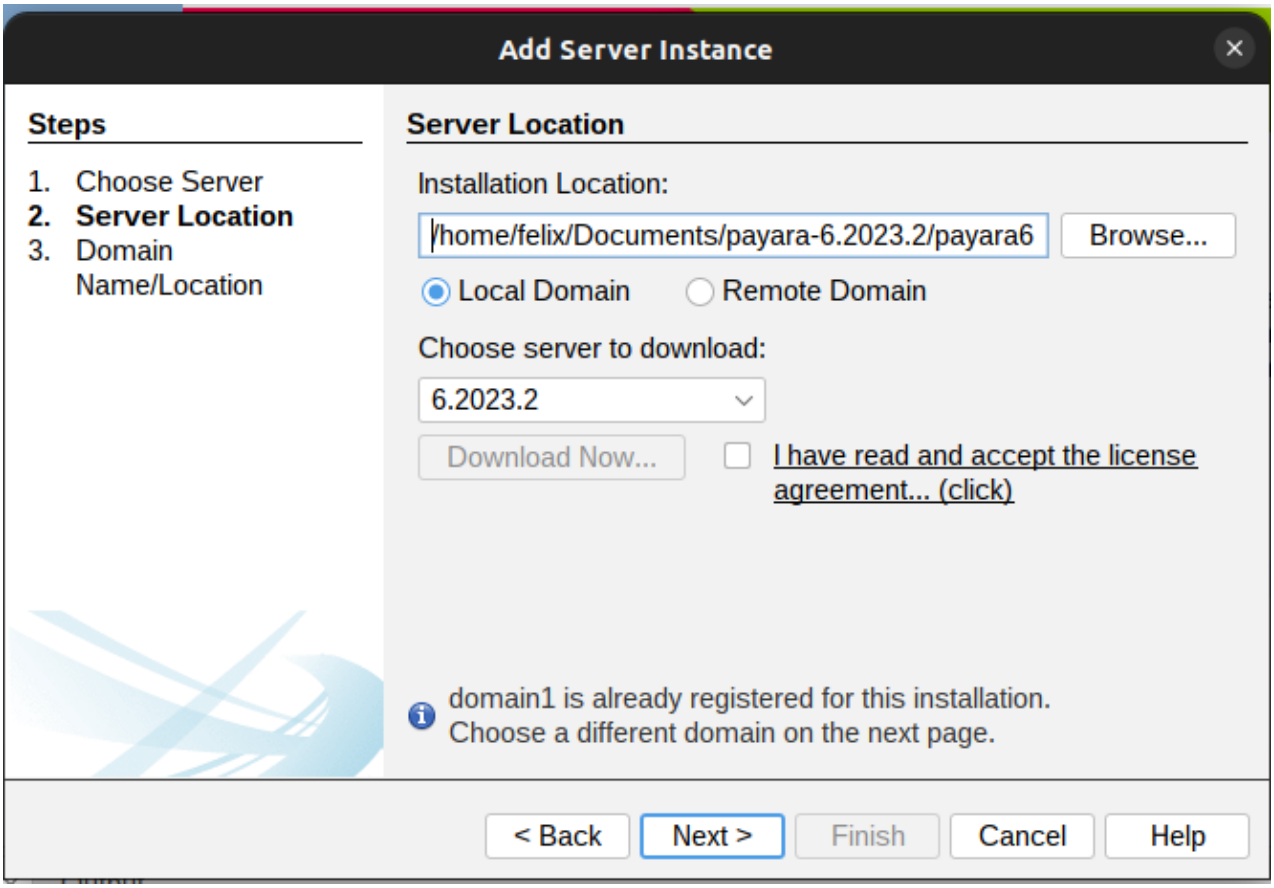
====== Adding Payara Server to Apache NetBeans IDE Open the project you want to deploy to Payara Server. Go to the Server tab and right click to add a new server.



Select Payara Server, choose a new name for the server and click Next.

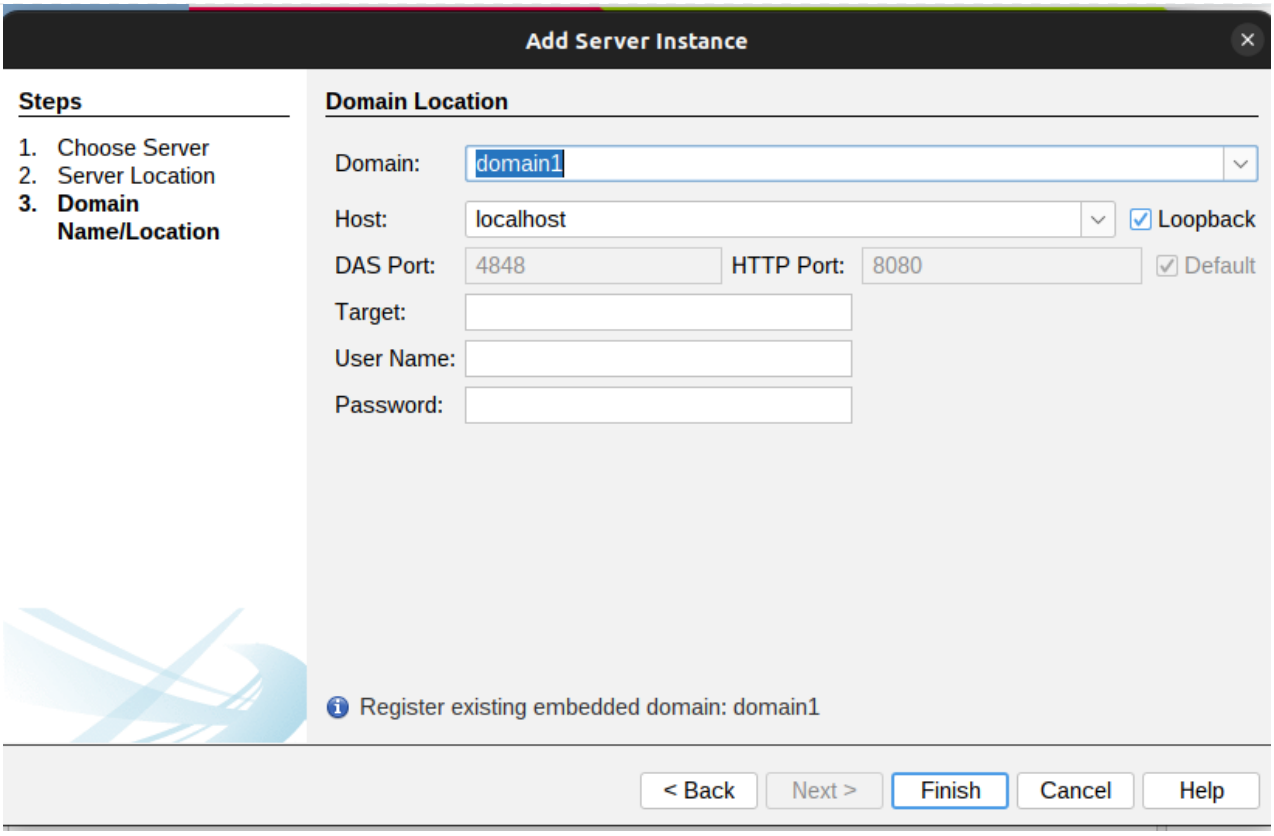


Browse to the location of the Payara Server installation. If the DAS is on another machine, make sure to select the remote domain option. Otherwise, use the local domain option.



The following details are configurable on the next screen:

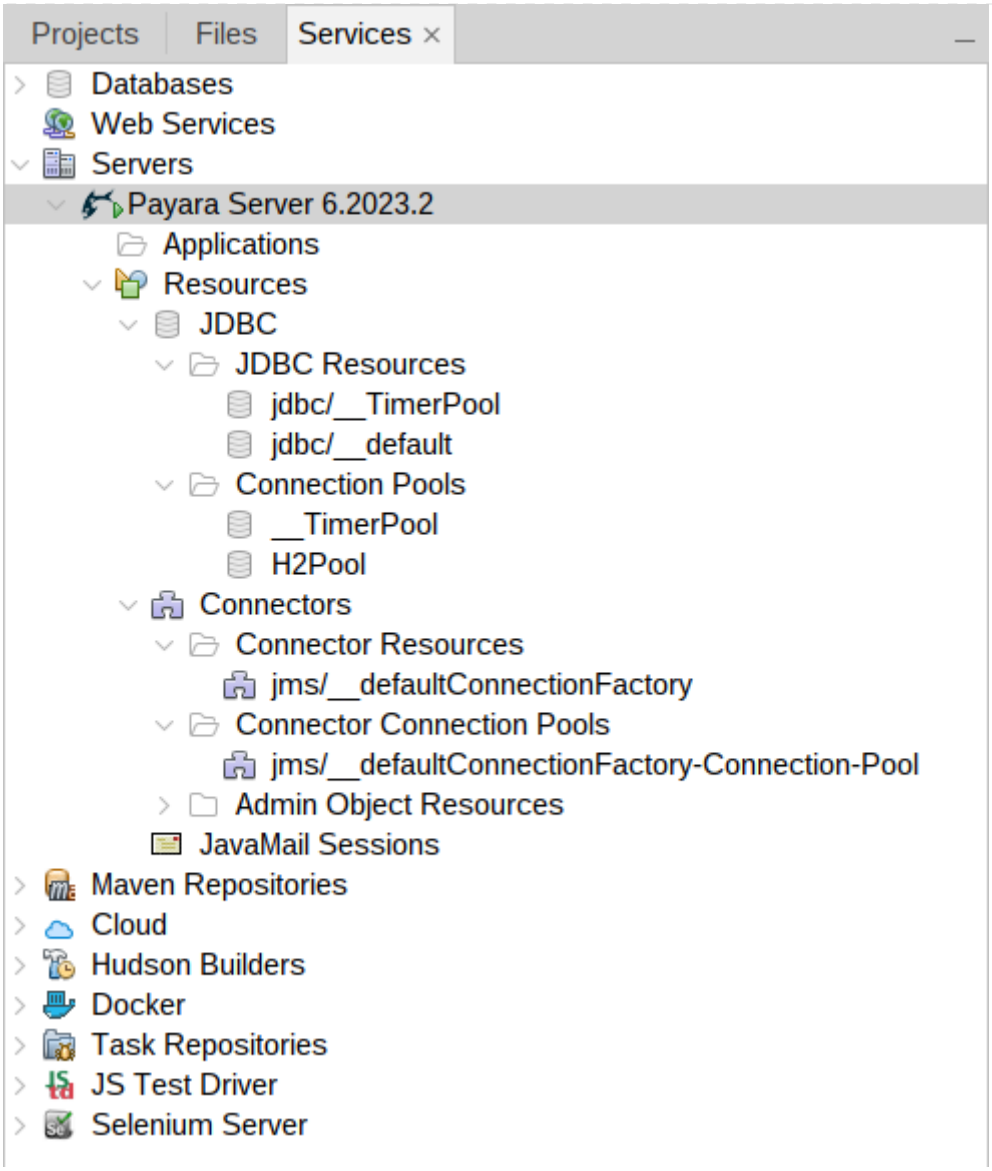
- Domain → The domain you want to use. The default domain is **domain1**.
- Host → The hostname the server will be listening on. the default hostname is **localhost**.
- DAS Port → The port used by the DAS. The default port is **4848**.
- HTTP Port → The port used by the deployed applications. The default port is **8080**.
- Target → The name of the node that the application will be getting deployed to. This can be left blank for a local installation.
- Username → The admin username for Payara Server. The default username is **admin**.
- Password → The admin password for Payara Server. The default password is blank.



====== Managing Payara Server from Apache NetBeans IDE

Once the configuration is complete, you can manage your Payara Server directly from Apache NetBeans. By right-clicking on the previously-configured server, we can do the following actions:

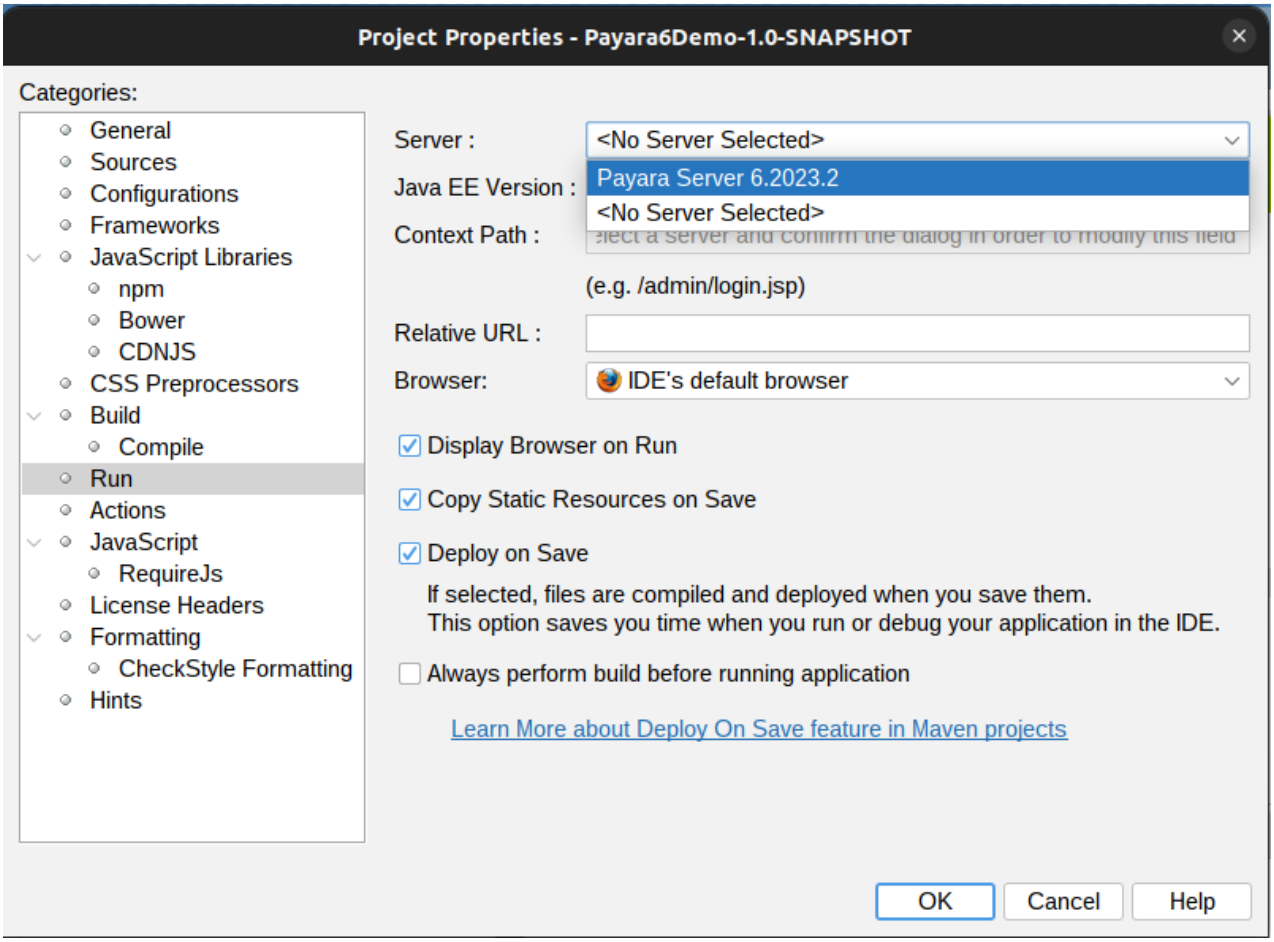
- Start or stop the server
- Start debugging the server
- Open the admin console
- Open the server.log file



Exploding the server dropdown will list Applications, Resources and Web Services. This allows you to view and manage certain Payara Server configurations, from the NetBeans interface.

====== Deploying Applications to Payara Server from Apache NetBeans IDE

An application can be deployed and un-deployed easily from within Apache NetBeans. First, the application run settings need to be configured to use Payara Server. Go to Properties on a project and then the Run section of this window. This menu lists the configuration for deploying the application.



Select the Payara Server you have configured. You can also select a context path for the application to be deployed to, as well as NetBeans behaviour when deploying.

Deploying to Payara Server now only requires running the application like any other NetBeans project. Once it's deployed, the Services view will then display the application under Payara Server, where you can undeploy, enable, disable and view the application in the browser.

====== Deploy Applications in a Local Docker Container

The Payara Server tools for Apache NetBeans include Docker integration, making it seamless to deploy exploded applications to a Payara Server instance running within a local Docker container.

To take advantage of this feature, follow these steps below:

1. Open Apache NetBeans and navigate to the *Services* tab.
2. Register a new Payara Server instance by performing the following:
    a. Click on the "*Add Server*" button.
    b. Select the "*Remote Domain*" option.
    c. Browse and locate the Payara Server installation directory with the same version as the one running in the Docker container.
    d. Enter the domain name, host, and necessary credentials.
    e. For the Docker integration, choose the "*Docker Volume*" option and provide the `HOST_PATH` (e.g., `D:/test`) and `CONTAINER_PATH` (e.g., `/mnt/test`) mapping details.

This mapping should align with the exploded application path or parent path of exploded application.

3. Run the Payara Server Docker container using the following command:

```
docker run -p 8080:8080 -p 4848:4848 -p 9009:9009 -v HOST_PATH:CONTAINER_PATH
payara/server-full:{page-version}
```

   Replace `HOST_PATH` with the actual host path and `CONTAINER_PATH` with the desired container path.

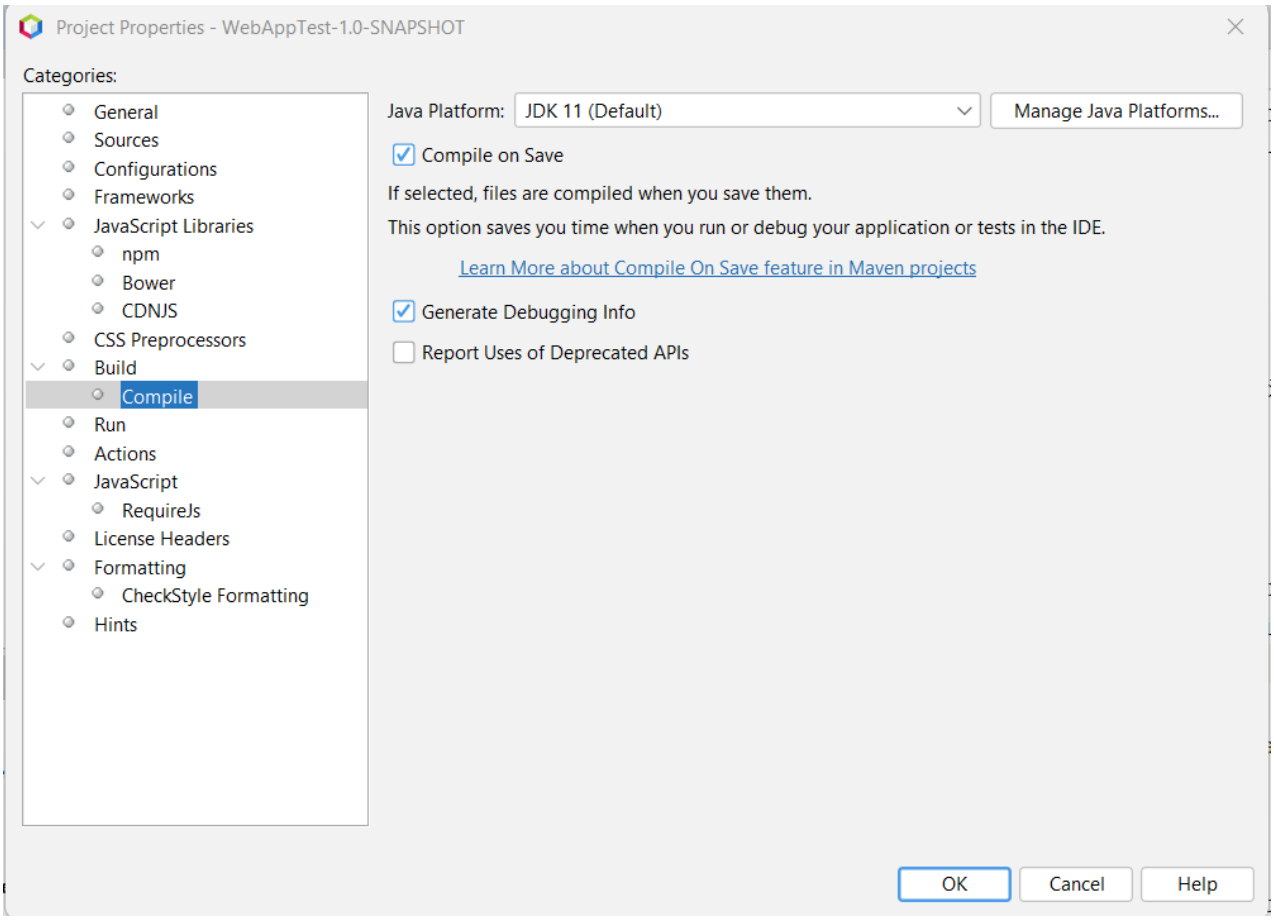
   The `HOST_PATH` points to the location on your host machine, and `CONTAINER_PATH` is the corresponding location inside the container.

4. Create your web application and deploy it to the registered Payara Server instance.

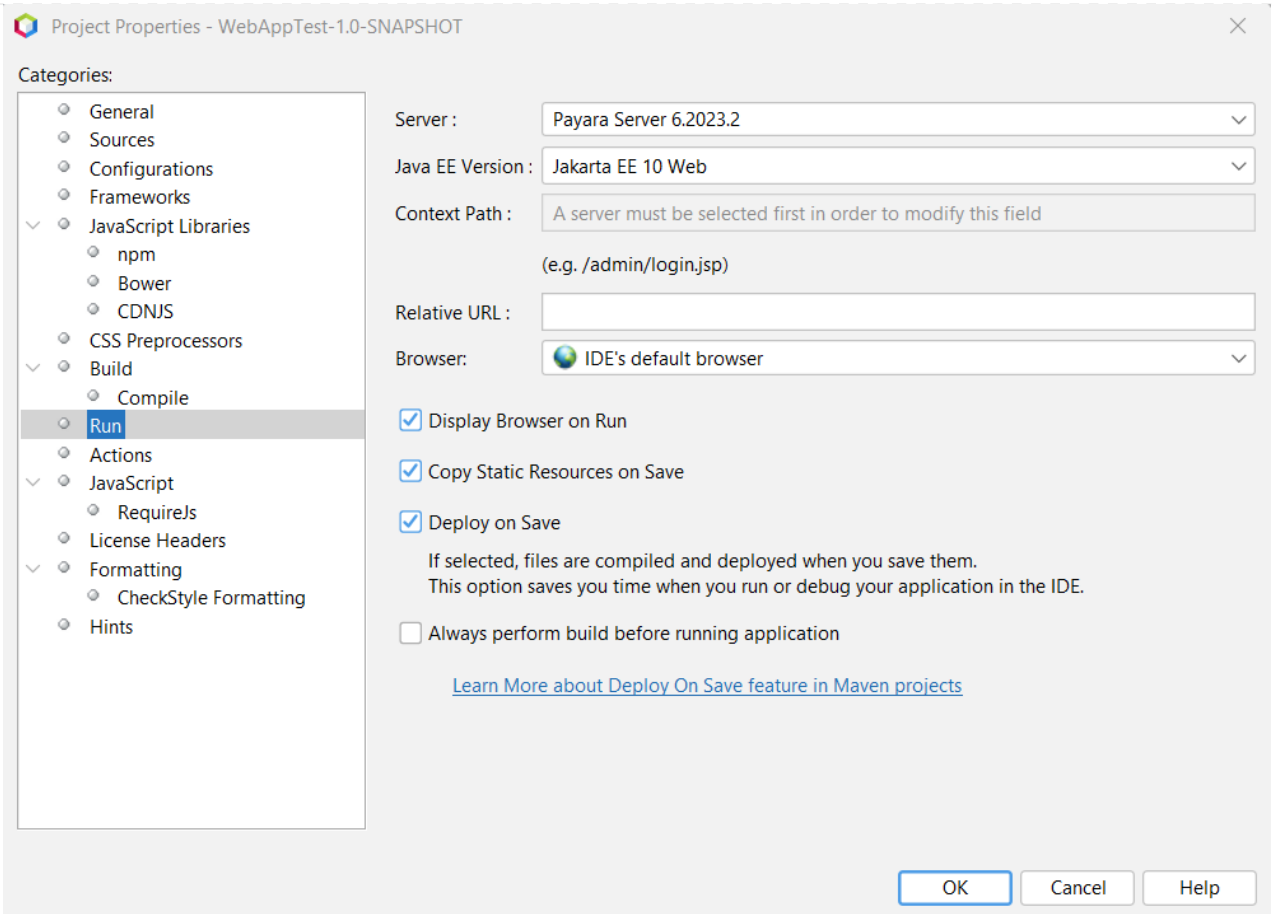
====== Hot Deploy and Auto Deploy Settings

To enable the **Auto Deploy** features for Payara Server on the Apache NetBeans IDE, you must enable the **Compile on Save** and **Deploy on Save** features from the **Project Properties**.

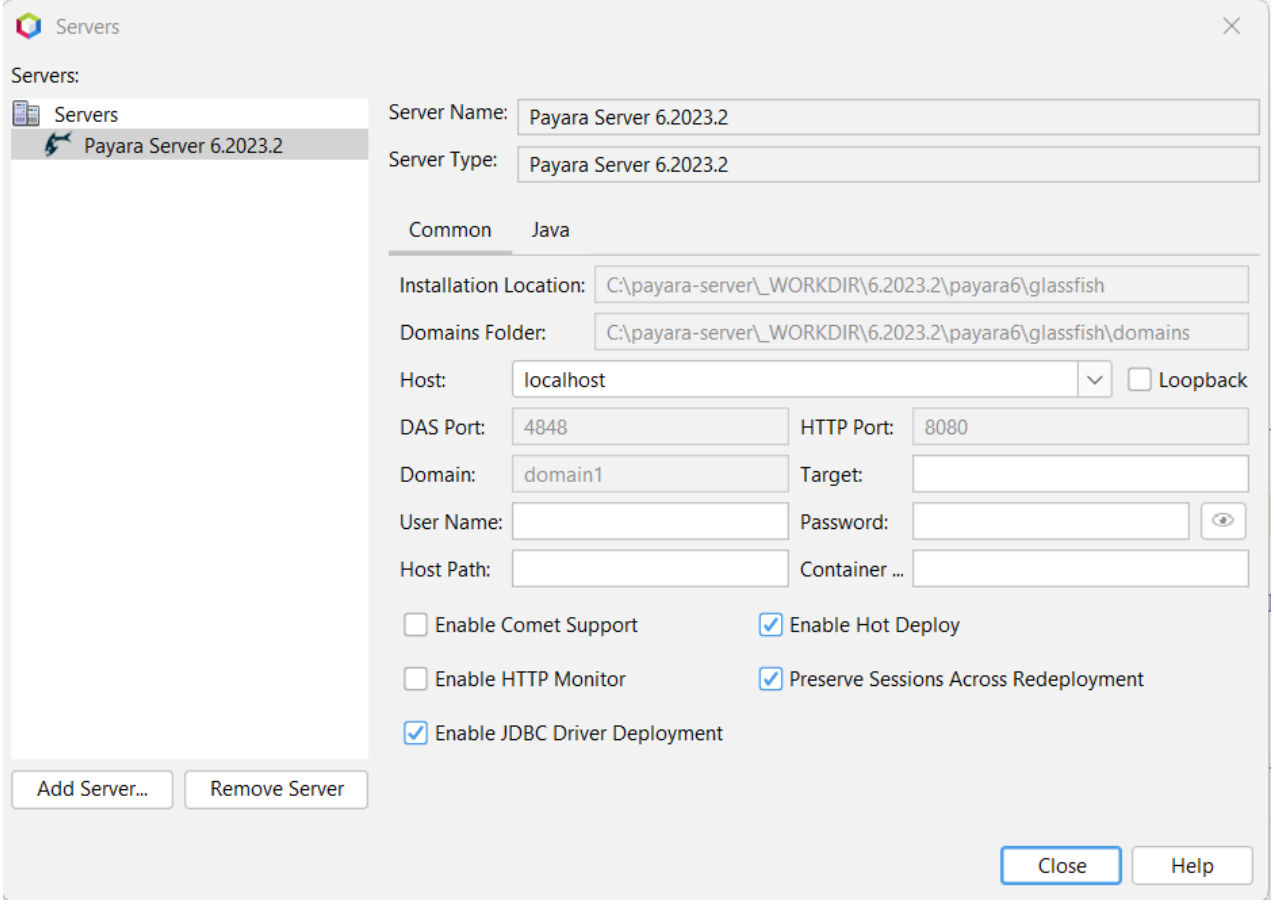
Compile on Save can be found in the **Build→Compile** submenu of the project properties.



Deploy on Save can be found in the Run submenu of the project properties.



To enable the **Hot Deploy** feature for Payara Server on the NetBeans IDE, you must right-click the Server under the Services tab and select **Properties**. From the Commons tab check the Enable Hot Deploy checkbox.



====== See Also Hot Deploy and Auto Deploy

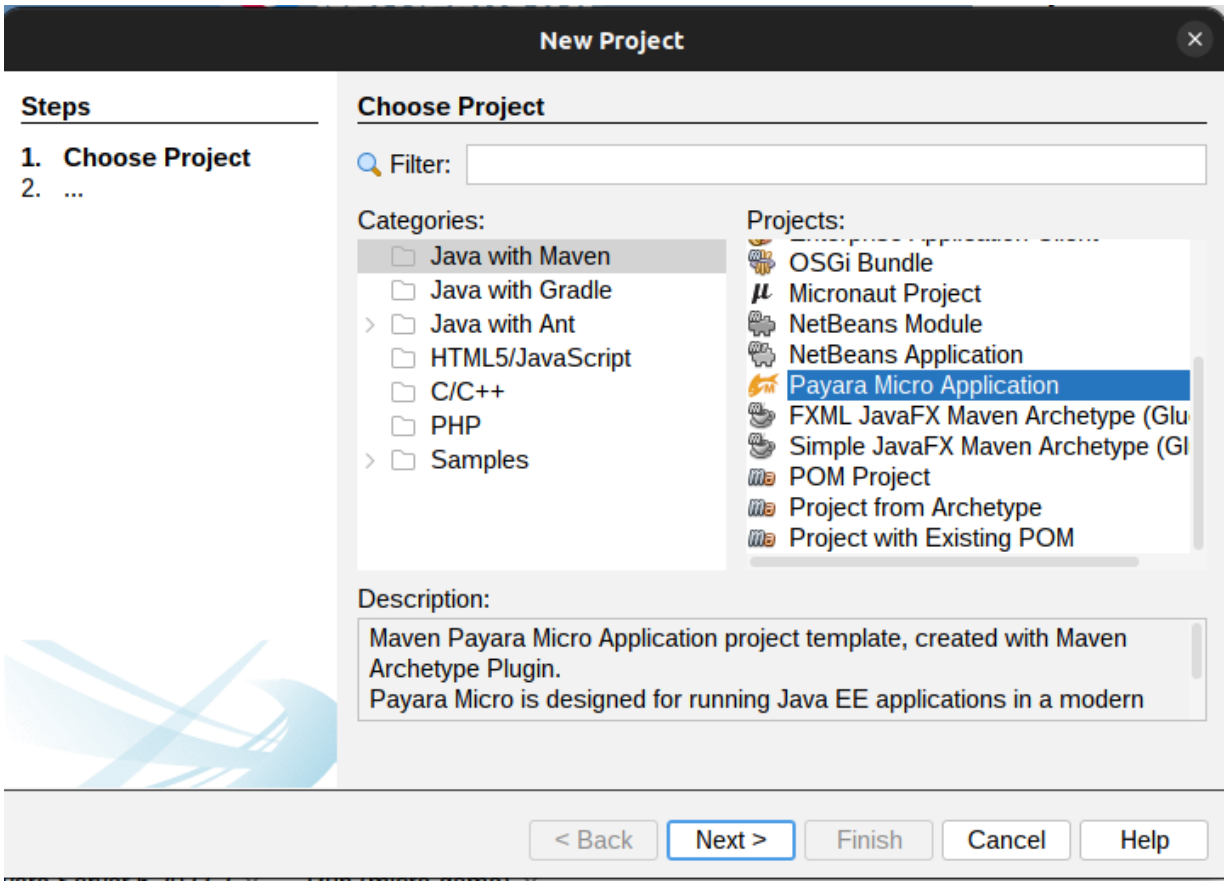
====== Payara Micro

Apache NetBeans has Payara Micro support built into the IDE, so there is no need to install a plugin to integrate and control Payara Micro from Apache NetBeans.

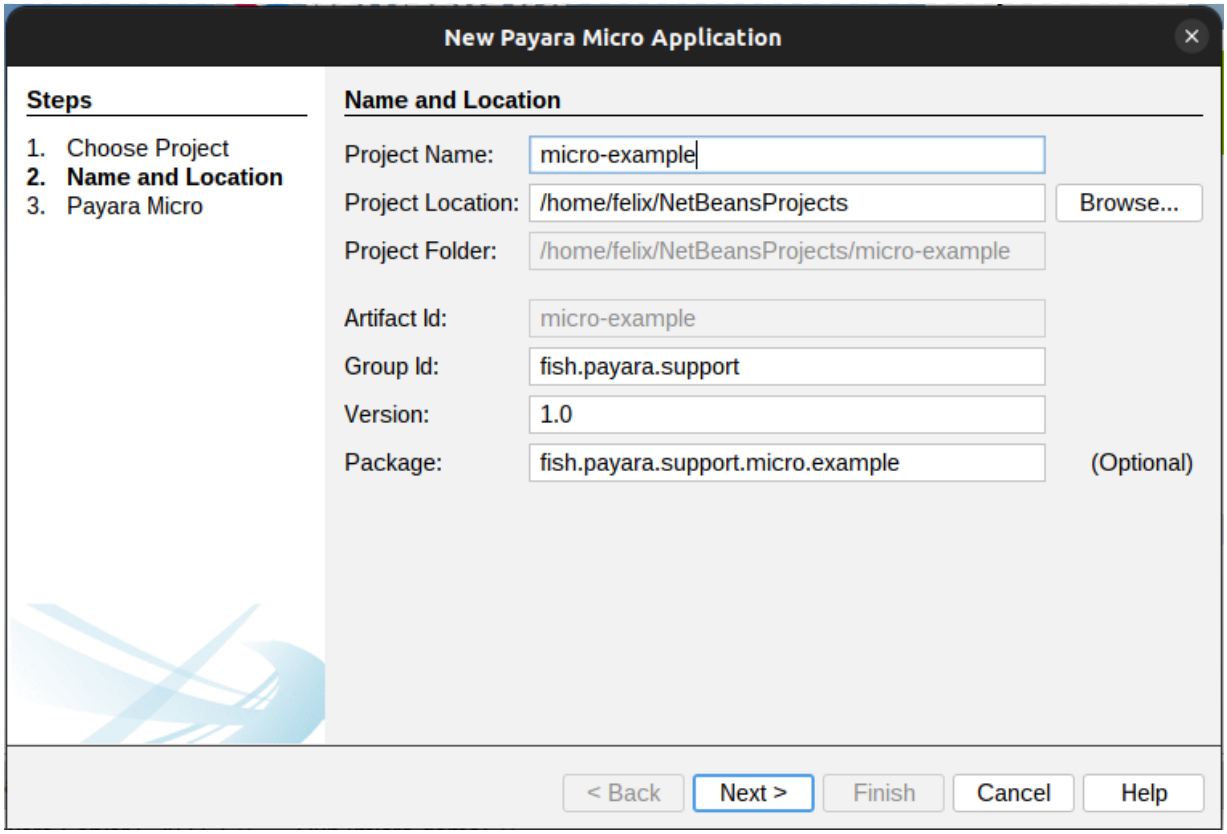
====== Creating a Payara Micro Project

Apache NetBeans IDE supports Payara Micro out of the box. To create a Payara Micro project, follow these steps:

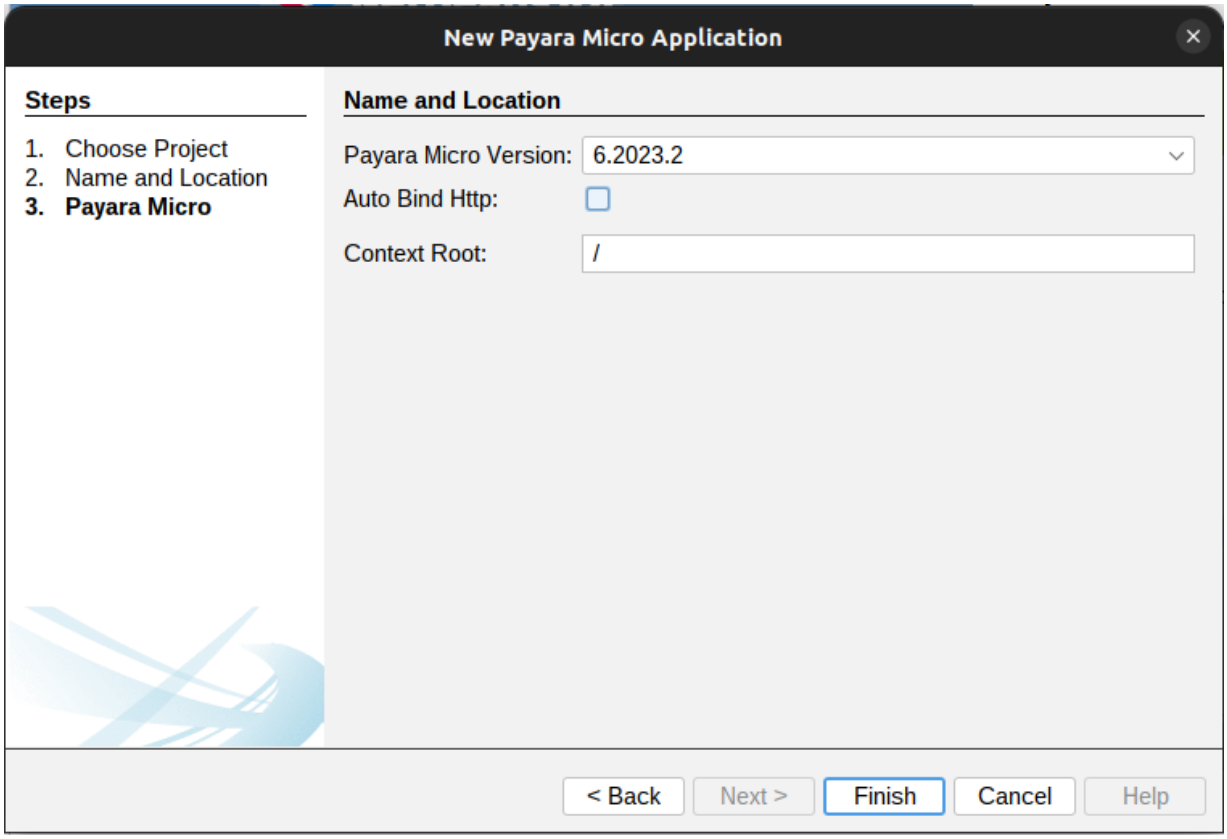
1. Create a new project using Payara Micro Application archetype under Java with Maven category.



2. Input the desired project name, project name, artifact id, group id and version.



3. Select the desired Payara Micro version. Make sure that Auto Bind HTTP is left unchecked.



====== Deploying the Payara Micro project

To deploy the Payara Micro project, simply run the application using the Run Project option from the Run menu. The Payara Micro application will be deployed and the URL will be displayed in the *Output* window:

```

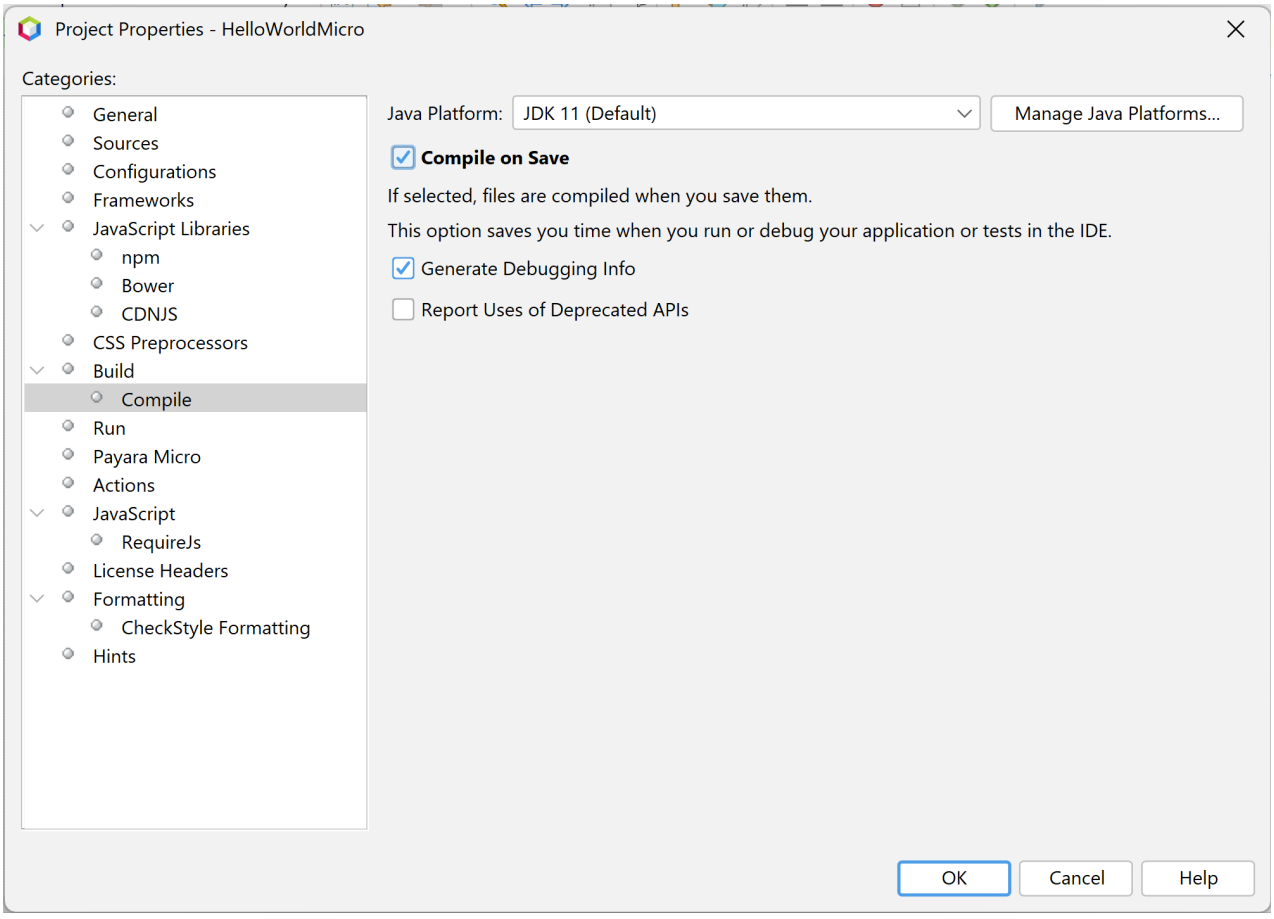
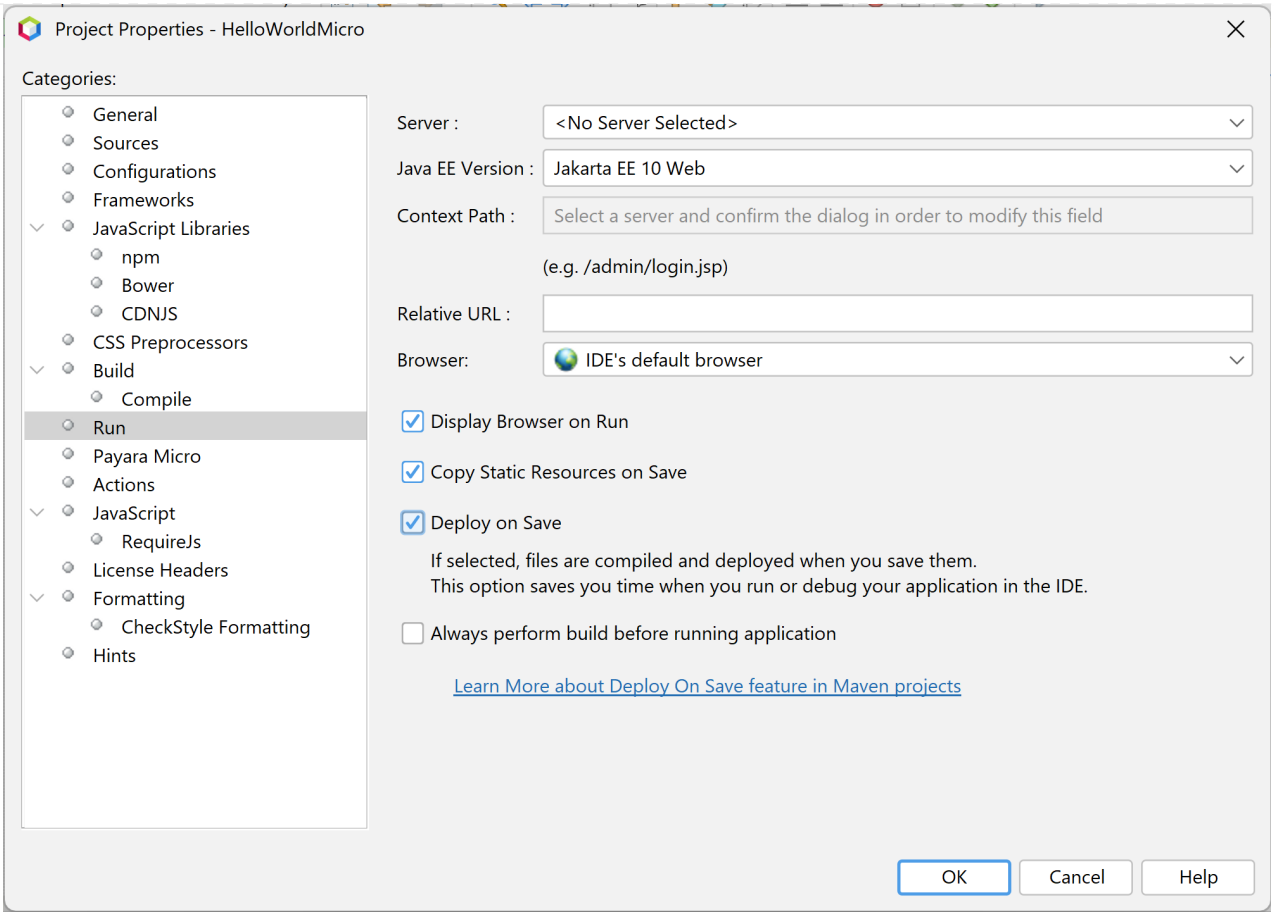
====== Hot Deploy and Auto Deploy Settings

To enable the **Auto Deploy** features for Payara Micro on the Apache NetBeans IDE, you must enable the **Compile on Save** and **Deploy on Save** features from the **Project Properties**.

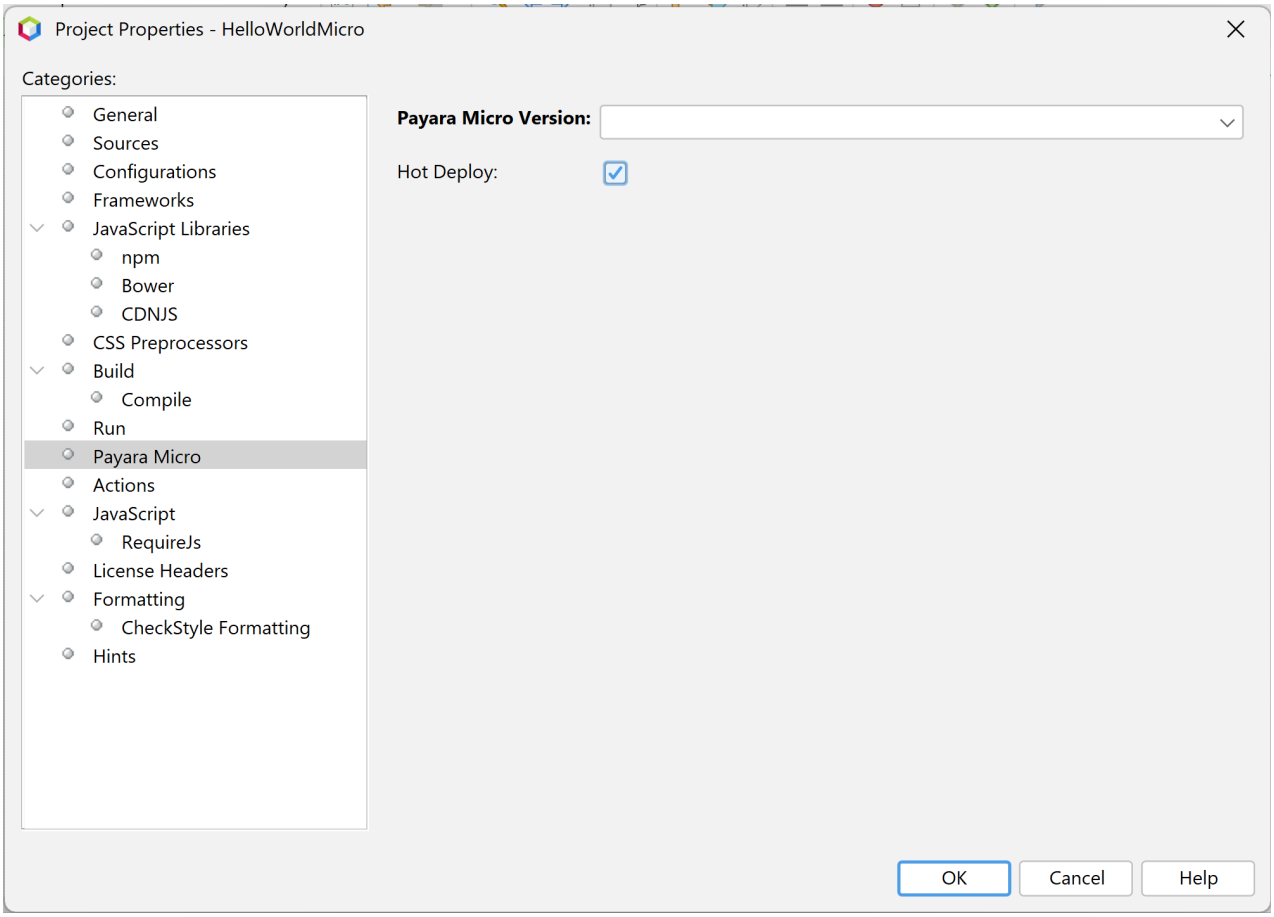
Compile on Save can be found in the **Build→Compile** submenu of the project properties.



Deploy on Save can be found in the Run submenu of the project properties.



To enable the **Hot Deploy** feature for Payara Micro on the Apache NetBeans IDE, you must enable the **Hot Deploy** checkbox which can be found in the **Payara Micro** submenu of the project properties.



====== See Also Hot Deploy and Auto Deploy

====== Building Apache NetBeans IDE

As Apache NetBeans IDE provides out-of-the-box support for Payara Platform, the source code for the Payara Platform tools is contained within the NetBeans Code Repository.

Full, up-to-date build instructions for the Apache NetBeans IDE can be read on the README file in the Apache NetBeans IDE repository

====== Prerequisites Before building the Apache NetBeans IDE and subsequently the Payara Platform Tools for Apache NetBeans IDE, you will need to configure your local environment. Subsequent builds will not require these steps.

Clone the Apache NetBeans Repository

You must first clone the repository where the plugin source code is stored. Apache NetBeans Code Repository

Install Apache Ant

Apache Ant is the build tool for the Apache NetBeans IDE and must be configured locally. Install Apache Ant

JDK 11

JDK 11 is required to build and run Apache NetBeans

If you are building Apache NetBeans on Windows. `Program Files` must be replaced with `PROGRA~1` and `Program Files (x86)` must be replaced with `PROGRA~2` in your `ANT_HOME` environment variable.

====== Payara Tools Code

The Payara Tools plugin code is split into five modules, these are all located under the `enterprise` directory:

- payara.common
- payara.eecommon
- payara.jakartaee
- payara.micro
- payara.tooling

To test any code changes, recompile the modified module, then rerun the IDE build using `ant tryme`.

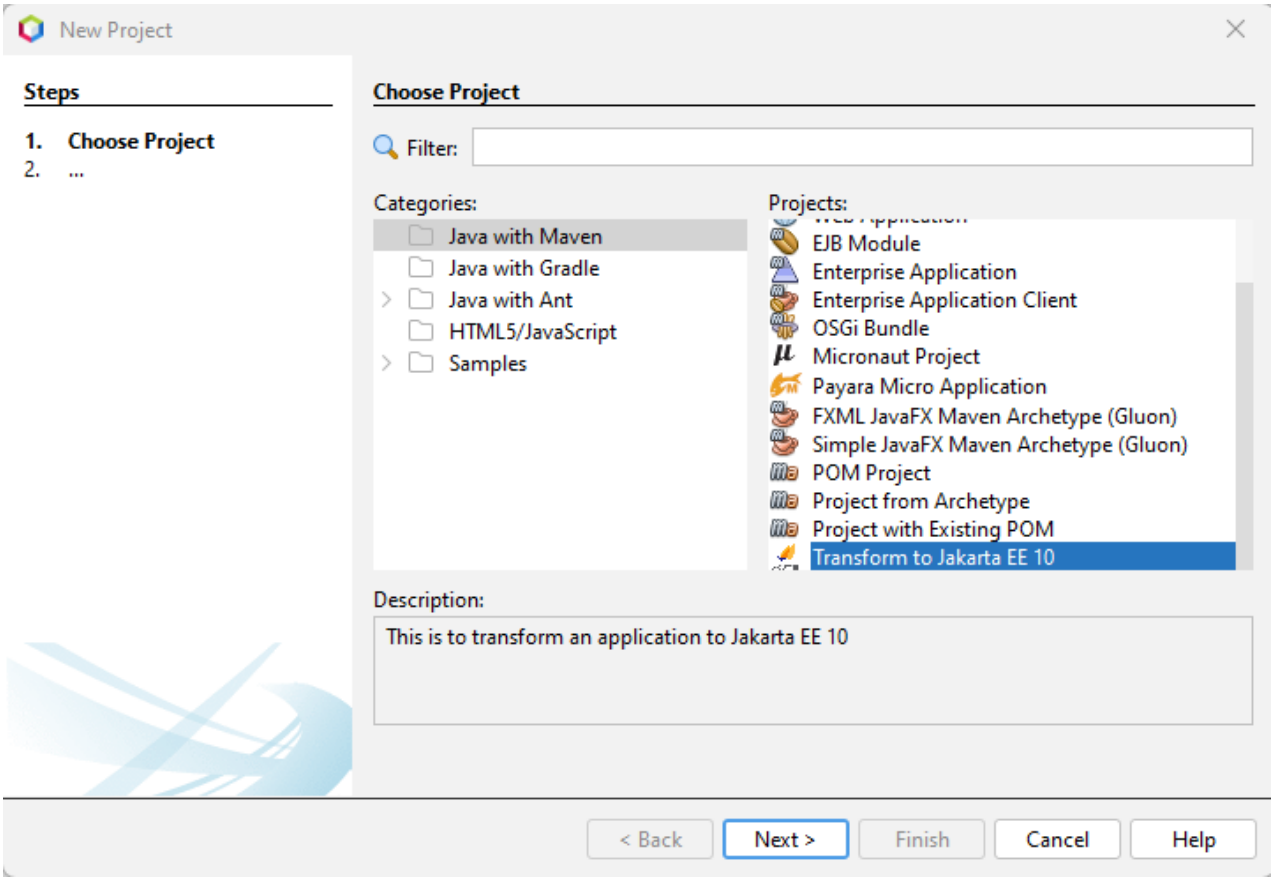
====== Transform to Jakarta-EE10

Apache NetBeans IDE provides tools to allow users to automatically convert the source code of Java/Jakarta EE 8 applications to Jakarta EE 10.

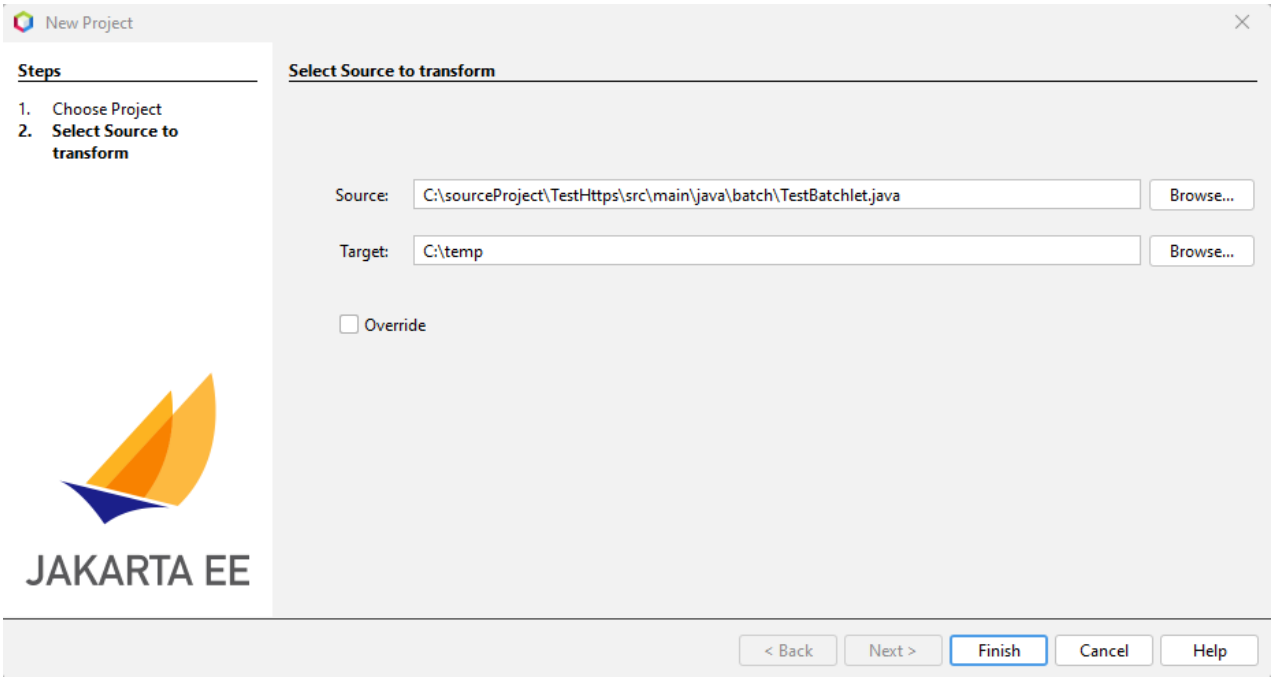
The features described on the following page will be available until Apache NetBeans 19 is released. You can see the release dates here: https://cwiki.apache.org/confluence/display/NETBEANS/Release+Schedule

====== Transform a Single File

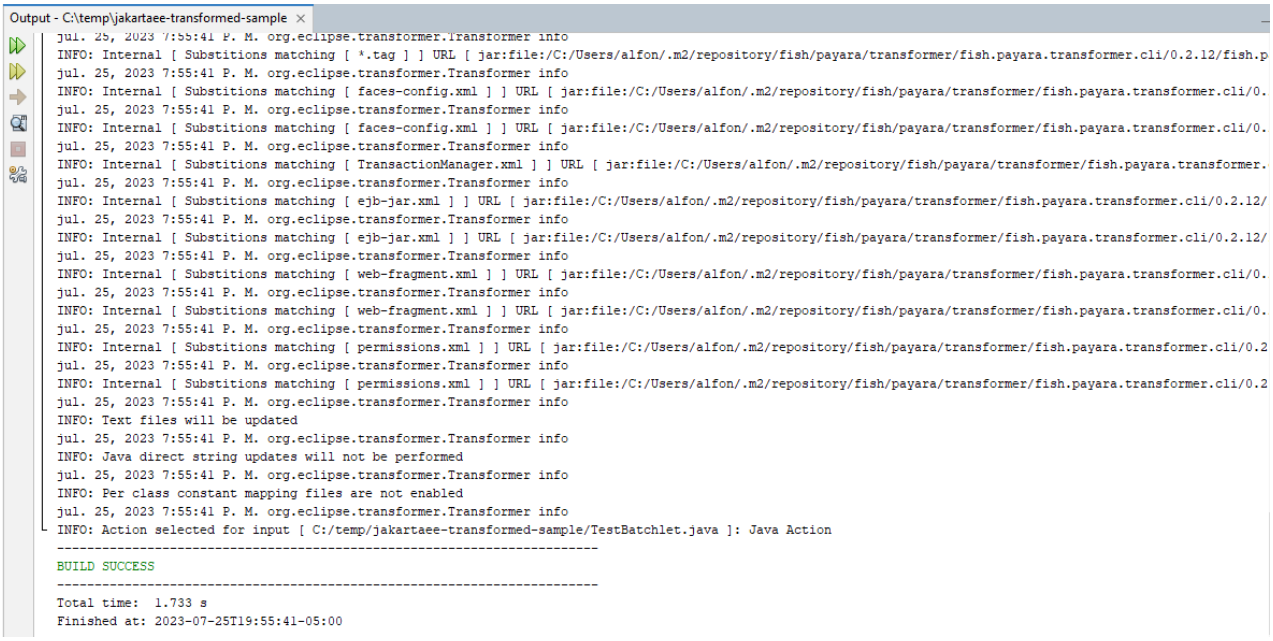
Select from New Project Wizard the option named **Transform to Jakarta EE 10**:



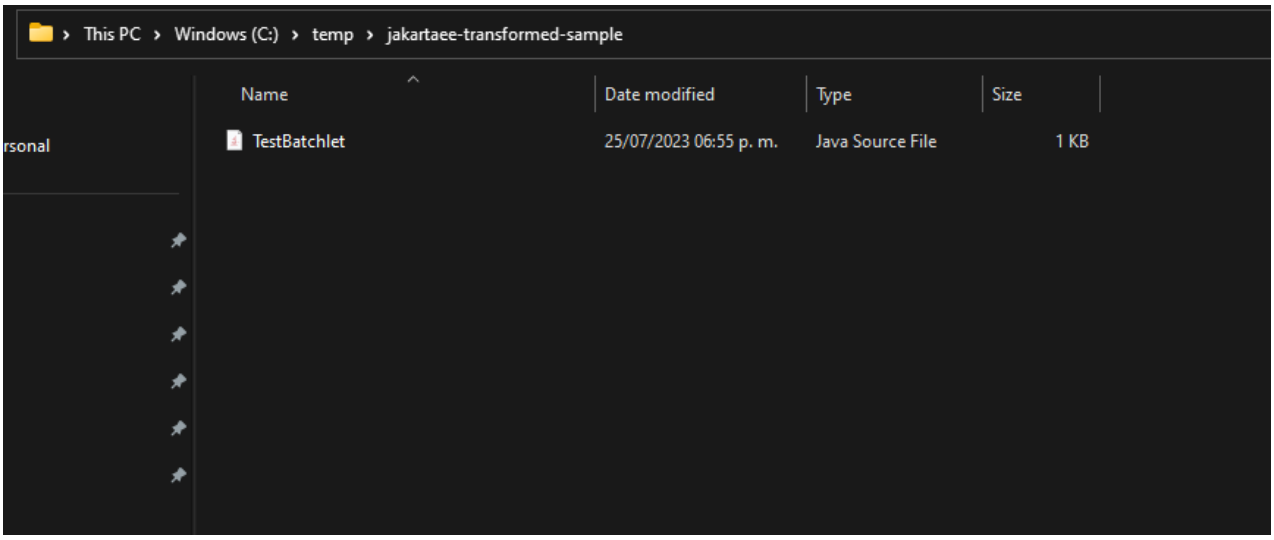
Proceed to select the source file and target folder and click **Finish** to start transformation:



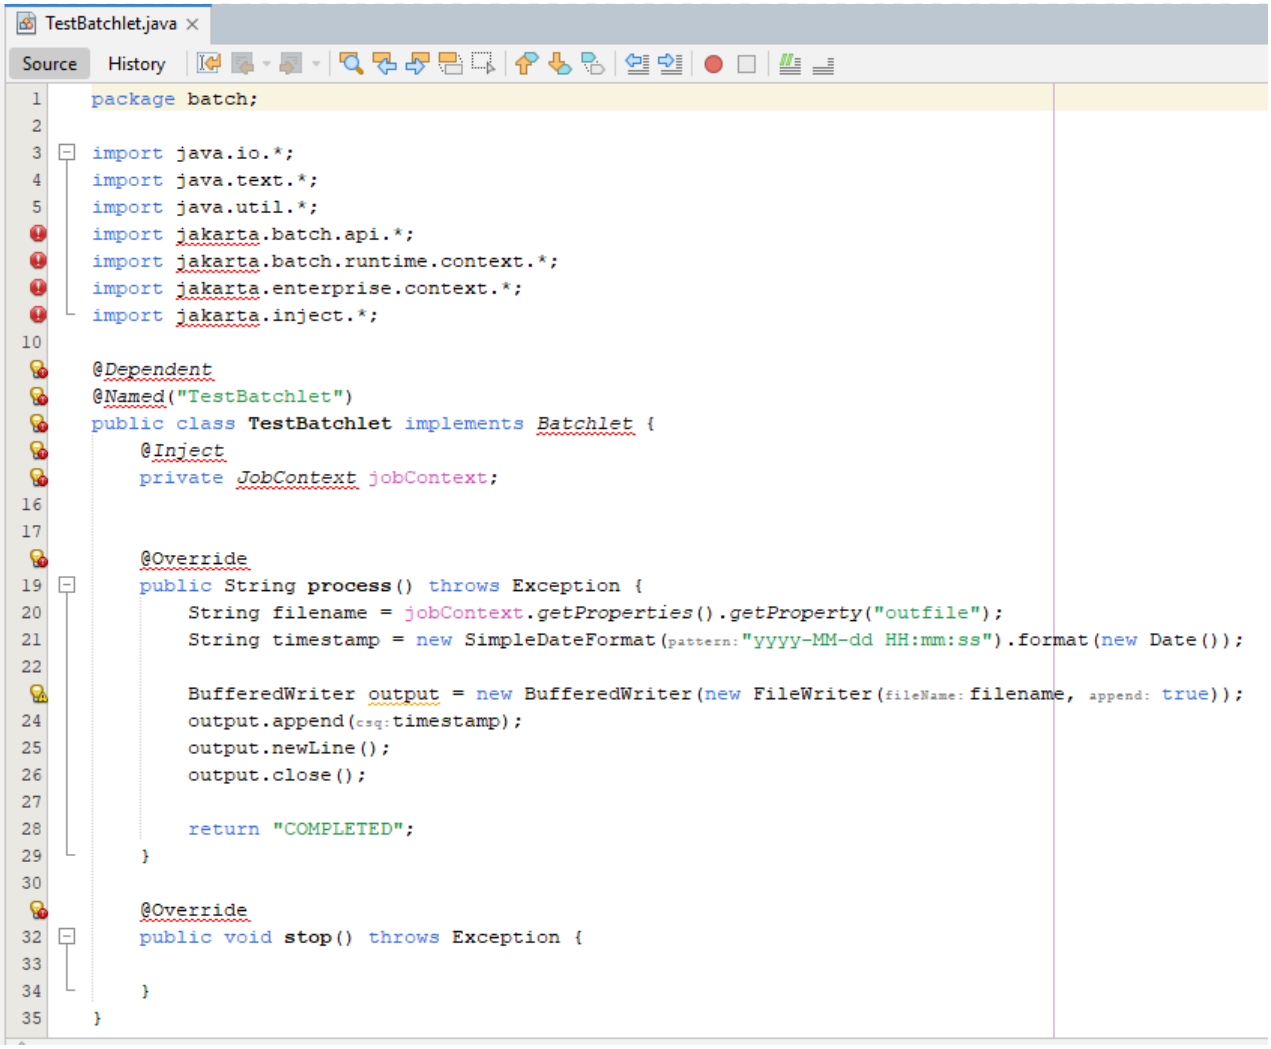
Check the progress and result of the operation on the **Output** tab:



This will create a folder named **jakartaee-transformed-sample** into the target folder (selected from the wizard) with the transformed file:



To verify the resulting file you'll have to open it using Apache NetBeans editor:

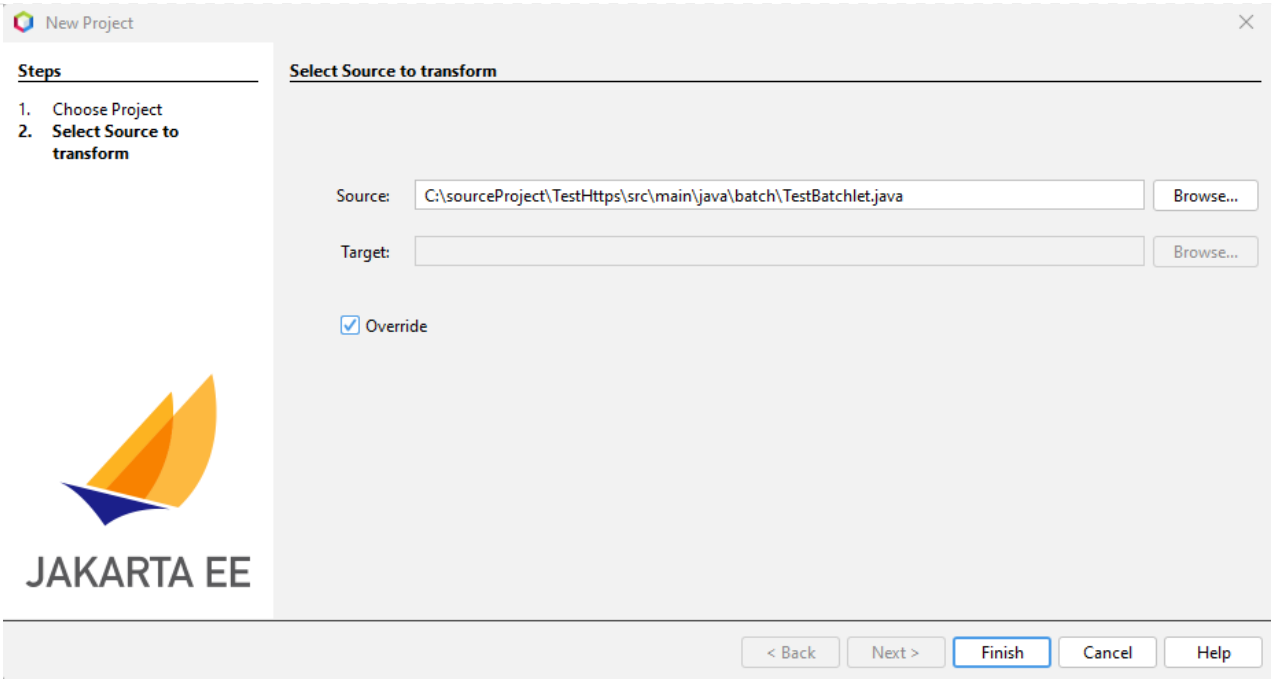


From the image you can see errors on the editor. This is happening because after doing the transform operation it is needed to change the jakarta dependency manually on the pom file associated with the project.

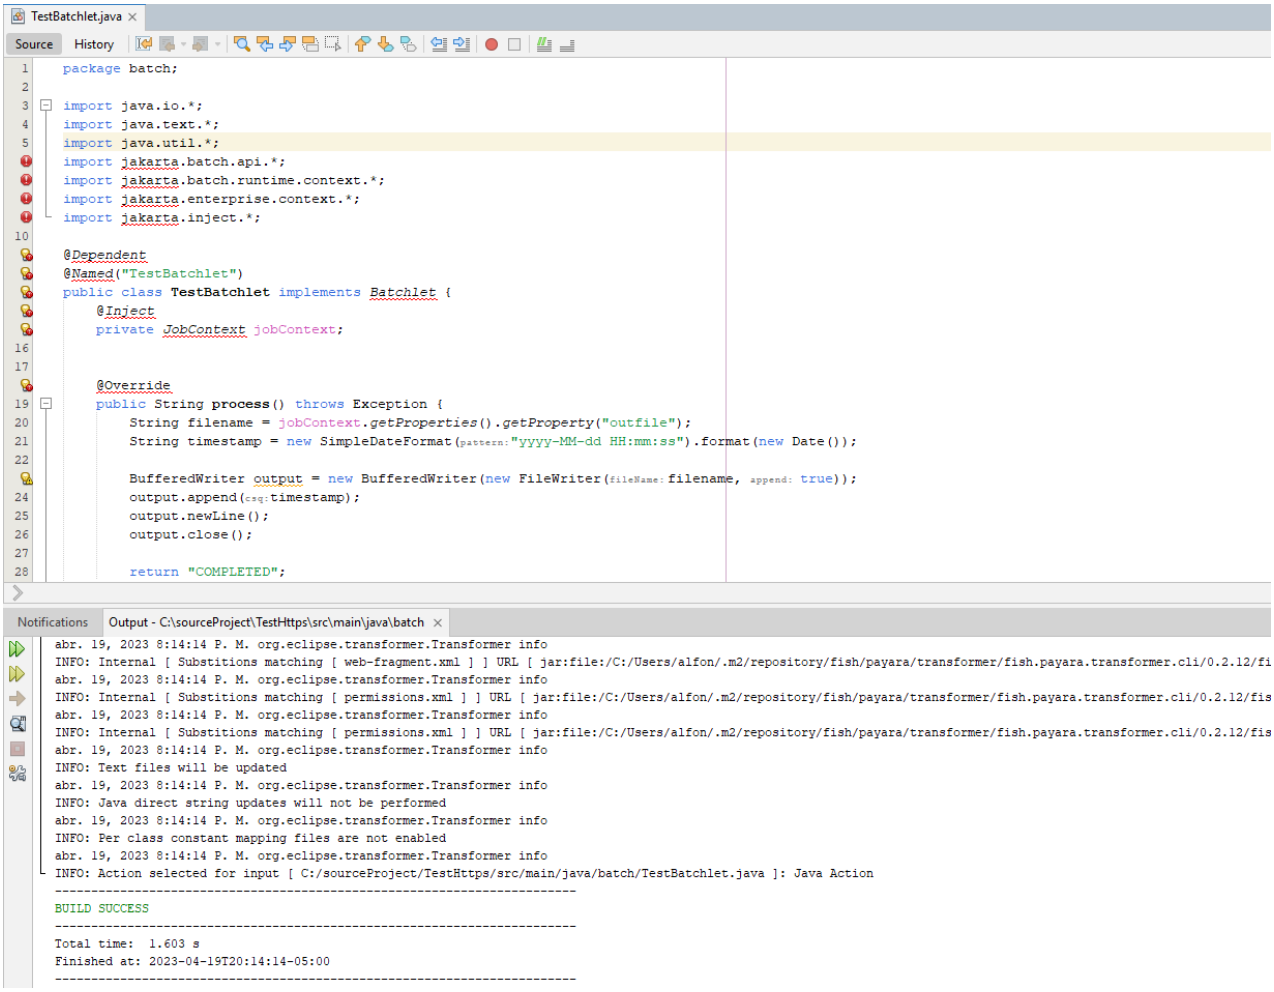
====== Transform a Single File in the Same Location

It is possible to save the transformed file in the same location where the original resides.

To do this, select the source location and then mark the **Override** option. This will disable and clean the target value, finally select **Finish**:



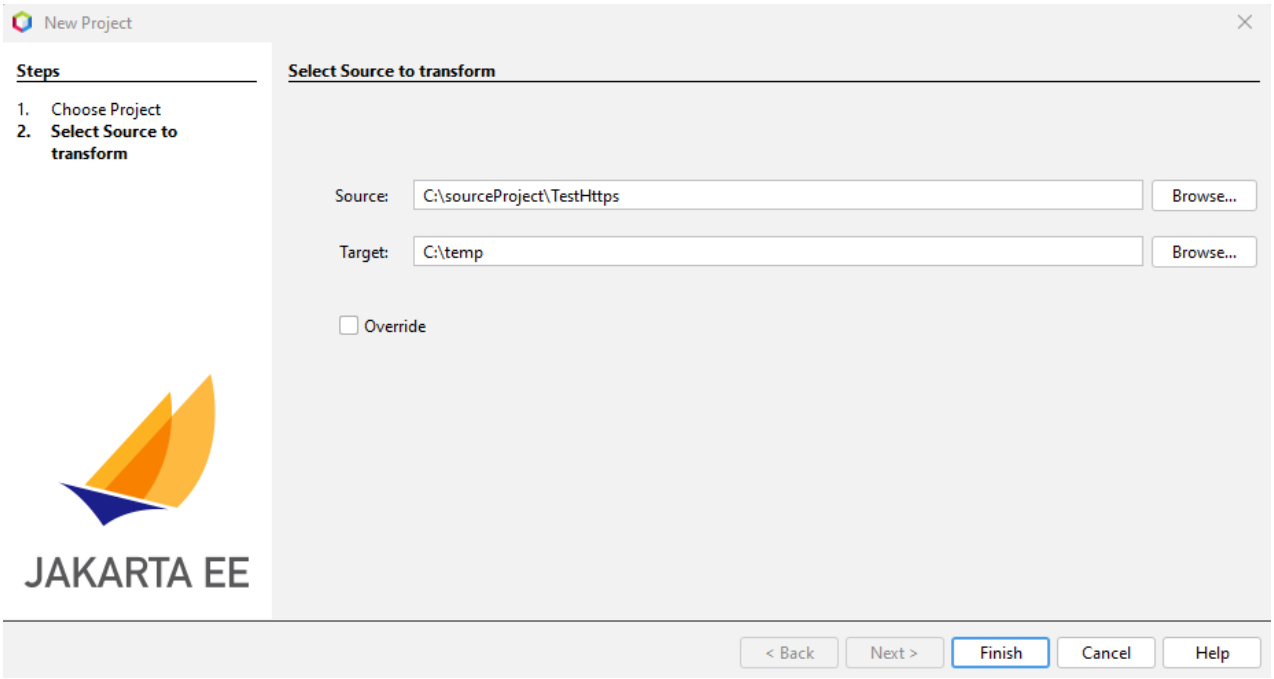
Once the file has been transformed, it will override the file. You can open with NetBeans editor:



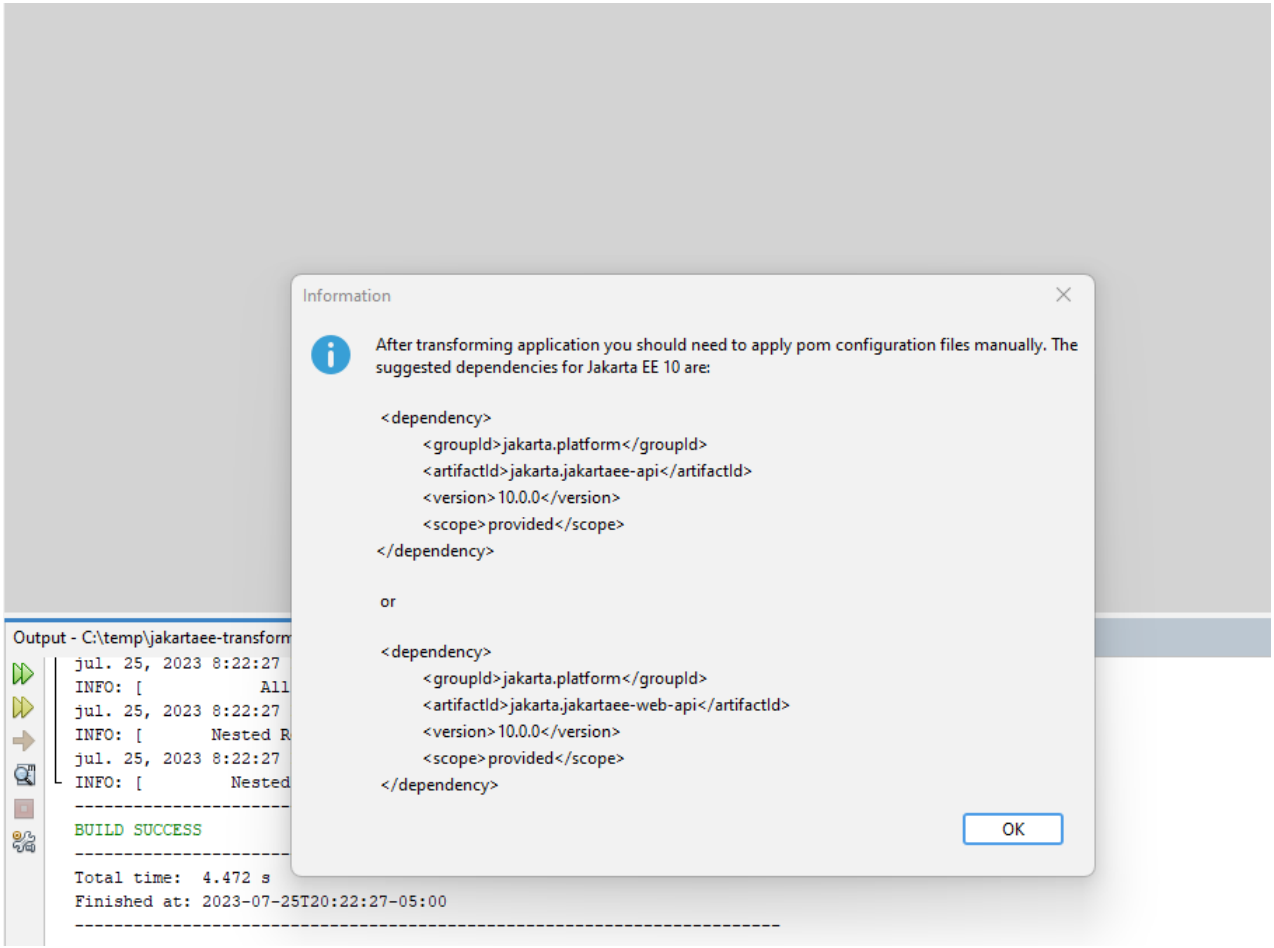
From the image you can see errors on the editor. This is happening because after doing the transform operation it is needed to change the jakarta dependency manually on the pom file associated with the project.

====== Transform All Files in a Folder

You can transform all source code files located in a folder. To do this you must select the source folder and the target folder, finally click **Finish**:



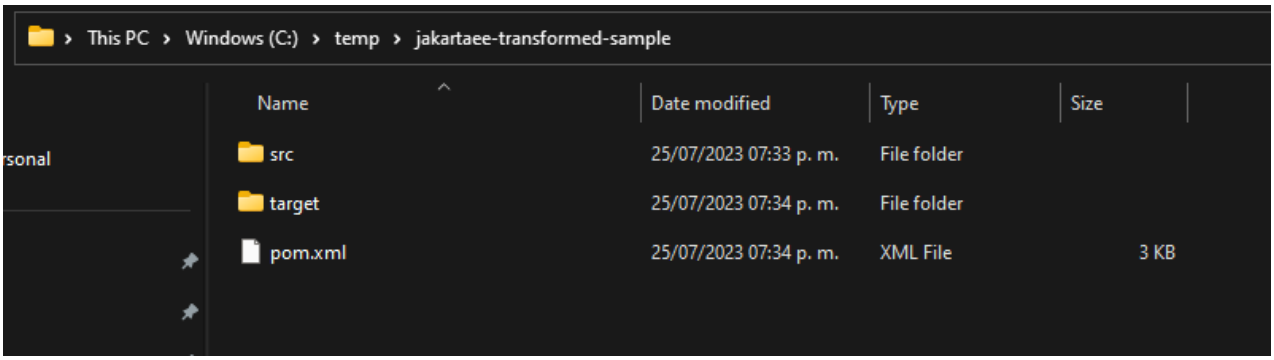
Check the progress and result of the operation on the **Output** tab:



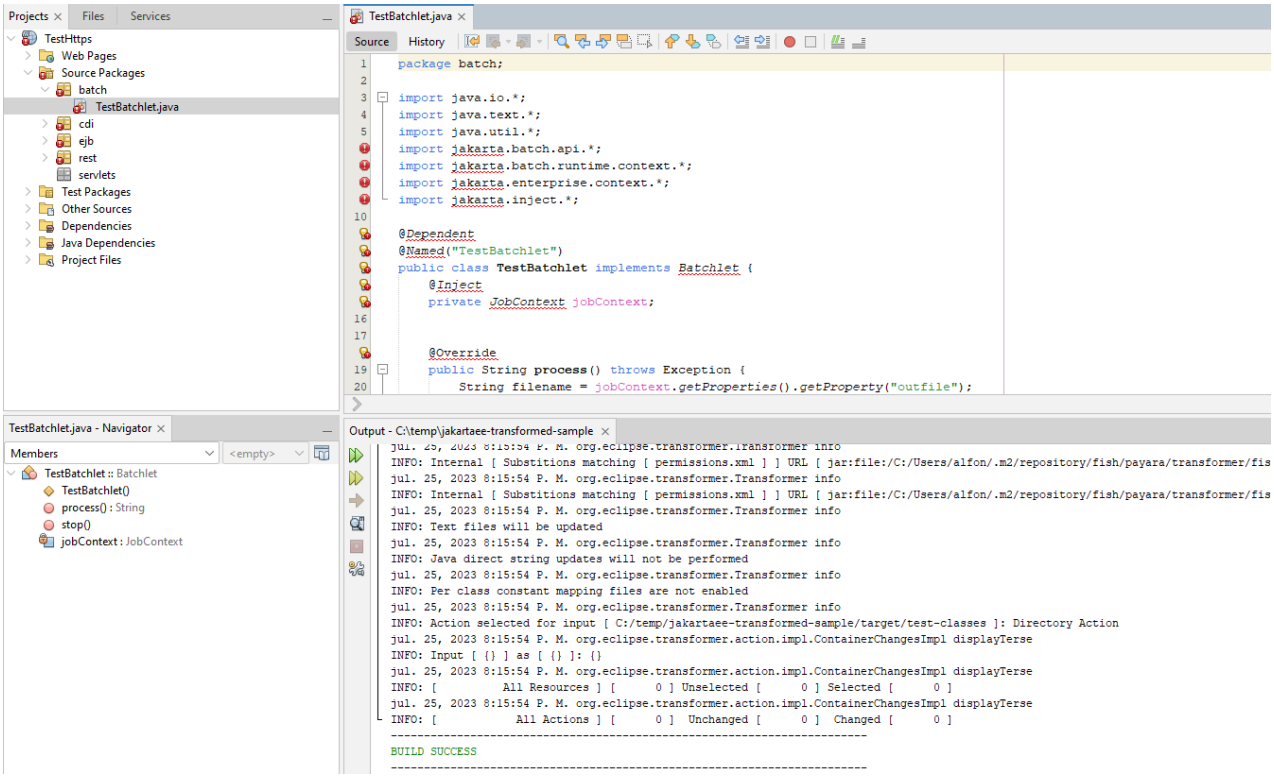
The IDE will also show a dialog with additional recommendations to

configure the source code's project POM configuration. These configuration changes will have to be done manually if required.

This will create a folder named **jakartaee-transformed-sample** into the target folder (selected from the wizard), with the transformed folder and the contents into it:



Apache NetBeans will automatically open the new folder and you can verify results within the IDE:

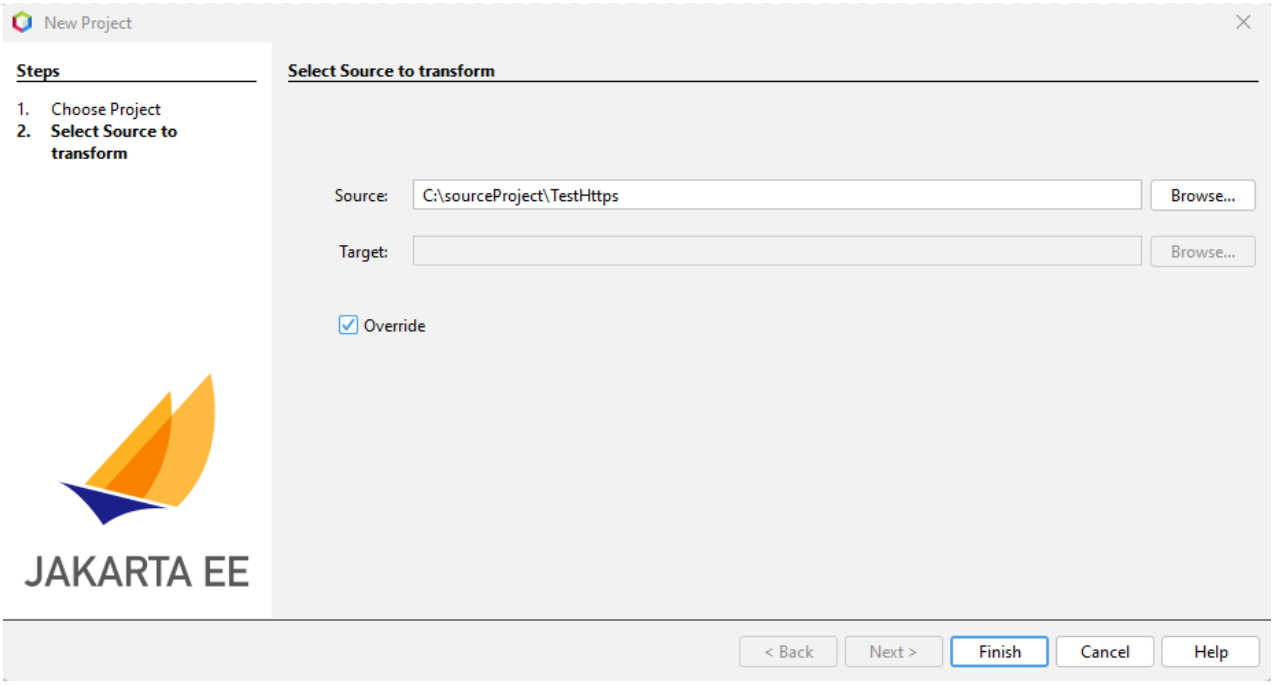


From the image you can see errors on the editor. This is happening because after doing the transform operation it is needed to change the jakarta dependency manually on the pom file associated with the project.

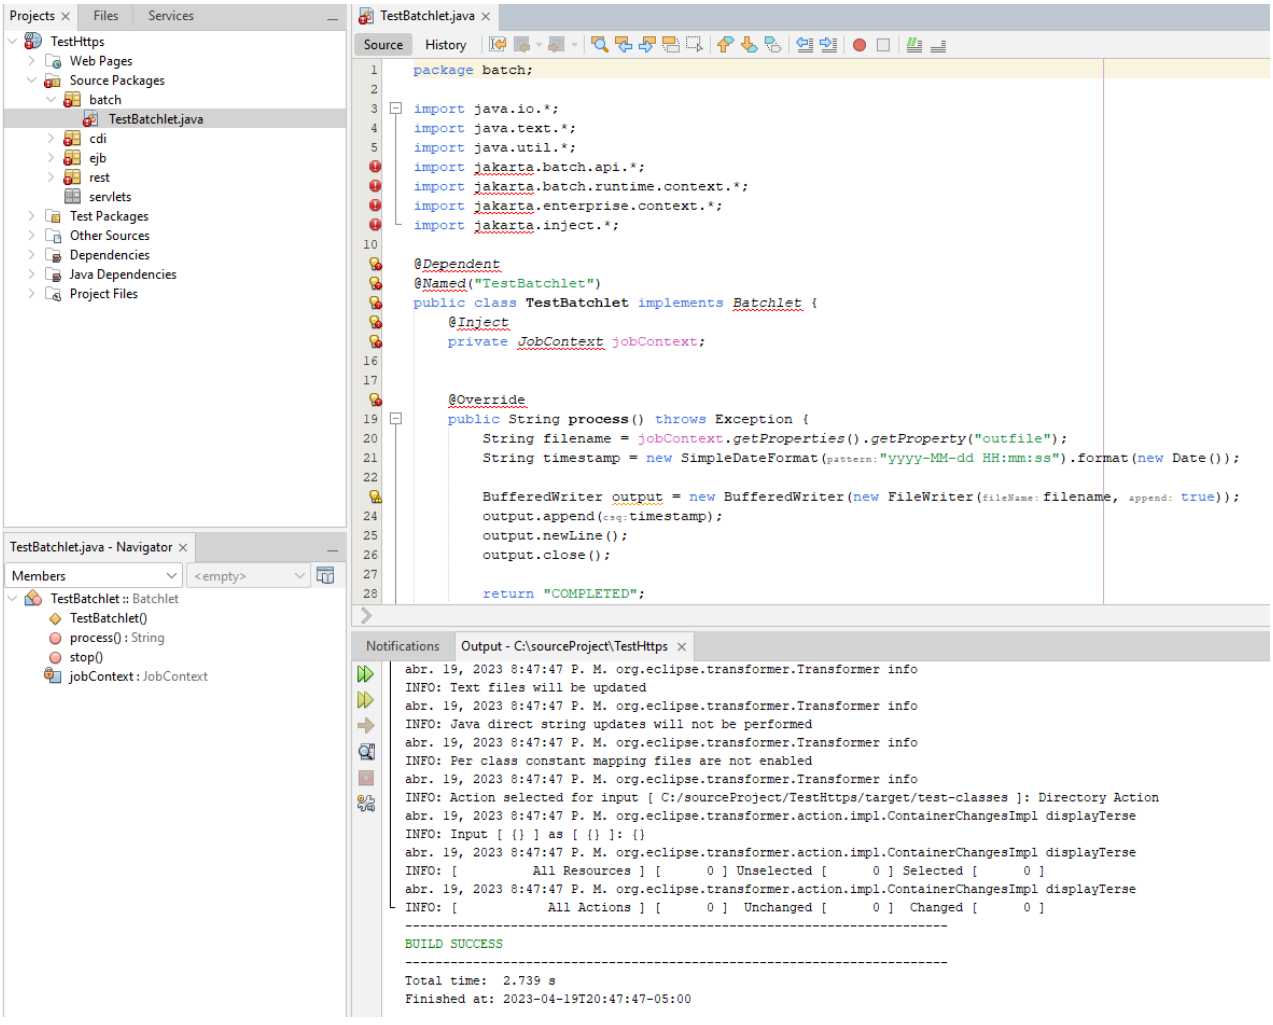
====== Transform All Files in a Folder in the Same Location

It is possible to save all transformed files in the same location where the originals reside.

To do this you should select the source folder and then mark the **Override** option, finally click **Finish**:



Once the contents of the folder have been transformed, the new files will override the current ones and the IDE will open the project to verify results:



From the image you can see errors on the editor. This is happening because after doing the transform operation it is needed to change the jakarta dependency manually on the pom file associated with the project.

===== VSCode Extension

====== Overview

The Payara VS Code extension enables Payara Server and Payara Micro integration with Visual Studio Code. The Payara Tools extension is available in the Visual Studio Marketplace.

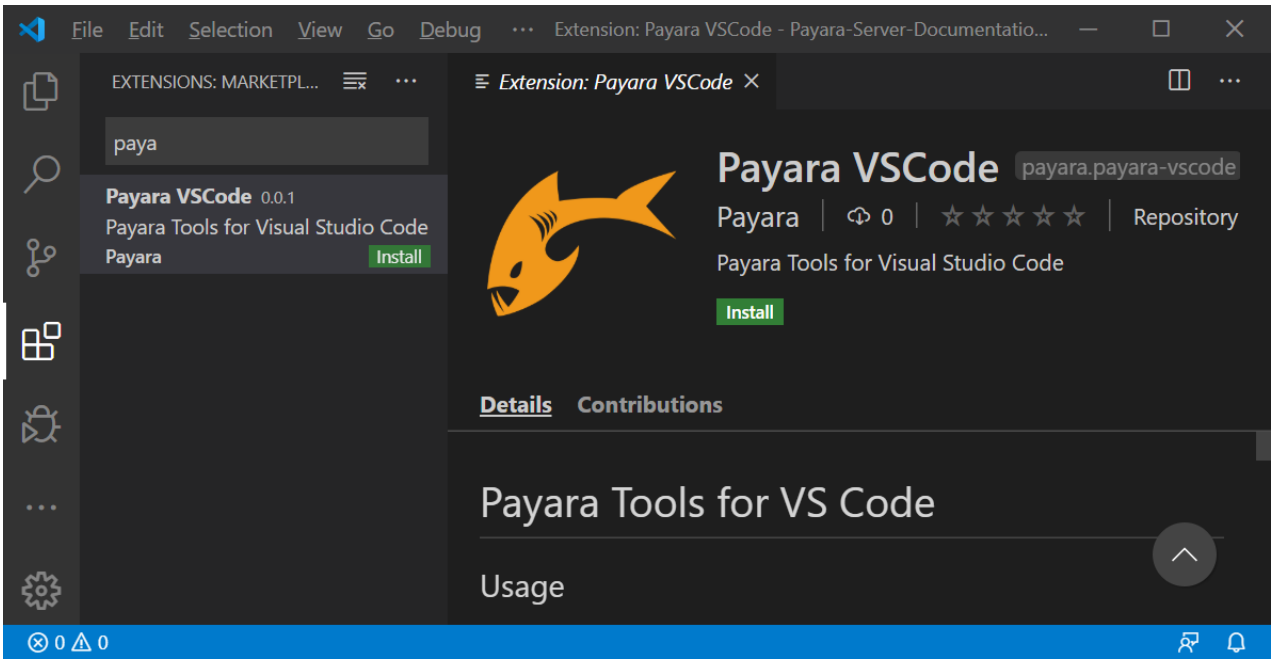
====== Prerequisites for Payara Tools on VS Code

The Java Extension Pack, by Microsoft must be installed first.

If you are using Maven or Gradle as the build tool in your project, the `MAVEN_HOME` or `GRADLE_HOME` environment variables must be set respectively.

====== Installing the Payara VS Code Extension

1. Open the **Extensions** panel on the left-most menu of the editor (`Ctrl + Shift + X`)
2. Search for the **Payara Tools** extension.
3. Click the **Install** button.



====== Payara Platform Tools

- Payara Server - The Payara VS Code extension enables developers to easily configure Payara Server and manage applications from Visual Studio Code.
- Payara Micro - The Payara VS Code extension provides first-class support to create and run Payara Micro maven web applications from VS Code. Payara Micro is the microservices-ready version of the Payara Server.

====== Payara Server

====== Adding Payara Server to VS Code

1. Open the command pallet using **Ctrl** + **Shift** + **P**, type **Payara** and select the **Add Payara**

Server option.

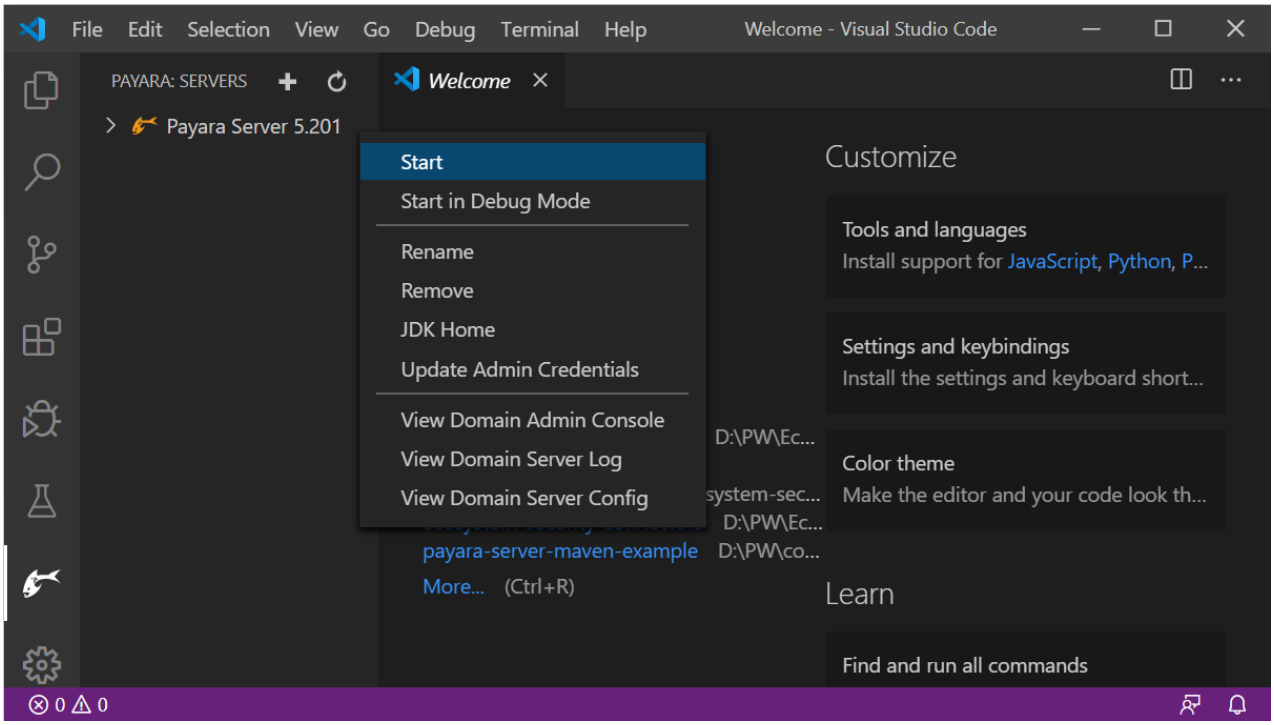
2. Browse the Payara Server installation path (recently used servers location are listed by default).
3. Choose a name for the server.
4. Then select a domain from the list or create a new domain by pressing the + button.

[Add Payara Server] | *../_images/vscode-extension/payara-server/Add Payara Server VS Code.gif*

====== Managing Payara Server from VS Code

Once Payara Server is added to VS Code it can be found under the Payara Servers explorer panel with the configured name. Right-clicking on the server lets you perform any of the following actions:

- Start, restart or stop the server
- Start debugging the server
- Rename or remove the server
- Open admin console
- Open server log
- Open server domain.xml config
- Update admin credentials
- Update JDK path



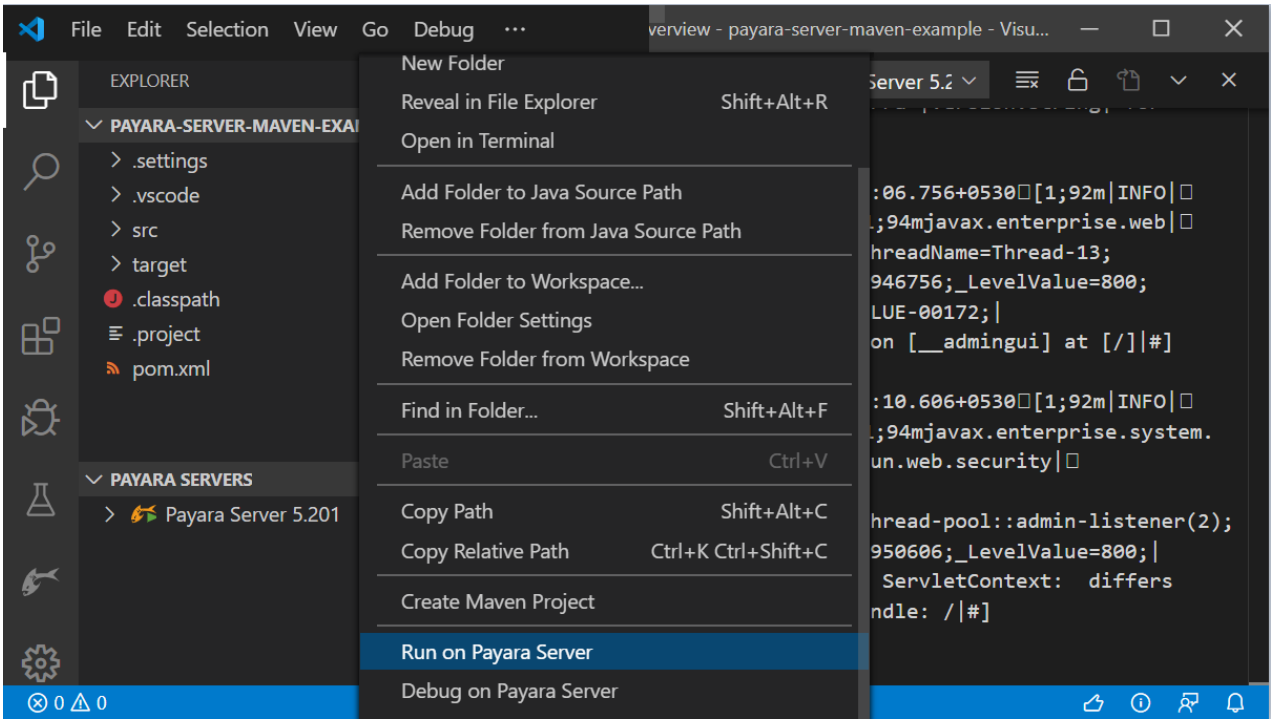
====== Managing Applications on Payara Server

====== Deploying Applications

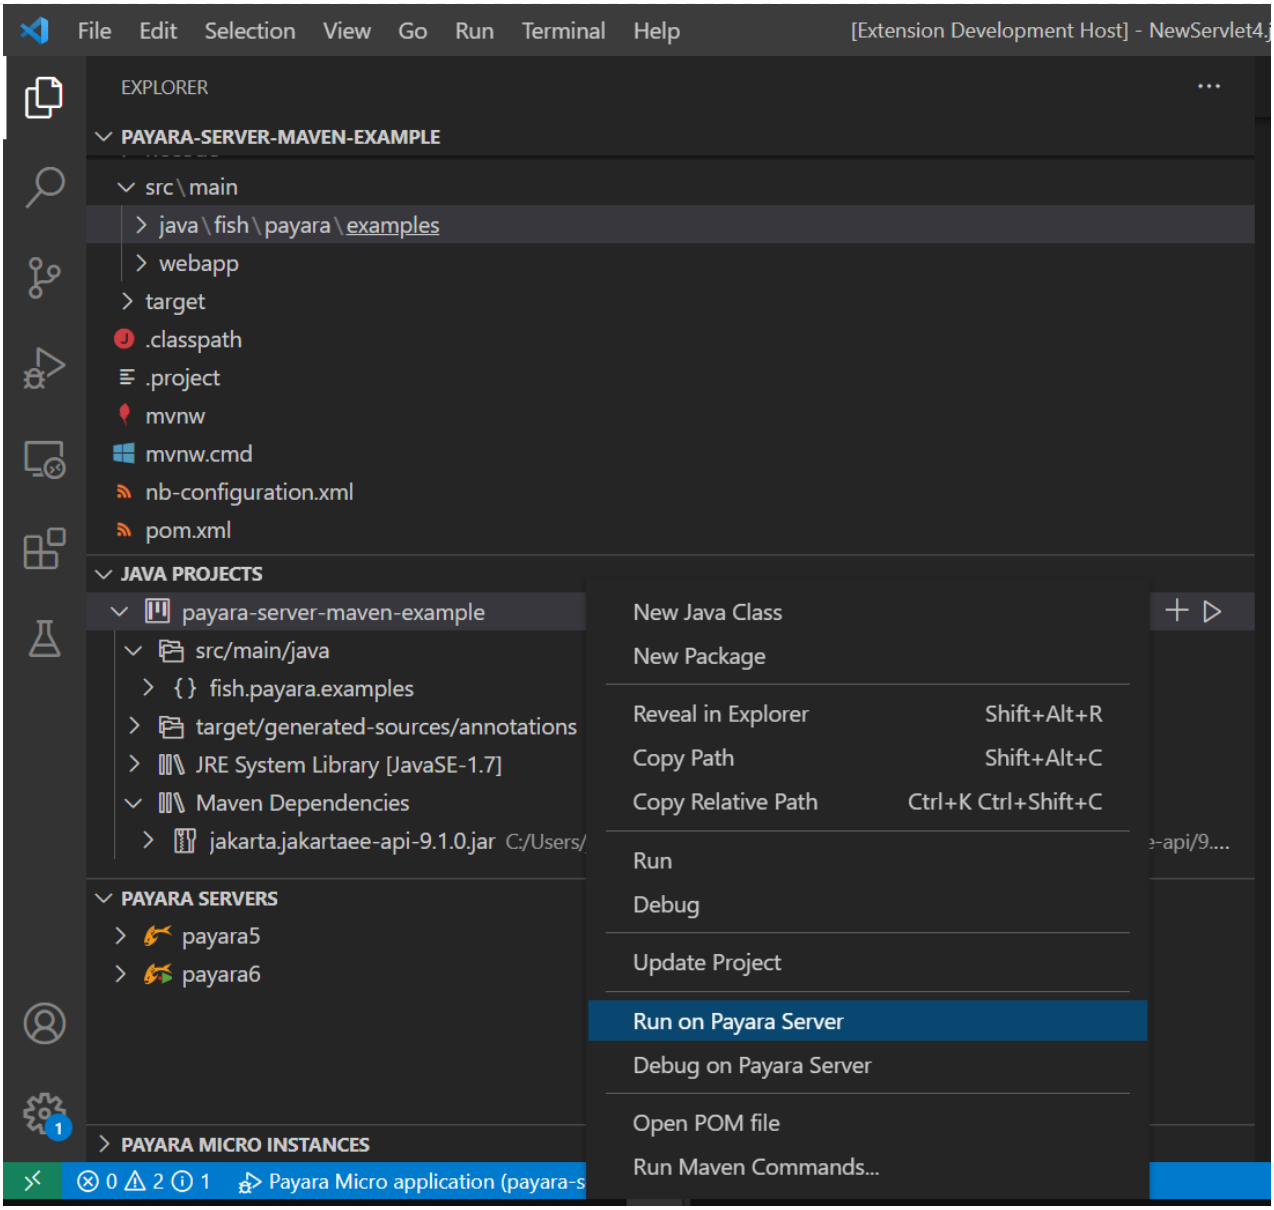
An application can be deployed to Payara Server easily though VS Code. Applications can be

deployed via either of the following two methods

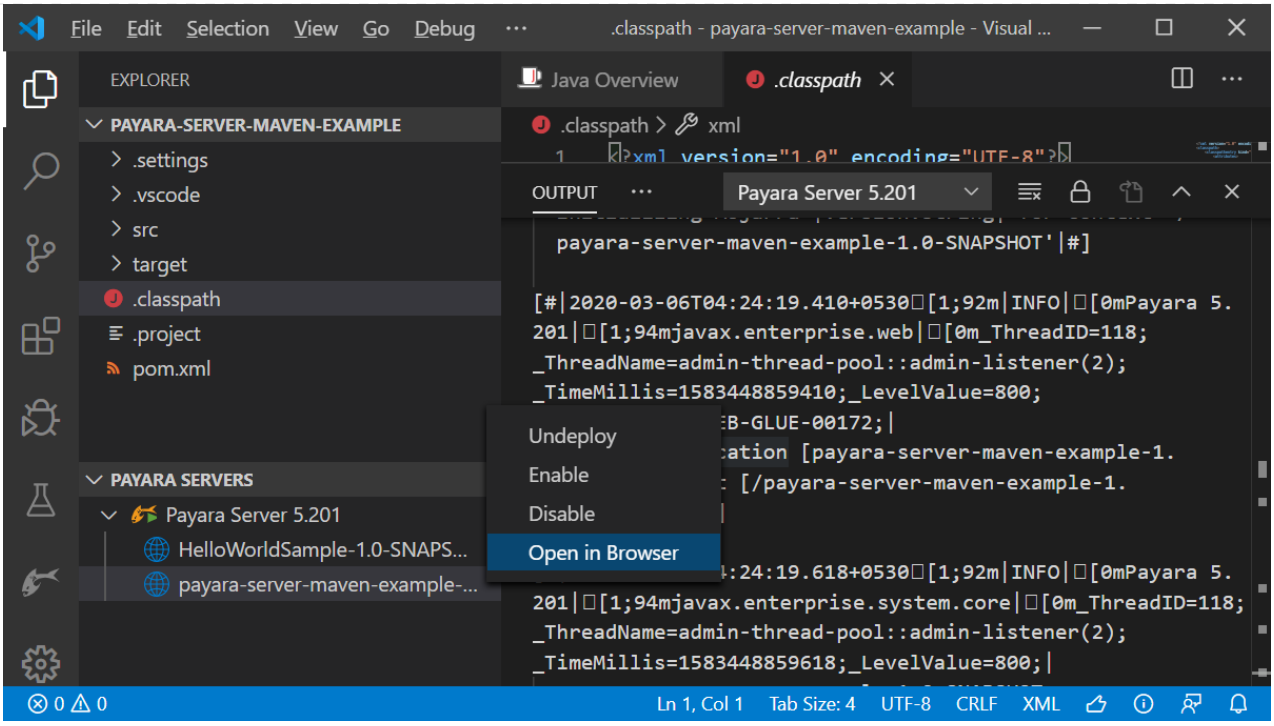
Right-click on the application and select **Run on Payara Server** to deploy the application:



Alternatively, an application can be deployed from the **Java Projects** interface:



====== Undeploying Applications Deployed applications can be opened in the browser, undeployed or disabled by right-clicking on the application in the **Payara Servers** interface:



====== Deploy Applications in a Local Docker Container

The Payara Server tools for the VS Code extension includes Docker integration, making it seamless to deploy exploded applications to a Payara Server instance running within a local Docker container.

To take advantage of this feature, follow these steps below:

1. Register a new Payara Server instance by performing the following:
    a. Open the command pallet using `Ctrl + Shift + P`, type **Payara** and select the **Add Payara Server** option.
    b. Select Remote Domain.
    c. For Docker integration, choose the "Docker" type and provide the `HOST_PATH` (e.g., `D:/test`) and `CONTAINER_PATH` (e.g., `/mnt/test`) mapping details.

    This mapping should align with the exploded application path or parent path of exploded application.

    d. Choose a name for the server.
    e. Enter the domain name, host name, and necessary credentials.
2. Run the Payara Server Docker container using the following command:

```
docker run -p 8080:8080 -p 4848:4848 -p 9009:9009 -v HOST_PATH:CONTAINER_PATH
payara/server-full:{page-version}
```

Replace `HOST_PATH` with the actual host path and `CONTAINER_PATH` with the desired container path. The `HOST_PATH` points to the location on your host machine, and `CONTAINER_PATH` is the corresponding location inside the container.

3. Create your web application and deploy it to the registered Payara Server instance.

====== Deploy Applications in a WSL Environment

Another noteworthy feature is the integration of the Payara Server Tools with Windows Subsystem for Linux (WSL).

This integration empowers developers to manage and deploy exploded applications to a Payara Server instance running within WSL.

Here's how you can make use of this feature:

1. Start the Payara Server instance within WSL:
    a. Run the following command to start the server:

```
./asadmin start-domain
```

    b. Set a password for the admin user:

```
./asadmin change-admin-password
```

    c. Enable secure admin:

```
./asadmin enable-secure-admin
```

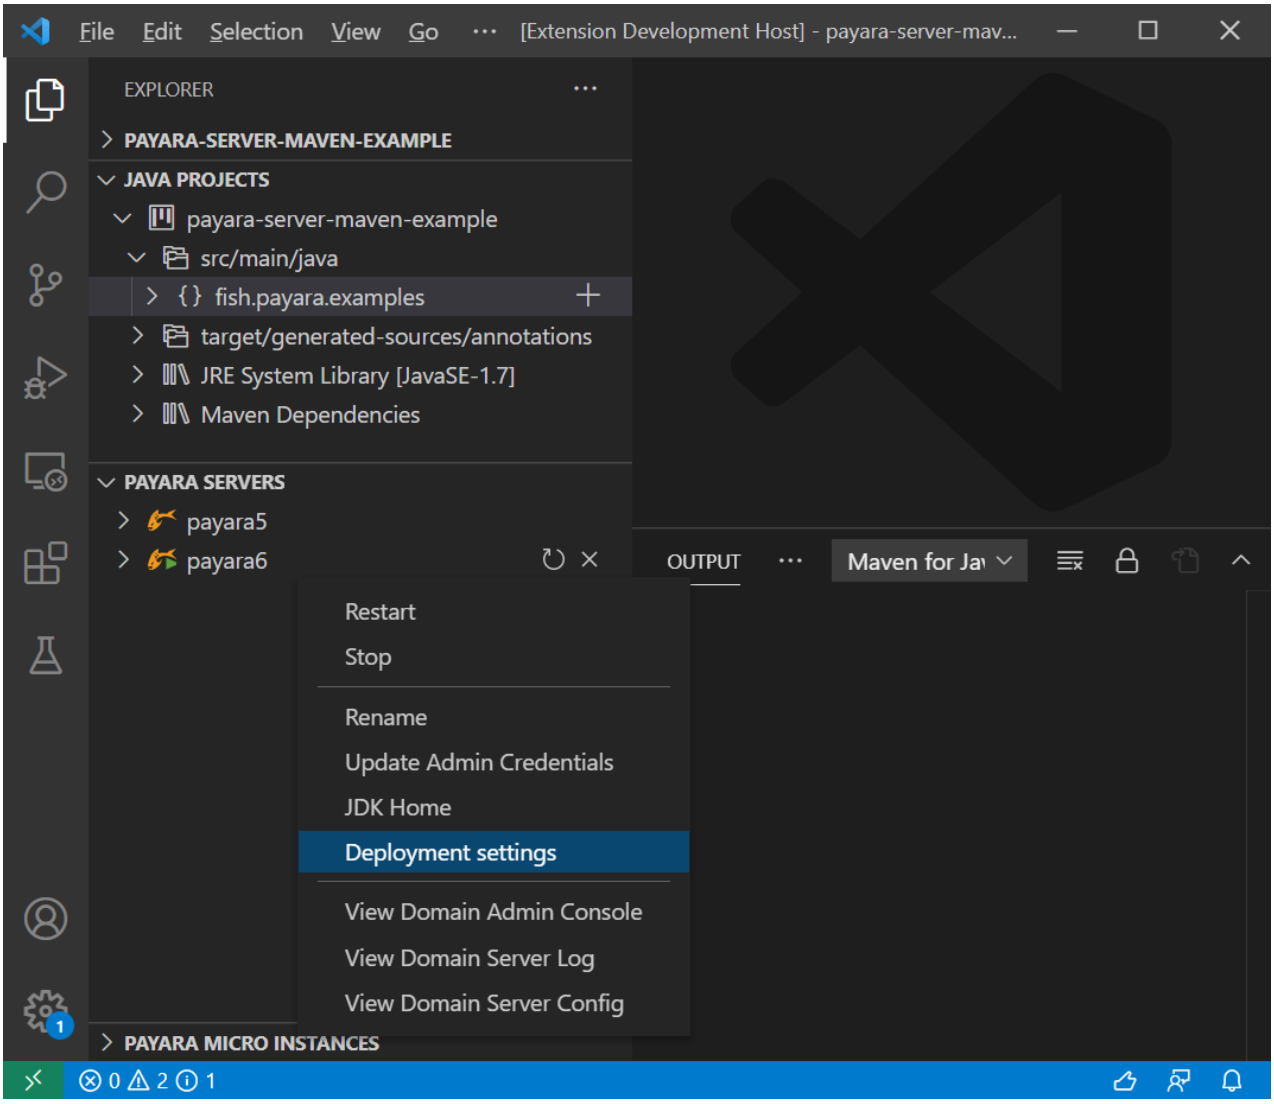
    d. Restart the Payara Server domain:

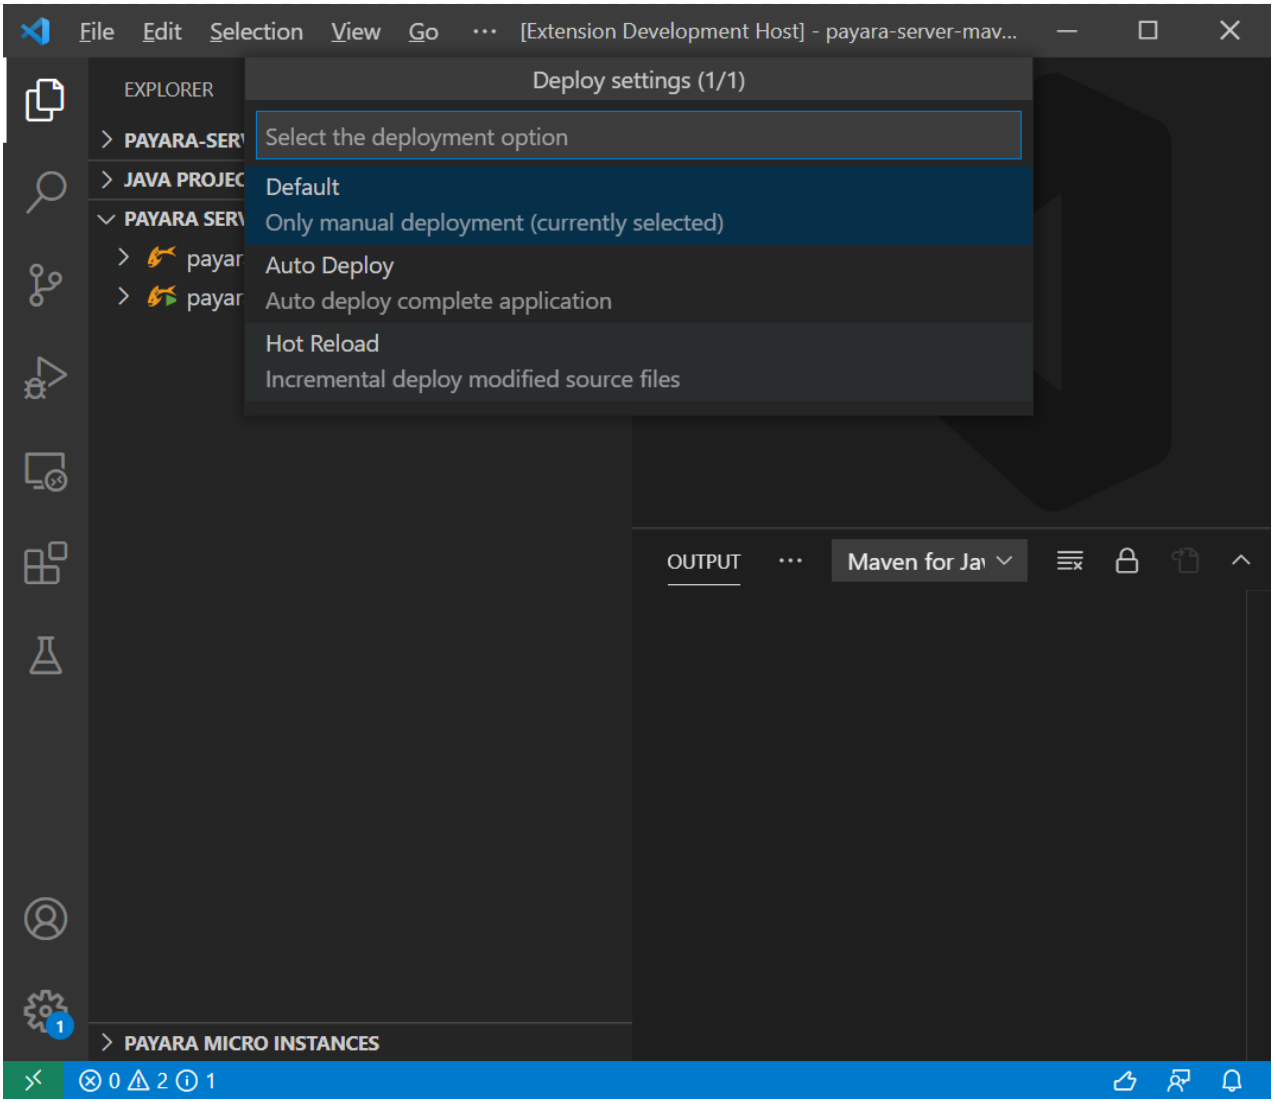
```
./asadmin restart-domain
```

    e. Fetch the IP address of WSL environment using the command `hostname -I` and enter it in the `host name` field in the VS Code settings.
2. Register the WSL-based Payara Server instance in VS Code:
    a. Open the command pallet using `Ctrl + Shift + P`, type **Payara** and select the **Add Payara Server** option.
    b. Select Remote Domain.
    c. For WSL integration, choose the `WSL` instance type.
    d. Choose a name for the server.
    e. Enter the domain name, host name (fetched via the command `hostname -I` in WSL instance), and necessary credentials.
3. Create your web application and deploy it to the registered Payara Server instance.

====== Hot Deploy and Auto Deploy Settings

Hot Deploy and **Auto Deploy** can be enabled in Visual Studio Code IDE from the **Deployment Settings** of Payara Server:





====== See Also Hot Deploy and Auto Deploy

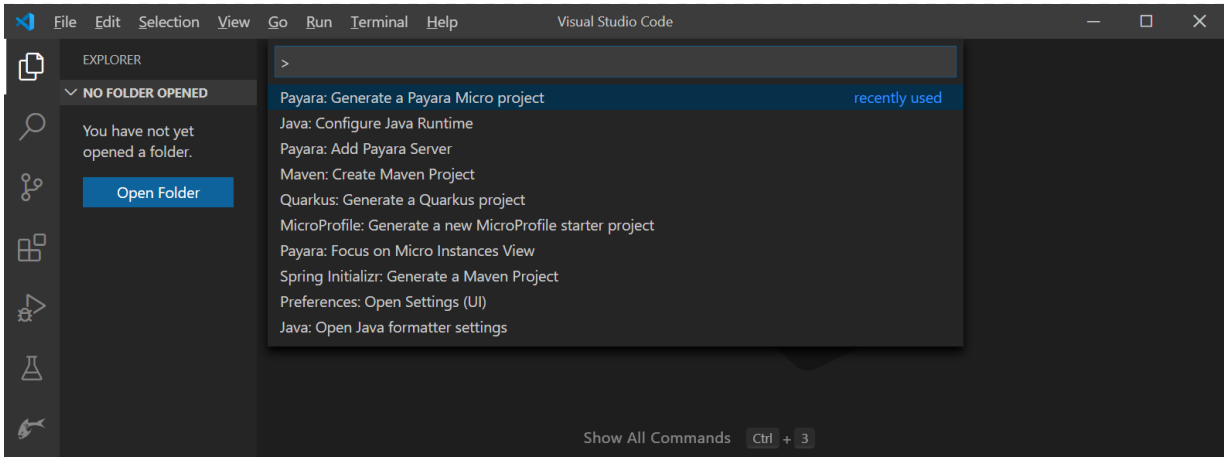
====== Payara Micro

Using the Payara Tools VS Code extension, you can integrate Payara Micro within the VS Code IDE to create new Payara Micro Maven applications, start, stop and deploy applications to Payara Micro.

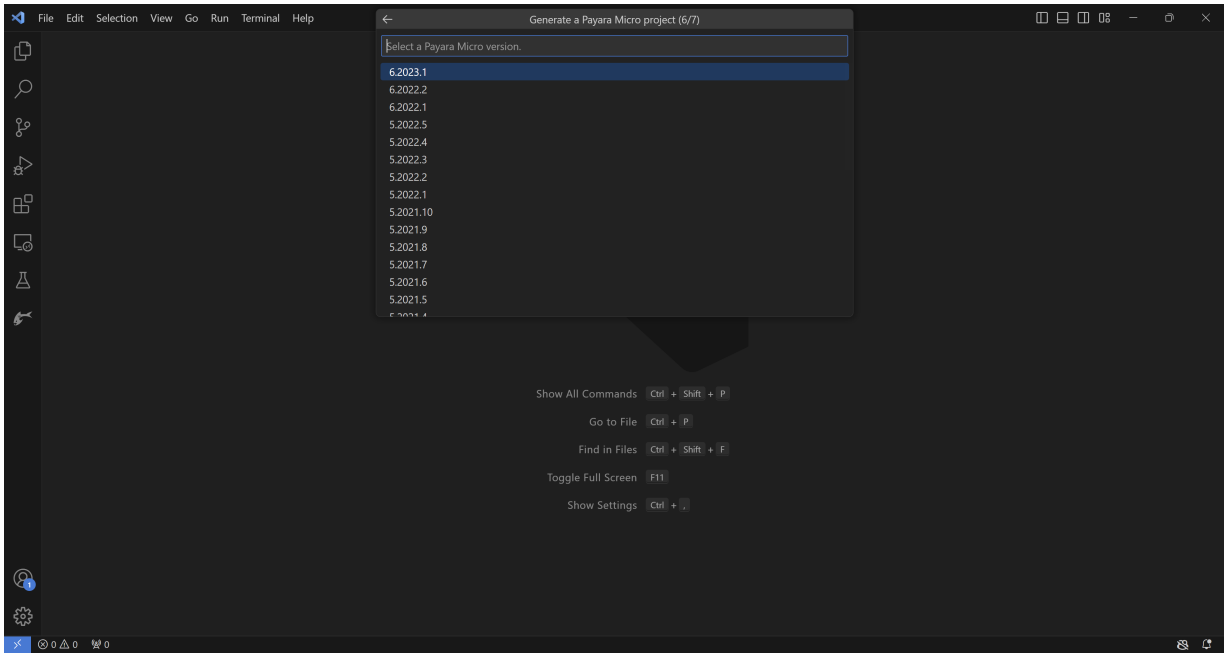
The extension also allows you to use the Hot Deploy and AutoDeploy features for a better developer experience.

====== Creating new Payara Micro Maven Application

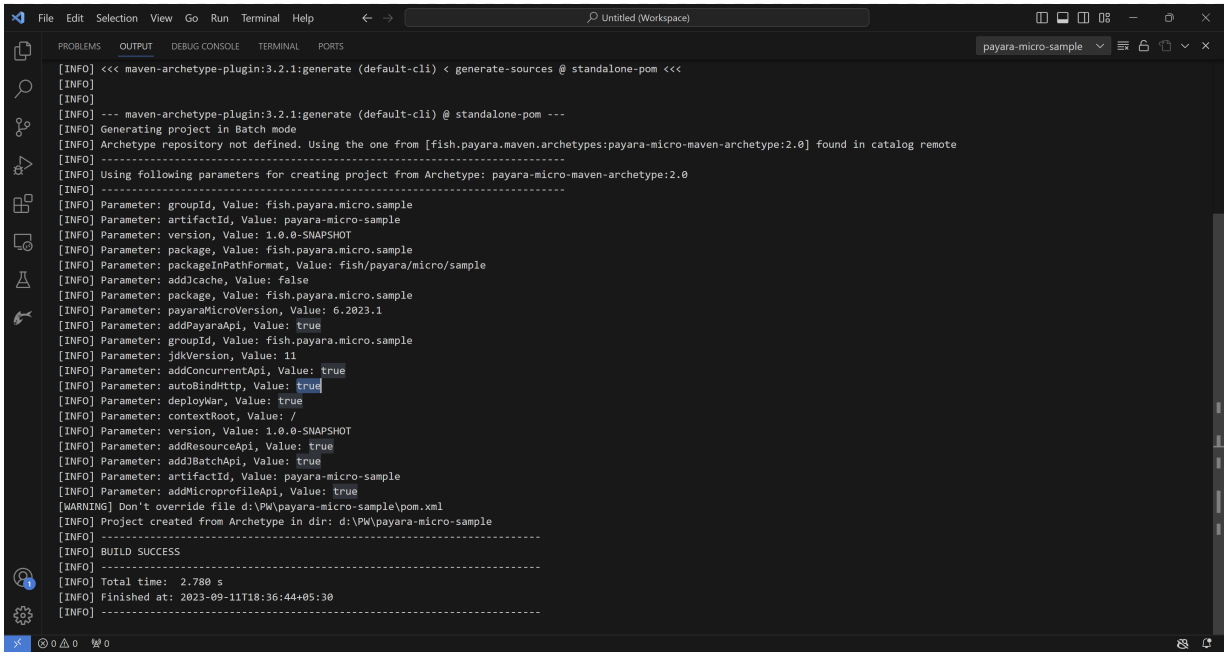
1. Open the command pallet using `Ctrl + Shift + P`.
2. Search **Generate a Payara Micro project** and select the available option:



3. Enter the `groupId`, `artifactId` and `version` to setup the project
4. Select the Payara Micro version and the destination folder, where the project will be generated:



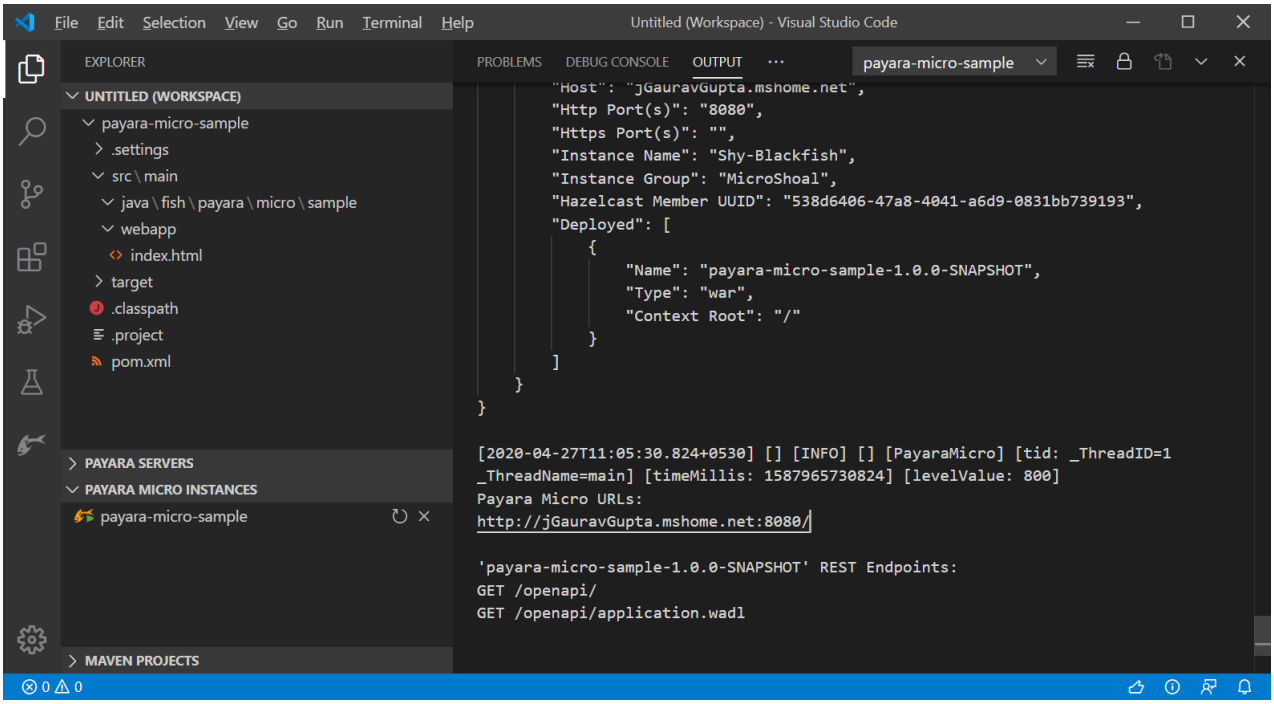
5. VS Code creates the new project from the Payara Micro Maven archetype. You may add the generated project to the current workspace or open in the new window:



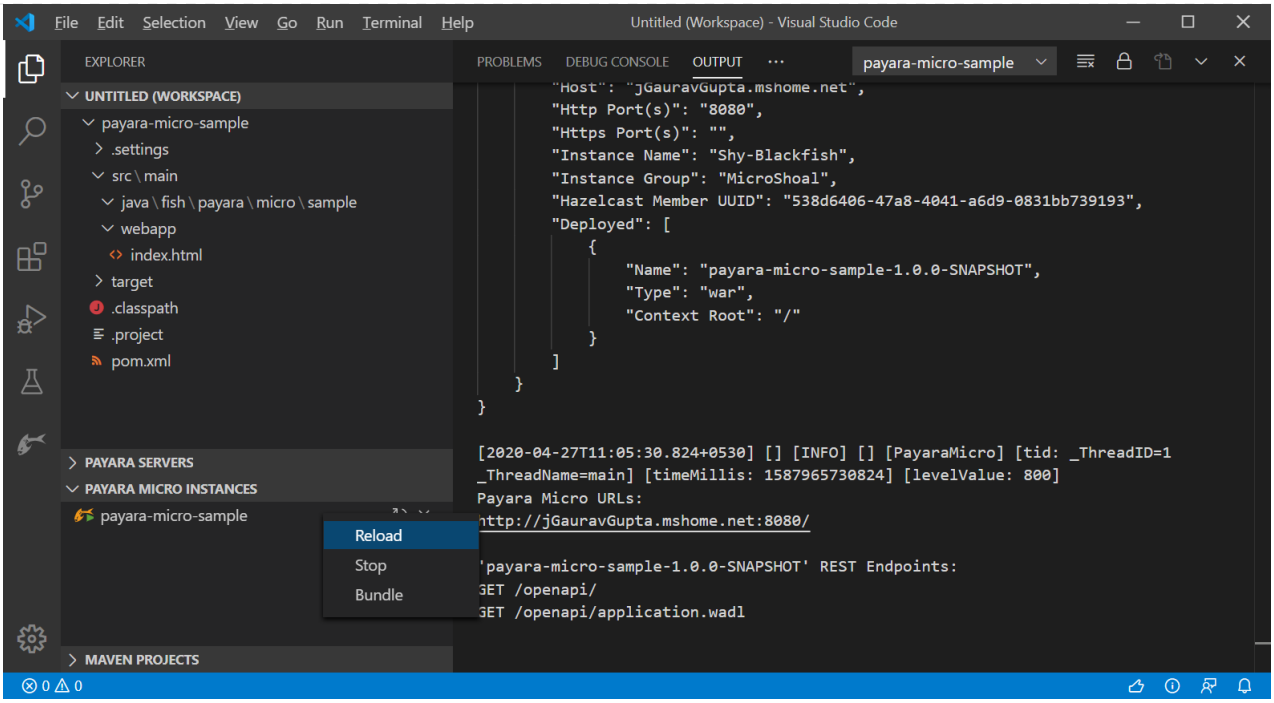
====== Run Payara Micro Application

To run the Payara Micro application from the VS Code IDE, go to the explorer sidebar or Payara activity bar, expand Payara Micro Instances, right-click on the listed Payara Micro instance and select **Start**.

After starting the Micro instance, you can view the server logs in the *OUTPUT* window:



To redeploy the application, right-click on the listed Payara Micro instance and select **Reload**.



====== See Also

Hot Deploy and Auto Deploy

====== Building VSCode Extension

The Payara Tools VS Code IDE Extension source code is available in the VS Code Extension repository.

====== Prerequisites Before building the Payara Tools VS Code extension, you will need to configure your local environment. Subsequent builds will not require these steps.

Clone the ecosystem-vscode-plugin repository

You must first clone the repository where the extension source code is stored. VS Code Extension repository

Install Yarn

Yarn is the build tool for the Payara Tools VS Code IDE Plugin and must be configured locally. Install Yarn

Install vsce

vsce is the tool to package VS Code extensions. Install vsce

====== Build Payara Tools To build the Payara Tools VS Code extension, run the following commands from the root directory where the project was cloned:

1. `yarn install`
2. `yarn run tslint`
3. `yarn run compile`

To package the extension into a file which can be added to VS Code, run the following

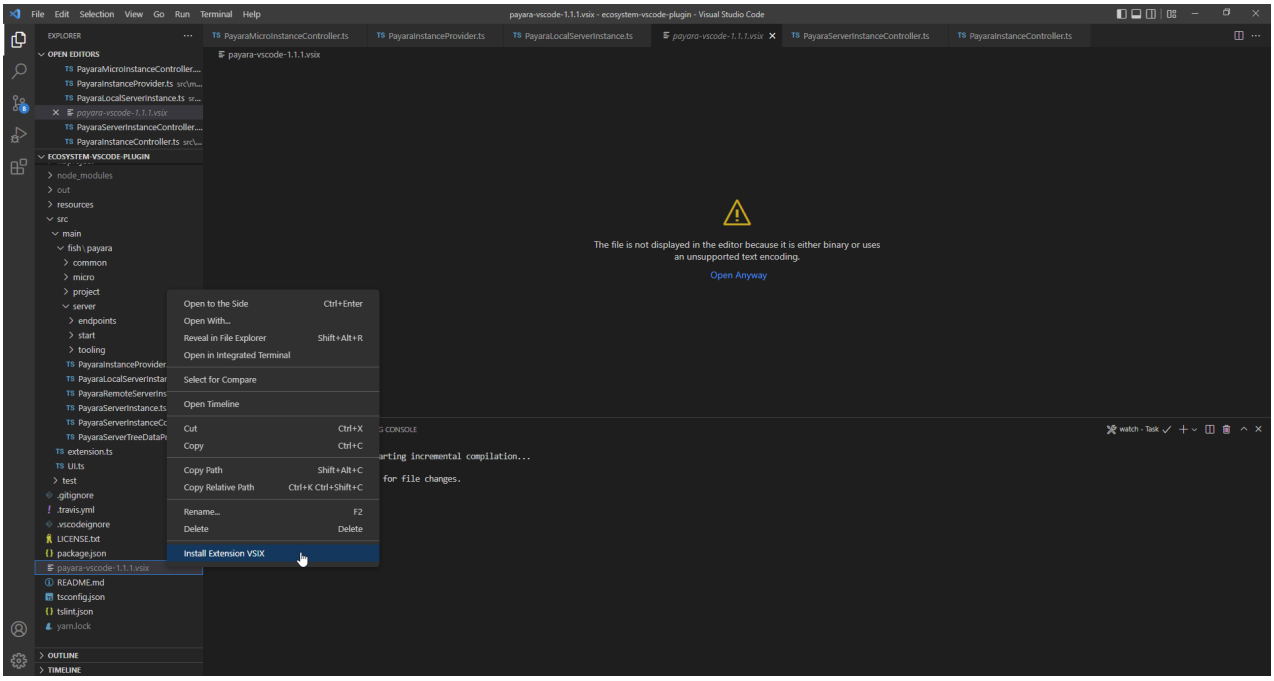
command:

1. `vsce package`

In the root directory of the project there will be a file `payara-vscode-{version-number}.vsix` which will be used to install into VS Code.

====== Install Payara Tools into VS Code After Payara Tools for VS Code has been compiled and packaged successfully, you need to add it into the VS Code IDE.

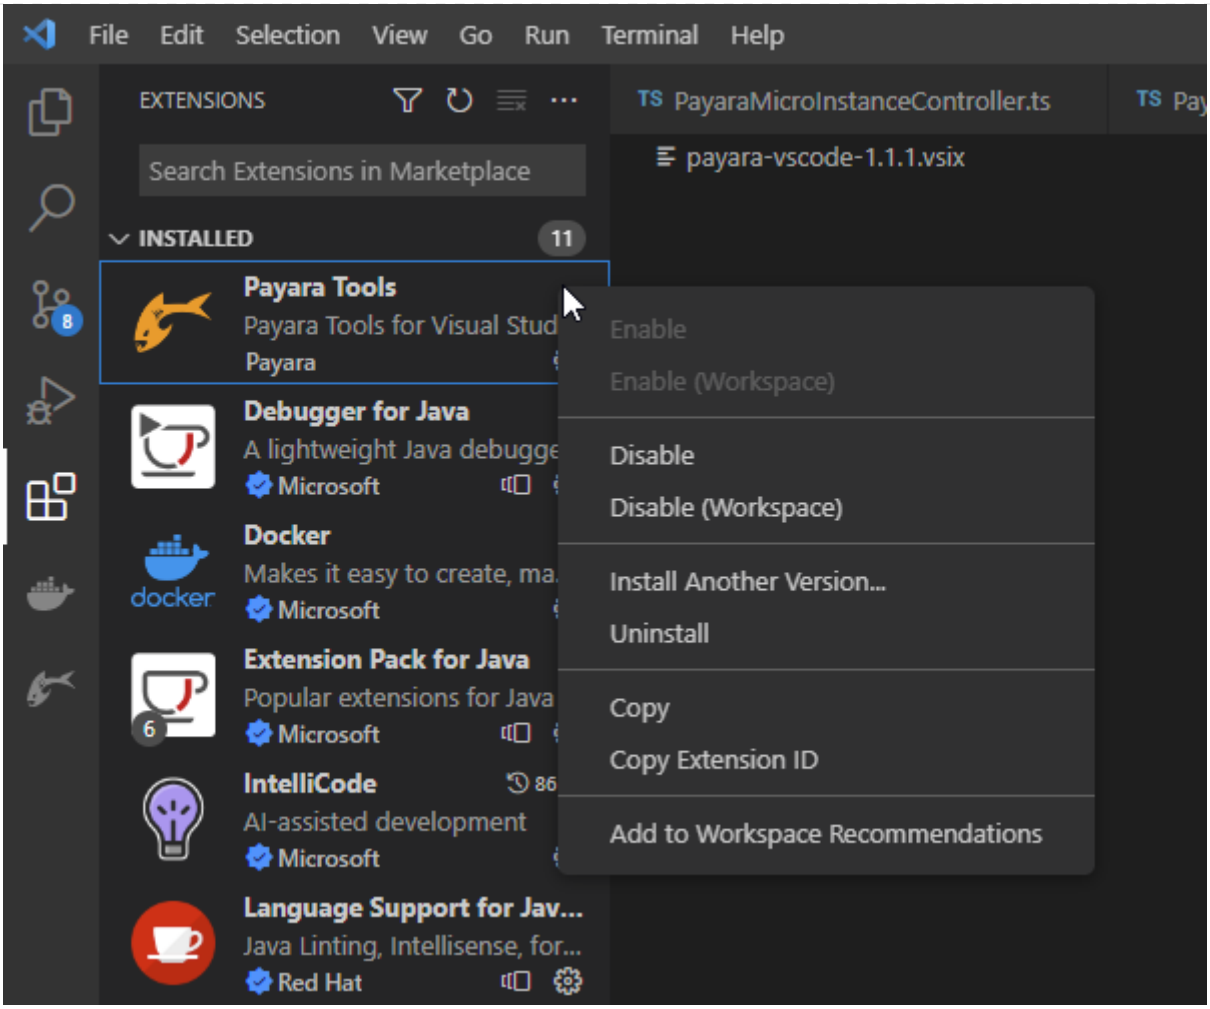
Installing a vsix file in VS Code is as simple as right clicking the file in the explorer, and selecting `Install Extension VSIX`



====== Removing Payara Tools from VS Code Removing Payara Tools from VS Code after installing using the method above is the same as removing any extension from VS Code.

Removing Payara Tools from VS Code

1. Navigate to Extensions (Ctrl + Shift + X)
2. Right click `Payara Tools` and click Uninstall

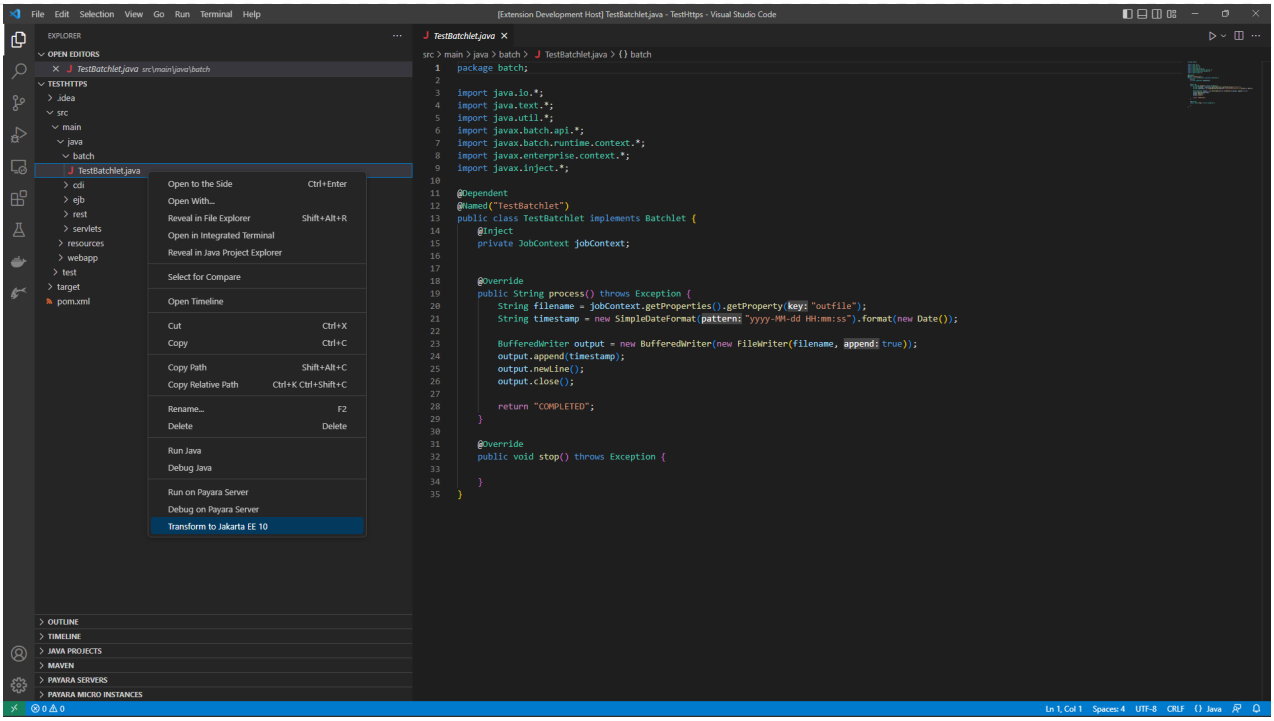


====== Transform to Jakarta-EE10

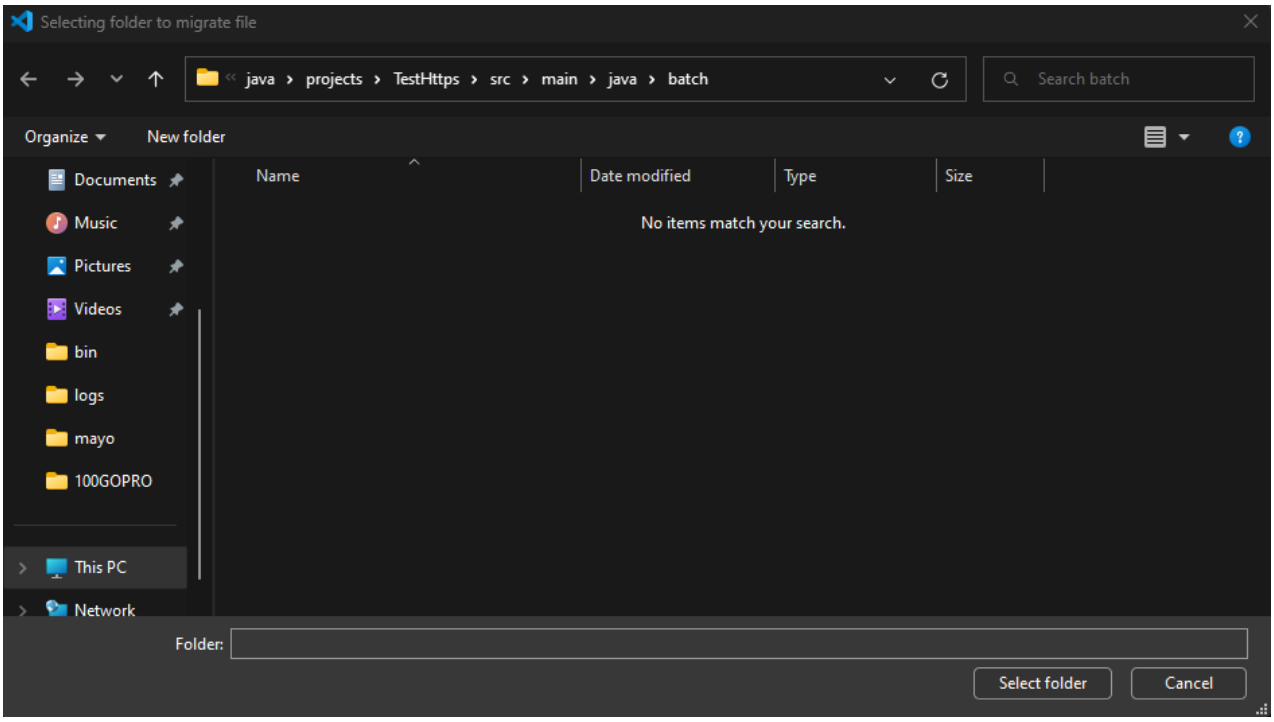
VSCode's Payara Tools allow users to automatically convert the source code of Java/Jakarta EE 8 applications to Jakarta EE 10.

====== Transform a Single File

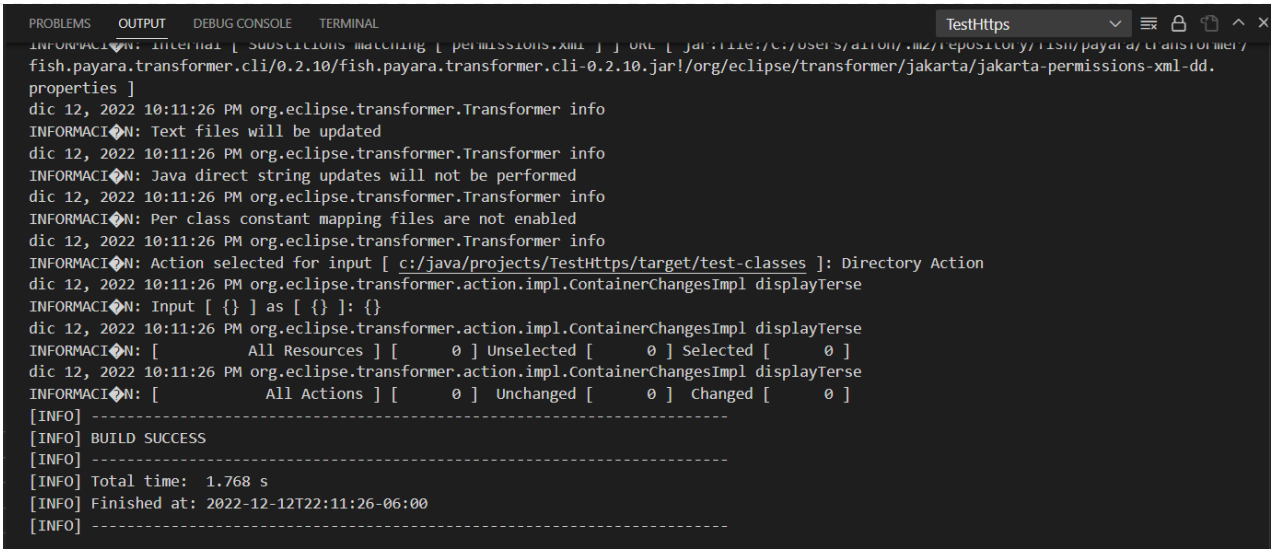
To transform a single file, select the file, right-click on it and select the **Transform to Jakarta EE 10** option:



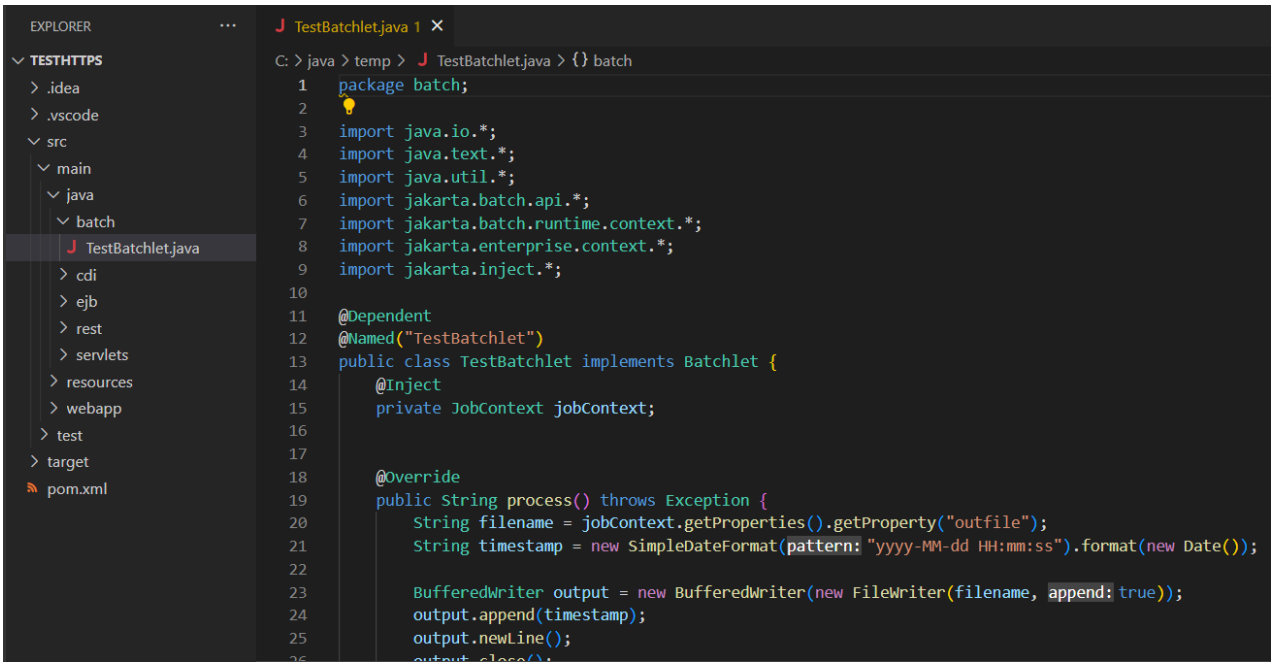
Proceed to select the destination folder of the transformed file:



Finally you can check the output of the transformation process using the **Output** tab:



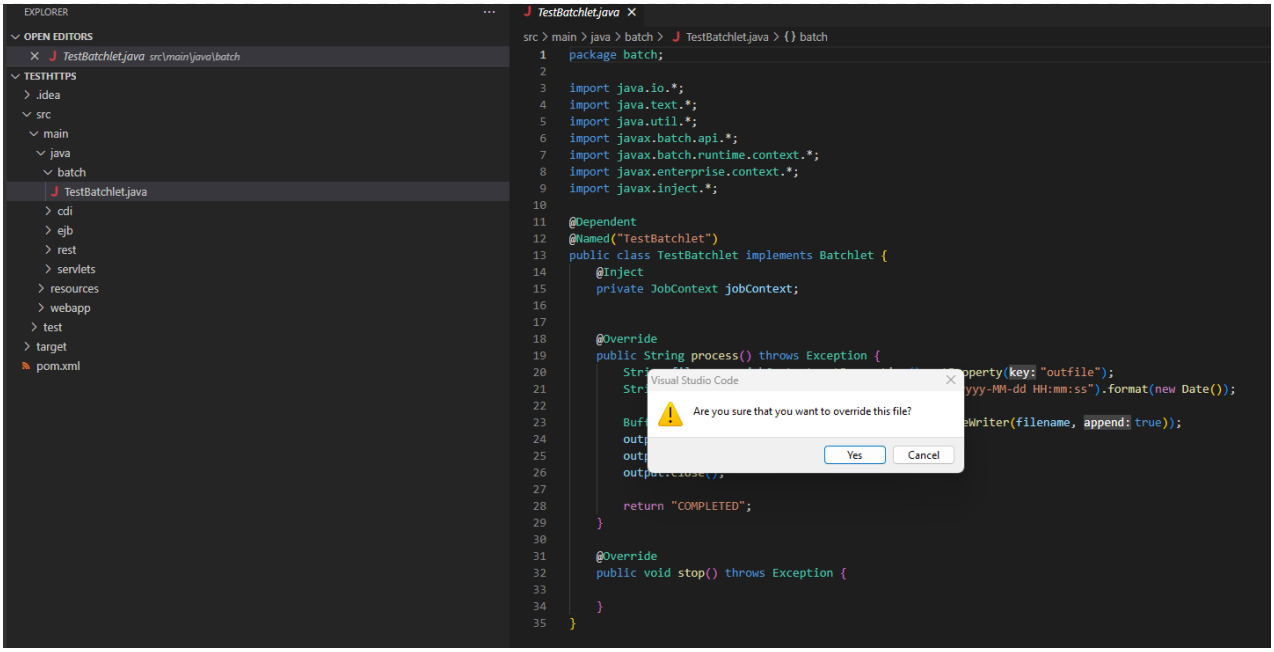
To verify that the resulting file is valid you'll have to open it using either VSCode or a different editor.



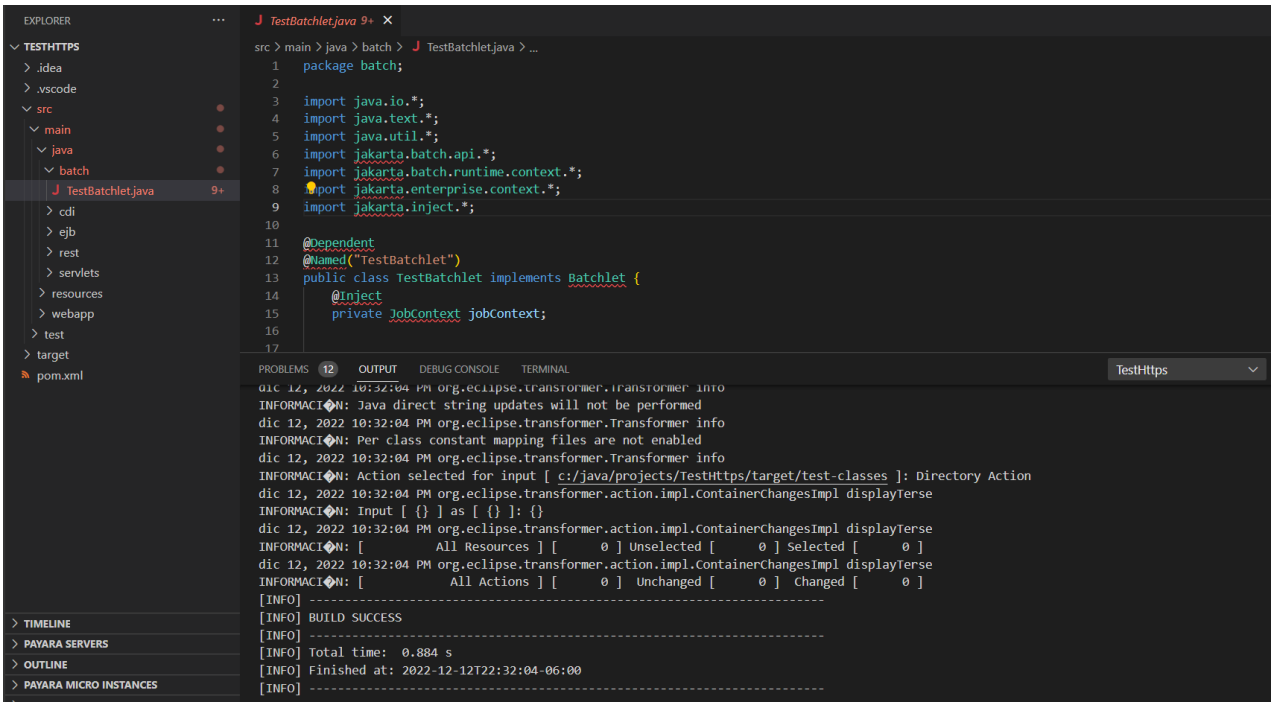
====== Transform a Single File in the same Location

It is possible to save the transformed file in the same location where the original resides.

To do this, select the same location folder when inputting the destination folder:

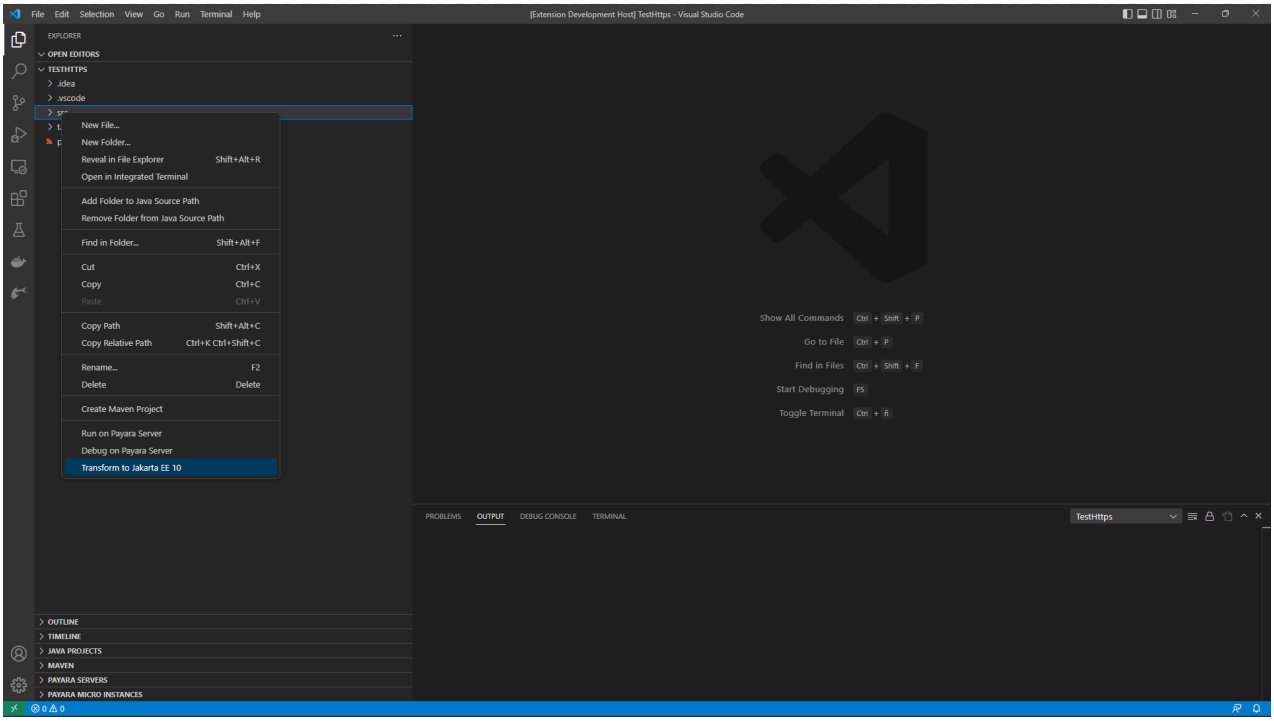


Once the file has been transformed, it will override the current file in the IDE:

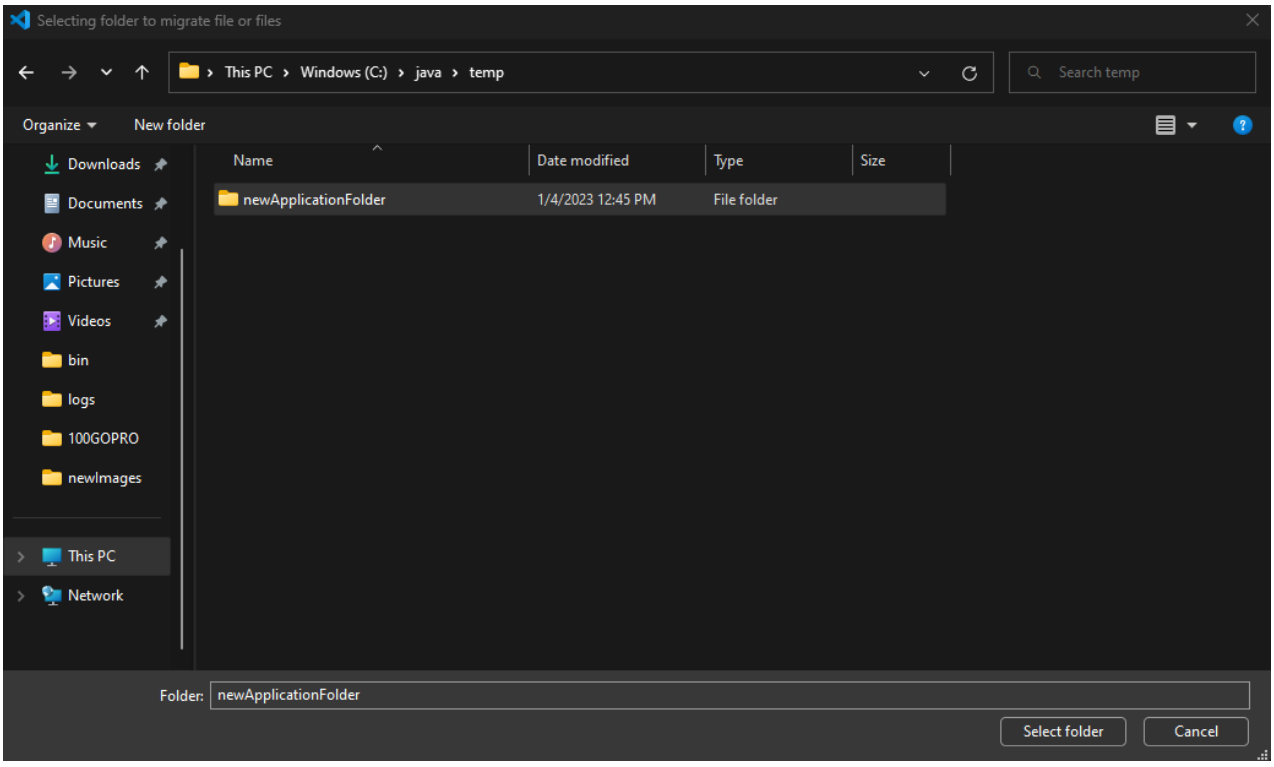


====== Transform all files in a Folder

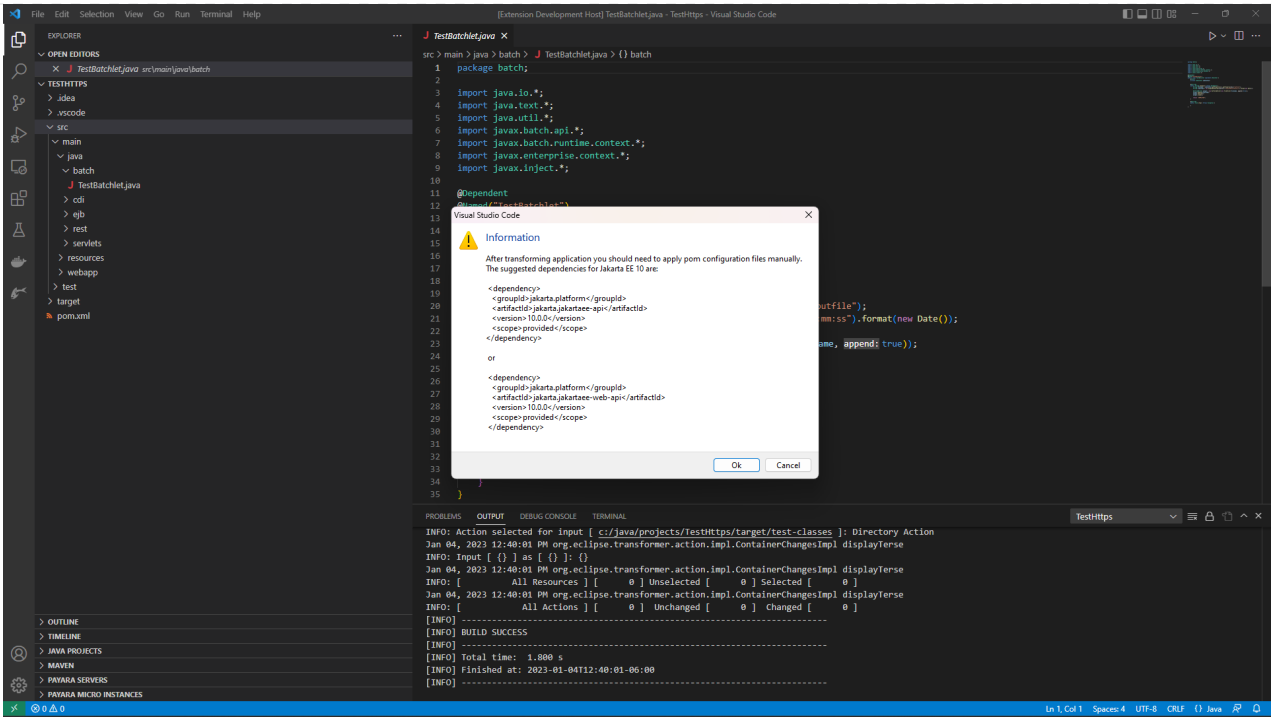
To transform all source code files located in a folder, select the folder, right click and select the **Transform to Jakarta EE 10** option.



Proceed to select the destination folder of the transformed files:

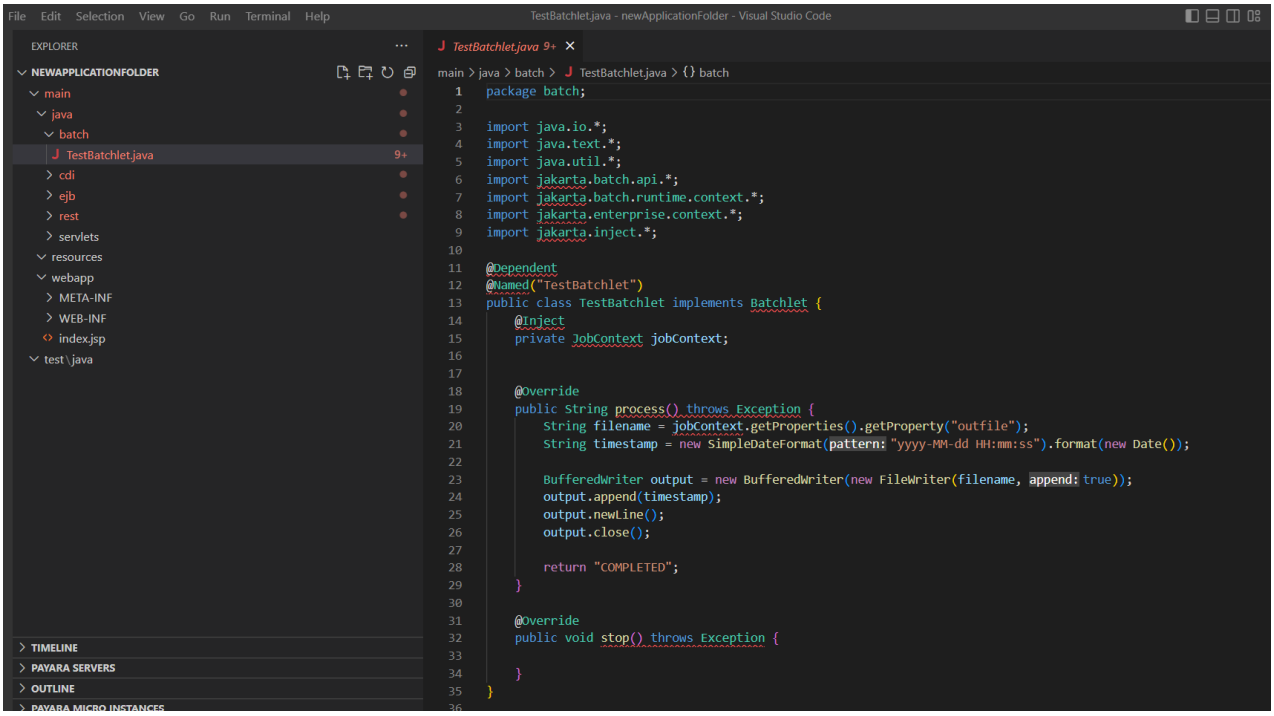


Finally you can check the output of the transformation process using the **Output** tab:



The IDE will also show a dialog with additional recommendations to configure the source code's project POM configuration. These configuration changes will have to be done manually if required.

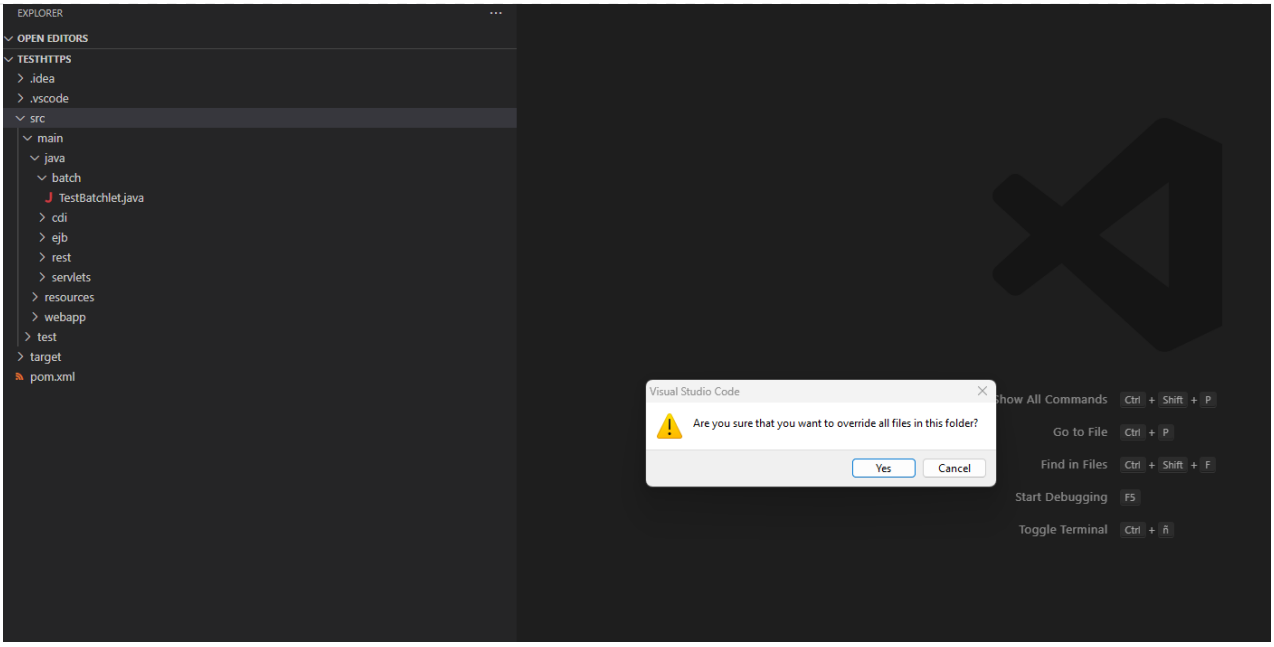
To verify that the resulting files in the new folder are valid, open it from within the IDE.



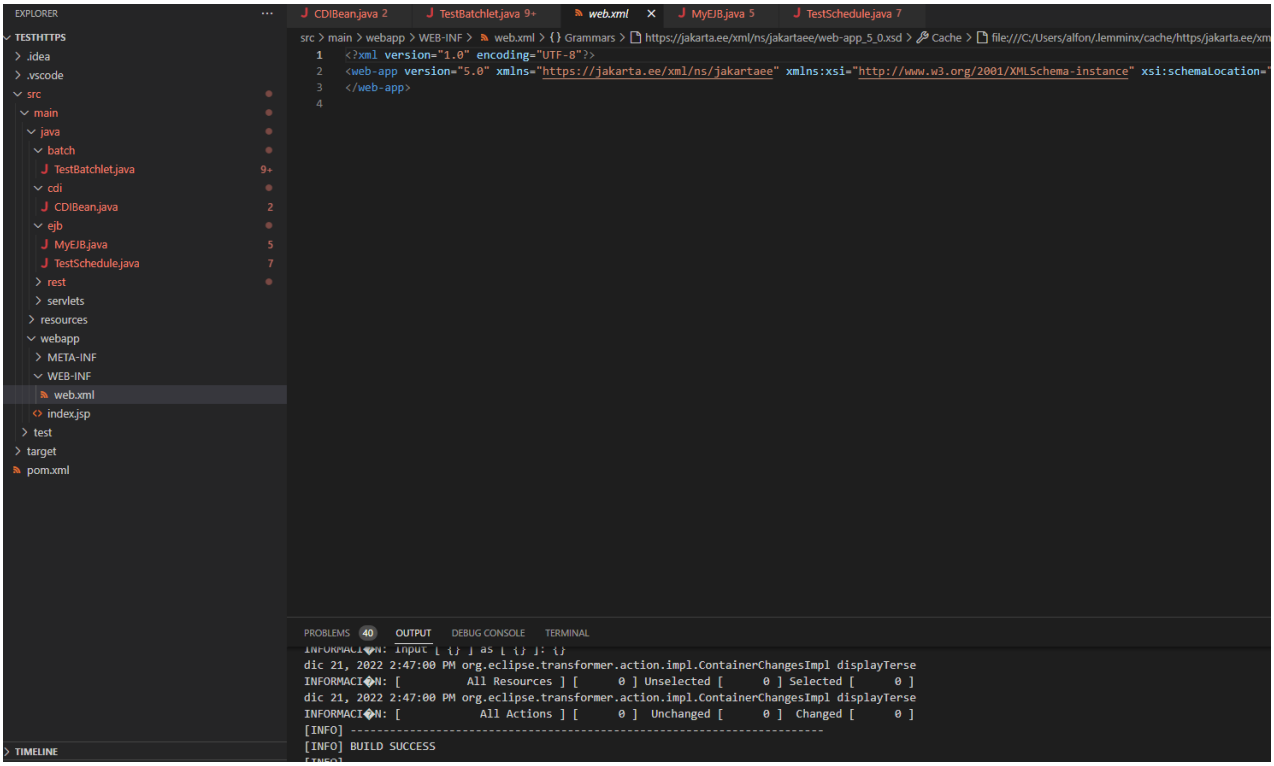
====== Transform all files in a Folder in the same Location

It is possible to save all transformed files in the same location where the originals reside, effectively overriding them.

To do this, select the same location folder when inputting the destination folder:



Once the contents of the folder have been transformed, the new files will override the current ones in the IDE:



===== Hot Deploy and Auto Deploy

To enable these features, the relevant ecosystem plugin to your IDE of choice must be installed.

The Payara Platform IDE ecosystem integrations fully support Hot Deployment and AutoDeployment of applications on a pre-configured Payara Server installation. Once enabled on your IDE of choice, you can simply deploy web applications to Payara Server (and Micro) and modify the source code of any Java class that belong to the application in question, upon save, any changed files within the application will be redeployed.

Both features are not available yet in the IntelliJ IDEA ecosystem integrations.

====== Hot Deployment

The Payara Platform provides the **Hot Deployment** capability, which boosts the performance of the application redeployment operation and dynamically replaces the classloader of the application on each redeployment when the feature is turned on.

Hot deploy is significantly faster than a vanilla redeployment, boosting developer productivity.

====== Auto Deployment

The Payara Platform also allows for a full redeployment of the application automatically via the **Auto Deployment** feature. It will un-deploy the application (if already deployed) and redeploy the new version of the application on every save action after making changes to the source code on your IDE of choice.

As the Auto Deploy feature performs a full redeploy of an application, it is slower than hot redeploy, which redeploys only the relevant updated components of the application in question.

====== Configuration

To configure the settings of these features on your IDE of choice, follow the instructions on the corresponding sections of each integration's documentation:

- Eclipse IDE:
  - Payara Server
  - Payara Micro
- Apache Netbeans:
  - Payara Server
  - Payara Micro
- Visual Studio Code:
  - Payara Server
  - Payara Micro

==== Connector Suites

===== Arquillian Containers

====== Overview

An **Arquillian container**, generally speaking, is a runtime with which Arquillian interacts when running an integration test. Arquillian may manage the container's lifecycle or simply bind to it. Arquillian may deploy archives or descriptors to the container. Arquillian may

transfer execution of the tests into the container, or it may simply make the URL of the deployed application available to the test which is acting as a client.

Arquillian supports multiple containers (among them Payara Platform distributions) through its extension mechanism. A **container adapter** is packaged as a JAR and is referenced, along with its dependencies, through as set of Maven GAV coordinates (`groupId`, `artifactId`, `version`). During the execution of tests, a container adapter must be present in the test classpath, allowing Arquillian to locate, load and use it.

In this context, the following container adapters have been implemented within the Payara Ecosystem tools to provide integration with Payara Platform distributions containers:

- For Payara Server:
  - link:/Technical Documentation/Ecosystem/Connector Suites/Arquillian Containers/Payara Server Embedded.adoc[Payara Server Embedded (`server-embedded`),role=unresolved]
  - link:/Technical Documentation/Ecosystem/Connector Suites/Arquillian Containers/Payara Server Managed.adoc[Payara Server Managed (`server-managed`),role=unresolved]
  - link:/Technical Documentation/Ecosystem/Connector Suites/Arquillian Containers/Payara Server Remote.adoc[Payara Server Remote (`server-remote`),role=unresolved]
- For Payara Micro:
  - link:/Technical Documentation/Ecosystem/Connector Suites/Arquillian Containers/Payara Micro Managed.adoc[Payara Micro Managed (`micro-managed`),role=unresolved]

====== Where can I get the adapters?

The Payara Arquillian container adapters are freely available in Maven Central under the following GAV coordinates :

```
<dependency>
    <groupId>fish.payara.arquillian</groupId>
    <artifactId>arquillian-payara-${container-name}</artifactId>
    <version>${version}</version>
</dependency>
```

Where `${container-name}` refers to the specific container in question (see their names in the previous section) and the `${version}` corresponds to the specific adapter version compatible with this Payara Platform version.

All adapters share the same version as part of their connector suite.

For Payara Platform 7.x, adapters in version `4.x` are compatible.

====== General Usage

An example application demonstrating how to create a test suite that runs the tests inside various Payara Platform distributions using Arquillian can be seen in the Payara Examples repository.

See specifically the ecosystem/arquillian-example subproject for an example of writing integration tests using Arquillian along with the corresponding container adapters described above.

Arquillian requires Junit4, but also offers a version compatible with Junit5. The Payara Arquillian connector remains compatible with this version of Arquillian. See ecosystem/arquillian-junit5-example subproject for the same integration test mentioned above, adapted to work with Junit5.

====== Payara Server Embedded

When using this adapter, the Payara Server container lifecycle is managed by Arquillian and resides in the same JVM where tests are executed using a local communication protocol.

====== Usage

The Payara Server Embedded Arquillian container adapter can be found on Maven Central, and can be included in your project using the following Maven GAV coordinates:

```
<dependency>
  <groupId>fish.payara.arquillian</groupId>
  <artifactId>arquillian-payara-server-embedded</artifactId>
  <version>${version}</version>
</dependency>
```

====== Container Configuration

The Payara Server container can be configured via the `arquillian.xml` file using the standard Arquillian Container Configuration mechanism.

Table 211. Configuration Options

Name	Description	Default
`bindHttpPort`	The port number of the http-listener for the embedded Payara Server.	`8181`
`bindHttpsPort`	The port number of the https-listener for the embedded Payara Server.	`8182`
`cleanup`	Specifies whether Arquillian should clean up on shutdown. This recursively deletes files in the `instanceRoot` directory.	`true`

Name	Description	Default
`configurationReadOnly`	Specifies whether Payara Server should write back any changes to specified configuration file or `config/domain.xml` at the specified instance root.	`true`
`configurationXml`	Set the location of configuration file i.e. `domain.xml` using which the Payara Server should run.	
`installRoot`	The installation root directory is the parent directory of a Payara Server instance directory and corresponds to the base directory for an installation of Payara Server.	
`instanceRoot`	The instance root directory is the domain directory and embedded Payara Server uses the server instance directory for domain configuration files.	The default domain directory
`resourcesXml`	A comma-separated list of Payara resources.xml files containing resources that will be added to the Payara instance using the `add-resources` command.	
`hazelcastConfigurationFile`	Full path to a hazelcast configuration file used to override the hazelcast bootstrap default configuration.	

====== Examples

To configure the Arquillian Container options, you need to use an `arquillian.xml` file placed on the test classpath.

Here's an example `arquillian.xml` file. It configures `adminPort` with a static value. It configures `bindHttpsPort` as a value of a system property `my.httpsport`, which you can specify for example in the maven `surefire` plugin using the `systemPropertyVariables` option or on the command line like `mvn -Dmy.httpsport=8081 test`.

It also overrides hazelcast bootstrap configuration indicating a path for an XML file in property `hazelcastConfigurationFile`.

Example `arquillian.xml` file

```
<?xml version="1.0"?>
<arquillian xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xmlns="http://jboss.org/schema/arquillian"
            xsi:schemaLocation="http://jboss.org/schema/arquillian
                http://jboss.org/schema/arquillian/arquillian_1_0.xsd">
    <container qualifier="payara-embedded" default="true">
        <configuration>
            <property name="bindHttpPort">8080</property>
            <property name="bindHttpsPort">${my.httpsport}</property>
            <property name="hazelcastConfigurationFile">/home/payara/hazelcast-
config.xml</property>
        </configuration>
```

```
    </container>
</arquillian>
```

If you want to configure more containers, you can switch between them by setting the `arquillian.launch` system property to the container's qualifier. This is how you can do it with the maven `surefire` plugin (`my.httpsport` system property is used to set the `bindHttpsPort` property in `arquillian.xml`):

Example - Surefire plugin configuration in the project's POM file

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-surefire-plugin</artifactId>
    <configuration>
        <systemPropertyVariables>
            <arquillian.launch>payara</arquillian.launch>
            <my.httpsport>8081</my.httpsport>
        </systemPropertyVariables>
    </configuration>
</plugin>
```

====== Payara Server Managed

When using this adapter, the Payara Server container lifecycle is managed by Arquillian by starting a separate JVM process to run Payara Server locally.

As a requirement, the adapter will need to use a local installation of Payara Server.

====== Usage

The Payara Server Managed Arquillian container adapter can be found on Maven Central, and can be included in your project using the following Maven GAV coordinates:

```
<dependency>
  <groupId>fish.payara.arquillian</groupId>
  <artifactId>arquillian-payara-server-managed</artifactId>
  <version>${version}</version>
</dependency>
```

====== Container Configuration

The Payara Server container can be configured via the `arquillian.xml` file using the standard Arquillian Container Configuration mechanism.

The following configuration options are mandatory:

- `payaraHome` - The local Payara Server installation directory. Can be also set using the

`payara.home` system property.

The following Arquillian Container configuration options are available:

Table 212. Configuration Options

Name	Description	Default
`adminHost`	The host to be used to access the Payara Server Admin interface.	`localhost`
`adminHttps`	You can use it to specify whether the HTTP or HTTPS protocol shall be used to access the DAS. The property value can be `true` or `false`.	`false`
`adminPort`	The port to be used to access the Payara Server Admin interface.	`4848`
`adminUser`	The name of the admin user of your DAS. If omitted, no authentication will be used to access the DAS. In this case the `adminPassword` property should also be empty.	
`adminPassword`	The password of the admin user of your DAS. Cannot be omitted if you declare the admin user. If no authentication will be used to access the DAS you must have empty password for your admin user of your domain.	
`allowConnectingToRunningServer`	Allow Arquillian to use an already running Payara Server instance and skips `start-domain` command invocation.	`false`
`authorisation`	If true, basic access authentication is enabled. It also indicates that remote server requires an `adminUser` and `adminPassword` configuration properties.	`false`
`debug`	Starts the server in debug mode using standard Payara Server debug port.	`false`
`domain`	The Payara Server domain to use or the default domain if not specified.	`domain1`
`enableH2`	Starts/Stops the registered H2 database server using the standard H2 port.	`false`
`ignoreCertificates`	If set to `true`, SSL certificate correctness is ignored. This is useful for Docker images / Testcontainers when certificates are not easily matched to internally generated ones and host names are also very hard to match.	`false`

Name	Description	Default
`libraries`	A comma-separated list of library JAR files. Specify the library JAR files by their relative or absolute paths. Specify relative paths relative to `domain-dir/lib/applibs`. The libraries are made available to the application in the order specified.	
`outputToConsole`	Show the output of the admin commands on the console.	`true`
`payaraHome`	The local Payara Server installation directory. Mandatory	Value of the `payara.home` system property.
`properties`	Optional keyword-value pair that specify additional properties for the deployment. The available properties are determined by the implementation of the component that is being deployed.	

Name	Description	Default

`target`	The deployment target of the applications involved in the test.
	
	Valid values of the target are:
	
	`server`
	Deploys the component to the default Admin Server instance (on your DAS server). This is the default value if the property is omitted.
	
	`instance_name`
	Deploys the component to the specified stand-alone server instance, which may be on the same hosts or can be on a different one as the DAS server.
	
	`deployment_group_name`
	Deploys the component to every server instance in the specified deployment group. They can be on the same or on several other hosts as the DAS server.
	
	 Arquillian will use only one instance to run the test case.
	
	The domain name as a target is not a reasonable deployment scenario in case of testing.
	
	The HOST address and port numbers of the test server instance used by Arquillian (determined by the target property) will be automatically retrieved from the DAS server.
	
	 You have to make them accessible for your test environment (consider any firewall or proxy configuration).
		`server`

`type`	If set to `osgi`, the component is packaged as an OSGi bundle. If the component is packaged as a regular archive, do not set this option.	

The context root that will be used to run the tests is also retrieved automatically from the DAS server. If the deployed application does have a `sun-web.xml`, `glassfish-web.xml` or `payara-web.xml` deployment descriptor, the container will use the name of your deployment without the extension as context root.
The same rule is applied for enterprise applications if there is no `application.xml` file. The JAR test-deployments are treated as a web application.

glassfish-web.xml and sun-web.xml are deprecated and support will be removed in a future release. It is recommended to use payara-web.xml

instead.

====== Examples

To configure the Arquillian Container options, you need to use an `arquillian.xml` file placed on the test classpath.

Here's an example `arquillian.xml` file. It configures `adminPort` with a static value.

It will configure the `adminPassword` as a value of a system property `my.admin.password`, which you can specify for example in the maven `surefire` plugin using the `systemPropertyVariables` option or on the command line like `mvn -Dmy.admin.password=mypassword test`.

Example `arquillian.xml` file

```
<?xml version="1.0"?>
<arquillian xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xmlns="http://jboss.org/schema/arquillian"
            xsi:schemaLocation="http://jboss.org/schema/arquillian
                http://jboss.org/schema/arquillian/arquillian_1_0.xsd">
    <container qualifier="payara" default="true">
        <configuration>
            <property name="adminPort">4848</property>
            <property name="adminPassword">${my.admin.password}</property>
        </configuration>
    </container>
</arquillian>
```

If you want to configure more containers, you can switch between them by setting the `arquillian.launch` system property to the container's qualifier.

This is how you can do it with the maven `surefire` plugin (`my.admin.password` system property is used to set the `adminPassword` property in `arquillian.xml`):

Example - Surefire plugin configuration in the project's POM file

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-surefire-plugin</artifactId>
    <configuration>
        <systemPropertyVariables>
            <arquillian.launch>payara</arquillian.launch>
            <payara.home>/path/to/payara</payara.home>
            <my.admin.password>mypassword</my.admin.password>
        </systemPropertyVariables>
    </configuration>
</plugin>
```

====== Downloading Payara Server automatically from Maven

You can configure your Maven project to automatically download and install the Payara Server version required by the container adapter.

To set up this installation, you can use the Maven Dependency Plugin (specifically the `unpack` goal) as follows:

Example - Dependency plugin configuration in the project's POM file

```
<plugins>
    <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-dependency-plugin</artifactId>
        <executions>
            <execution>
                <id>unpack</id>
                <phase>process-test-classes</phase>
                <goals>
                    <goal>unpack</goal>
                </goals>
                <configuration>
                    <artifactItems>
                        <artifactItem>
                            <groupId>fish.payara.distributions</groupId>
                            <artifactId>payara</artifactId>
                            <version>${payara.version}</version>
                            <type>zip</type>
                            <overWrite>false</overWrite>

<outputDirectory>${project.build.directory}</outputDirectory>
                        </artifactItem>
                    </artifactItems>
                </configuration>
            </execution>
        </executions>
    </plugin>
    <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-surefire-plugin</artifactId>
        <configuration>
            <systemPropertyVariables>
                <payara.home>${project.build.directory}/payara5</payara.home>
            </systemPropertyVariables>
        </configuration>
    </plugin>
</plugins>
```

====== Payara Server Remote

When using this adapter, the Payara Server container lifecycle is NOT managed by Arquillian. Instead, the adapter will connect to an already running Payara Server instance via a remote

communication protocol by talking to the server's DAS process directly. In this scenario, the integration test setup will have to bootstrap the server's domain startup and shutdown on its own.

This gives you the flexibility to use any possible deployment scenarios having your servers either on many different physical or virtual nodes, or on the same one.

====== Usage

The Payara Server Remote Arquillian container adapter can be found on Maven Central, and can be included in your project using the following Maven GAV coordinates:

```
<dependency>
  <groupId>fish.payara.arquillian</groupId>
  <artifactId>arquillian-payara-server-remote</artifactId>
  <version>${version}</version>
</dependency>
```

====== Container Configuration

The Payara Server container can be configured via the `arquillian.xml` file using the standard Arquillian Container Configuration mechanism.

The following Arquillian Container configuration options are available:

Table 213. Configuration Options

Name	Description	Default
`adminHost`	The host to be used to access the Payara Server Admin interface.	`localhost`
`adminHttps`	You can use it to specify whether the HTTP or HTTPS protocol shall be used to access the DAS. The property value can be `true` or `false`.	`false`
`adminPort`	The port to be used to access the Payara Server Admin interface.	`4848`
`adminUser`	The name of the admin user of your DAS. If omitted, no authentication will be used to access the DAS. In this case the `adminPassword` property should also be empty.	
`adminPassword`	The password of the admin user of your DAS. Cannot be omitted if you declare the admin user. If no authentication will be used to access the DAS you must have empty password for your admin user of your domain.	

Name	Description	Default
`authorisation`	If true, basic access authentication is enabled. It also indicates that remote server requires an `adminUser` and `adminPassword` configuration properties.	`false`
`ignoreCertificates`	If set to `true`, SSL certificate correctness is ignored. This is useful for Docker images / Testcontainers when certificates are not easily matched to internally generated ones and host names are also very hard to match.	`false`
`libraries`	A comma-separated list of library JAR files. Specify the library JAR files by their relative or absolute paths. Specify relative paths relative to `domain-dir/lib/applibs`. The libraries are made available to the application in the order specified.	
`properties`	Optional keyword-value pair that specify additional properties for the deployment. The available properties are determined by the implementation of the component that is being deployed.	

Name	Description	Default

`target`	The deployment target of the applications involved in the test.
	
	Valid values of the target are:
	
	`server`
	Deploys the component to the default Admin Server instance (on your DAS server). This is the default value if the property is omitted.
	
	`instance_name`
	Deploys the component to the specified stand-alone server instance, which may be on the same hosts or can be on a different one as the DAS server.
	
	`deployment_group_name`
	Deploys the component to every server instance in the specified deployment group. They can be on the same or on several other hosts as the DAS server.
	
	The domain name as a target is not a reasonable deployment scenario in case of testing.
	
	The HOST address and port numbers of the test server instance used by Arquillian (determined by the target property) will be automatically retrieved from the DAS server.
	
	 You have to make them accessible for your test environment (consider any firewall or proxy configuration).
		`server`

`type`	If set to `osgi`, the component is packaged as an OSGi bundle. If the component is packaged as a regular archive, do not set this option.	

The context root that will be used to run the tests is also retrieved automatically from the DAS server. If the deployed application does have a `sun-web.xml`, `glassfish-web.xml` or `payara-web.xml` deployment descriptor, the container will use the name of your deployment without the extension as context root.
The same rule is applied for enterprise applications if there is no `application.xml` file. The JAR test-deployments are treated as a web application.

glassfish-web.xml and sun-web.xml are deprecated and support will be removed in a future release. It is recommended to use payara-web.xml instead.

====== Examples

To configure the Arquillian Container options, you need to use an `arquillian.xml` file placed on

the test classpath. Here's an example `arquillian.xml` file. It configures `adminPort` with a static value. It configures `adminPassword` as a value of a system property `my.admin.password`, which you can specify for example in the maven `surefire` plugin using the `systemPropertyVariables` option or on the command line like `mvn -Dmy.admin.password=mypassword test`.

Example `arquillian.xml` file

```
<?xml version="1.0"?>
<arquillian xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xmlns="http://jboss.org/schema/arquillian"
            xsi:schemaLocation="http://jboss.org/schema/arquillian
                http://jboss.org/schema/arquillian/arquillian_1_0.xsd">
    <container qualifier="payara" default="true">
        <configuration>
            <property name="adminPort">4848</property>
            <property name="adminPassword">${my.admin.password}</property>
        </configuration>
    </container>
</arquillian>
```

If you want to configure more containers, you can switch between them by setting the `arquillian.launch` system property to the container's qualifier.

This is how you can do it with the maven `surefire` plugin (`my.admin.password` system property is used to set the `adminPassword` property in `arquillian.xml`):

Example - Surefire plugin configuration in the project's POM file

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-surefire-plugin</artifactId>
    <configuration>
        <systemPropertyVariables>
            <arquillian.launch>payara</arquillian.launch>
            <my.admin.password>mypassword</my.admin.password>
        </systemPropertyVariables>
    </configuration>
</plugin>
```

====== Payara Micro Managed

When using this adapter, the Payara Micro container lifecycle is managed by Arquillian by starting a separate JVM process to launch and stop a Payara Micro instance locally.

====== Usage

The Payara Micro Managed Arquillian container adapter can be found on Maven Central, and can be included in your project using the following Maven GAV coordinates:

```
<dependency>
  <groupId>fish.payara.arquillian</groupId>
  <artifactId>arquillian-payara-micro-managed</artifactId>
  <version>${version}</version>
</dependency>
```

====== Container Configuration

The Payara Micro container can be configured via the `arquillian.xml` file using the standard Arquillian Container Configuration mechanism.

The following configuration options are available:

Table 214. Configuration Options

Container Option	Description	System Property	Environment Variable	Default
`microJar`	Provides the location of the Payara Micro Jar.	`payara.microJar`	`MICRO_JAR`	
`startupTimeoutInSeconds`	Specifies the amount of time in seconds that the container will wait for Payara Micro to start.	`payara.startupTimeoutInSeconds`	`MICRO_STARTUP_TIMEOUT_IN_SECONDS`	`180`
`randomHttpPort`	Randomises the initial HTTP port of Payara Micro. This saves time by avoiding collisions with the default port.	`payara.randomHttpPort`	`MICRO_RANDOM_HTTP_PORT`	`true`
`autoBindHttp`	Enables the `--autoBindHttp` option for the Micro instance.	`payara.autoBindHttp`	`MICRO_AUTOBIND_HTTP`	`true`
`clusterEnabled`	Enables clustering on the Micro instance.	`payara.clusterEnabled`	`MICRO_CLUSTER_ENABLED`	`false`
`consoleOutput`	Enables/disables console output on the Micro instance.	`payara.consoleOutput`	`MICRO_CONSOLE_OUTPUT`	`true`

Container Option	Description	System Property	Environment Variable	Default
`debug`	Enables debugging on the Payara Micro instance. By default, Payara Micro will wait for the debugger on port `5005` before starting. Disables the startup timeout. To change this, provide java debug options to `cmdOptions`.	`payara.debug`	`MICRO_DEBUG`	`false`
`cmdOptions`	Provides JVM options to the Java process running the Micro instance.	`payara.cmdOptions`	`MICRO_CMD_OPTIONS`	
`extraMicroOptions`	Provides standard Payara Micro arguments for the server instance to launch with	`payara.extraMicroOptions`	`EXTRA_MICRO_OPTIONS`	

====== Examples

To configure the options using Arquillian container properties, you need to use an `arquillian.xml` file placed on the test classpath.

Here's an example `arquillian.xml` file. It configures `randomHttpPort` and `autoBindHttp` options.

Example `arquillian.xml` file

```
<?xml version="1.0"?>
<arquillian xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xmlns="http://jboss.org/schema/arquillian"
            xsi:schemaLocation="http://jboss.org/schema/arquillian
                http://jboss.org/schema/arquillian/arquillian_1_0.xsd">
    <container qualifier="payara-micro-managed" default="true">
        <configuration>
            <property name="randomHttpPort">false</property>
            <property name="autoBindHttp">false</property>
        </configuration>
    </container>
</arquillian>
```

You can configure the options also using system properties. Here's an example configuration if

you run your tests using the maven `surefire` plugin:

Example - Surefire plugin configuration in the project's POM file

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-surefire-plugin</artifactId>
    <configuration>
        <systemPropertyVariables>
            <arquillian.launch>payara-micro-managed</arquillian.launch>
            <payara.randomHttpPort>false</payara.randomHttpPort>
            <payara.autoBindHttp>false</payara.autoBindHttp>
        </systemPropertyVariables>
    </configuration>
</plugin>
```

You can also configure the options using environment variables, for example when running the maven `mvn test` command:

```
export MICRO_RANDOM_HTTP_PORT=false
export MICRO_AUTOBIND_HTTP=false

mvn test
```

===== Cloud Connectors

====== Overview

The Payara Cloud Connectors are a collection of JCA adapters for use with various popular cloud messaging providers. These connectors can be deployed to either Payara Server or Payara Micro.

The following connectors are available:

- Apache Kafka
- Amazon SQS
- MQTT
- Azure Service Bus

====== Obtaining the connectors

====== Nexus

Cloud Connectors are available in Binary form to Enterprise License users in the `payara-enterprise-downloadable-artifacts` repository.

The artifacts can be found in `/fish/payara/cloud/connectors`.

====== Building From Source

Cloud Connectors can be built from source as follows:

Clone the Cloud-Connectors git repository:

```
git clone git@github.com:payara/Cloud-Connectors.git
```

Build and install the connectors:

```
cd Cloud-Connectors/
mvn clean install
```

The connectors can be found in the following locations as JCA RARs:

- Kafka - ./Kafka/KafkaRAR/target/kafka-rar-0.8.0.rar
- Amazon SQS - ./AmazonSQS/AmazonSQSRAR/target/amazon-sqs-rar-2.1.0.rar
- MQTT - ./MQTT/MQTTRAR/target/mqtt-rar-0.8.0.rar
- Azure Service Bus - ./AzureServiceBus/AzureSBRAR/target/azure-sb-rar-0.8.0.rar

====== Installing a connector

Installing Cloud Connectors for Payara Server and Payara Micro both require the Cloud Connector jar to be deployed. However, Payara Server requires some additional configuration to classloading.

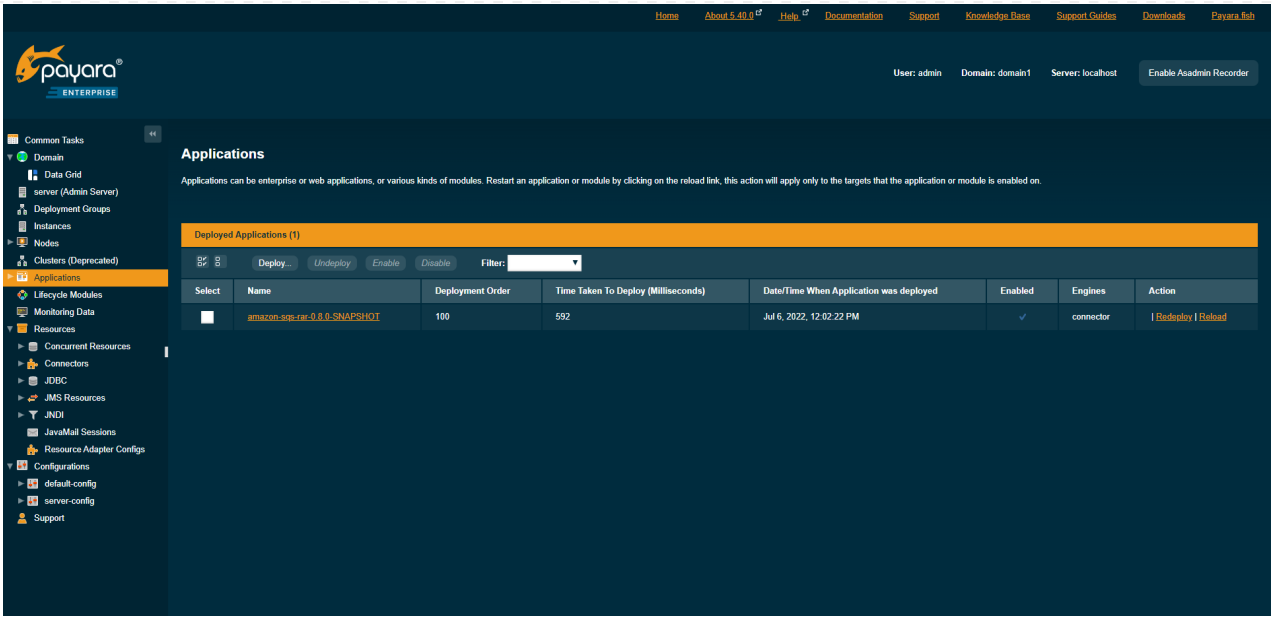
A connector (JCA rar) is installed by deploying it in the same way as an application archive (e.g. a .war) is deployed:

====== Payara Server

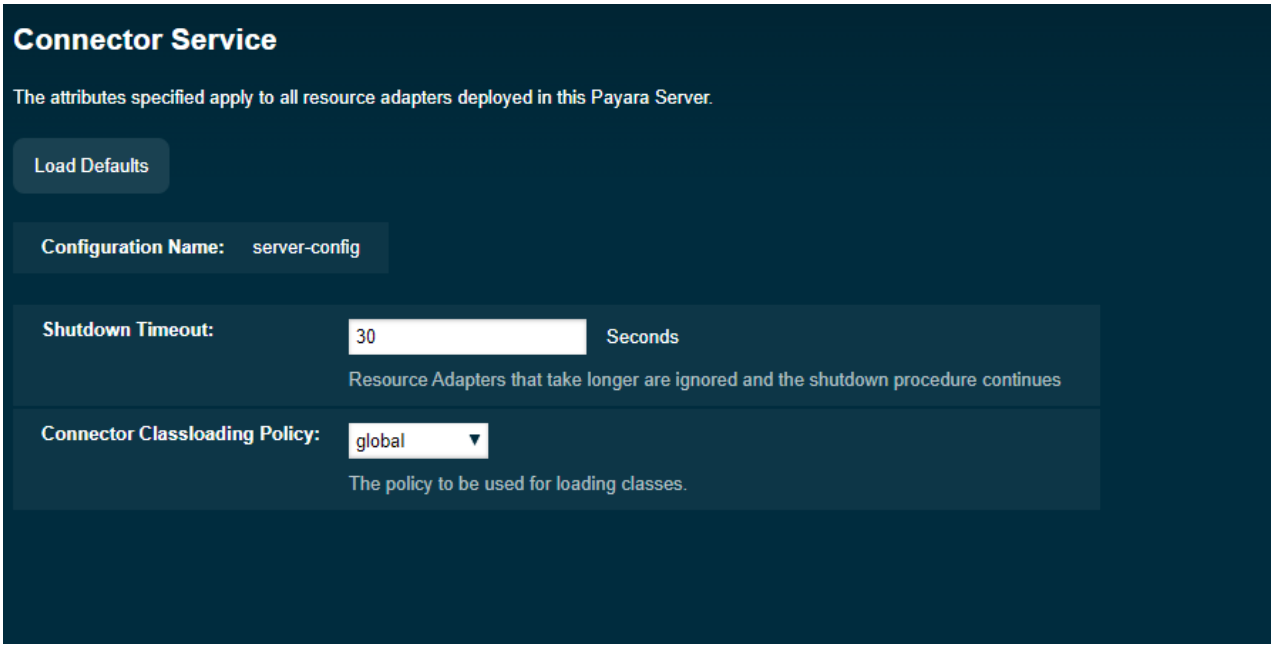
You can configure Payara Server through the Admin Console or through the Asadmin CLI.

====== Using the Admin Console

You can deploy the connector with the admin console;



Then configure the `Connector Classloading Policy` to `Global` in `{config} > Connector Service > Connector Classloading Policy`.



This allows the classes from the cloud connector to be globally available in the server.

====== Using the Asadmin CLI

Deploy the application with the CLI;

```
asadmin> deploy --target=server amazon-sqs-rar.rar
```

Configure the classloading policy;

```
asadmin> set configs.config.server-config.connector-service.class-loading-
policy=global
```

====== Payara Micro

```
java -jar payara-micro.jar --autobindhttp --deploy kafka-rar-0.8.0.rar
```

The connector is subsequently available to all other applications deployed to Payara Micro. An application using a connector and the connector itself can be deployed simultaneously:

```
java -jar payara-micro.jar --autobindhttp --deploy kafka-rar-0.8.0.rar --deploy
myapp.war
```

====== Securing credentials

In the documentation pages for the currently available cloud connectors, much of the configuration shown is done via annotations. This configuration contains credentials as well, which as a rule of thumb should not directly be placed in code. On Payara all properties can be replaced via System properties using the syntax ${system.property.name} or environment variables using the syntax `${ENV=evironment.property.name}` or password aliases using the syntax `${ALIAS=alias.name}`.

====== Amazon SQS

====== Overview

Amazon SQS (Simple Queue Service) is a hosted and highly scalable distributed message queue service.

To get the correct version of the artifact to use in your application (since it depends on a specific version of the Amazon Web Services Java SDK), please follow the instructions detailed in link:/Technical Documentation/Ecosystem/Connector Suites/Cloud Connectors/Amazon SQS/Versioning.adoc[Versioning,role=unresolved].

Once deployed, a message similar to this one should be printed out to the server's output:

```
[fish.payara.cloud.connectors.amazonsqs.api.inbound.AmazonSQSResourceAdapter]
[tid: _ThreadID=1 _ThreadName=main] [timeMillis: 1495398495490] [levelValue: 800]
Amazon SQS Resource Adapter Started..
```

====== Sending messages

Sending messages to Amazon SQS can be done via the JCA and an Amazon specific API. In order to start using this API to send messages, a resource has to be defined via the JCA API; a connection factory.

The connection factory has to be given a name, which can be any name that is valid for JNDI. The `java:app` namespace is typically recommended to be used. The type of the connection factory to be used for Amazon SQS is `fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSConnectionFactory`, and we have to

specify the resource adapter name which is here `amazon-sqs-rar-2.1.0.rar`.

Finally, the AWS account details have to be specified in the properties of the corresponding JMS resource definitions.

The following gives an example:

```
@ConnectionFactoryDefinition (
  name = "java:app/amazonsqs/factory",
  interfaceName =
"fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSConnectionFactory",
  resourceAdapter = "amazon-sqs-rar-2.1.0",
  properties = {"awsAccessKeyId=<accessKeyID>", "awsSecretKey=<secretKey>",
"region=eu-west-2"}
)
public class SendSQSMessage {
}
```

With the above definition in place, the following code shows an example of sending a message:

```
@Singleton
@Startup
public class SendSQSMessage {

 @Resource(lookup = "java:app/amazonsqs/factory")
 private AmazonSQSConnectionFactory factory;

 @PostConstruct
 public void init() {
    try (AmazonSQSConnection connection = factory.createConnection()) {
        SendMessageRequest sendMsgRequest = SendMessageRequest.builder()
                        .queueUrl("<queueURL>")
                        .messageBody("Hello World")
                        .build();
        connection.sendMessage(sendMsgRequest);
    }
    catch (Exception ex) {
    }
 }
}
```

====== Receiving messages

Messages can be received from Amazon SQS by creating an MDB (Message Driven Bean) that implements the `fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSListener` marker interface and has a single method annotated with `@OnSQSMessage` and the method signature `void method(Message message)`.

The following gives an example:

```
@MessageDriven(activationConfig = {
    @ActivationConfigProperty(propertyName = "awsAccessKeyId", propertyValue =
"someKey"),
    @ActivationConfigProperty(propertyName = "awsSecretKey", propertyValue =
"someSecretKey"),
    @ActivationConfigProperty(propertyName = "queueURL", propertyValue =
"someQueueURL"),
    @ActivationConfigProperty(propertyName = "pollInterval", propertyValue = "1"),
    @ActivationConfigProperty(propertyName = "region", propertyValue = "eu-west-
2")
})
public class ReceiveSQSMessage implements AmazonSQSListener {

    @OnSQSMessage
    public void receiveMessage(Message message) {
     // Handle message
    }
}
```

====== Large Message Support

By default, the AWS Java SDK has a message size limitation of `256KB`, which can be restrictive for certain use cases.

To address this limitation, the Payara Cloud Connector offers enhanced support for sending and receiving larger messages, surpassing the `256KB` restriction by leveraging Amazon S3 storage. To enable this feature, configure the S3 bucket name using the `s3BucketName` property.

====== Prerequisites for Larger message support

Before testing the larger message support feature, ensure the following prerequisites are met:

1. Create an S3 Bucket in AWS:
    - Create a new Amazon S3 bucket in your AWS account where larger messages will be stored.
2. IAM Role Permissions:
    - Add `AmazonS3FullAccess` or related permissions to the IAM role associated with your application.
    - This permission ensures that your application has the necessary access to the S3 bucket for storing and retrieving larger messages.

====== Sending Large Messages

To send messages larger than `256KB`, include the `s3BucketName` property in the connection factory definition. Specify the desired AWS S3 bucket name to store these larger messages.

For example:

```
@ConnectionFactoryDefinition (
    name = "java:app/amazonsqs/factory",
    interfaceName =
"fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSConnectionFactory",
    resourceAdapter = "amazon-sqs-rar-2.1.0",
    properties = {"awsAccessKeyId=<accessKeyID>", "awsSecretKey=<secretKey>",
"region=eu-west-2", "s3BucketName=MyS3Bucket"}
)
@Singleton
@Startup
public class SendSQSMessage {
}
```

After configuring the connection factory with the S3 bucket name, you can send larger messages using the provided Amazon SQS API, as demonstrated in the previous examples.

====== Receiving Large Messages

To receive larger messages, update the Message Driven Bean (MDB) configuration with the `s3BucketName` property:

```
@MessageDriven(activationConfig = {
    @ActivationConfigProperty(propertyName = "awsAccessKeyId", propertyValue =
"someKey"),
    @ActivationConfigProperty(propertyName = "awsSecretKey", propertyValue =
"someSecretKey"),
    @ActivationConfigProperty(propertyName = "queueURL", propertyValue =
"someQueueURL"),
    @ActivationConfigProperty(propertyName = "pollInterval", propertyValue = "1"),
    @ActivationConfigProperty(propertyName = "region", propertyValue = "eu-west-
2"),
    @ActivationConfigProperty(propertyName = "s3BucketName", propertyValue =
"MyS3Bucket"),
    @ActivationConfigProperty(propertyName = "s3FetchMessage", propertyValue =
"true")
})
public class ReceiveSQSMessage implements AmazonSQSListener {

    @OnSQSMessage
    public void receiveMessage(Message message) {
     // Handle larger message
    }
}
```

Configure the `s3BucketName` property along with other properties to specify the AWS S3 bucket where larger messages are stored.

====== Configuration Properties

The full list of configuration properties is given below:

Config Property Name	Type	Default	Notes
`awsAccessKeyId`	String	None	Must be set to the access key of your AWS account
`awsSecretKey`	String	None	Must be set to the secret key of your AWS account
`queueURL`	String	None	Must be set to the URL for an SQS queue
`region`	String	None	Must be set to the AWS region name of your queue
`maxMessages`	Integer	10	The maximum number of messages to download on a poll
`initialPollDelay`	Integer	1	The delay (in seconds) before polling the queue after MDB activation (MDB only)
`pollInterval`	Integer	3	How often should the adapter poll for messages (in seconds) (MDB Only)
`messageAttributeNames`	String	All	The list of message attribute names that should be fetched with the message (MDB Only)
`attributeNames`	String	All	The list of attribute names that should be fetched with the message (MDB Only)
`s3BucketName`	String	None	AWS S3 bucket name for storing larger messages
`s3SizeThreshold`	Integer	0	AWS S3 size threshold for storing messages (in bytes)
`s3KeyPrefix`	String	None	AWS S3 key prefix for organizing stored messages
`s3FetchMessage`	Boolean	true	Flag to fetch the full message from S3 when it exceeds the size threshold. If set to `false`, only the message metadata for larger messages, including the bucket name and message key, will be returned instead of the full message.

====== Versioning

The SQS connector's behavior and features are affected by the exact version of the Amazon Web Services Java SDK version being planned to use. For each version, there are separate versions of the connector's JCA adapter and its API.

The tags below are for the Cloud Connectors repository. You should use the one corresponding to the SQS and Jakarta version you require.

0.8.0

Amazon SQS Version 1 using JakartaEE 8 and the `javax` namespace

AmazonSQS-1.1.0

Amazon SQS Version 2 using JakartaEE 8 and the `javax` namespace

AmazonSQS-2.1.0

Amazon SQS Version 2 using JakartaEE 10 and the `jakarta` namespace

====== Amazon SQS Connector Version 1

This is the first version of the connector that is based on Amazon Web Services Java SDK v1.

====== Usage

The `amazon-sqs-rar-0.8.0.rar` JCA adapter has to be deployed as shown in the link:/Technical Documentation/Ecosystem/Connector Suites/Cloud Connectors/Overview.adoc#Installing-a-connector[Installing a connector section,role=unresolved] of the Cloud Connectors overview.

Additionally, to use the connector API add the following Maven dependencies to your application's project:

```
<dependency>
  <groupId>fish.payara.cloud.connectors.amazonsqs</groupId>
  <artifactId>amazon-sqs-jca-api</artifactId>
  <version>[,1.0.0)</version>
  <type>jar</type>
  <scope>provided</scope>
</dependency>

<dependency>
  <groupId>com.amazonaws</groupId>
  <artifactId>aws-java-sdk-sqs</artifactId>
  <version>[1.11.118,)</version>
  <type>jar</type>
  <scope>provided</scope>
</dependency>
```

These dependencies have a provided `scope` since the types within this dependency are globally available to every application deployed to Payara Micro after the `amazon-sqs-rar-0.8.0.rar` has been deployed.

====== Amazon SQS Connector Version 2

This is the second version of the connector that is based on Amazon Web Services SDK v2.

If you have selected to use SQS Connector 2.1.0, replace all occurunces of `1.0.0` with `2.1.0` for the following example.

====== Usage

The `amazon-sqs-rar-2.1.0.rar` JCA adapter can be downloaded from Maven Central, and has to be deployed as shown in the link:/Technical Documentation/Ecosystem/Connector Suites/Cloud Connectors/Overview.adoc#Installing-a-connector[Installing a connector section,role=unresolved] of the Cloud Connectors overview.

Additionally, to use the connector API add the following Maven dependencies to your application's project:

```
<dependency>
    <groupId>fish.payara.cloud.connectors.amazonsqs</groupId>
    <artifactId>amazon-sqs-jca-api</artifactId>
    <version>2.1.0</version>
    <type>jar</type>
    <scope>provided</scope>
</dependency>

<dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>sqs</artifactId>
    <version>[2.25.6,)</version>
    <type>jar</type>
    <scope>provided</scope>
</dependency>
```

The `amazon-sqs-jca-api` artifact has to be installed to your local Maven repository first.

====== SSO Integration

If you are using version 2 of the Amazon Web Services Java SDK, then it is possible to configure the SQS connector use Amazon SSO authentication instead of a `secretKey` and `keyID` set of credentials.

The Amazon Single Sign-On (AWS SSO) is also known as the AWS IAM Identity Center. This center is used by AWS administrators to centrally manage the data and access permissions of all user identities. To view more information about it please read here: AWS IAM Identity Center

In this case, instead of using a traditional "Service Account" to allow a deployed application to connect to a SQS Queue, instead you can allow individual AWS accounts to log in via SSO first and then make the calls as long as they have been configured with the right permissions. To configure this you must follow these steps:

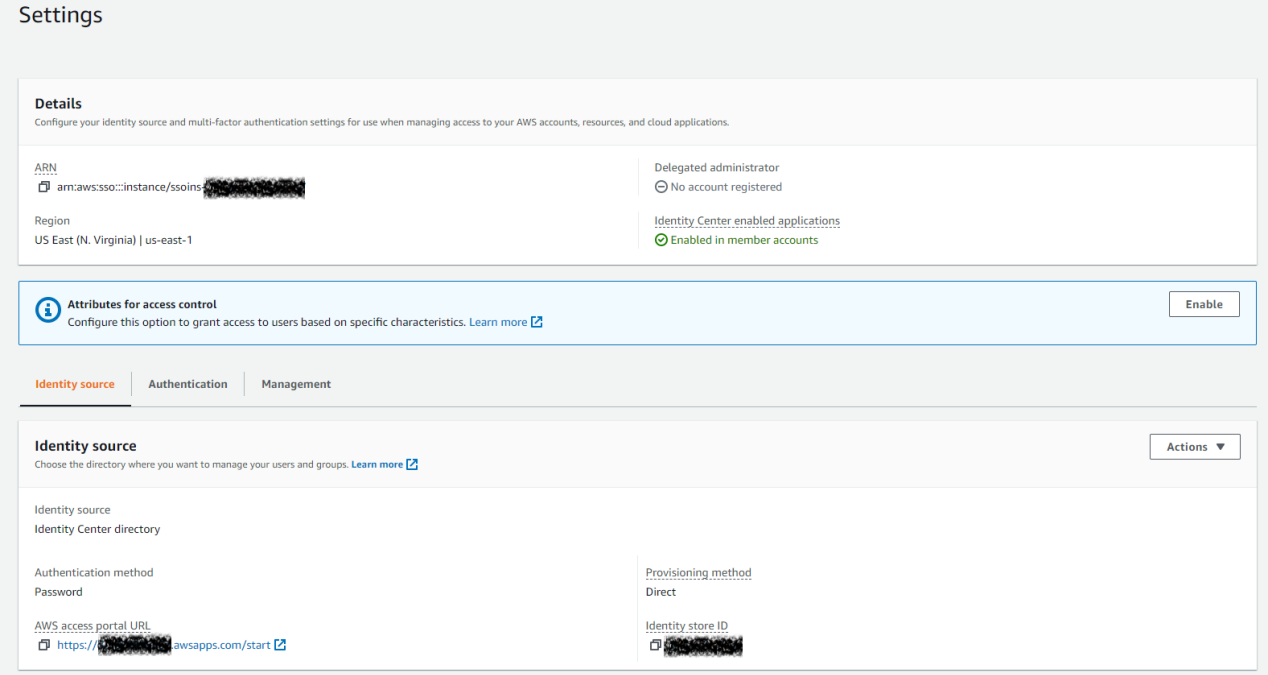
1. Configure AWS IAM Identity Center Accounts
2. Configure SQS Queue
3. Download and install the Amazon SQS Connector v2
4. Install the Amazon CLI locally
5. Configure the user credentials
6. Execute the SSO login

Using AWS SSO credentials is a recommended practice for development environment only. Please refrain from using this setup on production environments.

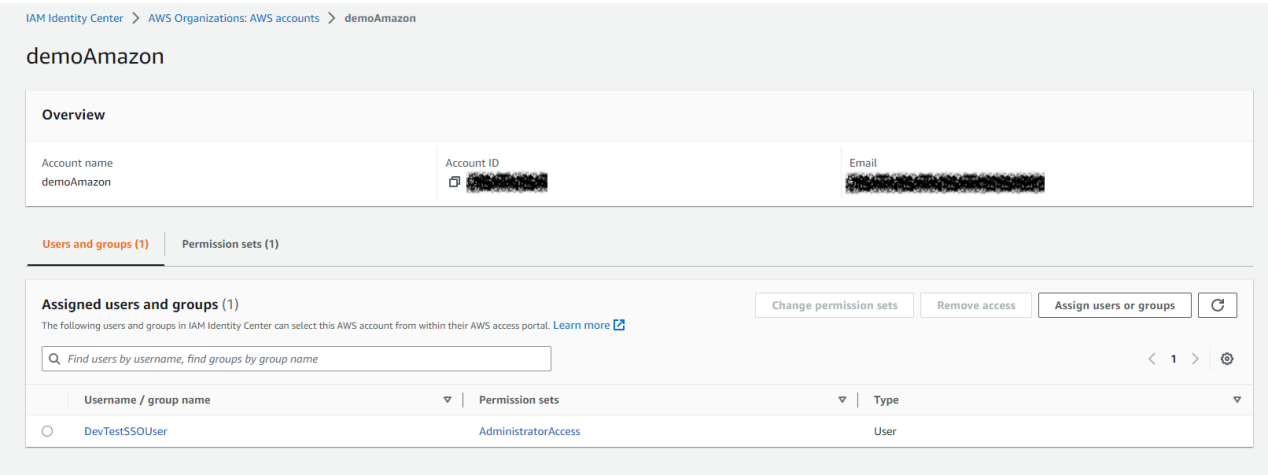
====== Configure AWS IAM Identity Center Accounts

To configure AWS IAM Identity Center Accounts, please read the instructions detailed in Create Users with AWS IAM Identity Center.

Here's an example identity that is ready to be used for SSO login:



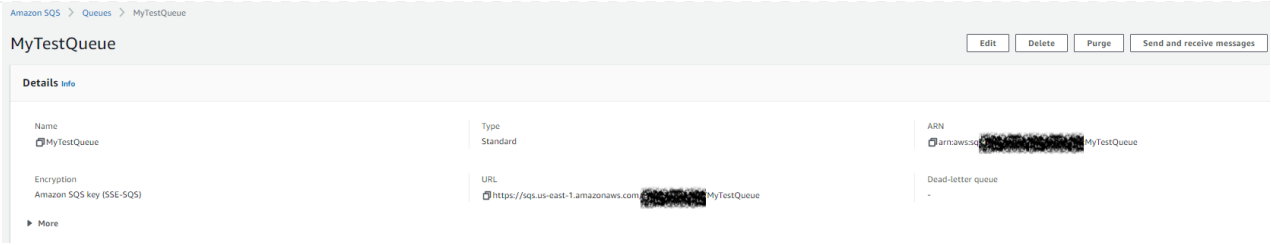
This account is also setup with full privileges so that it can access SQS resources:



====== Configure a SQS Queue

To configure an SQS Queue, please follow the instructions detailed in Create Amazon SQS Queue

Here's an example of a SQS Queue:



====== Download and install Amazon SQS Connector version 2 from Payara

To download and install Amazon SQS Connector V2, please check How to use of the Amazon SQS Versioning.

====== Install Amazon CLI Locally

To install the Amazon CLI toolset on you local environment, please check Amazon CLI getting started

You can verify that the CLI has been correctly installed with the following command:

```
>aws --version
aws-cli/2.8.11 Python/3.9.11 Windows/10 exe/AMD64 prompt/off
```

====== Setup Local Configuration

Next, you'll have to setup the Amazon IAM configuration file on your local machine to enable SSO authentication. Read detailed instructions on how to setup this configuration file on AWS SSO Credentials.

Here's a sample configuration file:

```
[default]
sso_start_url = https://d-9067bf6e6d.awsapps.com/start
sso_region = us-east-1
sso_account_id = <ACCOUNT_ID>
sso_role_name = <ROLE_NAME>
```

The `sso_start_url`, `sso_region` and `sso_role_name` are parameters associated with the SSO credentials for the user account identity. To get the `sso_account_id` find the instructions in Account ID.

Before proceeding, you'll have to set the URL of the SQS Queue and its corresponding region as Environment Variables:

```
>set queueURL=https://sqs.us-east-1.amazonaws.com/845692786875/MyTestQueue
>set region=us-east-1
```

====== AWS SSO Login

Next, execute the AWS SSO login from the command line:

```
>aws sso login --profile default

Attempting to automatically open the SSO authorization page in your default
browser.
If the browser does not open or you wish to use a different device to authorize
this request, open the following URL:

https://device.sso.us-east-1.amazonaws.com/

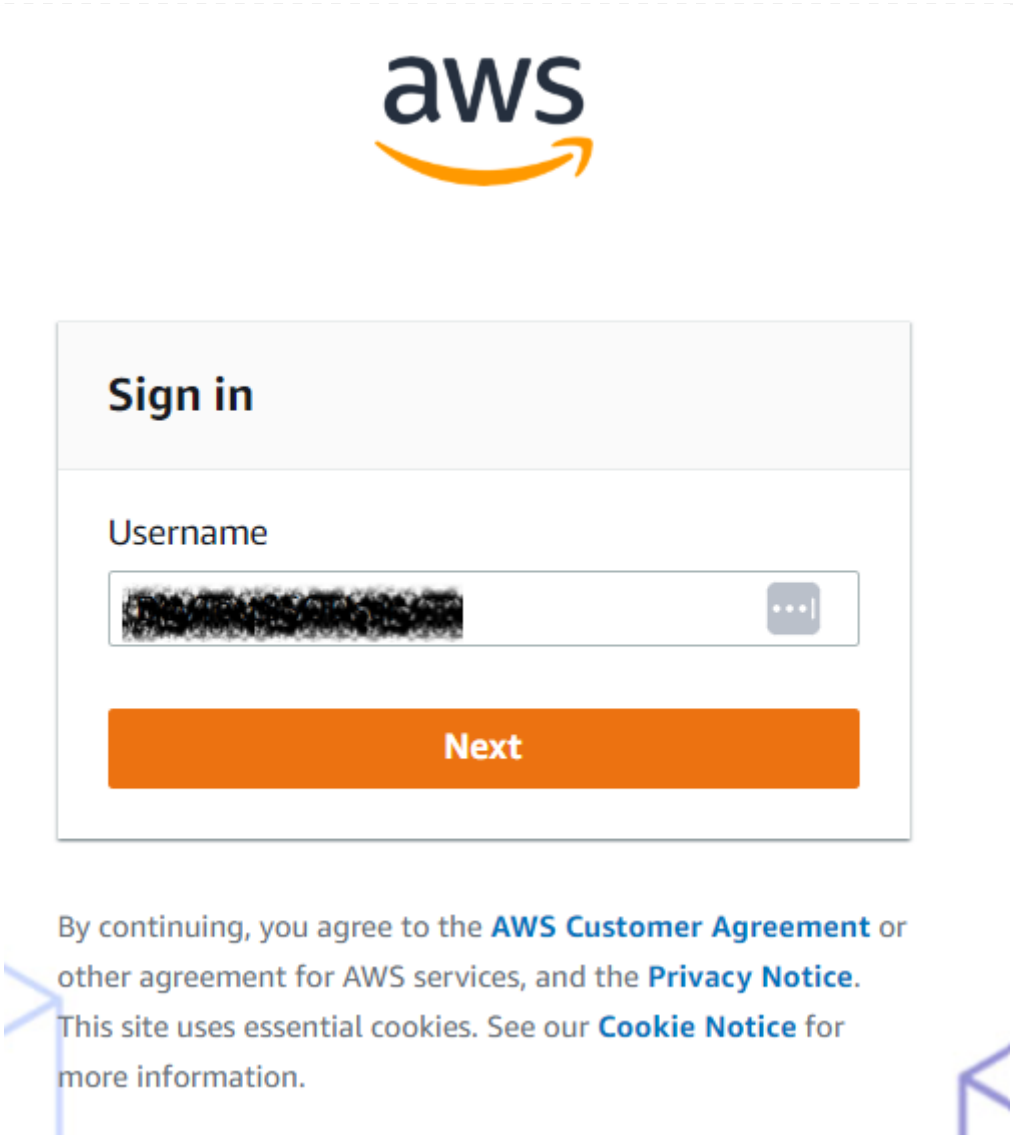
Then enter the code:

XXXX-XXXX

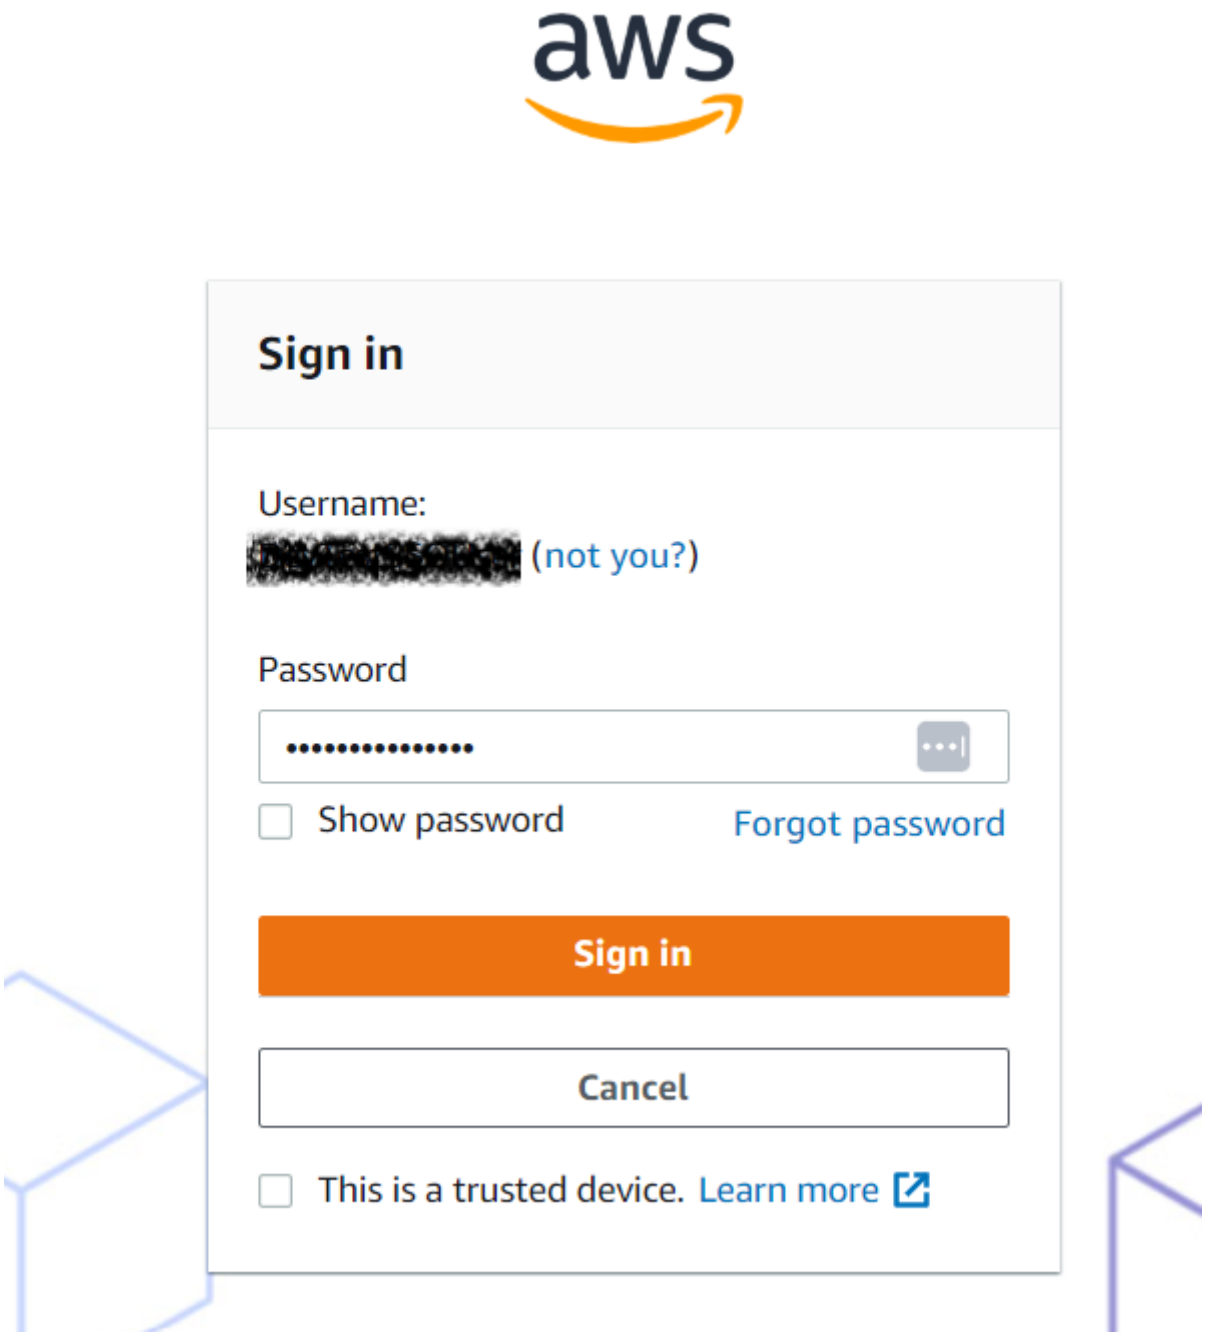
Successfully logged into Start URL: https://d-9067bf6e6d.awsapps.com/start
```

This process will open a local browser window so that the current user can provide its credentials using this simple process:

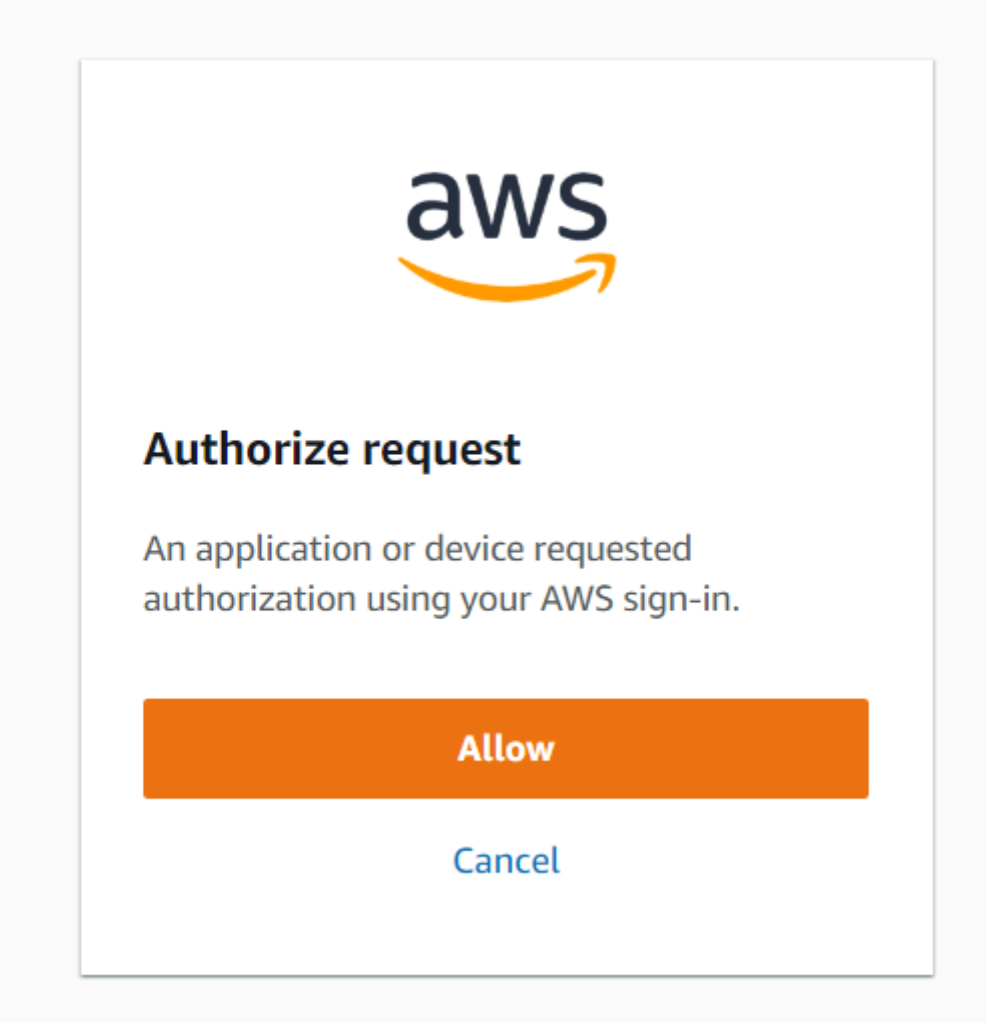
1. Start the session



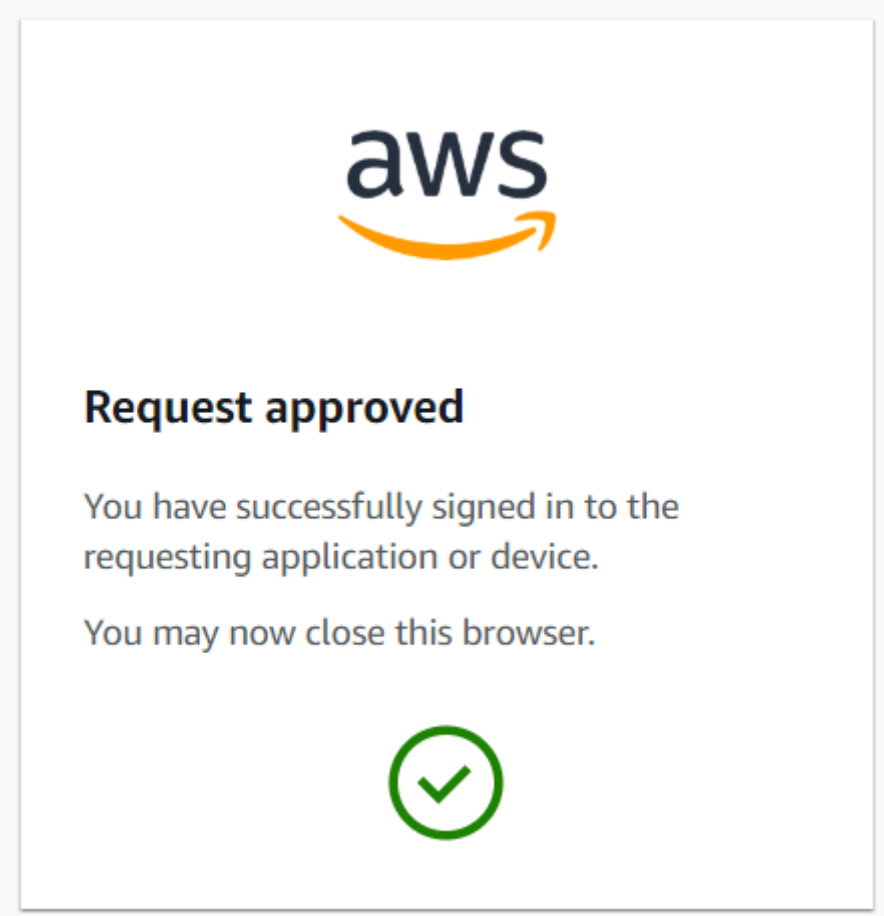
2. Set user password



3. Authorize the request



4. Receive login approval



====== Deploy and Test application

Before deploying and testing a sample application, remember to install the JCA adapter and configuring the API dependencies as described in link:/Technical Documentation/Ecosystem/Connector Suites/Cloud Connectors/Amazon SQS/Versioning.adoc[Versioning,role=unresolved].

Since the internal SSO credentials resolver will look for the required credentials on the local environment's configuration file, then you don't have to supply the AWS identity credentials on the configuration properties of your application's messaging components.

To send messages, here's how the connection factory definition looks like:

```
@ConnectionFactoryDefinition (
  name = "java:app/amazonsqs/factory",
  interfaceName =
"fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSConnectionFactory",
  resourceAdapter = "amazon-sqs-rar-2.1.0",
  properties = {"region=us-east-1"}
)
```

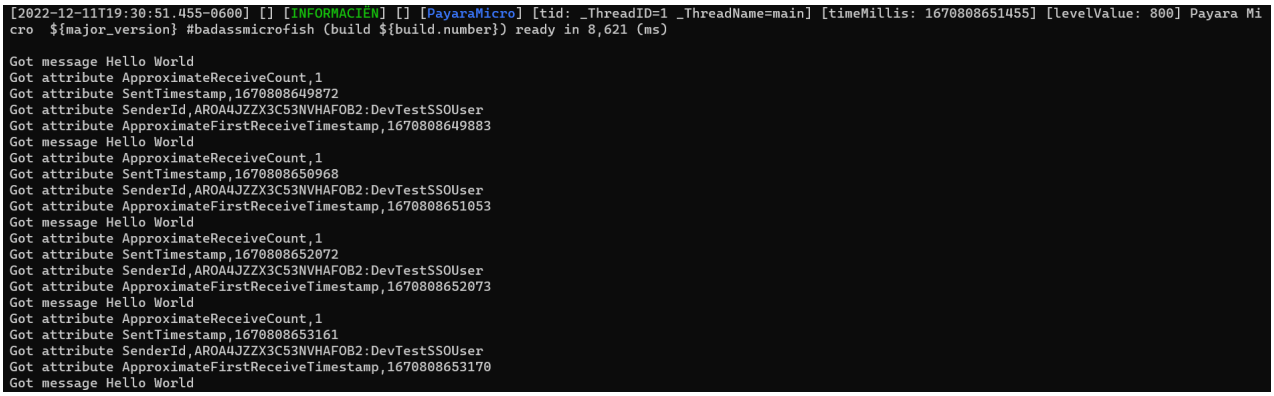
And for receiving messages, here's how the MDB definition looks like:

```
@MessageDriven(activationConfig = {
    @ActivationConfigProperty(propertyName = "queueURL", propertyValue =
```

```
"ENV={queueURL}"),
    @ActivationConfigProperty(propertyName = "region", propertyValue =
"ENV={region}"),
    @ActivationConfigProperty(propertyName = "pollInterval", propertyValue = "1")
})
public class ReceiveSQSMessage implements AmazonSQSListener {

    @OnSQSMessage
    public void receiveMessage(Message message) {
        // Handle message
    }
}
```

A simple log output of message processing would look like this:



====== STS Integration

To enhance security and provide temporary, limited-access credentials for your Jakarta EE application using Payara Cloud Connector for AWS SQS, you can integrate with AWS Security Token Service (STS) through Identity and Access Management (IAM). Follow the steps below to set up STS integration:

====== Creating IAM Role

To integrate Payara Cloud Connector for AWS SQS with your Jakarta EE application, you need to create an IAM (Identity and Access Management) role in the AWS Management Console. Follow the steps below to create an IAM role, retrieve the `roleArn`, and set a `roleSessionName` for use with Payara Cloud Connector AWS SQS.

====== Steps:

1. Open the IAM Console
    a. Navigate to the AWS Management Console and open the IAM console.
2. Retrieve User ARN
    a. Navigate back to the IAM console.
    b. In the left navigation pane, choose "**Users**."
    c. Select the IAM user (e.g., "MY-USER").

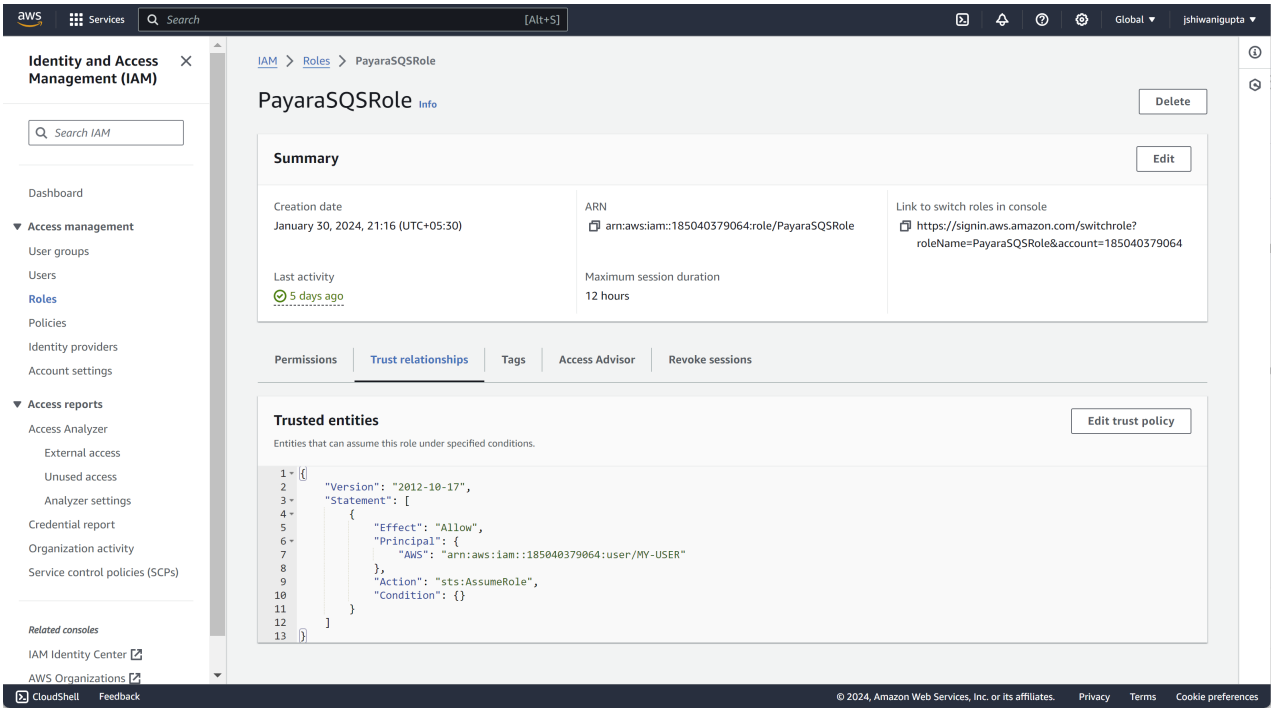
d. Copy the User ARN from the user's summary page (e.g., "arn:aws:iam::xxxxxxxxx:user/MY-USER").

3. Set Role Session Name
    a. For the `roleSessionName`, choose a logical name for your session (e.g., "PayaraSQSSession").
4. Create an IAM Role
    a. In the left navigation pane, choose "**Roles**".
    b. Choose "**Create role**".
    c. Select "**AWS account**".
    d. Enter the AWS account ID, If you're working within the same AWS account, you can skip this step.
    e. Choose "**Next**".
5. Add permissions
    a. Search for **AmazonSQSFullAccess** policiy and attach it.
    b. Choose "**Next**".
6. Role details
    a. Give the role a Name (e.g., "PayaraSQSRole").
    b. Add a meaningful description.
    c. Choose "**Create role**".
7. Retrieve Role ARN
    a. After creating the role, you'll see a summary page for the role. Copy the Role ARN (e.g., "arn:aws:iam::xxxxxxxxx:role/PayaraSQSRole").
8. Update Trust Relationship

To resolve potential authorization issues related to role assumption, ensure that the Trust Relationship in the IAM role is configured correctly. Update the Trust Relationship to explicitly allow the user to assume the role. Below is an example Trust Relationship JSON where root is replace with USER's ARN:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::xxxxxxxxx:user/MY-USER"
            },
            "Action": "sts:AssumeRole",
            "Condition": {}
        }
    ]
```

```
}
```



Make sure to replace the values with your specific IAM user ARN and role ARN.

It’s crucial to establish a link between the IAM user’s ARN and the IAM role’s Trust Relationship by configuring the Trust Relationship with the user’s ARN. This linkage ensures that the IAM user has the necessary permissions to assume the role. Additionally, for seamless integration, configure the `roleArn` and `roleSessionName` in the Payara Cloud Connector AWS SQS:

- `roleArn`: The ARN of the IAM role you’ve just created.
- `roleSessionName`: A logical name for your session (e.g., "PayaraSQSSession").

These values play a crucial role in the configuration of Payara Cloud Connector AWS SQS, enabling your Jakarta EE application to establish the necessary connections securely.

====== Sending messages

Sending messages to Amazon SQS can be done via the JCA and an Amazon specific API. In order to start using this API to send messages, a resource has to be defined via the JCA API; a connection factory.

The connection factory has to be given a name, which can be any name that is valid for JNDI. The `java:app` namespace is typically recommended to be used. The type of the connection factory to be used for Amazon SQS is `fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSConnectionFactory`, and we have to specify the resource adapter name which is here `amazon-sqs-rar-2.1.0.rar`.

Finally, the AWS account details have to be specified in the properties of the corresponding JMS resource definitions, including the `roleArn` and `roleSessionName`.

See the following example:

```
@ConnectionFactoryDefinition (
  name = "java:app/amazonsqs/factory",
  interfaceName =
"fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSConnectionFactory",
  resourceAdapter = "amazon-sqs-rar-2.1.0",
  properties = {
        "awsAccessKeyId=<accessKeyID>",
        "awsSecretKey=<secretKey>",
        "roleArn=arn:aws:iam::xxxxxxxxx:role/PayaraSQSRole",
        "roleSessionName=PayaraSQSSession",
        "region=eu-west-2"
    }
)
```

With the above definition in place the following code shows an example of sending a message:

```
@Singleton
@Startup
public class SendSQSMessage {

 @Resource(lookup = "java:app/amazonsqs/factory")
 private AmazonSQSConnectionFactory factory;

 @PostConstruct
 public void init() {
    try (AmazonSQSConnection connection = factory.createConnection()) {
        SendMessageRequest sendMsgRequest = SendMessageRequest.builder()
                        .queueUrl("<queueURL>")
                        .messageBody("Hello World")
                        .build();
        connection.sendMessage(sendMsgRequest);
    }
    catch (Exception ex) {
    }
 }
}
```

====== Receiving messages

Messages can be received from Amazon SQS by creating a MDB (Message Driven Bean) that implements the `fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSListener` marker interface and has a single method annotated with `@OnSQSMessage` and the method signature `void method(Message message)`.

See the following example:

```
@MessageDriven(activationConfig = {
 @ActivationConfigProperty(propertyName = "awsAccessKeyId", propertyValue =
"someKey"),
 @ActivationConfigProperty(propertyName = "awsSecretKey", propertyValue =
"someSecretKey"),
 @ActivationConfigProperty(propertyName = "queueURL", propertyValue =
"someQueueURL"),
 @ActivationConfigProperty(propertyName = "pollInterval", propertyValue = "1"),
 @ActivationConfigProperty(propertyName = "roleArn", propertyValue =
"arn:aws:iam::xxxxxxxxx:role/PayaraSQSRole") ,
 @ActivationConfigProperty(propertyName = "roleSessionName", propertyValue =
"PayaraSQSSession") ,
 @ActivationConfigProperty(propertyName = "region", propertyValue = "eu-west-2")
})
public class ReceiveSQSMessage implements AmazonSQSListener {

 @OnSQSMessage
 public void receiveMessage(Message message) {
     // Handle message
 }
}
```

====== Queue Management

Amazon SQS Queues (and other resources) can be managed through the use of the official Amazon SQS API, which allows programmatic control over them. In general, managing queues in Amazon SQS is crucial for effective message handling.

To simplify the setup needed to use the SQS API from a standard Jakarta EE application and manage SQS resources, the Payara Platform SQS connector offers easy access to the `com.amazonaws.services.sqs.AmazonSQSConnectionFactory` class through the Java Connector Architecture (JCA) API.

This section will show how to access these facilities and focus on key operations like creating, listing, and deleting queues.

====== Connection Factory Setup

To utilize the Amazon SQS API for managing SQS resources in a Jakarta EE application, you must define a connection factory using the JCA API (via the `@ConnectionFactoryDefinition` annotation). This involves specifying the connection factory type and resource adapter name.

Additionally, AWS account details are required in the properties of the corresponding JMS resource definitions.

Once the connection factory is defined within the application, Jakarta EE components can access it via resource injection to a `com.amazonaws.services.sqs.AmazonSQSConnectionFactory` typed object.

Here's a complete example of a singleton bean that defines the connection factory under the

`java:app/amazonsqs/factory` JNDI name, which is used later to located it for resource injection under the bean's attributes:

```
@ConnectionFactoryDefinition (
    name = "java:app/amazonsqs/factory",
    interfaceName =
"fish.payara.cloud.connectors.amazonsqs.api.AmazonSQSConnectionFactory",
    resourceAdapter = "amazon-sqs-rar-2.1.0",
    properties = {"awsAccessKeyId=<accessKeyID>", "awsSecretKey=<secretKey>",
"region=<aws-region>"}
)
@Singleton
public class ManageSQSQueueBean {

    @Resource(lookup = "java:app/amazonsqs/factory")
    private AmazonSQSConnectionFactory factory;

    @PostConstruct
    public void listQueues() {
        try (AmazonSQSConnection connection = factory.createConnection()) {
            // Manage queues using AmazonSQSConnection
        }
        catch (Exception ex) {
            ex.printStackTrace();
        }
    }
}
```

In the above example, The `@ConnectionFactoryDefinition` annotation sets up the connection factory, where properties like `awsAccessKeyId`, `awsSecretKey`, and `region` should be configured.

Within the `try` block, an instance of `AmazonSQSConnection` instance is created using the connection factory method (`factory.createConnection()`).

====== Management Operations

Once an `com.amazonaws.services.sqs.AmazonSQSConnection` instance is retrieved, it can be used to perform various queue management operations, such as creating a new queue, listing all queues, and deleting an existing queue.

====== Create Queue

Creating a new Amazon SQS queue is a fundamental operation. The following code snippet demonstrates how to create a queue:

```
@Singleton
public class ManageSQSQueueBean {

    public void createQueue(String name){
```

```
        try (var connection = factory.createConnection()) {
            var createQueueRequest = CreateQueueReque.builder()
                .queueName(name)
                .build();

            var createQueueResponse = connection.createQueue(createQueueRequest);
            System.out.println("Queue Created: " + createQueueResponse);
        }
    }
}
```

In this example, `MyNewQueue` is the name of the new queue. Additional parameters can be added to customize the queue creation.

====== List Queues

Listing queues provides insight into existing queues. The following code snippet demonstrates how to list all queues and those with a specific name prefix:

```
@Singleton
public class ManageSQSQueueBean {

    public void listAllQueues(){
        // List all queues
        try (var connection = factory.createConnection()) {
            var allQueues = connection.listQueues();
            System.out.println("All Queues:");
            for (var queueUrl : allQueues.queueUrls()) {
                System.out.println(" - " + queueUrl);
            }
        }
    }

    public void listQueues(String prefix){
        // List queues with a specific name prefix
        try (var connection = factory.createConnection()) {
            var prefixedQueues =
connection.listQueues(ListQueuesRequest.builder().queueNamePrefix(prefix).build())
;
            System.out.println("Prefixed Queues:");
            for (var queueUrl : prefixedQueues.queueUrls()) {
                System.out.println(" - " + queueUrl);
            }
        }
    }
}
```

Listing queues aids in monitoring and managing existing queues, allowing for targeted actions.

====== Delete Queue

Deleting an existing SQS queue is a critical operation. Ensure the complete queue URL is provided in the `DeleteQueueRequest`. The following code snippet illustrates how to delete a queue:

```
@Singleton
public class ManageSQSQueueBean {

    //Sample URL: https://sqs.<aws-region>.amazonaws.com/xxxxx/MyQueue
    public void delete(String url){
        try (var connection = factory.createConnection()) {
            var deleteQueueRequest = DeleteQueueRequest
                    .builder()
                    .queueUrl(url)
                    .build();

            var deleteQueueResponse = connection.deleteQueue(deleteQueueRequest);
            System.out.println("Queue Deleted: " + deleteQueueResponse);
        }
    }
}
```

Deleting a queue is an irreversible operation and results in the loss of all messages handled by the queue.

====== List Queue Tags

Listing queue tags provides metadata about a queue. The following code snippet demonstrates how to list tags for a specific queue:

```
@Singleton
public class ManageSQSQueueBean {

    public void listQueueTags(String url){
        try (var connection = factory.createConnection()) {
            ListQueueTagsRequest tagsRequest = ListQueueTagsRequest.builder()
                    .queueUrl(url)
                    .build();

            ListQueueTagsResponse tagsResponse =
connection.listQueueTags(tagsRequest);
            Map<String, String> tags = tagsResponse.tags();
            System.out.println("Queue Tags: " + tags);
        }
    }
}
```

Tags offer a way to categorize and organize queues based on specific attributes.

====== Purge Queue

Purging a queue deletes all messages within it. The following code snippet illustrates how to purge a queue:

```
@Singleton
public class ManageSQSQueueBean {

    public void purgeQueue(String url){
        try (var connection = factory.createConnection()) {
            var purgeRequest = PurgeQueueRequest.builder()
                    .queueUrl(url)
                    .build();

            var purgeResponse = connection.purgeQueue(purgeRequest);
            System.out.println("Queue Purged: " + purgeResponse);
        }
    }
}
```

Use this operation carefully, as it is irreversible, and it removes all messages from the specified queue.

====== Tag and Untag Queue

Adding and removing tags from a queue provides additional context. The following code snippet shows how to tag and untag a queue:

```
@Singleton
public class ManageSQSQueueBean {

    public void tagUntagQueue(String url){
        try (var connection = factory.createConnection()) {
            Map<String, String> tagsToAdd = Map.of("Environment", "Production",
"Team", "Dev");
            var tagQueueRequest = TagQueueRequest.builder()
                    .queueUrl(url)
                    .tags(tagsToAdd)
                    .build();
            var tagQueueResponse = connection.tagQueue(tagQueueRequest);
            System.out.println("Queue Tagged: " + tagQueueResponse);

            List<String> tagKeysToRemove = List.of("Environment");
            var untagQueueRequest = UntagQueueRequest.builder()
                    .queueUrl(url)
                    .tagKeys(tagKeysToRemove)
                    .build();
```

```
            var untagQueueResponse = connection.untagQueue(untagQueueRequest);
            System.out.println("Queue Untagged: " + untagQueueResponse);
        }
    }
}
```

Tagging allows for easy classification, while untagging removes unnecessary metadata.

Effectively managing Amazon SQS queues using the JCA API empowers developers to streamline message processing and maintain a well-organized messaging system.

====== See Also

For more detailed information on the Amazon SQS Java SDK, including additional features and advanced usage, refer to the official Javadocs.

====== Apache Kafka

Apache Kafka is an open-source stream processing platform. It is based on a massively scalable publish/subscribe message queue architected as a distributed transaction log.

====== Versioning The tags below are for the Cloud Connectors repository. You should use the one corresponding to the Jakarta version you require.

0.8.0

Kafka Connector using JakartaEE 8 and the `javax` namespace

Kafka-1.0.0

Kafka Connector using JakartaEE 10 and the `jakarta` namespace

====== Usage

If you have selected to use Kafka Connector 1.0.0, replace all occurunces of `0.8.0` with `1.0.0` for the following example.

In order to connect to Apache Kafka, the `kafka-rar-0.8.0.rar` has to be deployed as shown in the Installing a connector section of the Cloud Connectors overview.

Once deployed, something like the following should be printed to the startup log of Payara Micro:

```
[fish.payara.cloud.connectors.kafka.inbound.KafkaResourceAdapter] [tid:
_ThreadID=1 _ThreadName=main] [timeMillis: 1495395212347] [levelValue: 800] Kafka
Resource Adapter Started..
```

In order to make use of this connector in an application, the following Maven dependency is needed:

```
<dependency>
  <groupId>fish.payara.cloud.connectors.kafka</groupId>
  <artifactId>kafka-jca-api</artifactId>
  <version>0.8.0</version>
  <type>jar</type>
  <scope>provided</scope>
</dependency>
```

Note that this dependency has scope `provided` since the types within this dependency are globally available to every application deployed to Payara Micro after the `kafka-rar-0.8.0.rar` was deployed.

====== Sending messages Sending messages to Apache Kafka can be done via the JCA and a Kafka specific API. In order to start using this API to send messages, a resource has to be defined via the JCA API; a connection factory.

The connection factory has to be given a name, which can be any name that is valid for JNDI. The java:app namespace is typically recommended to be used. The type of the connection factory to be used for Kafka is `fish.payara.cloud.connectors.kafka.KafkaConnectionFactory`, and we have to specify the resource adapter name which is here `kafka-rar-0.8.0`.

The following gives an example:

```
@ConnectionFactoryDefinition (
    name = "java:app/kafka/factory",
    interfaceName = "fish.payara.cloud.connectors.kafka.KafkaConnectionFactory",
    resourceAdapter = "kafka-rar-0.8.0"
)
```

With the above shown definition in place the following code shows an example of sending a message:

```
@Singleton
@Startup
public class SendKafkaMessage {

 @Resource(lookup = "java:app/kafka/factory")
 private KafkaConnectionFactory factory;

 @PostConstruct
 public void init() {
    try (KafkaConnection connection = factory.createConnection()) {
        connection.send(new ProducerRecord("test","hello","world"));
    }
    catch (Exception ex) {
    }
 }
```

```
}
```

====== Receiving messages Messages can be received from Apache Kafka by creating an MDB (Message Driven Bean) that implements the `fish.payara.cloud.connectors.kafka.api.KafkaListener` marker interface and has one or more methods annotated with `@OnRecord` and the method signature `void method(ConsumerRecord record)`, or `@OnRecords` and the method signature `void method(ConsumerRecords records)`

The following gives an example:

```
@MessageDriven(activationConfig = {
 @ActivationConfigProperty(propertyName = "groupIdConfig", propertyValue =
"testGroup"),
 @ActivationConfigProperty(propertyName = "topics", propertyValue = "test,test2"),
 @ActivationConfigProperty(propertyName = "autoCommitInterval", propertyValue =
"100"),
 @ActivationConfigProperty(propertyName = "pollInterval", propertyValue = "3000")
})
public class ReceiveKafkaMessage implements KafkaListener {

 @OnRecord(topics="test")
 public void receiveMessage(ConsumerRecord record) {
     // Handle record
 }
}
```

The full list of config properties is given below:

Config Property Name	Type	Default	Notes
`bootstrapServersConfig`	String	localhost:9092	Kafka Servers to connect to
`clientId`	String	KafkaJCAClient	Client ID of the Producer
`valueSerializer`	String	`org.apache.kafka.common.serialization.StringSerializer`	Serializer class for value

Config Property Name	Type	Default	Notes
keySerializer	String	org.apache.kafka.common.serialization.StringSerializer	Serializer class for key
bufferMemory	Long	33554432	The total bytes the producer can use to buffer messages
acks	String	1	The number of acks the producer requires
retries	Integer	0	The number of retries if there is a transient error
batchSize	Long	16384	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition
lingerMS	Long	0	The producer groups together any records that arrive in between request transmissions into a single batched request.
maxBlockMS	Long	60000	How long can send block
maxRequestSize	Long	1048576	Maximum size of request (bytes)
receiveBufferBytes	Integer	32768	Receive Buffer (bytes)
requestTimeout	Integer	30000	Request Timeout (ms)
compression	String	"none"	Compression type of data sent
connectionsMaxIdle	Long	540000	Close Idle Kafka Connections
maxInflightConnections	Integer	5	Maximum unacknowledged requests to send before blocking
metadataMaxAge	Long	300000	Period of time before a refresh of Metadata (ms)
retryBackoff	Long	100	The amount of time to wait before attempting a retry (ms)
reconnectBackoff	Long	100	The amount of time to wait before attempting a reconnection (ms)

====== Azure SB

The Microsoft Azure Service Bus allows code that runs both outside and inside Azure to communicate with Azure.

====== Versioning The tags below are for the Cloud Connectors repository. You should use the one corresponding to the Jakarta version you require.

0.8.0

Azure Service Bus Connector using JakartaEE 8 and the `javax` namespace

AzureServiceBus-1.0.0

Azure Service Bus Connector using JakartaEE 10 and the `jakarta` namespace

====== Usage

If you have selected to use Azure Service Bus Connector 1.0.0, replace all occurunces of `0.8.0` with `1.0.0` for the following example.

In order to connect to Azure, the `azure-sb-rar-0.8.0.rar` has to be deployed as shown in the Installing a connector section of the Cloud Connectors overview.

In order to make use of this connector in an application, the following maven dependency is needed:

```
<dependency>
  <groupId>fish.payara.cloud.connectors</groupId>
  <artifactId>azure-sb-jca-api</artifactId>
  <version>0.8.0</version>
  <type>jar</type>
  <scope>provided</scope>
</dependency>
```

Note that this dependency have scope provided since the types within this dependency are globally available to every application deployed to Payara Micro after the `azure-sb-rar-0.8.0.rar` was deployed.

====== Sending messages

Sending messages to Azure can be done via the JCA and an Azure specific API. In order to start using this API to send messages, a resource has to be defined via the JCA API; a connection factory.

The connection factory has to be given a name, which can be any name that is valid for JNDI. The `java:app` namespace is typically recommended to be used. The type of the connection factory to be used for the Azure Service Bus is `fish.payara.cloud.connectors.azuresb.api.AzureSBConnectionFactory`, and we have to specify the resource adapter name which is here `AzureSBRAR-0.1.0-SNAPSHOT`.

Finally the Azure credentials have to be specified.

The following gives an example:

```
@ConnectionFactoryDefinition (
  name = "java:app/azuresb/factory",
  interfaceName =
```

```
"fish.payara.cloud.connectors.azuresb.api.AzureSBConnectionFactory",
  resourceAdapter = "azure-sb-rar-0.8.0"
  properties = {"nameSpace=payara", "sasKeyName=RootManageSharedAccessKey",
"sasKey=someKey"}
)
```

With the above shown definition in place the following code shows an example of sending a message:

```
@Singleton
@Startup
public class SendAzureMessage {

  @Resource(lookup = "java:app/azuresb/factory")
  private AzureSBConnectionFactory factory;

  @PostConstruct
  public void init() {
    try (AzureSBConnection connection = factory.createConnection()) {
        connection.sendMessage("testq", new BrokeredMessage("Hello World"));
    }
    catch (Exception ex) {
    }
  }
}
```

====== Receiving messages Messages can be received from Azure by creating an MDB (Message Driven Bean) that implements the `fish.payara.cloud.connectors.azuresb.api.AzureSBListener` marker interface and has a single method annotated with `@OnAzureSBMessage` and the method signature `void method(BrokeredMessage message)`.

The following gives an example:

```
@MessageDriven(activationConfig = {
 @ActivationConfigProperty(propertyName = "nameSpace", propertyValue = "payara"),
 @ActivationConfigProperty(propertyName = "sasKeyName", propertyValue =
"RootManageSharedAccessKey"),
 @ActivationConfigProperty(propertyName = "sasKey", propertyValue = "someKey"),
 @ActivationConfigProperty(propertyName = "queueName", propertyValue = "testq")
})
public class ReceiveAzureMessage implements AzureSBListener {
    @OnAzureSBMessage
    public void receiveMessage(BrokeredMessage message) {
        // Handle message
    }
}
```

The full list of config properties is given below:

Config Property Name	Type	Default	Notes
sasKeyName	String	none	The SAS Key Name defined in your Service Bus namespace
sasKey	String	none	The SAS Key. Environment variable replacement can be used so that this is not exposed in the code
nameSpace	String	none	The Azure namespace of your Service Bus
queueName	String	none	The Queue Name (MDB property only)
initialPollDelay	Integer	1	The Initial Poll Delay (in seconds) before the Adapter starts polling for messages after deployment (MDB Property Only)
pollInterval	Integer	1	The Poll interval (in seconds). This is how often the MDB polls for new messages (MDB Property Only)
pollTimeout	Integer	1	The Poll Timeout (in seconds). This is how long the MDB should wait for messages in a single poll (MDB Property Only)

====== MQTT

MQTT (Message Queue Telemetry Transport) is a lightweight publish-subscribe messaging protocol.

====== Versioning The tags below are for the Cloud Connectors repository. You should use the one corresponding to the Jakarta version you require.

0.8.0

MQTT Connector using JakartaEE 8 and the `javax` namespace

MQTT-1.0.0

Azure Service Bus Connector using JakartaEE 10 and the `jakarta` namespace

====== Usage

If you have selected to use MQTT Connector 1.0.0, replace all occurunces of `0.8.0` with `1.0.0` for the following example.

In order to connect to a MQTT broker, the `mqtt-rar-0.8.0.rar` has to be deployed as shown in the Installing a connector section of the Cloud Connectors overview.

In order to make use of this connector in an application, the following Maven dependency is needed:

```
<dependency>
  <groupId>fish.payara.cloud.connectors.MQTT</groupId>
  <artifactId>mqtt-jca-api</artifactId>
```

```
  <version>0.8.0</version>
  <type>jar</type>
  <scope>provided</scope>
</dependency>
```

Note that this dependency have scope provided since the types within this dependency are globally available to every application deployed to Payara Micro after the `mqtt-rar-0.8.0.rar` was deployed.

====== Sending messages Sending messages to a MQTT broker can be done via the JCA and an MQTT specific API. In order to start using this API to send messages, a resource has to be defined via the JCA API; a connection factory.

The connection factory has to be given a name, which can be any name that is valid for JNDI. The `java:app` namespace is typically recommended to be used. The type of the connection factory to be used for MQTT is `fish.payara.cloud.connectors.MQTT.api.MQTTConnectionFactory`, and we have to specify the resource adapter name which is here `mqtt-rar-0.8.0.rar`.

The following gives an example:

```
@ConnectionFactoryDefinition (
 name = "java:app/MQTT/factory",
 interfaceName = "fish.payara.cloud.connectors.MQTT.api.MQTTConnectionFactory",
 resourceAdapter = "mqtt-rar-0.8.0"
 properties = "cleanSession=true"
)
```

With the above shown definition in place the following code shows an example of sending a message:

```
@Singleton
@Startup
public class SendMQTTMessage {

 @Resource(lookup = "java:app/MQTT/factory")
 private MQTTConnectionFactory factory;

 @PostConstruct
 public void init() {
    try (MQTTConnection connection = factory.createConnection()) {
        connection.publish("test", "{\"test\": \"Hello World\"}".getBytes(), 0,
false);
    }
    catch (Exception ex) {
    }
  }
}
```

====== Receiving messages Messages can be received from an MQTT broker by creating an MDB (Message Driven Bean) that implements the `fish.payara.cloud.connectors.MQTT.api.MQTTListener` marker interface and has a single method annotated with `@OnMQTTMessage` and the method signature `void method(String topic, MqttMessage message)`.

The following gives an example:

```
@MessageDriven(activationConfig = {
 @ActivationConfigProperty(propertyName = "topicFilter", propertyValue = "test")
})
public class ReceiveMQTTMessage implements MQTTListener {
   @OnMQTTMessage
   public void receiveMessage(String topic, MqttMessage message) {
       // Handle message
   }
}
```

Config Property Name	Type	Default	Notes
`serverURIs`	String	tcp://localhost:1883	Server URIs for connection, comma separated
`cleanSession`	Boolean	false	Sets whether the client and server should remember state across reconnects
`automaticReconnect`	Boolean	true	Sets whether the client will automatically reconnect to the server if the connection is lost
`filePersistance`	Boolean	false	Whether the client should use file persistence for un-acknowledged messages
`persistenceDirectory`	String	.	Directory to use for file persistence
`connectionTimeout`	Integer	30	Sets the connection timeout value in seconds
`maxInflight`	Integer	10	Sets the maximum messages that can be sent without acknowledgements
`keepAliveInterval`	Integer	60	Sets the keep alive interval in seconds
`userName`	String	None	The username for the connection.
`password`	String	None	The password for the connection.
`topicFilter`	String	None	Topic Filter (For MDBs only)
`qos`	String	0	Quality of Service for the subscription (For MDBs only)

===== Security Connectors

Security Connectors are a collection of Jakarta EE Security adapters that implements industry-standard security protocols, specifications and integrates with third-party security artifacts & components.

The available connectors on Maven central are:

====== link:/Technical Documentation/Public API/OpenID Connect Support.adoc[OpenId Connect Client,role=unresolved]

Implements OpenId Connect standard protocol by implementing Jakarta EE Security HTTP Authentication Mechanism and Identity Store for authentication & authorization using `@OpenIdAuthenticationDefinition` annotation and also provides access to the user's profile info, Identity token, Access token, & Refresh token using CDI based injection.

Maven Coordinates: `fish.payara.security.connectors:security-connector-oidc-client`

====== link:/Technical Documentation/Public API/OAuth Support.adoc[OAuth 2.0 Client:,role=unresolved]

Implements OAuth 2.0 standard protocol by implementing Jakarta EE Security HTTP Authentication Mechanism and Identity Store for authorization using `@OAuth2AuthenticationDefinition` annotation and provides access to the Identity token and Access token using CDI based injection.

Maven Coordinates: `fish.payara.security.connectors:security-connector-oauth2-client`

==== Jakarta EE Upgrade Advisor

The Upgrade Advisor is a special Maven Plugin utility tool that offers developer advice about specific changes introduced in Jakarta EE 10 that affect Jakarta EE 8 applications and are necessary for these applications to be upgraded successfully.

The purpose of the tool is to summarize all changes that affect your application based on breaking changes introduced in the different Jakarta EE specifications by report log entries that indicate how the code of the application is affected and how it should be modified to be in full compliance of the Jakarta EE 10 specifications.

===== Usage

As with any other Maven plugins, the upgrade advisor can be run directly from the command line without any extra configuration required.

The tool is freely available in Maven Central.

To run the upgrade advisor, you must go to the root of your project folder and execute the following command:

```
mvn fish.payara.advisor:advisor-maven-plugin:1.0:advise
```

The advisor then will output its summary details:

```
[INFO] Showing Advisories
[INFO] ***************
[INFO] Line of code: 14 | Expression: public String registerConfigProvider(String
s, Map map, String s1, String s2, String s3)
Source file: TestAuthConfigFactory.java
Jakarta Authentication 3.0 Issue # 87
 jakarta.security.auth.message.config.AuthConfigFactory.registerConfigProvider was
changed from
 String registerConfigProvider(String className, Map properties, String layer,
String appContext, String description)
 to
 String registerConfigProvider(String className, Map<String, String> properties,
String layer, String appContext, String description)
This issue won't affect your application.
 The recommendation is to take care of the generic version.
[INFO] Line of code: 20 | Expression: public Class[] getSupportedMessageTypes()
Source file: TestAuthModule.java
Jakarta Authentication 3.0 Issue # 87
 jakarta.security.auth.message.module.ServerAuthModule.getSupportedMessageTypes
was changed from
 Class[] getSupportedMessageTypes()
 to
 Class<?>[] getSupportedMessageTypes()
This issue won't affect your application.
 The recommendation is to take care of the generic version.
```

===== Structure of the Advisor's Summary

The issues reported by the advisor's summary output will follow this structure, in order:

1. On the first line:
    a. A standard message with the `[Message Type] [Line of code] [Expression]` format.

        Message Type

        This can be either `INFO`, `WARNING` or `ERROR`

        Line of Code

        Indicates the location of this occurrence in the code.

        Expression

        The Java code expression or statement that triggered the occurrence of the advisory.

        For example:

        - A method declaration
        - A method call,
        - An annotation property

etc.

2. On the second line:
    - The source file where the occurrence of the issue is reported.
3. On the third line:
    - A brief summary of the issue reported.
4. On the fourth line:
    - A set of recommendations given by the advisor to resolve the issue.

The following are examples of the different severity levels of findings reported by the advisor tool:

====== Example INFO message

```
[INFO] Line of code: 27 | Expression: public Map getMap()
Source file: TestMessageInfo.java
Jakarta Authentication 3.0 Issue # 87
 jakarta.security.auth.message.MessageInfo.getMap was changed from
 Map getMap();
 to
 Map<String, Object> getMap();
This issue won't affect your application.
 The recommendation is to take care of the generic version.
```

====== Example WARNING message

```
[WARNING] Line of code: 7 | Expression: @JsonbProperty(nillable = true)
Source file: JsonBeanTest.java
Jakarta JSON Binding 3.0
 property nillable from the JsonbProperty annotation was deprecated.
This issue won't affect your application.
 and the recommendation is to stop use of the deprecated property nillable and
 start to use the JsonbNillable annotation.
```

====== Example ERROR message

```
[ERROR] Line of code: 23 | Expression: myMethodExpression.isParametersProvided()
Source file: TestBatchlet.java
Jakarta Expression Language 5.0 issue 117
 MethodExpression.isParametersProvided() has been removed.
Your application won't work, please remove MethodExpression.isParametersProvided()
call.
```

===== Basic Showcase Example

To showcase a specific example of the analysis done by the upgrade advisor, consider the following code snippet:

```
package fish.payara.upgrade;

import jakarta.json.bind.annotation.JsonbProperty;

public class JsonBeanTest {

    @JsonbProperty(nillable = true)
    private String name;
}
```

In Jakarta EE 10 the Jakarta JSON Binding 3.0 API's `@JsonbProperty` annotation was modified: Its `nillable` attribute has been marked as deprecated.

The upgrade advisor will report it as such when analysing this code snippet and will present advice in what to do regarding this change:

```
[WARNING] Line of code: 7 | Expression: @JsonbProperty(nillable = true)
Source file: JsonBeanTest.java
Jakarta JSON Binding 3.0
 property nillable from the JsonbProperty annotation was deprecated.
This issue won't affect your application.
 and the recommendation is to stop use of the deprecated property nillable and
 start to use the JsonbNillable annotation.
```

From the message we can see that the advisor recommends to use the new annotation `JsonbNillable` instead, like this:

```
package fish.payara.upgrade;

import jakarta.json.bind.annotation.JsonbNillable;
import jakarta.json.bind.annotation.JsonbProperty;

public class JsonBeanTest {

    @JsonbProperty
    @JsonbNillable
    private String name;
}
```

Developers are encouraged to follow the recommendations given by the advisor to circumvent most of the challenges and pain points involved in the upgrade of any application to Jakarta EE 10.

==== Miscellaneous

===== JAX-RS Extension

The JAX-RS Extension is an application specific extension that can assist you in improving the coding of certain aspects of any application that uses the standard JAX-RS Client API. At the moment the following features are supported:

- Define the `alias` of SSL certificate entry that will be used to establish secure communication in a mutual TLS transport setting.

====== Installation

To install this extension, simply include its JAR file in the application's WAR file. Using Maven, it is as simple as declaring the dependency through its GAV coordinates:

```
<dependency>
  <groupId>fish.payara.ecosystem.jaxrs</groupId>
  <artifactId>rest-ssl-configuration</artifactId>
  <version>2.0</version>
</dependency>
```

====== Usage

====== SSL Certificate Alias Configuration

To configure the alias of the SSL certificate to be used in secure communications established by the client, the following system property must be defined when establishing a new REST client call through the use of the `jakarta.ws.rs.client.ClientBuilder` class:

Property	Description
`fish.payara.jaxrs.client.certificate.alias`	`PayaraConstants.JAXRS_CLIENT_CERTIFICATE_ALIAS`

The name of the property is defined as a constant in the `fish.payara.security.client.PayaraConstants` class.

The certificate that corresponds to the given alias must exist in the domain's configured keystore.

====== Example

Here's an example of how to set up the property when executing a new JAX-RS client call:

```
ClientBuilder.newBuilder()
              .property(PayaraConstants.JAXRS_CLIENT_CERTIFICATE_ALIAS,
"someAliasName")
              .build()
              .target(new URI("https://localhost:8080/service"))
              .request()
```

```
                .get(Service.class)
```

For this example to work, you need to include the certificate with the given alias in the default Payara Server keystore.

== Jakarta EE Certification

=== Overview

Payara Server is a certified Jakarta EE implementation. The following specifications are fully certified:

- Jakarta EE 11

As proof of compatibility, output of Jakarta EE Compatibility Test Suite tests are presented for each certified version

=== 7.0.0

==== 7.0.0 Platform TCK Results

As required by the Eclipse Foundation Technology Compatibility Kit License, following is a summary of the TCK results for Payara Server releases for Jakarta EE Platform 11.

===== Payara Server 7.0.0 Jakarta EE 11 Platform Certification Summary

As required by the Eclipse Foundation Technology Compatibility Kit License, following is a summary of the TCK results for Payara Server releases for Jakarta EE Platform 11.

- Product Name, Version and download URL (if applicable):

Payara Server 7.0.0

- Specification Name, Version and download URL:

Jakarta EE Platform 11

Jakarta EE Platform TCK 11.0.1.zip , SHA-256: b2c0ad6db0514b75ff612dd7d855a3976c8ae9f240a3b690a684f61bf503bead

- Public URL of TCK Results Summary:

==== 7.0.0 Web TCK Results

As required by the Eclipse Foundation Technology Compatibility Kit License, following is a summary of the TCK results for Payara Server releases for Jakarta EE Platform 11.

===== Payara Server 7.0.0 (Web Profile) Jakarta EE 11 Web Profile Certification Summary

- Product Name, Version and download URL (if applicable):

Payara Server 7.0.0 (Web Profile)

- Specification Name, Version and download URL:

Jakarta EE Web Profile 11

- TCK Version, digital SHA-256 fingerprint and download URL:

  Jakarta EE Platform TCK 11.0.1.zip , SHA-256: b2c0ad6db0514b75ff612dd7d855a3976c8ae9f240a3b690a684f61bf503bead

- Public URL of TCK Results Summary:

  7.0.0 Web TCK Results

- Any Additional Specification Certification Requirements:
  - Jakarta Authentication 3.1.0

    See test results in section `authentication`.
    Download URL & SHA-256: jakarta-authentication-tck-3.1.0.zip, SHA-256: 9421c6ca66274d32dfb408848f75a42d57f120599fe0d8403c5c5c1141d5ac4d

  - Jakarta Annotations 3.0.0

    See test results in section `annotations`.
    Download URL & SHA-256: jakarta-annotations-tck-3.0.0.zip, SHA-256: 8b916f1b4aed828337bd88b34bb39b133f04611c2dfe71541c2ec5d2dd22cd54

  - Jakarta Concurrency 3.1.1 TCK

    See test results in section `concurrency`.
    Download URL & SHA-256: concurrency-tck-3.1.1.zip, SHA-256: 22728d729f620d6a85ae903e7d1184e0a7508a4328491b785f1b4f3d7215ca93

  - Jakarta Contexts and Dependency Injection 4.1.0 TCK

    See test results in sections `cdi` and `cdi-lang-model`.
    Download URL & SHA-256: cdi-tck-4.1.0-dist.zip, SHA-256: 566c547e1a9c66792eefcc6feafea87ab0c0f2e3f71385bf96865359a685df00

  - Jakarta Dependency Injection 2.0.2 TCK

    See test results in section `di`.
    Download URL & SHA-256: jakarta.inject-tck-2.0.2-bin.zip, SHA-256: 23bce4317ca061c3de648566cdf65c74b57e1264d6891f366567955d6b834972

  - Jakarta Faces 4.1.1 TCK

    See test results in section `jsf`.
    Download URL & SHA-256: jakarta-faces-tck-4.1.1.zip, SHA-256: e2024aabb0c784d23c076165a4f16e03892cc68c06f67517eec5ba66b9fb17f0

  - Jakarta JSON Binding 3.0.0 TCK

    See test results in section `jsonb`.
    Download URL & SHA-256: jakarta-jsonb-tck-3.0.0.zip, SHA-256: 954fd9a3a67059ddeabe5f51462a6a3b542c94fc798094dd8c312a6a28ef2d0b

- Jakarta JSON Processing 2.1.1 TCK

  See test results in section `jsonp`.
  Download URL & SHA-256: jakarta-jsonp-tck-2.1.1.zip, SHA-256: `949f203de84deffa8c7892b555918e42f1dd220ccb7b6800741ea58af62737c1`

- Jakarta RESTful Web Services 4.0.0 TCK

  See test results in section `jaxrs`.
  Download URL & SHA-256: jakarta-restful-ws-tck-4.0.0.zip, SHA-256: `9494caaf67a3e5524a5ee1d6e4b749782ca1cbc920c6451583b6249e51c4ac18`

- Jakarta Security 4.0.0 TCK

  See test results in section `security`.
  Download URL & SHA-256: jakarta-security-tck-4.0.0.zip, SHA-256: `e21a3d8251bf954c99a3f9a5f71911696509a1ed40c23673760785a3b88e4172`

- Jakarta WebSocket 2.2.0 TCK

  See test results in section `websocket`.
  Download URL & SHA-256: jakarta-websocket-tck-2.2.0.zip, SHA-256: `ff50825305bd1318a4e6bdfab21b829cfd8cf89fab8a970f007b52636d3f2629`

- Jakarta Pages 4.0.0 TCK

  See test results in section `pages`.
  Download URL & SHA-256: jakarta-pages-tck-4.0.0.zip, SHA-256: `5446aa866601a7c4c425f74054590cfc7f4fc05592a572d399ecc8694e265489`

- Jakarta Servlet 6.1.0 TCK

  See test results in section `servlet`.
  Download URL & SHA-256: jakarta-servlet-tck-6.1.0.zip, SHA-256: `1170697a87622a920bd50f0a68ed594c6efc5e17dd370566312194c4e12bec29`

- Jakarta Expression-Language 6.0.0 TCK

  See test results in section `expression-language`.
  Download URL & SHA-256: jakarta-expression-language-tck-6.0.0.zip, SHA-256: `90cc60b9d3340675e3224d9c4ab7a82b3cf63857f39f0006e143277eaa82bbce`

- Jakarta Tags 3.0.1 TCK

  See test results in section `tags`.
  Download URL & SHA-256: jakarta-tags-tck-3.0.1.zip, SHA-256: `b779d125ea36480b206629830ca80c1e506f65e6e8235b22e846a9cb40aaba04`

- Jakarta Validation 3.1.1 TCK

  See test results in section `validation`.
  Download URL & SHA-256: validation-tck-dist-3.1.1.zip, SHA-256: `bda9de47960845a7c73aa9a1616e4bbed3e346de3516f768819cf5af77bf969f`

- Java runtime used to run the implementation:

  `OpenJDK Runtime Environment zulu21.0.7 (build 21.0.7+6)`

- Summary of the information for the certification environment:

  Apache Derby, Linux, Ubuntu 20.04 LTS

===== Test Results

annotations

```

```

== Eclipse MicroProfile Certification

=== Overview

Payara Server is a certified Eclipse Microprofile implementation. As proof of compatibility, output of MicroProfile Compatibility Test Suite tests are presented for each certified version in each release.

== Security

=== Overview

This section describes Payara's official policy for managing Payara Platform's security vulnerabilities.

The CVE Program

Payara, a leading provider of Jakarta EE and MicroProfile runtimes, is authorized by the Common Vulnerabilities and Exposures (CVE) Program as a CVE Numbering Authority (CNA).

Payara will publish authoritative cybersecurity vulnerability information about its products via the CVE Program. Vulnerabilities will be given a unique, alphanumeric identifier, building the CVE List that feeds into the U.S. National Vulnerability Database (NVD), and playing a role in the CVE Program's mission to identify, define and catalogue cybersecurity vulnerabilities.

The CVE Program is sponsored by the Cybersecurity and Infrastructure Security Agency (CISA) of the U.S. Department of Homeland Security (DHS).

Developers using Payara Platform products will benefit from the collaboration, as vulnerabilities will be part of the standardized and publicly disclosed CVE List. This will result in time and cost savings for those using Payara products, as security issues can be discussed,

dealt with and prevented through the use of a trusted, standardized catalogue.

In general, Payara follows the CVE Program's CNA Operational rules to make decisions on reported vulnerabilities and CVE record management.

General Guidelines

- Payara is committed to fixing any vulnerabilities and exploits identified in any Payara Platform products and distributions.
- Any reported vulnerabilities will be fixed with celerity as soon as they are reported and confirmed.
- Security vulnerabilities will have to be verified to affect a Payara Platform product before getting a CVE ID assigned.
- Vulnerabilities reported on product versions that are no longer supported due to having reached their End-of-Support will be disclosed but will NOT be fixed.
- Vulnerabilities not related to the Payara Platform will be ignored and not disclosed as CVE records. These include:
  - Operating system vulnerabilities
  - JVM-specific vulnerabilities
  - Conditions or behaviors that do not lead to a security impact.
    - These include an increase in access for an attacker, a decrease in availability of a target, or a violation of an implemented security policy.
  - Physical attacks unless there is a specific security feature, supported claim, or policy that defends against the physical attack.
  - Well-documented or commonly understood non-default configuration or runtime changes made by an authorized user
  - Brute-force denial-of-service (DoS) and brute-force resource exhaustion attacks, for example, high-rate or high-bandwidth denial-of-service attacks.
    - Failure to implement common defenses against such attacks will also be determined NOT to be valid vulnerabilities.
- Payara Enterprise customers can request security fixes to be back-ported to any supported releases (if allowed by their corresponding Enterprise support lifecycle) used on their environments.

Vulnerabilities on Third-party Components

As the Payara Platform depends on third-party components of other software packages like Apache Guava, Jackson, Smack, etc. Vulnerabilities on specific versions of these components may be reported as well. Payara is committed to analysing any reported vulnerabilities and upgrading them to a patched version whether applicable.

In these cases, reports SHOULD if possible reference an existing CVE record that details the vulnerability in question.

Reporting Security Vulnerabilities

To report a vulnerability, make an official request through the Customer Support Portal. Please make sure to describe the vulnerability encountered in great detail, along with detailed steps on how to reproduce or exploit the vulnerability and environmental details like:

- Payara Platform distribution (i.e, Server, Micro, Embedded, Docker Image) and version
- Operating System
- JDK Version

If the report is related to a Vulnerabilities on Third-party Components, please include the CVE ID of the vulnerability that affects the third-party component if you have access to it.

CVE ID Assignment

Once a report it's received, we'll determine if it exposes a valid vulnerability that needs to be disclosed and assign a CVE ID to it as established by the CNA Program rules. We'll assign a CVE ID when:

1. Payara reasonable evidence to determine the existence of a vulnerability on the report.
2. The vulnerability has been or is expected to be **publicly disclosed**.
3. The vulnerability has the potential to cause significant harm.

If these conditions are not met, Payara will not address the vulnerability and will NOT assign a CVE ID.

If a report includes evidence of multiple **independently fixable** vulnerabilities, Payara will assign separate CVE IDs for each confirmed vulnerability in the report.

CVE Record Disclosure

Once a security vulnerability is fixed and published in an official release of Payara Platform Enterprise, the following will occur:

- The details of the vulnerability will be published in the release notes in this documentation site.
- The CVE record will be officially published.
- Customers will be notified of any necessary mitigation measures to be considered if they are affected by the vulnerability.

CVE Record Rejection

In some cases, the investigation of a vulnerability that has a CVE ID assigned may yield a result where the vulnerability in question does not warrant a fix (it cannot be reproduced, it doesn't affect the Payara Platform, is not considered as harmful as originally reported).

In cases like this, the CVE record will be rejected along with a reason explaining why the vulnerability didn't require disclosure.

CVE Disputes

If as a reporter, you do not agree with the assessment that Payara has made on a reported vulnerability when a CVE has not been assigned or an assigned CVE has been rejected, you may let us know through the corresponding customer portal ticket. We'll follow the CVE Program Policy and Procedure for Disputing a CVE Record to handle the resolution of this dispute within our scope as a CNA.

Payara will be open to negotiating any disputes and reconsider our position on previous assessments if enough evidence and information is provided by the reported.

Security Advisories

All security reports, that correspond to either fixes to vulnerabilities that affect the Payara Platform directly or vulnerabilities to its third-party dependencies are catalogued under the Security Advisories page.

Each vulnerability entry will contain:

- Its CVE ID
- The CVE record's CVSS Score
- The status of the vulnerability (`FIXED`, `REJECTED`, `N/A`)
- The summary of the exploit
- The release where a fix was published (if applicable)
- Additional observations on the resolution of the vulnerability.

Credits

If you are interested in being credited as the finder and/or reporter of the vulnerability, please let us know explicitly on your report and provide the following details:

- Your **name** or an **alias**.
- *(Optional)* The name of an organisation you belong to and wants to be credited.

=== Security Fix List

The following is a list of reported ***C**ommon **V**ulnerabilities and **E**xposures* that have been analyzed and documented across releases:

==== Non-CVE Vulnerabilities

Here is a collection of historic non-**CVE** vulnerabilities that may warrant attention:

Reference	Status	Summary	Release	Observations
FISH-13363	FIXED	Restrict Access To Vulnerable EL Expressions	7.0.0	Fixed by upgrading jsftemplating
Payara Enterprise Support Ticket	FIXED	Vulnerability in Metro's WSDL Code Importing/Parsing - Remote Code Execution	5.28.0	Recommended to immediately upgrade to this release if using any JAX-WS features in applications deployed in public-facing environments.
OWASP Docs	FIXED	Web administration console is vulnerable against clickjacking/UI redress attacks.	4.1.2.174	
Payara Support Ticket	FIXED	Under some circumstances authenticated caller/user identities get confused.	4.1.1.171.11	
Payara Support Ticket	FIXED	CORBA security context gets corrupted under certain conditions	4.1.2.181.2, 4.1.2.182, 5.182
